Malaria in Brazil is endemic in the Amazon, although autochthonous cases, mostly asymptomatic, have been reported in the Atlantic Forest near the coastal area. Epidemiological investigations in this region revealed carriers that represent a challenge for blood banks since the proportion of submicroscopic infections in such low transmission areas (prevalence by microscopy ≤ 10%) can reach 70 - 80%. Moreover, the pre-donation questionnaire may fail to detect individuals harboring ***Plasmodium*** due to its low parasitemia and absence of symptoms. In order to improve transfusion safety we evaluated molecular and serological tests on a population of risky blood donors. We tested samples from 91 candidates for blood donation from non-endemic areas where asymptomatic infections have been reported. Thick blood smear, qPCR, nested PCR, ELISA with both recombinant ***P. vivax*** MSP119 (ELISA-Pv) and total ***P. falciparum*** extract (ELISA-Pf) and indirect fluorescent assay with P. malariae (IFA-Pm) were used. Two samples (2.2%) (0.6-7.6) were positive by thick blood smear with very low parasitemia. Genus qPCR exhibited amplification in 3.3% (1.1-9.2) and species-specific nested PCR in 2.2% (0.6-7.6%) indicating the presence of P. malariae. ELISA detected 42.8% (33.2- 53.1) of samples reagent for ***P. vivax*** and 6.6% (3.1-13.6) for ***P. falciparum***. IFA-Pm was reagent for P. malariae in 15.4% (9.4-24.2). Among the 40 positive samples by serology, 97.5% were detected by ELISA-Pv, 35.0% by IFA-Pm and 15.0% by ELISA-Pf (Chi^2, p<0.001). Considering parasitological and molecular methods, 4/91 blood donors (4.4%) were probably infectious. Based on serology, 44.0% were exposed to ***Plasmodium***. The high prevalence of antigens and antibodies in this population points out to the risk of transfusional malaria in this area, as asymptomatic donors are currently missed by the clinical-epidemiological screening. We are currently evaluating the power of a few specific questions on donor's proximity to the Atlantic Forest in addition to laboratorial methods to disclose ***Plasmodium*** carriers, aiming to reduce the risk of transfusional malaria in this area.

COMPARISON OF DIFFERENT DIAGNOSTIC TOOLS FOR THE DETECTION OF ASYMPTOMATIC *PLASMODIUM FALCIPARUM* INFECTIONS ACROSS GEOGRAPHICALLY DIVERSE AREAS

Xavier C. Ding[1], Didier Ménard[2], Dionicia Gamboa[3], Babacar Faye[4], Roxanne R. Rees-Channer[5], James S. McCarthy[6], Qin Cheng[7], Peter L. Chiodini[5], Iveth J. González[1]

[1]Foundation for Innovative New Diagnostics, Geneva, Switzerland, [2]Institut Pasteur in Cambodia, Phnom Penh, Cambodia, [3]Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Service de Parasitologie, Faculté de Médecine, Université Cheikh Anta Diop, Dakar, Senegal, [5]Department of Clinical Parasitology, Hospital for Tropical Diseases, University College London NHS Foundation Trust, London, United Kingdom, [6]QIMR Berghofer Medical Research Institute, University of Queensland, Brisbane, Australia, [7]Drug Resistance and Diagnostics, Australian Army Malaria Institute, Enoggera, Brisbane, Australia

Global malaria control has been drastically improved in the recent past, resulting in an almost halved mortality rate and a 26% decrease in infections worldwide since the year 2000. The significant epidemiological shifts that this has led to need to be fully understood to progress the elimination agenda. Foremost is the increasing fraction of malaria transmission due to asymptomatic infections in low endemicity settings, a large part of which is characterized by submicroscopic parasitaemia. Such individuals are extremely difficult to identify for treatment. Indeed, recent data suggest that up to 50% of human-to-mosquito transmission could be caused by such infections in very low endemicity areas. To evaluate the extent and detectability of asymptomatic ***Plasmodium falciparum*** infections, we recently collected large sets of venous whole blood samples from asymptomatic adult volunteers in several areas of low malaria endemicity in Cambodia, Peru and Senegal. Sample sets were constructed to include one fifth asymptomatic ***P. falciparum*** positive specimens and four fifths negative specimens as determined by locally performed molecular detection tests (PCR or loop-mediated isothermal amplification). The ability of reverse transcription quantitative PCR, rapid diagnostic tests (RDTs), and microscopy to correctly identify ***P. falciparum*** infections in our sample sets was measured in reference laboratories and compared to conventional nested PCR. In addition, the ***histidine-rich protein 2*** gene (***pfhrp2***), a key biomarker for parasite detection by RDTs, was sequenced and the whole blood concentration of HRP2 determined for positive specimens by ELISA. By correlating the presence of ***P. falciparum*** infection in asymptomatic individuals with parasitaemia, detectability by multiple techniques of varying sensitivity, and HRP2 expression level,

this study provides unique insights into this significant parasite reservoir. Analysis of this comprehensive data will inform the optimization of strategies to identify asymptomatic but infective carriers of ***P. falciparum***.

A NEW, ROBUST AND FASTER SINGLE-STEP PCR FOR *PLASMODIUM* SPOROZOITE DETECTION IN MOSQUITOES

Diego F. Echeverri-Garcia[1], Victoria Makuru[1], Jenna Davidson[1], Nicholas A. Deason[1], Honglin Xiao[1], Tanya Russell[2], Thomas R. Burkot[2], Frank H. Collins[1], Neil F. Lobo[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]James Cook University, Townsville, Australia

Malaria is the most important vector-borne disease. Countries as well as organizations all over the world are working towards its control and/or elimination. Knowledge on infective ***Anopheles species*** (mosquitoes carrying ***Plasmodium*** spp sporozoites in their salivary glands and bucal parts) in the field, is fundamental to this goal. The detection of infective mosquitoes is required for vector incrimination, the determination of entomological inoculation rate (EIR), and for interventions monitoring toward the reduction of malaria transmission. Currently sporozoite detection relies on PCR methods, where the 18s-rRNA nested PCR assay is the most extensively used. This standard technique is not amenable for high throughput analyses, due to being laborious and time-consuming. In addition, this assay is affected by debris and carry-over from host cells as well as traces of reagents/template used during DNA extraction and reactions in this multi-step process. In this study, over 3000 mosquitoes collected in the Western Province, Solomon Islands, were evaluated for sporozoite infection using a newly developed assay based on the cytochrome oxidase I gene (COX-1). This assay, is faster, simpler, amenable for high-throughput studies, and has a higher detection limit when compared to the standard 18s-rRNA.

847

CARDIAC SAFETY OF ARTEMISININ-BASED COMBINATION THERAPY AMONG ADULTS INFECTED WITH HUMAN IMMUNODEFICIENCY VIRUS AND STABILIZED ON ANTIRETROVIRAL THERAPY IN MALAWI

Clifford G. Banda[1], Eva Maria Hodel[2], Mavuto Mukaka[1], Richard Kamwezi[3], Maxwell Yohane[3], Fraction Dzinjalamala[3], Jane Mallewa[3], Dianne J. Terlouw[2], Victor Mwapasa[3]

[1]Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]University of Malawi, College of Medicine, Blantyre, Malawi

Human Immunodeficiency Virus (HIV) and ***Plasmodium falciparum*** malaria co-infections frequently occur in sub-Saharan Africa but there are limited data on the safety of artemisinin-based combination therapy (ACT) in HIV-infected individuals taking antiretroviral (ARV) drugs. ACT components (piperaquine, amodiaquine and lumefantrine) have been associated with cardiac abnormalities in a concentration dependent manner, and have triggered a call for more safety data from various high risk sub-populations. ARV drugs such as protease inhibitors (PIs) and non-nucleoside reverse transcriptase inhibitors (NNRTIs) that affect activity of cytochrome P-450 enzymes may elevate concentrations of ACTs and have raised concerns about increased risk of cardiac toxicity. As part of a pharmacokinetic trial assessing safety of ACTs among non-malaria HIV infected individuals stabilised on ART, we compared the incidence and severity of QTc prolongation and cardiac related adverse events in ARV-naïve individuals (n=41) and those taking NNRTIs (n=71) and PIs (n=42) in combination with a standard three-day regimen of dihydroartemisinin-piperaquine, artesunate-amodiaquine or artemether-lumefantrine. We will present the QTc interval prolongation and its correlation with ACT plasma levels and treatment emergent cardiac adverse events. Effect of predictors such as age, gender, electrolyte levels and intake of cotrimoxazole prophylaxis on QTc prolongation across study arms are assessed using logistic regression. Robust safety profiles of ACTs in malaria-HIV co-infected populations will help inform treatment guidelines and support national malaria control programs which consider large ACT mass drug administration campaigns

848

EXPOSURE TO ARTEMISININS IN PREGNANCY AND THE RISK OF ADVERSE PREGNANCY OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Stephanie D. Kovacs[1], Annemieke van Eijk[2], Stephanie Dellicour[2], Esperanca Sevene[3], Halidou Tinto[4], Umberto D'Alessandro[5], Feiko ter Kuile[2], Andy Stergachis[1]

[1]University of Washington, Seattle, WA, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Universidade Eduardo Mondlane, Maputo, Mozambique, [4]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [5]Medical Research Council, Faraja, Gambia

Malaria in pregnancy is responsible for up to 100,000 neonatal deaths and 10,000 maternal deaths annually. Severe malaria may lead to severe maternal anemia miscarriage, stillbirth, prematurity, and low birth weight. In animal models, artemisinin derivatives may be embryotoxic and teratogenic if administered at specific times of pregnancy. No increased risk of adverse pregnancy outcomes has been observed in humans but the studies were limited by too small sample sizes to detect rare but clinically significant differences in adverse pregnancy outcomes. The purpose of this meta-analysis is to examine the association between exposure to artemisinins during pregnancy and the risk of adverse pregnancy outcomes including miscarriage, stillbirth, and congenital anomalies. We conducted a comprehensive search of MEDLINE, EMBASE, and the Malaria in Pregnancy Consortium (MiPc) Library to identify prospective cohort and randomized controlled trials of pregnant women exposed to artemisinins that followed the women through pregnancy and presented pregnancy outcomes. In addition, we reviewed the citations list of key publications and reached out to authors for additional, unpublished data. Our search identified 22 published studies that met our inclusion criteria. Additional outcome data has been requested from six studies, and five studies offered to-date to provide individual level data for analysis. The 22 studies enrolled 26,430 women, of whom 3,772 were exposed to an artemisinin during pregnancy, 554 exposed during the first trimester. The proportion of women experiencing a stillbirth or congenital anomaly after exposure to an artemisinin in the 2nd and 3rd trimester of pregnancy ranged from 0% to 8.5% and 0% to 5.9% respectively in the study populations. Pooled analyses of the data are ongoing and will be presented to the World Health Organization as part of an Evidence Review Group on the safety of artemisinins in pregnancy. The results of the systematic review highlight the need for additional data on artemisinins exposure, especially during early pregnancy.

849

FOSMIDOMYCIN AS AN ANTIMALARIAL DRUG: A META-ANALYSIS OF CLINICAL TRIALS

José F. Fernandes, Benjamin Mordmüller, Martin P. Grobusch

CERMEL Albert Schweitzer Hospital, Lambaréné, Gabon

With first indications of resistance against artemisinin compounds, the development of novel alternative antimalarials remains an urgent need. One candidate is fosmidomycin (Fos), a phosphonic acid derivative. This PRISMA guideline-adhering and PROSPERO registered systematic review and meta-analysis provides an overview of the state-of-the-art of the clinical development of Fos as an antimalarial. Pooling six clinical trials of Fos against uncomplicated malaria in African children yielded an overall day 28 cure rate of 85% [95% CI: 71-98%]; a parasite clearance time of 39 hours; and a fever clearance time of 30 hours. In four adult cohorts, the corresponding values were 70% [95% CI: 40-100%], 49 hours

and 42 hours, respectively. Data suggest that, besides the partner drug, formulation determines efficacy. We advocate further clinical development Fos-combinations. PROSPERO registration number: CRD42014013688

ARTEMISININ-BASED COMBINATION THERAPY EFFICACY IN KISUMU, WESTERN KENYA: ESTABLISHMENT AND ANALYSIS OF PARASITES USING THE RING-STAGE ASSAY

Hoseah M. Akala[1], Reginald O. Jura[2], Lorna J. Chebon[3], Luiser A. Ingasia[1], Agnes C. Cheruiyot[1], Ben Andagalu[1], Edwin Kamau[1]

[1]Kenya Medical Research Institute/US Army Medical Research Unit - Kenya, Kisumu, Kenya, [2]Department of Zoology, Maseno University, Maseno, Kenya, [3]Institute of Tropical Medicine and Infectious Diseases, College of Health Sciences, Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Artemisinin resistance leads to reduced parasite clearance rate, marked by higher survival rate of exposed ring-stage parasites during ring stage survival assay (RSA). Although adequate clinical and parasitological response to artemisinin-based therapies (ACTs) remain high in Africa including Kenya, the efficacy of these compounds must be constantly monitored. This study reports the establishment of RSA to monitor the efficacy of ACTs in western Kenya. Clinical isolates collected from field sites as part of routine surveillance and those from an efficacy clinical trial were used in the study. Patients with uncomplicated malaria were recruited into the study where blood samples were collected and analyzed using immediate ***ex vivo*** RSA. The assay was performed as previously described (Witkowski et al, 2013). Artemisinin sensitive (F32-TEM) and resistant (F32-ART) clonal lines were used as controls. A total of 102 clinical isolates were analyzed, 28 from the efficacy study. For the clinical isolates, the RSA median (interquartile range) was 0.78% (0 - 4.62). Twenty eight samples had RSA of 0% whereas 16 had RSA above 10%. The highest RSA values recorded were 58% and 60%; these were from the surveillance study samples. The highest RSA from the efficacy clinical study samples were 20% and 31%. For the controls, F32-TEM had RSA of 0 (n = 6) and F32-ART had RSA of 11% (n = 4). Genetic analyses of these samples including population structure and drug resistance markers are underway. Compared to the controls and previous reports, our data show an underlying concern for efficacy of ACTs in western Kenya. This is in line with our recent study which showed that there has been significant change in parasite genotype in western Kenya in recent years. Genetic analyses of the samples in this study should yield critical data. There is need for continued close monitoring of parasite genotype, phenotype and clinical dynamics in response to continued use of ACTs in western Kenya.

851

OBSERVED QTC PROLONGATION AND PHARMACOKINETIC PROFILE OF A PROGRAMMATIC REGIMEN WITH AN INCREASED DOSE OF DIHYDROARTEMISININ-PIPERAQUINE IN YOUNG CHILDREN 5-24 KG IN MALAWI

Eva Maria Hodel[1], Gertrude Chapotera-Kalanda[2], Tikhala Makhaza-Jere[3], Clifford G. Banda[3], Clyton A. Munthali[2], Vincent J. Samuel[2], Anna Maria van Eijk[1], Mavuto Mukaka[3], Queen Dube[3], Cheryl Pace[1], Karen I. Barnes[4], David G. Lalloo[1], Dianne J. Terlouw[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]College of Medicine, Blantyre, Malawi, [3]Malawi-Liverpool-Wellcome Trust Clinical Programme, Blantyre, Malawi, [4]University of Cape Town, Cape Town, South Africa

Dihydroartemisinin-piperaquine (DHA-PPQ) is highly efficacious against uncomplicated falciparum malaria. Due to its long half-life and associated chemoprophylactic effect, DHA-PPQ is also considered a promising candidate for mass drug administration in transmission reduction settings. However, PPQ has a relatively narrow, poorly defined therapeutic dose range which poses dosing challenges. Concerns particularly remain whether observed PPQ concentration-dependent cardiac QTc prolongation could vary between (and pose a clinical risk in) specific vulnerable population subgroups. While recent pooled efficacy and pharmacokinetic (PK) analyses suggest that young children require a higher weight-adjusted dose due to increased PPQ clearance, no paediatric cardiac safety data exists at these higher doses. This hampers DHA-PPQ's safe and effective introduction into national control programmes. We conducted an open-label dose optimization study to describe the population PK profile of PPQ and cardiac safety of a regimen with a higher average dose of DHA-PPQ in children of 5–24 kg with uncomplicated falciparum malaria [PACTR201303000506302]. Children (n = 100) received a dosing regimen with supervised doses of 1.7–3.8 mg/kg DHA and 13.6–30.0 mg/kg PPQ given once daily over three days, using whole or half-tablets (20/160 mg and 40/320 mg DHA/PPQ). Follow-up was 63 days. QTc was measured before and 4–6 h after the last dose and compared to baseline and Day 28 using digital 12-lead electrocardiograms. No Fridericia corrected QT interval (QTcF) >500 ms or clinical cardiac safety signals were observed with this regimen. However, a substantial QTcF prolongation was measured 4–6 h after the last DHA-PPQ dose compared with baseline: Mean 54 ms, <30 ms in 13%, 30–60 ms in 49% and >60 ms in 37% of children. We will present the results from the population pharmacokinetic/pharmacodynamics (PK/PD) analysis and describe the association between drug exposure and cardiac response. Targeted, small PK/PD safety studies can provide key data on subgroups and inform safe and effective DHA-PPQ dosing regimens for control programmes.

852

A QUANTITATIVE TOOL FOR ASSESSING IDEAL DRUG COMBINATIONS FOR MALARIA THERAPY

Wesley C. Van Voorhis[1], Stephan Chalon[2], Joerg J. Moehrle[2], Stephan Duparc[2], Thomas Rueckle[2], Paul A. Willis[2], Jeremy Burrows[2], Timothy Wells[2]

[1]University of Washington, Seattle, WA, United States, [2]Medicines for Malaria Venture, Geneva, Switzerland

Drug combinations are recommended for effective malaria therapy and to prevent emergence of resistance by the WHO and MMV. Yet we are not aware of quantitative criteria for assessing potential antimalarial combinations for their compatibility, efficacy, and safety. We developed a quantitative score to assess drug combinations covering marketed antimalarials, as well as compounds in clinical development and preclinical evaluation. The score includes 13 values, representing different criteria that are important in drug combinations, and each value can be variably prioritized to provide a quantitative score for the combination. These values are: 1) anticipated efficacy in planned use (e.g. Single Exposure Radical Cure and Prophylaxis [SERCaP]); 2) safety of the drugs alone and in combination (worse if both have the same adverse effects); 3) developmental stage of the drugs (later in development is better); 4) pharmacokinetic/dynamic compatibility (matched time above minimum paracidal concentration is best); 5) total dose (in mg, less is better); 6) anticipated co-formulation issues; 7) prophylactic activity against liver stages; 8) probability of emergence of resistance; 9) food effect with administration; 10) drug-drug interaction between the partners; 11) drug-drug interaction of the combinations with other drugs; 12) differing mechanisms of actions; and, 13) intellectual property flexibility. Applying these criteria, and weighting SERCaP success ten-fold, showed OZ-439 to be an optimal partner with: KAF-156, DSM-265, and Ferroquine. This scoring procedure will help to clarify potential antimalarial partners to prioritize for further pre-clinical and clinical testing as effective malaria combination therapy.

853

SAFETY AND EFFICACY OF REPEATED OF REPEATED ADMINISTRATION OF PYRONARIDINE-ARTESUNATE OR DIHYDROARTEMISININ-PIPERAQUINE VS ARTESUNATE-AMODIAQUINE IN CHILDREN AND ADULT PATIENTS WITH ACUTE UNCOMPLICATED *PLASMODIUM* SP MALARIA OVER OF TWO YEARS PERIOD AT BANFORA/NIANGOLOKO SITES IN BURKINA FASO

Issiaka Soulama, Aboubacar S. Coulibaly, Jean Moise T. Kabore, Maurice S. Ouattara, Edith C. Bougouma, Souleymane Sanon, Noelie Henry, Amidou Diarra, Daouda Ouattara, Adama Gansane, Issa N. Ouedraogo, Alfred B. Tiono, Sodiomon B. Sirima

Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso

The safety and efficacy of repeated administration of three ACTs [(pyronaridine-artesunate (PYR) or dihydroartemisinin-piperaquine (DHA-PQ) vs artesunate-amodiaquine (ASAQ)] are in evaluation in three West African Countries, part of the West African Network of Clinical trials for AntiMalarial drugs (WANECAM). The current study presents the partial data of safety and efficacy of repeated administration of PYR or DHA-PQ vs ASAQ over a period of 2 year in children and adults with uncomplicated ***Plasmodium*** sp malaria at Banfora/Niangoloko sites in Burkina Faso. This study is a comparative, randomized, open label longitudinal clinical trial involving children and adults with uncomplicated ***Plasmodium*** sp. malaria. Following the screening, 763 participants were enrolled in ASAQ (315), DHA-PQ (224) and PYR (224) arm, from July 2012 to December 2013. Each of the participants received during their subsequent episodes the same drug and went through the same trial procedures as for the initial episode. The partial results at the end of the enrolment in December 2013 showed that 185 of 315 (58.7%) patients, 129 of 224 (57.6%); and 138 of 224 (61.6%) experienced at least 2 malaria episodes and 10.8%, 7.3% , 9.4 % experienced 5 malaria episodes in the ASAQ, DHA-PQ and PYR arms respectively. The average time between the first and the second malaria episode was statistically longer ($p<0.05$) in DHA (157 days) compared to ASAQ (135 days) and PYR (117 days) arms. Adequate clinical and parasitological response (ACPR) by day 28 was 93.0 %, 97.8% and 98.2% in ASAQ, DHA and PYR arm respectively. The 42 day cure rate (not adjusted by PCR) was 80.3 %, 93.8% and 78.2% in ASAQ, DHA-PQ and PYR arms respectively. Our preliminary results confirmed the two news drugs (DHA-PQ and PYR) are safe and their efficacy comparable to the ASAQ in uncomplicated malaria treatment in high malaria transmission region. The study is still ongoing to complete the follow of the all the patients over a period of two years.

854

MORTALITY, MORBIDITY AND DEVELOPMENTAL OUTCOMES IN CHILDREN BORN TO WOMEN RECEIVING EITHER MEFLOQUINE OR SULPHADOXINE-PYRIMETHAMINE AS INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY: A RANDOMIZED CONTROLLED TRIAL

María Rupérez[1], Raquel González[1], Ghyslain Mombo-Ngoma[2], Smaïla Ouédraogo[3], Mwaka A Kakolwa[4], Salim Abdulla[4], Manfred Accrombessi[3], John J Aponte[1], Daisy Akerey-Diop[2], Arti Basra[2], Valérie Briand[5], Meskure Capan[2], Michel Cot[5], Abdunoor M Kabanywanyi[4], Christian Kleine[6], Peter G Kremsner[6], Eusebio Macete[7], Jean-Rodolphe Mackanga[2], Achille Massougbodgi[3], Alfredo Mayor[1], Arsenio Nhacolo[7], Golbahar Pahlavan[1], Michael Ramharter[6], Esperança Sevene[7], Anifa Vala[7], Rella Zoleko-Manego[8], Clara Menéndez[1]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon, [3]Faculté des Sciences de la Santé, Université d'Abomé y Calavi, Cotonou, Benin, [4]Ifakara Health Institute, Dodoma, United Republic of Tanzania, [5]Institut de Recherche pour le Développement, Paris, France, [6]Institute of Tropical Medicine, University of Tübingen, Tübingen, Germany, [7]Manhiça Health Research Center, Manhiça, Mozambique, [8]Ngounie Medical Research Centre, Fougamou, Gabon

Malaria infection during pregnancy confers substantial risks for the woman, her fetus and the newborn child. Mefloquine (MQ) has showed to be an effective antimalarial in sub-Saharan Africa, though controversy about its safety in pregnancy has been subject of debate. A recent trial showed that African pregnant women receiving MQ for intermittent preventive treatment of malaria in pregnancy (IPTp) had less clinical malaria than those receiving sulphadoxine-pyrimethamine (SP) while the safety profile was similar. Furthermore, MQ is recommended for prophylaxis in non-immune pregnant women travelling to endemic areas and is a potential partner drug in artemisinin-based combination treatment (ACT) recommended in pregnancy or for women of childbearing age. However, safety of MQ in pregnancy has been poorly assessed in children over the first month of life and little is known about its long-term impact on infant's morbidity, mortality and development. In the context of a multicenter randomized controlled trial to evaluate the safety and efficacy of IPTp with MQ compared to SP in pregnant women from Mozambique, Benin, Gabon and Tanzania, 4247 newborns were followed up until 12 months of age. Nutritional status and psychomotor development were assessed at months 1, 9 and 12 and incidence of malaria, anemia, hospital admissions, outpatient visits and mortality calculated for their first year of life. No differences in the proportion of stunting, underweight, wasting and severe acute malnutrition at month 1, 9 and 12 of age between infants born to women who had IPTp with MQ or SP were found. Higher risk of being unable to stand without help, walk without support and bring solid food to the mouth were observed in the MQ group at month 9 (RR 1.07 [95%CI 1.00-1.14] p= 0.040, RR 1.10 [95%CI 1.01-1.21] p= 0.039 and RR 1.32 [95%CI 1.03-1.70] p= 0.031) though no significant differences were found in the other psychomotor development milestones assessed. Incidence of malaria, anemia, hospital admissions, outpatient visits and mortality were similar in both groups.

855

A TRIAL OF THE SAFETY OF SINGLE LOW DOSE PRIMAQUINE IN ADDITION TO ACTS COMMONLY USED IN SENEGAL: PRELIMINARY RESULTS

Roger C. Tine[1], Eugenie Poirot[2], Khadime Sylla[1], Fatou B. Fall[3], Paul Milligan[4], Doudou Sow[1], Babacar Faye[1], Jean L. Ndiaye[1], Magatte Ndiaye[1], Kouakou Folly[1], Oumar Gaye[1]

[1]University Cheikh Anta Diop, Dakar, Senegal, [2]Global Health Group, University of California San Francisco, San Francisco, CA, United States, [3]National Malaria Control Program, Dakar, Senegal, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

WHO recommends the addition of a single dose of primaquine (0.25 mg base/kg) to artemisinin combination treatments (ACTs) as a component of pre-elimination or elimination programs. However, primaquine has been little used in Africa and there are concerns about its safety, as the drug can cause acute haemolytic anaemia in individuals with G6PD deficiency. This open randomised controlled trial was conducted to assess the safety of adding low-dose primaquine to the normal ACT regimen in adult patients in Senegal. Patients with ***P. falciparum*** malaria (parasitaemia{1,000-100,000} trophozoites/µL) were randomized to receive treatment with ACT or ACT plus low-dose primaquine. Haemoglobin concentration was measured at enrolment, and on day 3 and day 7 after the start of treatment. G6PD status was determined for each patient using a qualitative field test (CareStart™). The primary outcome was the change in haemoglobin concentration from day 0 to day 7, which was compared between trial arms using analysis of covariance. Secondary endpoints included haemoglobin concentration on day 3 and gametocyte carriage on day 7. One hundred and thirteen patients (56 in the ACT arm and 57 in ACT plus primaquine arm) were randomized. At enrolment, gender, mean weight, parasitaemia, haemoglobin, and prevalence of G6PD deficiency were similar in the two arms. Mean haemoglobin concentration on day 7, was similar in primaquine and control groups (11.9 and 12.1 g/dL respectively). The difference in Hb concentration on day 7 in the primaquine group compared to controls after adjusting for Hb at baseline, was -0.029 (95%CI -0.51,0.45) g/dL. Haemoglobin change at day 7 was significantly associated with haemoglobin at enrolment, weight and gender. There was no evidence of an association with treatment drug, G6PD status, and parasiteamia at enrolment. This study provided preliminary evidence that the administration of single low dose primaquine (0.25 mg/kg) in addition to ACT treatment, to adult patients with acute ***P. falciparum*** malaria, is safe and does not induced significant drop in haemoglobin level both for G6PD normal and deficient individuals.

856

IMPACT OF SCREENING FAILURE ON RECRUITMENT PROCESS DURING A CLINICAL TRIAL OF THE WEST AFRICAN NETWORK OF CLINICAL TRIALS OF ANTIMALARIAL DRUG (WANECAM), BOUGOULA-HAMEAU, MALI

Bakary Fofana

Malaria Research and Training Center/USTT of Bamako, Bamako, Mali

The conduct of antimalarial's drug or vaccine clinical trials required a rigorous selection of the study volunteers for their participation to the clinical study. The inclusion and exclusion criteria would have an impact on the enrollment rate in a specific study site although the prevalence of the disease indicates an appropriate enrollment rate at a predefined time. The objective of this study was to assess the impact of the screening failure on the recruitment of study volunteers planned for a defined period. During a phase IIIb/IV multicenter clinical trial study of WANECAM, we consented patients with positive blood smears, performed a clinical examination including an Electrocardiogram (ECG) and blood draw for hematology and liver function tests (LFT). Patients with QTc > 450ms and/or LFTs (ALT/AST)> 2x ULN were not eligible as well as those with Hemoglobin less than 7.0 g/dL and females of 12 years or older with a positive urine pregnancy test etc. From December 17, 2012 to January 15, 2015, a total of 1380 infants and adult male and female with positive blood smear freely consented/ assented for the study and underwent the screening procedures. From them we enrolled 1173 patients in the WANECAM study. The rate of screening failure was 15.0%. The proportion of prolonged QTc (Bazet) among screening failure (n =207) was 58.7% followed by low Hemoglobin rate (18.4%) and Liver Function Tests (ASAT/ALAT) > 2xULN (10%). Details on the other exclusion criteria will be provided. When calculating the sample size and study duration for drug or vaccine trial, previous knowledge of possible causes and proportions of screening failures is necessary in addition to the usual parameters such as prevalence of the disease and loss of follow up.

857

A PHASE IIA PROOF-OF-CONCEPT STUDY TO ASSESS THE EFFICACY, SAFETY, TOLERABILITY AND PHARMACOKINETICS OF SINGLE DOSES OF DSM265 IN ADULT PATIENTS WITH ACUTE, UNCOMPLICATED *PLASMODIUM FALCIPARUM* OR *VIVAX* MALARIA MONO-INFECTION OVER A 28-DAY-EXTENDED OBSERVATION PERIOD IN IQUITOS, PERU

DSM265 is from a new class of antimalarial chemotherapy that inhibits the pyrimidine biosynthetic enzyme, dihyroorotate dehydrogenase (DHODH). The DHODH enzyme is essential to ***Plasmodium*** parasites, as they lack pyrimidine salvage pathways and require de novo synthesis to supply the pyrimidine source. DSM265 entered clinical development in 2013 and could potentially be a novel component of either a new combination single-dose treatment or chemoprophylaxis of uncomplicated malaria. Here, we discuss interim results on efficacy, safety, tolerability and pharmacokinetics of DSM265 when administered as single dose to adult patients with acute, uncomplicated ***Plasmodium falciparum*** or ***vivax*** malaria mono-infection in Iquitos, Peru. Beyond the primary objective of determining the efficacy of DSM265 as monotherapy in uncomplicated malaria on Day 14, we followed patients over a 28-Day-extended observation period for parasite recrudescence/reinfection and safety, tolerability and pharmacokinetics of DSM265. We report data on post-treatment prophylaxis over the extended observation period. In a third part, we show how the results from the previously reported induced blood-stage malaria (IBSM) study using ***P. falciparum*** infected red-blood cells together with a refined PK/PD model and ***ex vivo*** experiments from field isolates guided optimal dose selection of the starting dose for this POC study. The independent two arm study design was adaptive sequential. This design allowed flexibility in dose selection of subsequent cohorts and thereby enabled us to calculate the PRR and MIC of DSM265 for both ***Plasmodium*** species.

858

RANDOMIZED CLINICAL TRIAL OF AQ-13 (AN INVESTIGATIONAL ANTIMALARIAL) IN COMPARISON TO COARTEM FOR UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA

Ousmane A. Koita[1], Sahare Fongoro[1], Sounkalo Dao[1], Aliou Sissako[1], Lansana Sangare[1], Trevor A. Thompson[2], Bouubakar Diallo[1], Samba Diop[1], Djeneba Tamboura[1], Donald J. Krogstad[2]

[1]University of Science, Technologies and Techniques, Bamako, Mali, [2]Tulane University, New Orleans, LA, United States

Our previous studies have shown that AQ-13 and other 4-aminoquinolines with modified side chains are active against chloroquine (CQ)-, mefloquine- and multi-resistant ***Plasmodium falciparum in vitro***. Because previous studies have also shown that AQ-13 is as safe as CQ in human subjects, we performed a randomized clinical trial to test whether AQ-13 was as effective as artemether + lumefantrine (AL, Coartem) for the treatment of uncomplicated ***P. falciparum*** malaria in human subjects. Subjects enrolled in this study were Malian males ≥ 18 years of age with uncomplicated ***P. falciparum*** malaria and asexual parasite counts between 2,000 and 199,999 parasites per µl (NTC Clinical Trial Number 01614964). After oral treatment with either AQ-13 (1,750 mg in doses of 700, 700 and 350 mg on days 1, 2 and 3) or AL (4 tablets twice daily x 3 days=480 mg artemether and 2880 mg lumefantrine), subjects were followed as inpatients on a Clinical Research Center for days 1-7 and twice weekly as outpatients from days 8-42. Although the second group of 33 subjects is still being enrolled, there have been no differences between AQ-13 and Coartem in terms of efficacy (0 early parasitologic or clinical treatment failures on or before day 3 in either group, no subjects in either group has failed to clear all asexual parasites on or before day 7), safety and adverse events including ocular side effects (0 adverse events, Grade 3, Grade 4, serious adverse events, arrhythmias or ocular side effects in either group). These results suggest that both AQ-13 and other AQs with similarly modified side chains (with 2-3 or 10-12 carbons vs. the 5 carbon [isopentyl] side chain of CQ) may be effective for the treatment of human subjects with uncomplicated malaria due to CQ-resistant ***P. falciparum***.

859

HIGH-RESOLUTION MELT ANALYSIS TO COMPARE THE EFFICACY OF AN INVESTIGATIONAL ANTIMALARIAL (AQ-13) WITH COARTEM (ARTEMETHER-LUMEFANTRINE) FOR TREATMENT OF UNCOMPLICATED MALARIA DUE TO CHLOROQUINE-RESISTANT VS. CHLOROQUINE-SUSCEPTIBLE *PLASMODIUM FALCIPARUM*

Trevor A. Thompson[1], Lansana Sangare[2], Aliou Sissako[2], Kotou Sangare[2], Sahare Fongoro[2], Daouda Ndiaye[3], Sarah K. Volkman[4], Donald J. Krogstad[1], Ousmane A. Koita[2]

[1]Tulane University, New Orleans, LA, United States, [2]University of Science, Technologies and Techniques, Bamako, Mali, [3]University Cheikh Anta Diop, Dakar, Senegal, [4]Harvard T.H. Chan School of Public Health, Boston, MA, United States

The use of High Resolution Melt (HRM) analysis to distinguish between specific parasite genotypes during the evaluation of a candidate antimalarial can provide additional information about its efficacy against parasites that do (or do not) have the point mutation (resistance) of interest. To test this hypothesis, we are using HRM to identify (and distinguish between) chloroquine-resistant (CQ-R) and chloroquine-susceptible (CQ-S) parasites containing the T76 and K76 point mutations, respectively. Because the T76 point mutation (SNP) within the ***Plasmodium falciparum*** chloroquine transport gene (PfCRT) is necessary for CQ-R, the frequency of the T76 genotype among the parasites causing the initial infections is being compared for subjects randomized to receive the investigational antimalarial (AQ-13) vs. the control treatment (Coartem) in a Phase 2 clinical trial of efficacy for the treatment of uncomplicated ***P. falciparum*** malaria. Although the mutant (T76) and wild-type (K76) alleles can be distinguished by gel electrophoresis after restriction endonuclease digestion with ApoI, that method can yield false-negative results for genotypes present as minority variants within a polyclonal infection because of the limited sensitivity of gel electrophoresis. In contrast, HRM can detect alleles comprising less than 10% of the parasites present in polyclonal infections. For this reason, we are using HRM genotyping to make this distinction and this assay has now been established and standardized at the University of Bamako within the West African International Center of Excellence in Malaria Research (ICEMR). The results obtained thus far have shown no differences between the two treatment groups. After the second group of 33 subjects has been enrolled and studied this summer, the codes for treatment groups will be broken during September so the uncoded results can be presented at the ASTMH Meeting.

860

DEVELOPMENT OF A CONTROLLED HUMAN MALARIA INFECTION MODEL FOR THE ASSESSMENT OF TRANSMISSION BLOCKING INTERVENTIONS

Katharine Collins[1], Maggy Sikulu[1], Cielo Pasay[1], Romal Stewart[1], Paul Griffin[2], Claire Wang[3], Caroline Dobbin[1], Stephan Chalon[4], Joerg J. Moehrle[4], James McCarthy[1]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Q-Pharm Pty Ltd, Brisbane, Australia, [3]QPID Pty Ltd, Brisbane, Australia, [4]Medicines for Malaria Venture, Geneva, Switzerland

With the declining burden of malaria and the increasing focus on elimination the development of tools to evaluate interventions that interrupt transmission is assuming increasing priority. Rapid and cost-effective evaluation of transmission-blocking drugs and vaccines requires a model that accurately predicts efficacy in humans. Although controlled human malaria infection (CHMI) studies have been used successfully to assess pre-erythrocytic and blood stage interventions, these current models do not assess the ability of interventions to interrupt ***Plasmodium falciparum*** transmission from humans to mosquitoes. The reason for this is that during CHMI, treatment must be initiated promptly once a threshold of asexual parasitemia is reached, thus preventing the normal development of gametocytes, which usually only appear after an extended period of asexual stage infection. In an ongoing study we are exploiting our observation that piperaquine treatment of blood stage ***P. falciparum*** infection clears asexual parasitemia and is followed by the appearance of gametocytes in peripheral circulation ~2 weeks post treatment. The aims of this clinical trial are i) determine if these gametocytes can be transmitted to Anopheles mosquitoes and complete the sexual stage of development, and ii) assess the transmission-blocking activity of the experimental synthetic ozonide, OZ439. The study is being undertaken in 3 cohorts of 6 volunteers, with 2 subjects in each cohort receiving no gametocytocidal intervention (-ve control), 2 subjects receiving primaquine (+ve control) and 2 receiving OZ439. Parasitemia and gametocytemia will be monitored by qPCR and following gametocyte detection, transmission studies will be performed using both direct feeds on volunteers and direct membrane feeding assays on venepuncture blood. Successful mosquito infection will be determined by oocyst/sporozoite visualisation and confirmed by qPCR. This study aims to develop and optimise a reproducible model that can assess both gametocytocidal and transmission-blocking activity for the rapid selection of effective drugs and vaccines. Results of this trial will be presented.

861

EXPLORATION OF 5-AMINOPYRAZOLE-4-CARBOXAMIDE AS POTENTIAL MALARIA TRANSMISSION BLOCKING THERAPY

Kayode K. Ojo[1], Wenlin Huang[1], Mark Kennedy[2], Zhongsheng Zhang[1], Kasey L. Rivas[1], Ryan Choi[1], Matthew A. Hulverson[1], Molly C. Reid[1], Katelyn R. Keyloun[1], Scott E. Lindner[2], Lynn K. Barrett[1], Erkang Fan[1], Ethan A. Merritt[1], Wesley C. Van Voorhis[1]

[1]University of Washington, Seattle, WA, United States, [2]Pennsylvania State University, University Park, PA, United States

Currently available drugs to treat malignant malaria, caused by ***Plasmodium falciparum***, kill the asexual blood stage parasites and treat the symptoms, but do not kill the gametocytes, and do not stop transmission of malaria to mosquitoes. Thus, the vicious cycle of malaria continues, leading to an estimated 584,000 deaths a year. Effective control and eradication of malaria will require new tools to prevent transmission of ***P. falciparum***. We previously established the efficacy of a pyrazolopyrimidine (PP) scaffold of bumped kinase inhibitors (BKIs) in malaria transmission blocking. BKIs block transmission of malaria to mosquitoes by inhibition of ***P. falciparum*** calcium dependent protein kinase 4 (PfCDPK4), which blocks exflagellation of ***P. falciparum*** male gametocytes. We explored alternative inhibitor scaffolds, and report here the design of malaria transmission blocking inhibitors with a 5-aminopyrazole-4-carboxamide (AC) scaffold that specifically exploits the PfCDPK4 atypical gatekeeper pocket. We characterized the AC BKIs for inhibition of PfCDPK4 and ***P. falciparum*** gametocyte exflagellation. To date, 28 compounds have been found to inhibit PfCDPK4 with an IC50 of <100 nM and a further 7 with IC50 of <50 nM. In addition, 26 compounds reduced parasite exflagellation by >50% at 1 μM, Most of these compounds lacked evident toxicity issues, in that at >10uM, there was no inhibition of the mammalian kinase Src, hERG activity, or proliferation two mammalian cell lines, CRL8155 and HepG2. The AC BKIs will be further optimized, through iterative study using ***in vitro*** and ***in vivo*** PK and toxicity models, to optimize clinical safety and efficacy, with long-lasting transmission blocking exposure. The AC and PP BKI scaffolds have yielded valuable compounds to block transmission and show promise to help malaria control and eradication programs.

862

DEFINING EFFECTIVE, APPROPRIATE, IMPLEMENTABLE STRATEGIES FOR MALARIA ELIMINATION IN MILITARY FORCES IN CAMBODIA AS A MODEL FOR MOBILE POPULATIONS

Chanthap Lon[1], **Jessica Manning**[1], Sok Somethy[2], Soklyda Chann[1], Sabaithip Sriwichai[1], Huy Rekol[3], Lek Dysoley[3], Muth Sinoun[3], Prom Satharath[4], David Saunders[1]

[1]Armed Forces Reseach Institute of Medical Sciences, Bangkok, Thailand, [2]Armed Forces Reseach Institute of Medical Sciences, Phnom Penh, Cambodia, [3]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [4]Ministry of National Defense, Department of Health, Phnom Penh, Cambodia

Multidrug resistant malaria remains a critical public health problem in Southeast Asia despite intensive containment efforts. This has led to refocused efforts on malaria elimination, and Cambodia has declared an ambitious goal of achieving elimination by 2025. However, important gaps remain in case management, service delivery, prevention, and vector control, particularly in hard-to-reach mobile populations including military personnel, an under-recognized malaria transmission reservoir. The operational elements of a comprehensive malaria elimination initiative in mobile and migrant populations in Southeast Asia have yet to be rigorously tested in a clinical trial design. We will conduct a two-arm, controlled, cluster-randomized, open-label pilot study to determine the effectiveness of monthly malaria prophylaxis (MMP). Monthly dihydroartemisinin-piperaquine and weekly low dose primaquine for 3 months will be compared to a focused screen and treat (FSAT) strategy following recently updated Cambodian national treatment guidelines. Military encampments will be randomized to the MMP or FSAT intervention in order to treat a total of up to 1200 soldiers. In addition, each site will be randomized to a single-blind treatment of duty uniforms with permethrin to guard against outdoor biting mosquitoes, or sham treatment with water. Conventional malaria microscopy with be compared with RT-PCR and rapid diagnostic testing. All G6PD deficiency screening will be done via two commercially available rapid diagnostic tests, qualitative and quantitative testing to allow for comparison. By including all currently available screening, preventive, and diagnostic modalities, the study aims to identify whether elimination is currently possible and to determine the most cost-effective and efficient approaches in the military as a model mobile population in Cambodia.

863

OPTIMIZING ALLOCATION OF COMMUNITY HEALTH WORKERS USING A NOVEL GEOSPATIAL TOOL IN NAMIBIA

Christopher Lourenço[1], Charlotte Dolenz[1], Stark Katokele[2], Nick Ruktanonchai[3], Andrew J. Tatem[3], Arnaud Le Menach[1], Justin M. Cohen[1], Bradley Didier[1]

[1]Clinton Health Access Initiative, Boston, MA, United States, [2]National Vector-borne Diseases Control Programme, Windhoek, Namibia, [3]University of Southampton, Southampton, United Kingdom

Namibia's malaria burden continues to decrease from 439,760 cases in 2002 to 4,745 in 2013. However, the country is challenged by having one of the lowest population densities in Africa, with people distributed unevenly across enormous distances. It is reported that over 60% of the rural population need to walk to the nearest health facility, the majority of which are 3-4 hours away. Increasing access to healthcare at the community level was supported by the rollout of community health workers (CHWs) in 2014. The initial placement of CHWs was evenly distributed and the National Vector-borne Diseases Control Programme (NVDCP) sought advice on how to best re-allocate CHWs to ensure maximized coverage of communities in need. For the efficient allocation of resources, CHWs should be placed in highly populated communities where there is limited access to healthcare and a high malaria transmission potential. Allocation was prioritized in communities with the greatest population density (>5 people per square km), highest predicted risk of malaria (incidence >5 cases per 1000), and with location furthest from health facilities, based on expert recommendations from the NVDCP. The ideal CHW allocation resulting from this analysis suggested targeting 625 priority villages out of the 6988 endemic villages (8.9%) and comparison of the recommended deployment with current CHW locations demonstrates substantial gaps in recent CHW placement. This methodology was translated into a simple, web-based dashboard, which does not require any advanced geospatial analysis skills and could be accessed by the NVDCP and regional partners. In an elimination setting, malaria burden is dynamic, and CHW placement should be iteratively reassessed and updated as the epidemiology of malaria evolves. The findings for the allocation of CHW in Namibia will be used to plan for the next malaria season in 2016, while this methodology could be beneficial for resource allocation in other elimination settings.

864

MASS SCREENING AND TREATMENT DOES NOT IMPACT MALARIA INCIDENCE IN WEST TIMOR, INDONESIA

Inge Sutanto[1], Ayleen A. Kosasih[1], Iqbal Elyazar[2], Deddy R. Simanjuntak[1], Tri A. Larasati[1], Sopiyudin Dachlan[3], Isra Wahid[4], Kevin Baird[2], Ivo Mueller[5], Rita Kusriastuti[6], Asik Surya[6], William Hawley[7], Neil F. Lobo[8]

Mass screening and treatment (MST) is an intervention strategy used in Indonesia towards the goal of eliminating malaria. The aim of this study was to identify the impact of two regimens of MST on malaria incidence and prevalence in a region of moderate malaria transmission. Inhabitants (n=1,868) of 3 villages (Lamea, Seserai and Weoe) and 1 hamlet (Metanamasi) in Belu Regency, West Timor, were randomly allocated into 3 arms, i.e. one that received MST twice (arm-1, n=649) in 3 months, an arm that received MST only once (arm-2, n=422) and a control arm that did not receive MST (arm 3=777) during the same time span. Dihydroartemisinin-piperaquine plus primaquine was used to treat positive cases based on microscopic blood slide results. The malaria status of a cohort of primary school children from these 3 arms were also examined monthly for 6 months Results of the study will be presented.

865

SERIAL MOLECULAR IDENTIFICATION TO CONFIRM THE PRESENCE OF *PLASMODIUM KNOWLESI* IN INDONESIA

Farah Coutrier[1], Chris Cotter[2], Yusrifar K. Tirta[1], Alanna Schwartz[3], Iska Zarlinda[1], Herdiana H. Basri[4], Jutta Marfurt[5], Nicholas Anstey[5], William A. Hawley[6], Asik Surya[7], Brittany Zelman[2], Iveth J. Gonzales[8], Bryan Greenhouse[3], Roly D. Gosling[2], Michelle S. Hsiang[9], Rintis Noviyanti[1]

[1]Eijkman Institute for Molecular Biology, Jakarta, Indonesia, [2]Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, [3]Department of Medicine, University of California San Francisco, San Francisco, CA, United States, [4]United Nation Children's Fund, Aceh, Indonesia, [5]Menzies School of Health Research, Darwin, Australia, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]National Malaria Control Programme – Indonesian Ministry of Health, Jakarta, Indonesia, [8]Foundation for Innovative New Diagnostics, Geneva, Switzerland, [9]University of Texas Southwestern Medical Center, Dallas, TX, United States

In order to achieve malaria elimination, intervention efforts must target all ***Plasmodium*** species, including zoonotic ones. The use of sensitive and specific molecular detection of malaria parasites can address this challenge. We introduced the use of molecular detection for reactive case detection of malaria in Aceh Besar District, Aceh Province, Indonesia, an area in the pre-elimination stage with known endemicity of ***P. vivax*** (Pv) and ***P. falciparum*** (Pf), but not ***P. knowlesi*** (Pk). ***Plasmodium***-specific loop-mediated isothermal amplification (LAMP) was performed on dried blood spots collected from microscopy confirmed cases identified at 5 sentinel health facilities as well as family members and neighbors residing within the reactive case detection radius. From June 2014 - March 2015, passive and active case detection (testing 778 household members and neighbors of passively detected cases) using microscopy detected 20 cases (7 Pf, 11 Pv, 1 P. malariae, 1 suspected Pk). LAMP detection confirmed microscopy findings and identified 3 additional submicroscopic infections in the community. ***Plasmodium*** speciation by nested PCR targeting the ***cytochrome b*** (***cytb***) gene followed by restriction digests were done and confirmed some but not all of the microscopy results (4 Pf, 1 Pm and 1 suspected Pk cases were identified as Pv). Further PCR and sequencing of ***P. knowlesi***-specific small subunit ribosomal RNA gene identified that 7 of 21 cases identified as Pv by ***cytb***-PCR were actually Pk, including one found in active case detection. We report the first cases of Pk identified in Indonesia outside of Borneo island, through passive and active case detection. Pk detection by microscopy is difficult because the morphology of different stages of Pk life-cycle is very much similar to other malaria species. Moreover, commonly used molecular methods mis-identify Pk as Pv. These findings pose challenges to areas with ***P. vivax*** and possible ***P. knowlesi*** endemicity, particularly those aiming to eliminate malaria. Simple molecular methods to detect all ***Plasmodium*** species are needed to support malaria control and elimination efforts.

866

HOUSING QUALITY AS A POTENTIAL RISK FACTOR FOR LOCALLY ACQUIRED MALARIA INFECTION IN SWAZILAND

Nomcebo Mkhonta[1], Deepa Pindolia[2], Nyasatu Ntshalintshali[3], Joseph Novotny[4], Mi-suk Kang Dufour[5], Roly Gosling[6], Arnaud Le Menach[2], Justin Cohen[2], Bryan Greenhouse[5], Michelle Hsiang[6], Simon Kunene[1]

[1]Swaziland National Malaria Control Programme, Manzini, Swaziland, [2]Clinton Health Access Initiative, Boston, MA, United States, [3]Clinton Health Access Initiative, Manzini, Swaziland, [4]Clinton Health Access Initiative, Phnom Penh, Cambodia, [5]Department of Medicine, University of California, San Francisco, CA, United States, [6]Malaria Elimination Initiative, Global Health Group, University of California, San Francisco, CA, United States

Poor housing quality may contribute to mosquito exposure and increase risk of malaria infection, but evidence in elimination settings is lacking. Here, surveillance data was used to study the association between housing quality and locally-acquired infection in Swaziland. Subjects were malaria index cases detected through passive surveillance and their household and community contacts screened in reactive case detection from August 2012 to January 2015. Cases were defined as Loop-mediated isothermal amplification (LAMP) positives with no travel history and controls as LAMP negatives with no travel history. Housing quality was defined using wall, roof and window type variables, which were then combined to develop a composite housing quality index. Bivariate and multivariable logistic regressions, adjusted for household-level clustering, were used to analyze relationships between infection, housing quality and other risk factors. Of the 993 index cases, 840 (85%) received a LAMP test and 102 (12%) were locally-acquired cases. Of the 11,464 people screened, 11,079 (97%) received a LAMP test and 138 (1%) were locally-acquired cases. In bivariate model with separate housing quality predictors, higher odds of infection were associated with poor quality external wall (OR 2.1 95%CI 1.4-3.1), poor quality internal wall (OR 1.8 95%CI 1.2-2.7) and poor quality roof (OR 2.1 95%CI 1.4-3.2). Higher infection odds were also associated with farming and manual labour occupations (OR 2.5 95%CI 1.6-3.9). In the multivariable model, only poor quality external wall was associated with higher infection odds (OR 2.5 95%CI 1.3-4.9). Overall, poor housing was associated with higher infection odds in bivariate (OR 1.7 95%CI 1.2-2.5) and multivariable models (OR 1.8 95%CI 1.2-2.8). Insecticide-treated bed net use and sleeping under a sprayed structure were associated with non-significant reductions in infection odds. There were no associations with age, gender, region and nationality. Housing quality was an important determinant of locally-acquired infection in Swaziland, suggesting improved housing as a potential elimination strategy.

867

LEVERAGING COMMUNITIES TO PURSUE MALARIA ELIMINATION: A COMPARISON OF NATIONAL-LEVEL CERTIFICATION TO VILLAGE-LEVEL CERTIFICATION AND SUBSEQUENT EFFECTS ON COMMUNITY ENGAGEMENT

Jillian Berkowitz[1], Daniel J. Bridges[1], Matthew Burns[1], Anna Winters[1], David A. Larsen[2]

[1]Akros, Lusaka, Zambia, [2]Syracuse University, Syracuse, NY, United States

The World Health Organization certifies malaria elimination exclusively at the national scale and has no mechanism to certify smaller geo-political units as malaria free. This certification process fails to recognize that malaria epidemiology is highly heterogeneous and smaller geo-political units may become malaria free long before an entire country. The WASH sector, in contrast, certifies open defecation free (ODF) status at village-level. The use of smaller geo-political units in the WASH sector has two advantages: 1) it drives the construction and use of latrines and hand washing stations and 2) it engenders community engagement. In Zambia, real-time feedback of WASH data to villages regarding their success or failure in attaining ODF status has resulted in great gains in the number of ODF villages. ODF status has been achieved at district-level in Chiengi (the first district in sub-Saharan Africa to achieve this certification) and other districts are close. The direct connection between those responsible for action at village-level and the certification of ODF status has fostered the community-driven progress in Zambia's WASH sector. Related to malaria elimination, several districts in Southern Zambia have made great progress towards eliminating malaria transmission, including the capital city, Lusaka. With certification for "malaria free" only applying at national level, however, a country like Zambia which possesses high heterogeneity of malaria transmission is far from country-wide attainment. We propose that sub-national certifications of malaria elimination or even a muted "malaria safe" designation at the facility or village level would better engage and empower communities to achieve and sustain malaria-prevention behavioral change and eventually malaria elimination. Additionally, we suggest a sub-national malaria elimination framework to catalog and communicate decentralized malaria elimination status and to better motivate communities and provide evidence that efforts are continuing to shrink the malaria map.

868

MAPPING OF POPULATION MOVEMENT PATTERNS AND ESTIMATING OF IMPORTED MALARIA IN MALARIA-FREE JAVA/BALI IN INDONESIA

Iqbal Elyazar

Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia

Controlling and eliminating malaria in Indonesia is a challenging endeavor. About 60% of Indonesian lives the islands of Java and Bali where malaria-free and low risk of infection zones occur. However, sustaining this achievement and preventing the re-introduction of malaria will be very difficult. These movements incur substantial risk of importing and re-establishing malaria transmission on islands that have eliminated malaria. This project is designed to quantifying population movements, along with understanding the geographic and demographic dimensions of such movements, as the key to combating threats to sustaining elimination. Knowing the importation risks, high risk visit periods and the most important paths of malaria importation will allow malaria control authorities to design interventions that can reduce transmission in all regions that are primary sources of infected travelers. Techniques to estimate specific patterns and numbers of human movements using mobile phone usage data among the islands will be explained.

869

TOWARDS MALARIA ELIMINATION: ETHNOGRAPHIC AND MALARIA EPIDEMIOLOGICAL RESEARCH IN EASTERN INDONESIA

Lenny L. Ekawati

Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia

Malaria continues to be a severe public health problem in Indonesia with approximately 130 million Indonesians living at risk. In the absence of effective prevention, appropriate treatment-seeking behavior and accessibility of adequate health services are essential for decreasing the risk of severe complications, deaths and transmission of the disease. This cross-sectional study aimed to investigate factors affecting treatment-seeking in 3 malaria-endemic communities in Alor district in eastern Indonesia. Mixed (qualitative/quantitative) methods used, include (1) a GPS-aided household census to enumerate the study population (n=3077); (2) ethnographic research, including observations and semi-structured interviews with community members and health care providers (n=44); (3) a structured community-based survey (n=350) and semi-structured interviews with health care providers (n=6), and a check of diagnostic facilities and malaria treatment records at the field sites. Guided by a socio-ecological framework, thematic content analysis identifies different spheres of influence on malaria-treatment seeking behavior, including local (mis-)understandings about the disease and its transmission, as well as competing socio-economic concerns at the individual and social levels, and the lack of adequate diagnostic and treatment facilities at the structural level. Multiple regression analyses explore associations of personal and socio-economic correlates with appropriate treatment-seeking behavior. This study highlights that in order to address the needs of populations in malaria-endemic areas in eastern Indonesia, we must understand the complexity of multiple interacting factors, avoiding simplified assumptions about obstacles to appropriate treatment-seeking behaviors.

870

CHARACTERIZATION AND ANTIBIORESISTANCE OF CULTURABLE MICROFLORA BACTERIA IN THE MIDGUT OF ADULT *ANOPHELES GAMBIAE* AND *AN. COLUZZII*

Aminata Fofana[1], Mathilde Gendrin[2], Ibrahim Sangare[3], Soufiane Sanou[4], Soumeya Wangraoua[5], Aly Drabo[5], George Christophides[2], Jean Bosco Ouedraogo[1], Rakiswendé Serge Yerbanga[1]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]Department of Life Sciences, Imperial College, London, United Kingdom, [3]Université Polytechnique Centre Hospiltalier Universitaire Sanou Sourou, Bobo-Dioulasso, Burkina Faso, [4]Centre Hospitalier Universitaire Sanou Sourou, Bobo-Dioulasso, Burkina Faso, [5]Centre Muraz, Bobo-Dioulasso, Burkina Faso

The bacterial microbiota colonizing the mosquito midgut plays an important role in interactions between mosquitoes and parasites, thus modulating the level of malaria transmission. Characterization of the bacterial flora living in the mosquito vector of malaria may inform new control strategies aiming to reduce malaria transmission. In this study, we isolated and identified the bacteria flora present in the gut of adults female ***Anopheles*** by conventional ***in vitro*** culture techniques and sequencing. To verify the stability of paratransgenesis bacteria candidate and refractoriness bacteria pathogens for human, we evaluated the susceptibility of bacteria flora isolated in the midgut of ***An. coluzzii*** and ***An. gambiae***. We showed that the composition of the midgut bacteria in field-collected mosquitoes exhibits a great variability in contrast to laboratory-reared mosquitoes, which could be explain by the bacterial richness of the larval habitats. Among the isolated bacteria, Enterobacteriaceae and Staphyloccocacea families were most prevalent. A species-specifics association, ***An. coluzzii*** and ***An. gambiae*** has founded. We also observed interest bacteria as Asaia sp and Pantoea sp for

paratransgenesis and potentially pathogenic bacteria for Human such as ***Escherichia coli, Serratia ficaria*** or Klebsiella pneumonia. The antibiotic susceptibility test showed that the ideal candidate of paratransgenesis were sensitive an different antibiotics using abusively in Burkina Faso.

871

FOUL WIND, SPIRITS AND WITCHCRAFT: ILLNESS CONCEPTIONS AND HEALTH-SEEKING BEHAVIOR FOR MALARIA IN THE GAMBIA

Sarah O'Neill[1], Charlotte Gryseels[1], Susan Dierickx[1], Julia Mwesigwa[2], Joseph Okebe[2], Umberto d'Alessandro[2], Koen Peeters Grietens[1]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Medical Research Council, Fajara, Gambia

As the disease burden in the Gambia has reduced considerably over the last decade, heterogeneity in malaria transmission has become more marked, with infected but asymptomatic individuals maintaining the reservoir. The identification, timely diagnosis and treatment of malaria-infected individuals are crucial to further reduce or eliminate the human parasite reservoir. This ethnographic study focused on the relationship between local beliefs of the cause of malaria and treatment itineraries of suspected cases. An ethnographic qualitative study was conducted in twelve rural communities in the Upper River Region and the Central River Region in the Gambia. The data collection methods included in-depth interviews, participant observation, informal conversations, and focus group discussions. While at first glance, the majority of people seek biomedical treatment for 'malaria', there are several constraints to seeking treatment at health centres. Certain folk illnesses, such as Jontinooje and Kajeje, translated and interpreted as 'malaria' by healthcare professionals, are often not considered to be malaria by local populations but rather as self-limiting febrile illnesses - consequently not leading to seeking care in the biomedical sector. Furthermore, respondents reported delaying treatment at a health centre while seeking financial resources, and consequently relying on herbal treatments. In addition, when malaria cases present symptoms such as convulsions, hallucinations and/or loss of consciousness, the illness is often interpreted as having a supernatural aetiology, leading to diagnosis and treatment by traditional healers. In conclusion, although malaria diagnostics and treatment seeking in the biomedical sector has been reported to be relatively high in the Gambia, local symptom interpretation and illness conceptions can delay or stop people from seeking timely biomedical treatment, which may contribute to maintaining a parasite reservoir of undiagnosed and untreated malaria patients.

872

INTENSIFYING SURVEILLANCE OF ANTIMALARIAL MULTI-DRUG RESISTANCE IN THE CAMBODIAN NATIONAL CONTROL PROGRAM BY INTEGRATING GENETIC EPIDEMIOLOGY INTO ROUTINE ACTIVITIES OF VILLAGE MALARIA WORKERS

Rekol Huy[1], Sara E. Canavati[2], Rithea Leang[1], Jack S. Richards[3], Olivo Miotto[4], Arjen M. Dondorp[5]

[1]The National Centre for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [2]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University; Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Burnet Institute of Medical Research, Department of Microbiology, Monash University, Melbourne, Victoria, Australia, [4]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University; Wellcome Trust Sanger Institute, Centre for Genomics and Global Health, University of Oxford, Bangkok, Thailand, [5]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Drug resistant ***Plasmodium falciparum*** parasites are the most serious threat to malaria control in Cambodia and to the Greater Mekong System (GMS). Monitoring of genetic markers of drug resistance and parasite diversity provides an important tool for mapping the geographical distribution of resistance and for identifying subpopulations of parasites. This can be used to respond to local outbreaks of malaria by distinguishing clonal expansion of multidrug resistant parasites from other causes of increased transmission. Furthermore, through the application of population genetics and mathematical modelling, geographical corridors of spread of resistance can be identified, informing intervention policies. We have established a genetic epidemiological surveillance system to guide malaria elimination in Cambodia, in particular targeting multidrug resistant falciparum malaria. The system leverages on an existing malaria information system (MIS) which records slide-confirmed malaria cases data notified by village health workers (VMWs) or health facility staff in 2539 villages in endemic areas of Cambodia. VMWs and other health facility staff provide a first point of care by diagnosing and treating malaria cases, and collect basic epidemiological data on age, sex, location, pregnancy status, and likely location of infection. To support genetic surveillance, the collection of dried blood spot (DBS) samples on filter paper for all confirmed cases of falciparum and mixed species infection has been integrated in the routine diagnosis and treatment workflow. Samples are then routed for processing and genotyping using existing sample referral mechanisms; the resulting data is used to create maps of markers, population analyses and mathematical modelling. Here, we describe the initial phases of implementation of this new approach to surveillance and its findings. The National malaria control program of Cambodia aims to intensify elimination efforts by further integrating genetic epidemiological approaches into village-based surveillance programs.

IMPLEMENTING ENHANCED HIGH-RESOLUTION SURVEILLANCE USING SPATIAL DECISION SUPPORT SYSTEMS (SDSS) TO GUIDE TARGETED RAPID RESPONSE IN MULTI-DRUG RESISTANT AREAS OF VIETNAM

Gerard C. Kelly[1], Thang X. Nguyen[2], Thang D. Ngo[2], Andrew A. Lover[1], Hung Q. Pham[1], Nicholas Martin[3], Xa X. Nguyen[2], Anh Q. Nguyen[2], Thinh D. Ngo[2], Duong T. Tran[2], **Colin Ohrt**[1]

Emerging untreatable malaria in the Greater Mekong Subregion (GMS) could result in a public health disaster when it reaches Africa. A project was established to research, develop and implement enhanced surveillance

and targeted appropriate intervention measures to stop the spread of multi-drug resistant malaria through elimination of the disease in the region. The aims of the project are to implement a spatial decision support system (SDSS) approach to conduct high-resolution surveillance to guide swift and targeted responses. Sites have been established in Phu Yen and Quang Tri Provinces of Vietnam. Publically available topographic geographic information have been uploaded as baseline information. In Phu Yen province, 4683 households with 17653 people have been georeferenced. Seventy five current and recent malaria cases have linked to the geolocated households. Only 5-10% acquired malaria at the household level. Most patients could specifically identify the likely transmission location where they were 8-16 days (liver incubation period) earlier. Remote area geographic reconnaissance data is currently being systematically collected from the largely forested transmission locations. Data with GPS coordinates are being collected with handheld computers and inexpensive smart phones using Open Data Kit (ODK). All new cases are being reported within 24 hours on smart phones. Current and historical case and entomology data are being captured to automatically classify transmission ***foci*** and generate response areas-of-interest (AOI). Supporting data (e.g. population, indoor residual spraying status, bed need distribution/use, location and number of sleeping locations) will be used to automatically produce output for village health workers and district level units to mobilize appropriate responses. The current project, ending in August 2015, will allow the full SDSS system will be presented. This new approach utilizes novel geo-spatial tools to support targeted, appropriate and aggressive response measures to support malaria elimination in areas of global significance.

874

MALARIA CASE INVESTIGATION IN SENTINEL SITES IN VIETNAM

Xa X. Nguyen[1], Hung Q. Pham[2], Duong T. Tran[1], Thang X. Nguyen[1], Andrew A. Lover[2], Nicholas Martin[3], Anh Q. Nguyen[1], **Colin Ohrt**[2], Thang D. Ngo[1]

[1]National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, [2]University of California, San Francisco, Hanoi, Vietnam, [3]Naval Medical Research Center-Asia, Singapore, Singapore

The National Malaria Control Program in Vietnam established seven sentinel sites in areas of different malaria endemnicity in Vietnam in 2014 in preparation for malaria elimination by 2030. One component of this project involved case interviewers to better understand the factors leading to on-going malaria transmission. Between July 2014 and March 2015, 322 confirmed malaria cases were interviewed in 4 provinces as follows: Binh Phuoc 217, Phu Yen 72, Gai Lai 31 and Lai Chau 1. Sixty-one percent of cases were reported as ***Plasmodium falciparum***, 34% ***P. vivax*** and 4% both species. 97.5% of cases had a diagnosis by microscopy, 80% both microscopy and RDT and the remainder only RDT. The concordance rate between the diagnostic tests was very high. Of the 214 cases with available data, 86% reported a diagnosis made within two days or fewer from the onset of symptoms. ***P. falciparum*** cases were treated with dihydroartemisinin-piperaquine and ***P. vivax with*** chloroquine. For both species, 98% were given primaquine according to national guidelines. Follow-up on day 3 was conducted in 134 people; only one person had not cleared parastiemia. Overall, 16% of patients were women, ranging from 8% in Phu Yen to 39% in Gai Lai ($p < 0.001$), while 11% of cases were in children < 16 years. Sixty percent of cases were reported from 9 different ethnic minority groups. The probable transmission locations were described as follows: at home 6%, in the forest or on a forest-fringe farm 47%, and while traveling 26%. For 102 cases (32%), the transmission site was suspected to be across borders, of which Cambodia was specifically mentioned in 42. Of the cases from Cambodia, 79% were Pf, all were in men and 83% occurred in forest workers. Of the 163 individuals asked, 30% reported knowing of family or neighbors who had malaria recently. Information presented here reveals that the quality of malaria diagnosis and treatment is good in the public health sector in Vietnam. This questionnaire is now being rolled out all malaria-endemic areas in Vietnam. In Phu Yen province, additional information are now being captured to more specifically identify transmission locations in preparation for pilot implementation of reactive case detection.

875

AN EXTENDED MOLECULAR BARCODE FOR TRACKING *PLASMODIUM FALCIPARUM* PARASITE POPULATIONS

Nicholas K. Baro[1], Rachel Daniels[1], Eli Moss[2], Wesley Wong[1], Daniel L. Hartl[3], Daniel E. Neafsey[2], Sarah K. Volkman[1], Dyann F. Wirth[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Broad Institute, Cambridge, MA, United States, [3]Harvard University, Boston, MA, United States

Major epidemiological shifts associated with the transition toward malaria-elimination are mirrored by changes in the genetic diversity of malaria parasite populations. These genetic signatures can be monitored using population genetic-based tools to determine efficacy of malaria intervention efforts prior to measurable changes in disease prevalence. We sought to develop a genotyping tool that would detect key changes in parasite population structure as transmission declines that would be cost-effective and applied to large-scale population analysis. We also wanted a tool that would facilitate our understanding of basic biological processes of parasite transmission. Thus, we strategically increased the number of informative loci to develop a readily deployable and robust panel of single nucleotide polymorphism (SNP) assays comprising an extended molecular barcode. The extended barcode assays, designed using Agena's (Sequenom) mass spectrometry-based technology include SNPs exhibiting high minor allele frequency and low divergence (e.g. FST), filtered from screening over 500 whole genome sequenced samples. We found 99% concordance across a set of previously sequenced monogenomic samples, identified the limit of detection (50 pg/ul), and found the dynamic range of the minor allele could be accurately resolved when present > 10-15% of the sample. The increased number of loci and allele frequency information improve our ability to predict the number of distinct parasite genomes in samples with higher complexity of infection. In silico barcodes, derived from whole genome sequencing data, demonstrate the extended barcodes utility for detecting ancestry among parasites on a more cost-effective basis compared to whole genome sequencing. Agena assay concordance across clinical samples using DNA extracted from monogenomic samples collected on filter paper from Senegal was 98% concordant with Taqman genotyping. We are now applying this extended barcode approach to follow changing population genetic signals in Africa as campaign interventions such as mass drug administration are being applied toward malaria elimination.

USE OF SURVEILLANCE AND MOBILE PHONE DATA TO PREDICT SPATIAL PATTERNS OF MALARIA TRANSMISSION AND INFORM TARGETED INTERVENTION STRATEGIES IN HAITI

Darlene Bhavnani[1], Nick Ruktanonchai[2], Gedeon Gelin[1], Luis M. Perez[1], Kimberly E. Mace[3], Andrew J. Tatem[2], Michelle Chang[3], Jean F. Lemoine[4], Justin M. Cohen[1], Arnaud Le Menach[1]

[1]Clinton Health Access Initiative, Boston, MA, United States, [2]Department of Geography and Environment, University of Southampton, Southampton, United Kingdom, [3]Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Programme national de lutte contre la malaria, Port-au-Prince, Haiti

To achieve malaria elimination goals with limited resources, national programs will need to design and target interventions strategically. Spatial targeting of interventions can be guided by understanding heterogeneity of risk and human movement between areas of differential risk. We assessed risk and exportation of malaria via human movement across Haiti, where the national program aims to interrupt local transmission by

2020. Malaria Test Positivity Rates (TPR) among symptomatic individuals, reported to the national sentinel site surveillance system (2011-2013), were combined with demographic and ecological covariates using logistic regression to predict spatial patterns of transmission. The resulting risk map was overlaid with human mobility patterns predicted using anonymized mobile phone call data records from September to November 2010. Geographic communities with highly connected infected individuals were identified and within communities, administrative units likely to export infection were highlighted. We estimated that 15-30% of Haiti's population lived in areas of medium to high transmission risk (TPR >15%). Combining risk with mobility data, Haiti was divided into six communities, between which travel is relatively low but, within which there is likely substantial movement of infected individuals. Malaria exportation rates and the number of cases exported by administrative unit were estimated. While any combination of these results can be used for geographic targeting of interventions, we highlighted three administrative units in each community with the highest exportation rates. For optimal efficiency, malaria interventions may be targeted within a community simultaneously, reserving those most aggressive for high risk ***foci*** that export infection. At the same time, strong passive surveillance should be maintained across the country. Although use of TPR to estimate risk is limited by health seeking behavior and diagnostic practices, evidence generated by the combination of surveillance and mobility data can help programs design targeted interventions to interrupt local malaria transmission.

877

TEMPORAL INSTABILITY OF SPATIAL CLUSTERS OF *PLASMODIUM FALCIPARUM* INFECTION IN AN AREA OF LOW MALARIA TRANSMISSION IN SOUTHERN ZAMBIA

Kelly M. Searle[1], Timothy Shields[1], Jailos Lubinda[2], Harry Hamapumbu[2], Tamaki Kobayashi[1], Philip E. Thuma[2], Frank Curriero[1], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Macha, Zambia

The spatio-temporal dynamics of malaria transmission are not well characterized in areas transitioning from endemic transmission to pre-elimination and elimination. Data from a population-based, serial cross-sectional cohort study were used to detect spatial clusters of malaria in a low transmission setting of southern Zambia. The prevalence of malaria was determined using an algorithm that included those positive by polymerase chain reaction (PCR) and those positive by rapid diagnostic test but negative by PCR who reported taking anti-malarials in the prior two weeks. The malaria prevalence decreased from 9% in 2008 to <1% in 2013. Spatial only cluster detection analysis (SaTScan) was preformed to identify clusters for each year from 2008-2013. Space-time cluster detection analysis was performed to identify spatial clusters over the years 2008 to 2013 accounting for temporal trends. Statistically significant spatial clusters were detected with the spatial only analysis for 2008, 2009, 2010, and 2012; however, these clusters did not overlap. The space-time cluster detection analysis detected two statistically significant space-time clusters that were stable over time after accounting for temporal trends. These two temporally stable clusters overlapped spatially with clusters detected in the spatial only model from 2008, 2009, and 2010. The spatio-temporal stability of clusters between 2008 and 2010 suggests a persistent ecological reservoir of malaria transmission. However, as transmission further decreased after 2010, the absence of spatio-temporal clusters suggests the disappearance of a stable reservoir, with malaria likely to be imported rather than locally acquired. As areas transition from endemic and pre-elimination to elimination, targeting control measures to eliminate the remaining few cases is essential. When there is evidence of spatial clusters and a persistent malaria transmission reservoir, interventions such as reactive drug administration can be effective. But when this reservoir is eliminated, passive detection of imported cases and measures to reduce re-establishment of a reservoir are warranted.

878

PILOT STUDIES OF *GRAMMOMYS SURDASTER (G. DOLICHURUS)*, THE NATURAL HOST FOR *PLASMODIUM BERGHEI* PARASITES, AS A MODEL TO STUDY WHOLE ORGANISM VACCINES AGAINST MALARIA

Solomon Conteh[1], Charles Anderson[1], Lynn Lambert[1], Sachy Orr-Gonzales[1], Jessica Herrod[1], Yvette L. Robbins[1], Dariyen Carter[1], Stomy Karhemere[2], Pati Pyana[2], Philippe Büscher[3], Patrick Duffy[1]

[1]National Institutes of Health, Rockville, MD, United States, [2]Institut National de Recherche Bio-Médicale, Kinshasa, Democratic Republic of the Congo, [3]Unit of Parasite Diagnostics, Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp, Belgium

A highly efficacious vaccine to prevent infection is needed for the goal of malaria eradication. Inbred mice are commonly used to test candidate malaria vaccines, yet are unreliable to predict efficacy in humans. To establish a more rigorous animal model, we acquired African woodland thicket rats (TR) of the genus ***Grammomys***, the natural hosts for *Plasmodium berghei* (Pb). TR were transferred from a colony at INRB in Kinshasa to establish a breeding colony at NIAID in Rockville, MD, and were identified as ***G. dolichurus (surdaster***) by skull and teeth measurements and mitochondrial DNA genotyping. We established that TR are highly susceptible to infection by all rodent malaria strains tested (Pb ANKA, Pb NK65, ***P. chabaudi chabaudi*** (Pcc) AS, Pcc CB and ***P. yoelii*** 17XNL): for all parasite species, 1-2 infected mosquito bites or 25-100 sporozoites (SPZ) administered intravenously consistently resulted in patent parasitemia. We then assessed efficacy of whole organism vaccines (WOV) to induce sterile immunity. Using Pb radiation attenuated SPZ (RAS), C57BL/6 mice were 100% protected after immunization with a total of 30K RAS PbSPZ administered in 3 doses (10K RAS PbSPZ per dose) at 3-4 weeks interval, against challenge with 200 PbSPZ or 1K PbSPZ. In contrast, this regimen protected only 40% of TR against challenge with 200 PbSPZ, and 0% against challenge with 1K PbSPZ. A higher immunizing dose of 200K RAS PbSPZ administered in 3 doses at 3-4 weeks interval (100K +50K +50K) protected 100 % of TR from challenge with 200 PbSPZ, but only 20% from challenge with 1K PbSPZ. Using a chemoprophylaxis vaccination approach, we again observed differences between laboratory mice and TR. After 3 doses of 3K PySPZ under Pyrimethamine drug (PYR) cover at 3-4 weeks intervals, 75% of BALB/c mice but 0% TR were protected from challenge with 200 ***P. yoelii*** 17XNL SPZ (PySPZ). After 3 doses of 10K PySPZ under PYR treatment at 3-4 weeks interval, 50% of TR were protected from challenge with 200 PySPZ. The results show that TR are a more stringent rodent model for evaluating WOV for malaria, and also confirm that WOV efficacy in a stringent model can be enhanced by increasing SPZ dose.

EFFICIENCY OF REACTIVE CASE DETECTION WITH FOCAL DRUG ADMINISTRATION FOR MALARIA ELIMINATION: SIMULATION STUDY BASED ON CROSS-SECTIONAL SURVEYS IN RURAL SOUTHERN ZAMBIA

Jessie Pinchoff[1], Kelly M. Searle[1], Timothy M. Shields[1], Harry Hamapumbu[2], Tamaki Kobayashi[1], Natasha M. Laban[2], Philip E. Thuma[2], William J. Moss[1], Frank C. Curriero[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Macha, Zambia

As malaria elimination is pursued, identifying and treating all remaining infected individuals will be critical. Passive or reactive case detection (RACD) with rapid diagnostic tests (RDTs) may not identify individuals with sub-patent or asymptomatic infection who serve as persistent reservoirs. Focal mass drug administration is a strategy in which individuals residing within a specified radius of an index case are presumptively treated for malaria without testing. RACD and focal mass drug administration are potential strategies to eliminate parasite reservoirs in low transmission

settings. Household malaria surveys were conducted within Choma District, Zambia between 2009 - 2013. Questionnaires were administered and a blood sample was collected to detect ***Plasmodium falciparum*** by RDT and polymerase chain reaction (PCR). Household structures within the study area were enumerated using satellite imagery. Simulations were performed to extrapolate data from surveyed to non-surveyed households. Residents who were RDT-positive, reported seeking care at health facilities, experienced fever or headache as symptoms were considered index cases detected through passive surveillance. Radii of increasing size around each index household were examined to determine the proportion of households with an infected individual detected through RACD or treated through focal drug administration. Based on simulated data, cross-K function analysis identified spatial clustering of missed asymptomatic and sub-patent infection in residents of households around index houses. RACD and treatment of residents of households within 500 meters of the index case would have identified only 56% of all households with an RDT-positive asymptomatic resident and only 54% of individuals with sub-patent infection. RACD will identify asymptomatic individuals who do not seek care but will not be sufficient to eliminate malaria in this setting.

880

IVERMECTIN FOR MALARIA CONTROL: MODEL VALIDATION TO EXISTING DATA AND DESIGNING TRIALS TO DETECT AN IMPACT USING CLINICAL AND ENTOMOLOGICAL METRICS

Hannah C. Slater[1], Kevin Kobylinski[2], Brian Foy[3], Haoues Alout[3], Thomas Churcher[1], Teun Bousema[4], Azra Ghani[1]

[1]Imperial College, London, United Kingdom, [2]Department of Entomology, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Arthropod-borne and Infectious Diseases Laboratory, Department of Microbiology, Immunology and Pathology, Colorado State University, Fort Collins, CO, United States, [4]Radboud University, Medical Center, Nijmegen, Netherlands

Ivermectin has been identified as a potential new addition to the arsenal of interventions to control and eliminate malaria. The mosquitocidal impact of ivermectin is well documented and well understood, however it remains unclear how mass treatment using ivermectin in malaria endemic populations would impact transmission. Nearly all the studies investigating the effect of ivermectin on vector mortality use laboratory reared mosquitoes, which live considerably longer than wild mosquitoes. Cluster randomised trials are needed to see how the mosquitocidal effect translates to a population level impact, on both mosquitoes and humans. In this study we use a previously published mathematical model of the impact of ivermectin on malaria transmission to estimate the optimal timing and frequency of mass ivermectin treatment to maximise the impact on clinical incidence and entomological metrics (parity rate, survival rate and sporozoite rate). We perform sample size calculations to estimate the number of mosquitoes that would need to be caught and the number of clinical cases to be detected each day to significantly detect an impact on transmission. The optimal time to start a mass ivermectin intervention is during the peak of the rainy season, as this is when mosquito density is greatest. The total maximum reduction in clinical incidence is achieved when ivermectin is distributed monthly; however this reduction is over a longer period of time, and fluctuates more; meaning detecting a significant impact requires more monitoring and larger sample sizes. Treating every 2-3 week's results in a more sustained, albeit shorter, reduction in incidence, which would be easier to detect in a trial. To eliminate malaria, ivermectin alone is very unlikely to be the answer; however it could be a useful adjunct to other malaria interventions. In particular, adding ivermectin to mass treatment with an ACT could result in the same overall impact on transmission, but at a lower coverage level. Here, we argue that well designed, adequately powered cluster randomised trials are an essential step to determine the potential impact of ivermectin as a malaria control tool.

881

EVALUATING THE COSTS OF IMPLEMENTING A PACKAGE OF INTERVENTIONS AND SURVEILLANCE SYSTEMS TO SUPPORT MALARIA ELIMINATION IN SOUTHERN PROVINCE, ZAMBIA: A MICRO-COSTING ANALYSIS

Callie Scott[1], Thandiwe Ngoma[2], Bruce Larson[3], Kafula Silumbe[2], Busiku Hamainza[4], Joshua Yukich[5], John M. Miller[2]

[1]PATH Malaria Control and Elimination Partnership in Africa, Seattle, WA, United States, [2]PATH Malaria Control and Elimination Partnership in Africa, Lusaka, Zambia, [3]Center for Global Health and Development, Boston University School of Public Health, Boston, MA, United States, [4]National Malaria Control Programme, Zambia Ministry of Health, Lusaka, Zambia, [5]Department of Global Health Systems and Development, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

The Zambian Ministry of Health and partners are implementing several interventions and surveillance systems in Southern Province, Zambia, in support of the national malaria control and elimination agenda. These include: (1) long-lasting insecticide-treated net distribution; (2) indoor residual spraying; (3) rapid reporting of malaria surveillance indicators; (4) systematic case investigation with reactive focal testing and treatment using rapid diagnostic tests and artemether-lumefantrine; and (5) population-wide mass drug administration and household-level focal drug administration with dihydroartemisinin-piperaquine. Accurate and comparable information on the costs of implementing these interventions and surveillance systems is necessary to inform operational and resourcing decisions for malaria elimination. We are estimating the costs of implementing these interventions and surveillance systems in 173 health facility catchment areas in ten districts in Southern Province in 2014-2015. Costs are being estimated from the providers' perspective using an ingredients-based approach. Data on resource utilization (labor, equipment, drugs, diagnostics, and other supplies), unit prices, and intervention and surveillance system outputs are being collected from programmatic records, interviews with program managers and staff, and other sources to estimate implementation costs and cost drivers for each intervention and surveillance system. This information will be useful for budgeting and planning; identifying opportunities to improve program efficiency; and informing additional analyses on the cost-effectiveness and budget impact of different approaches to malaria elimination.

882

EXCLUSIVE BREASTFEEDING AND CLINICAL MALARIA RISK IN INFANTS IN KINSHASA, DEMOCRATIC REPUBLIC OF THE CONGO

Nicholas F. Brazeau[1], Martine Tabala[2], Landry Kiketa[2], Dyna Kayembe[2], Jean Lambert Chalachala[2], Bienvenu Kawende[2], Bruno Lapika[3], Steven Meshnick[1], Marcel Yotebieng[4]

[1]University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC, United States, [2]University of Kinshasa, School of Public Health, Kinshasa, Democratic Republic of the Congo, [3]University of Kinshasa, Department of Anthropology, Kinshasa, Democratic Republic of the Congo, [4]Ohio State University, College of Public Health, Columbus, OH, United States

Malaria remains a significant health burden in the developing world, and particularly, in Sub-Saharan Africa. Children under the age of five years bear the greatest burden, suffering the highest rates of malaria-related mortality and morbidity. The World Health Organization recommends exclusive breastfeeding (EBF) for the first six months of life because it offers protection against various infectious diseases. However, the effects of EBF on the risk of malaria infection among infants are unclear. In the present study, 495 infants were evaluated for parasitemia using qualitative PCR on dried blood spots collected from the infants during their 24-week follow-up appointment. During the visit, information on infant feeding

practices, fevers in the past month, medication use, and bed net use was also collected. The main exposure of interest was EBF. The outcomes of interest were parasitemia, defined by a positive PCR, and clinical malaria, defined as parasitemia with fever. Of the 495 infants, 137 (27.7%) were EBF at 24-weeks. Malaria parasitemia was confirmed by PCR in 52 (10.5%) of the infants. Of the infants with parasitemia, 21 (4.2%) were reported to be febrile at the 6-month visit or anytime in the month prior to the visit, and were classified as clinical malaria cases. EBF was not associated with a reduced risk of parasitemia OR = 0.82 (95% CI 0.39, 1.62) but was associated with a reduced risk of clinical malaria OR = 0.13 (95% CI 0.00, 0.80). Of the 21 infants with clinical malaria, only one case was from an EBF infant. This study suggests that EBF is protective against clinical malaria and should be supported in malaria-holoendemic areas. However, to better understand the relationship between EBF, parasitemia risk, and malaria immunity, further investigation is needed.

883

AN APPLICATION OF BOOSTED MODELS FOR PROPENSITY SCORE ESTIMATION WITH A MULTIFACTOR EXPOSURE IN AN INTERMITTENT PREVENTIVE THERAPY IN PREGNANCY FOR MALARIA OBSERVATIONAL STUDY

Ryan E. Wiegand[1], Julie Gutman[1], Carole Khairallah[2], Meghna Desai[1], Feiko O. ter Kuile[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The World Health Organization recommends the use of intermittent preventive therapy in pregnancy (IPTp) with sulfadoxine-pyrimethamine (SP) in sub-Saharan Africa to prevent the adverse consequences of malaria in pregnancy. Increasing parasite resistance to SP has called into question the effectiveness of IPTp with SP. The effectiveness of IPTp-SP on multiple birth outcomes was assessed in eight sites in six countries with varying degrees of parasite resistance. In an attempt to minimize the effect of potential confounders, we fit propensity scores models. SP dose is best treated as a categorical variable (0, 1, 2, or 3+ doses) and standard, two-group propensity score models are suboptimal. Hence, we implemented generalized boosted models allowing the exposure to have a multinomial distribution. Boosted models are a machine learning technique that utilizes non-parametric, tree-based regression models to calculate propensity scores and derive weights designed to estimate the average treatment effect. Outcome models incorporated weights for each individual as sampling weights and included site as a cluster-level term. We focus on the application of this approach to -IPTp-SP observational data, explain the modelling process and the outcome model inferences, and discuss the impact on estimating SP treatment efficacy.

884

SPATIO-TEMPORAL ANALYSIS OF MALARIA FEVERS IN A LARGE OPEN COHORT IN WESTERN KENYA; IMPLICATIONS FOR TARGETING 'HOTSPOTS'

Alyssa Platt[1], Wendy Prudhomme O'Meara[1], Charles MacIntyre[1], Daniel Aswa[2], Andrew Obala[2]

[1]Duke University, Durham, NC, United States, [2]Moi University College of Health Sciences, Eldoret, Kenya

Geographic variation in malaria burden or risk of infection between villages and households within a village has been documented. As malaria transmission declines, these variations become more pronounced, giving rise to 'hotspots'. A hotspot of malaria transmission is defined as 'a geographical area within an endemic focus of malaria transmission where transmission intensity exceeds the average level'. Controlling hotspots may be strategic in moving towards malaria elimination if hotspots 'fuel' continual transmission within a larger area. Targeting control measures towards these hotspots is predicted to be more effective than spreading equivalent resources over larger areas or populations. Most of the information available about febrile malaria hotspots comes from data collected over small geographic areas and/or short time intervals. What is unclear from previous analyses is whether such hotspots are stable across multiple seasons and years. Here we present a spatio-temporal analysis of 3 years of morbidity data collected from a population census of 75,000 people. Every 6 months, individual morbidity events were recorded in a 'round' of data collection. We explore the stability in space and time of ***foci*** of self-reported malaria fevers. On average, residents reported 1050 malaria morbidity events in each 6-month period, 35% in children under-5 years. There were significant differences in incidence between rounds. Six-monthly rounds had between 2 and 11 significant clusters. Clusters in children under 5 did not coincide geographically with those in the 6 + years group. Clusters moved consistently from South to North in subsequent rounds, with the trend most apparent in young children. Cluster locations are not consistent across time; only 14.2% of the household falls into a cluster in more than one round. We will present further analyses on the relationship of locally moving clusters to dynamic factors such as local environment measured via satellite imagery, and population factors such as migration and births. Malaria fever hotspots that move in space over time present challenges to targeting control measures.

885

A SCHOOL-BASED SEROLOGY STUDY TO VALIDATE USE OF ROUTINE DATA FOR TARGETING MALARIA INTERVENTIONS IN THE CENTRAL HIGHLANDS OF MADAGASCAR

Laura C. Steinhardt[1], Elisabeth Ravaoarisoa[2], Ryan Wiegand[1], Aina Harimanana[2], Judith Hedje[3], Annett Cotte[4], Sixte Zigirumugabe[5], Thomas Kesteman[2], Tsikiniaina L. Rasoloharimanana[2], Emma Rakotomalala[2], Jessie Butts[1], Christophe Rogier[2], Patrice Piola[2], Milijaona Randrianarivelojosia[2], Inès Vigan-Womas[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Institut Pasteur Madagascar, Antananarivo, Madagascar, [3]Centers for Disease Control and Prevention/US President's Malaria Initiative, Antananarivo, Madagascar, [4]Centers for Disease Control and Prevention/US President's Malaria Initiative, Atlanta, GA, United States, [5]United States Agency for International Development/US President's Malaria Initiative, Antananarivo, Madagascar

The Central Highlands in Madagascar are an area of unstable malaria transmission and remain epidemic-prone. Donors funded district-wide indoor residual spraying there from 2009-2011, but transitioned to targeted spraying in 2012, using health facility (HF) data to identify communes with the highest malaria incidence. To assess the validity of HF surveillance data to identify high-transmission ***foci***, we conducted a school-based serology study in 7 districts. Using serology as a gold standard for detecting ***foci*** in low-transmission settings, we assessed how well HF surveillance data identified high-transmission communes. From May-July 2014, teams visited 93 accessible communes (of 106) in the 7 districts, and two primary schools per commune. At each school, 30 children and their caregivers had capillary blood taken for a malaria rapid diagnostic test (RDT) and immunological analysis, and a brief questionnaire administered. Teams also collected school absenteeism data from registers and visited health facilities for information on data quality. Seropositivity was defined using mixture models for several antigens, including PfMSP1 and PfAMA1. School-based seroprevalence for each commune was compared to malaria incidence (HF RDT-positive cases per population). In total 12,771 children and parents at 186 schools had complete data. RDT positivity was very low at 0.53%, ranging from 0% (66/93 (71%) communes) to 13.3% by commune. Seroprevalence of MSP1 was 18.2% (range: 3.0% to 63.0% by commune) and for AMA1 was 26.5% (range: 4.4% to 70.4%). Correlation between seroprevalence and malaria incidence at commune level was 0.46 for MSP1 and 0.45 for AMA1, $p<0.001$ for each. HF data identified 21 of 30 communes with the highest transmission according to MSP1 and AMA1 (sensitivity=70% (95%CI: 50-85%)). Thus, routine HF surveillance data was relatively reliable for

identifying areas of higher transmission but missed 30% of malaria ***foci***. Additional analyses will be presented, including catalytic models of seroconversion rates and exploration of HF data quality and school absenteeism in predicting malaria ***foci*** to aid targeting of interventions.

886

ASYMPTOMATIC AND UNCOMPLICATED MALARIA HOTSPOTS ACT AS YEAR-ROUND RESERVOIRS IN THE CHITTAGONG HILL DISTRICTS

Kerry L. Shannon[1], Sabeena Ahmed[2], Jacob Khyang[2], Chai S. Prue[2], Jasmin Akter[2], Mohammad S. Alam[2], Wasif A. Khan[2], Malathi Ram[1], Myaing M. Nyunt[3], Greg Glass[4], Timothy Shields[1], Frank Curriero[1], David A. Sack[1], David J. Sullivan[1]

[1]Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Centre for Population, Urbanization and Climate Change, International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of Maryland School of Medicine, Baltimore, MD, United States, [4]Emerging Pathogens Institute, University of Florida, Gainsville, FL, United States

Malaria is endemic in 13 of 64 districts in Bangladesh, with the highest rates in the Chittagong Hill Districts, where ***Plasmodium falciparum*** is the predominant species. This study describes the epidemiology of asymptomatic and uncomplicated malaria infections in two unions of Bandarban, an area with a population of 23,000. Active surveillance for malaria infection was conducted by testing a random sample of 3,999 people from October 2010 to October 2012, without regard to symptoms. Of this sample, 53 tested positive for ***P. falciparum*** malaria through RDT and/or microscopy and 1 tested positive for ***P. vivax*** infection via microscopy, equating to a ***P. falciparum*** prevalence estimate of 13.4 (10.2-17.6) per 1,000 population. There was no difference in prevalence of these actively detected infections between the high and low seasons (p-value 0.78). These infections clustered in similar areas as symptomatic malaria cases. 72% of those with actively detected ***P. falciparum*** malaria reported at least one symptom commonly associated with malaria (fever, muscle aches, fatigue and headache) in the prior two weeks compared to only 21% of those not infected with ***P. falciparum*** malaria (OR (95% CI) = 9.3(5.0-18.3). We found a higher prevalence of these infections among those who were older, from tribal populations, did not use bed nets, and whose homes had animals, were closer to the forest, and were located less than 100 meters from an open drain or further than 100 meters from a river or stream. A subset of 1,275 people were selected from the active surveillance study to be followed every three months for 9 months to estimate malaria incidence. ***P. falciparum*** incidence was estimated to be 23.4 (15.2-36.1) per 1,000 person-years in this population. We conclude that hypoendemic asymptomatic and uncomplicated ***P. falciparum*** malaria continues in the Chittagong Hill Districts; the infections clustered in hot spots similar to the areas of symptomatic malaria and were associated with a number of household and demographic factors. Unlike symptomatic malaria which is highly seasonal, these actively detected infections were present year round and act as reservoirs for infection.

887

ACUTE FEBRILE SURVEILLANCE IN CAMBODIA: MALARIA TRENDS AND CORRELATION WITH CLINICAL DIAGNOSIS

Catherine M. Berjohn[1], Agus Rachmat[2], Chenda Yi[2], Gavin W. Ford[3], Shan D. Putnam[4], Andrew F. Vaughn[2], Surveillance and Etiology of Undifferentiated Febrile Illness Study in Cambodia Working Group[2]

[1]Naval Medical Center San Diego, San Diego, CA, United States, [2]US Naval Medical Research Unit - 2, Phnom Penh, Cambodia, [3]Walter Reed National Military Medical Center Bethesda, Bethesda, MD, United States, [4]Naval Medical Research Center, San Diego, CA, United States

Malaria is one of many potentially life-threatening infectious causes of fever in Cambodia. However, antimalarials are often given empirically, and confirmatory testing is not always available. With the rise of resistance in the SE Asia region, it is of increasing importance to ensure that medications are used judiciously on a population scale. For the benefit of the individual patients, it is important to ensure that other treatable causes of febrile illness are identified, if present. Data were reviewed from a subset of the Surveillance and Etiology of Undifferentiated Febrile Illness Study in Cambodia collected by Naval Medical Research Unit-2 Phnom Penh. Retrospective analysis of the passive surveillance data collected from 2010 through 2014 was conducted to assess for prevalence and the strength of association between clinical and laboratory-confirmed diagnoses, as well as the presence of other causes of fever. Overall, 13,618 febrile patient records were reviewed. Blood specimens were obtained for microscopy and rapid diagnostic testing. Of these, 4820 patients had been assigned a clinical diagnosis of malaria. 1477 patients (30.6%) were laboratory-confirmed for malaria by at least one test, giving an overall incidence of 10.8%. 78% of these patients were adults, and mean age was 25.1 years. Although a clinical diagnosis of malaria suggested a high odds of having malaria (OR 23.9, CI 20.0-28.6, p< 0.0001) and was highly sensitive (90.6%, CI 89.0-92.0%), the specificity was poor (71.3%, CI 70.5-72.1%) and positive predictive value was only 27.8% (CI 26.5-29.1%). Additionally, 73 of the laboratory-confirmed malaria patients were also confirmed to have either viral or rickettsial co-infection. Among febrile patients in whom alternate diagnoses were identified, influenza, dengue, chikungunya, and rickettsial illnesses were represented. It is therefore concluded that in an endemic region, it is prudent to maintain a high index of suspicion for malaria, including the presence of subacute malaria co-infection, but not to discount the possibility that other explanations for fever exist.

888

SPATIAL AND TEMPORAL DYNAMICS OF *PLASMODIUM FALCIPARUM* INFECTION AND VECTOR DISTRIBUTION IN A SETTING OF HIGH COVERAGE OF CONTROL INTERVENTIONS

Dr Julia Mwesigwa[1], Dr Jane Achan[1], Dr Muna Affara[1], Musa Jawara[1], Schadrac Agbla[1], Archibald Worwui[1], Gian Luca DiTanna[2], Prof Umberto D'Alessandro[1]

[1]Medical Research Council Unit, The Gambia, Banjul, Gambia, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom

The reduction in the malaria burden previously reported in The Gambia is largely due to the successful scaling up of control interventions. Understanding the current dynamics of malaria transmission in a context of high coverage of control interventions is critical to inform pre-elimination efforts. A prospective cohort study was conducted in twelve villages across the country. During the transmission season, all residents aged over 6 months old had a blood sample collected monthly for later molecular analysis and clinical malaria cases were captured by passive detection at local health facilities. Mosquito abundance and species distribution were determined by collections with CDC light traps, human landing catches and larval surveys. From June to December 2013, 4235 participants were followed up. The median age was 13 years (IQR 5, 28) and bed net coverage was 71.6% (2774/3876). Overall incidence rate of ***Plasmodium falciparum*** infections was 0.33 per person per year. Incidence was markedly heterogeneous, with lower values in the west (0.4 to 0.5 infections per person year) and higher in the east (1.4 to 2.8 per person year). Overall, 68 % of the infections were asymptomatic. The highest incidence of infection was in November (0.81 per person year) while the highest mosquito densities were found in September. ***Anopheles (An.) gambiae s.l.*** was the predominant species (80.4%) in all regions except the central region where ***An. funestus*** was predominant. Children aged 5-15 years (HR=1.4, 95% CI; 1.2-1.9) and adults (HR=1.2, 95% CI, 1.0 - 1.7) had a higher risk of asymptomatic infection. Individuals with severe anaemia had a significantly higher risk of being infected (HR=2.3, 95% CI; 1.5 - 3.6). Bed net ownership and female gender were associated with a reduced risk of infection. In The Gambia,

despite high coverage of control interventions, there is still significant ongoing malaria transmission. Additional interventions targeting residual transmission are urgently needed.

889

THE BURDEN OF MALARIA INFECTION AMONG YOUNG AFRICAN INFANTS IN DIFFERENT MALARIA TRANSMISSION SETTINGS

Serign J. Ceesay[1], **Jane Achan**[1], Lamine Koivogui[2], Alain Nahum[3], Makie Abdoulie Taal[4], Lama Eugène Kaman[2], Joseph Okebe[1], Muna Affara[1], Francis Bohissou[2], Carine Agbowai[2], Benoit Gniouma Tolno[2], Alfred A. Ngwa[1], NFaly Bangoura[5], Abdul Khalie Muhammad[1], Stephan Duparc[6], Kamal Hamed[7], David Ubben[6], Kalifa Bojang[1], Umberto D'Alessandro[1]

[1]MRC Unit, Banjul, Gambia, [2]Institut National de Santé Publique, Conakry, Guinea, [3]Centre de Recherches Entomologiques de Cotonou, Cotonou, Benin, [4]National Public Health Laboratory, Kotu, Gambia, [5]Préfectoral de la santé de Faranah, Conakry, Guinea, [6]Medicines for Malaria Venture, Geneva, Switzerland, [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

Infants are thought to be protected against malaria during the first 6 months of life largely due to transfer of maternal antibodies and presence of foetal haemoglobin. However, the true burden of malaria in infants is not well characterized and may be underestimated. A better understanding of malaria risk in early infancy is therefore critical for drug development and policy setting. A cross sectional survey was conducted in three West African countries: The Gambia, Benin and Guinea Conakry, representing areas of low, moderate and high malaria transmission respectively. Infants aged 0-6 months were enrolled and two children aged 1-9 years and 10-15 years in the same household were included to estimate the difference in risk of infection between infants and older children. Malaria diagnosis was by RDT, microscopy and molecular methods. Prevalence of antibodies against MSP119 was determined by indirect ELISA. A total of 6,761 children were enrolled; 2,270 from The Gambia, 2,276 from Benin and 2,215 from Guinea Conakry. Prevalence of malaria infection using PCR in infants up to 6 months old was 11.8%, with a significantly higher prevalence (21.7%) in Guinea Conakry compared to The Gambia (3.7%) and Benin (10.2%). Seroprevalence ranged from 5.7% in The Gambia to 41.6% in Guinea Conakry. Mean parasite densities were significantly lower in infants than in children 1-9 years in The Gambia and Benin. Malaria infection in infants was significantly associated with fever or history of fever and anaemia. Infants <5 kg had a significantly higher odds of malaria infection. There was a lower odds of malaria infection in infants aged 0-3 months with subsequently increasing odds of infection from 3 to 6 months of age. Malaria in young infants is therefore not rare, can be symptomatic, and has major health consequences, most notably anaemia. Our findings provide evidence that the period of perinatal protection may be shorter than 6 months and that 0-6 month is not a homogenous age group. The sizeable burden of malaria among young infants in endemic countries should be addressed by targeted preventive interventions, adequate drug formulations and treatment guidelines.

890

ROLE OF ANTE-NATAL CLINICS (ANCS) ON THE COMPLIANCE OF USE OF LLINS AMONG PREGNANT WOMEN IN PORT HARCOURT RIVERS STATE

Florence Onyemachi Nduka, Michael N. Wogu

University of Port Harcourt, Choba Port Harcourt, Nigeria

A study to evaluate the role of Antenatal Clinics (ANCs) on the compliance of Long Lasting Insecticide Nets (LLINs) among some pregnant women in Rivers State was carried out. A total of 300 pregnant women (150 from government and 150 from private ANCs) were randomly selected and examined in this study. Information on LLINs usage and personal data were gotten through well-structured questionnaires. This study showed that 90% (135 out of 150) of the pregnant women attending ANCs in private healthcare centres used LLINs while 80% (120 out of 150) of the pregnant women attending ANCs in a government healthcare centre used LLINs. High LLINs compliance rates were recorded in both private and government healthcare centres and maybe due to increased malaria awareness and health lectures from ANCs health workers. LLINs have been shown to play a vital role in reducing malaria infection among pregnant women and should be encouraged.

MALARIA SURVEILLANCE IN SELECT TANZANIAN MILITARY HEALTH FACILITIES THROUGH PASSIVE CASE DETECTION

Lalaine Anova[1], Akili Kalinga[2], Christopher Mswanya[3], Lucky Temu[4], Geeta Bhat[5], Charles E. Mwanziva[3], Eyako Wurapa[6], Mark Hickman[6], Dennis Janga[3]

[1]ClinicalRM, Hinckley, OH, United States, [2]National Institute for Medical Research, Tukuyu Research Centre, Tukuyu, United Republic of Tanzania, [3]Tanzania Peoples Defence Forces, Dar es Salaam, United Republic of Tanzania, [4]Walter Reed Malaria Programme-Tanzania, Dar es Salaam, United Republic of Tanzania, [5]Fio Corporation, Toronto, ON, Canada, [6]Walter Reed Army Institute of Research, Silver Spring, MD, United States

Malaria surveillance is the foundation for control and elimination programs, resource allocation, clinical research, and is essential for measuring the success of any intervention. Quality malaria surveillance is hindered by the challenges of performing accurate malaria diagnostics and the need to efficiently gather and analyze incidence data from multiple sources in a timely manner. Researchers at the Walter Reed Army Institute of Research (WRAIR) have partnered with the Tanzanian Peoples Defence Forces (TPDF) to implement a passive malaria surveillance strategy based on the use of malaria rapid diagnostic tests (RDTs) in 8 Tanzanian military camps. The strategy managed RDT quality and efficient data aggregation through the use of Deki Readers (***in vitro*** diagnostic devices used for reading and quality controlling commercially available RDTs). The readers were used with RDT testing when possible, which then transmitted de-identified patient data, diagnostic results and RDT digital images to Fionet (mobile software with a secured web-based portal). The data was available on-line for approved users for external QC, real-time monitoring, permanent data storage, and report generation. Quarterly assessments were conducted to collect data from RDT tests not performed with the readers. The malaria surveillance data from 2014 from the regions of Pwani, Morogoro, Tanga, Mara, Tabora, Kigoma, and Kagera will be presented. The data trends articulate the dynamic seasonality (based on the rainy seasons) or persistently high prevalence of malaria per camp, and variations in the timing of malaria seasons between sites. The data also highlighted which camps suffered the highest malaria incidence and were in most need of resources. However, device failures and lapses in power supply, RDT stock out, and poor telecommunication are known factors which have compromised the data integrity. The logistical challenges of implementation and general evaluations/observations of the strategy will therefore also be discussed. Despite the challenges, the Fionet system has been useful to efficiently collect quality passive malaria surveillance data.

ASSESSMENT OF *PLASMODIUM FALCIPARUM* CASE-BASED SURVEILLANCE AT THE TWO MAJOR UNIVERSITY TEACHING HOSPITAL SOUTHWESTERN NIGERIA: A COMPARATIVE STUDY

Joseph Omololu-Aso[1], Anthonia O. Oluduro[1], Oluwaseun O. Omololu-Aso[2], Alexander T. Owolabi[1], Adekunle O. Adejuwon[1], Olapeju O. Ajayi[1]

[1]Obafemi Awolowo University, Ile Ife, Nigeria, [2]University College Hospital, Ibadan, Nigeria

Guidelines focusing on National core indicators tools and methodology for monitoring and evaluating of Roll Back Malaria in Nigeria, in conformity

with other countries in Africa region has been developed. This study gives an insight on screened patient blood presented with ***Plasmodium falciparum*** focusing on diverse tools of surveillance ranging from age differences, gender status, education, level of awareness and individual therapeutic approach. Blood samples were collected from the fingers pricked of 200 patients (100 from each Hospital) who visited either of the two university teaching hospital (Obafemi Awolowo University (OAUTHC) and university college hospital (UCH), Nigeria) between August-December 2010 for Malaria parasite test. Rapid Test Kit Global device was used in detection of the presence of ***P. falciparum***. All data generated was presented with Chi-square description statistical analysis using Statistical Package for Social Sciences (SPSS) version 15.0 for windows. Difference were shown to be statistically significant where p<0.05. In the OAUTH, higher infection rate observed among age group <20 years (71.4%), followed by 20-30 years (18.2%) and less than 40 years (16.7%). The prevalence rate increased among male which constituted 23 (49.2%), compared with female subjects 15(31.3%), Un-educated 29(62.1%), Educated 20(10%), Semi-educated 43(37.2%) , Non -experience 8(25%), Non-drug compliance individuals 7(57.1%) Patients on malaria medication 70(38.6), Local herb users 8(25%). Also, 84(38.1%) showed higher level of awareness to ***P. falciparum*** while Non-awareness 7(42.9%), Indifference, 9(33.3%). Frequently infected individuals 22(40.9%), Non-frequent infected 30(36.7%). Rarely infected 36(36.17%), Non- response 12(41.7%). Patients utilized other means of protection, 22(31.8%), Insecticides, 36(55.6%), Mosquito net 40(22.5%). At the UCH, 12 positive results were recorded out of 100 patients tested. Higher infection rate was observed among age group <20(19%), 20-30(13%), >40(4.0%), The prevalence rate increased among female which contributed 9(12.2%), compared with male subjects which constituted 3(11.5%). Semi-educated 36(25%), Uneducated 21(4.8%), Educated 43(4.7%). Patients on malaria medication showed 65(13.8%), Non-drug compliance individuals 27(11.1%), Local-drugs/herbs users showed no attack, insecticides means of protection constituted 39(15.4%), Mosquito net 18(11.1%), Patients utilized other means of protection 43(9.3%), Level of awareness 84(38.1%), Non-awareness 7(42.9%), Indifference 9(33.3%). Frequent infected individuals showed 10(20%), Non-frequent 54(14.8%) and Rarely infected constituted 36(5.6%). Development of adequate information on ***P. falciparum*** infection risks is highly needed in the studied tertiary hospitals. Novel technologies to prevent, monitor, diagnose and efficient treatment of malaria mostly among lower age group must be adopted through Local and National Malaria Control Programme.

893

BURDEN OF ASYMPTOMATIC AND SYMPTOMATIC FALCIPARUM AND VIVAX MALARIA ON CHINA-MYANMAR BORDER

Fang Huang[1], Hui Liu[2], Jianwei Xu[2], Jianwei Xu[2], Henglin Yang[2], Amy Mu[1], Biraj Shrestha[1], Gillian Mbambo[1], Matthew Adams[1], Shuisen Zhou[3], Zhigui Xia[3], Shannon Takala-Harison[1], Christopher V. Plowe[1], Myaing M. Nyunt[1]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]Yunnan Institute of Parasitic Diseases, Puer, China, [3]National Institute of Parasitic Diseases, China Centers for Disease Control and Prevention, Shanghai, China

China launched a national malaria elimination program to end local malaria transmission by 2015, excluding the Yunnan province bordering Myanmar, Vietnam and Laos. Both ***Plasmodium falciparum*** and ***P. vivax*** are endemic in Yunnan presenting as they are elsewhere in the greater Mekong subregion (GMS). Malaria infection may be present in the human host with or without symptoms of illness, and both symptomatic and asymptomatic infections must be eradicated for successful malaria elimination. Asymptomatic infection poses a unique challenge to elimination strategies, since it typically harbors low density parasitemia, and the ability to detect it is limited by the sensitivity of detection methods as well as the volume of blood examined. The prevalence of asymptomatic malaria infection is higher when measured using sensitive molecular methods than when using standard diagnostic methods such as microscopy or rapid diagnostic tests (RDTs). We conducted a prospective cross-sectional field study in Mong Pawk and Laiza, two remote communities residing in the China-Myanmar border in July 2014 (rainy season) to estimate the prevalence of malaria, using multiplexed real-time PCR (RT-PCR), nested PCR, and RDT. Blood samples were collected on filter paper (50µL) from 765 participants (731 asymptomatic and 34 symptomatic). Overall the prevalence of ***P. falciparum*** and ***P. vivax***, detected by the multiplexed RT-PCR, was 4.71% (36/765) and 7.58 %(58/765), respectively. Important risk factors for asymptomatic infection, assessed by a logistic regression analysis, appeared to be the site and age. We found that 88% and 54% of asymptomatic infection were missed by RDT and nested PCR, respectively, whereas all symptomatic infections were identified uniformly by all three methods. We conclude that while RDT or nested PCR can sufficiently detect symptomatic infections in this setting, more sensitive detection methods, such as multiplexed RT-PCR, are required to accurately identify asymptomatic malaria and accurately measure the true prevalence of malaria infection to inform elimination strategies along the China-Myanmar border.

894

THE ECOLOGY AND EPIDEMIOLOGY OF *PLASMODIUM* PARASITES CIRCULATING AMONG WILD CHIMPANZEE RESERVOIRS LIVING IN EAST AFRICA

Erik J. Scully[1], Weimin Liu[2], Deus C. Mjungu[3], Anne E. Pusey[4], Manoj T. Duraisingh[5], Beatrice H. Hahn[2], Richard W. Wrangham[1]

[1]Harvard University, Cambridge, MA, United States, [2]University of Pennsylvania, Philadelphia, PA, United States, [3]Gombe Stream Research Centre, Kigoma, United Republic of Tanzania, [4]Duke University, Durham, NC, United States, [5]Harvard School of Public Health, Boston, MA, United States

Molecular epidemiological analyses have traced the origins of human ***Plasmodium falciparum*** and ***P. vivax*** to ***Plasmodium*** parasites circulating among African great apes. These sylvatic hosts harbor a diverse assemblage of ***Plasmodium*** species capable of reaching notable prevalence (***Laverania*** relatives of ***P. falciparum***: up to 48%; ape ***P. vivax***: up to 8%). Although there is currently no evidence that humans are susceptible to ape ***Laverania*** parasites on contemporary timescales, surveys have revealed occasional cross-species transmission of ***P. vivax*** from apes to humans. Evaluation of the zoonotic potential of these reservoirs first necessitates elucidation of the ecological factors that underlie spatiotemporal variation in parasite prevalence. We exploited the infrastructure afforded by a long-term longitudinal study of wild chimpanzees in western Uganda to quantify the interaction between chimpanzee ecology and ***Plasmodium*** parasite infection. In agreement with previous analyses, chimpanzee fecal samples tested positive for mtDNA from three ***Laverania*** species—***P. gaboni*** (~13% of fecal samples), ***P. reichenowi*** (~6%), ***P. billcollinsi*** (~2%)—and ape ***P. vivax*** (~1%). Our analyses also confirm that the probability of infection declines with age, suggesting that analogous immunological processes may mediate ***Plasmodium*** infection of humans and chimpanzees. Other ecological factors, such as temporal variation in dietary quality, also influence the probability of infection. The nature of these relationships varies among representatives of the ***Laverania***, highlighting a source of epidemiological variation that has previously been overlooked. Finally, data from multiple chimpanzee communities highlight spatial variation in parasite prevalence, including the absence of infection within a Tanzanian population despite intensive sampling. Integration of these results with analyses of vector population dynamics and erythrocyte invasion assays will facilitate more rigorous evaluation of the co-evolutionary dynamics and zoonotic potential of ***Plasmodium*** parasites circulating among great apes in sub-Saharan Africa.

895

THE USE OF SEROLOGICAL DATA TO PREDICT *PLASMODIUM FALCIPARUM* TRANSMISSION IN THE LOW-ENDEMIC NATION OF HAITI

Eric Rogier[1], Jean Frantz Lemoine[2], Ito Journel[3], Ryan Wiegand[1], Kimberly E. Mace[1], Michelle Chang[1], Delynn Moss[1], Jeff Priest[1], Samuel E. Jean[4], John W. Barnwell[1], Venkatachalam Udhayakumar[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Programme National de Contrôle de la Malaria, Ministère de la Santé Publique et de la Population, Port au Prince, Haiti, [3]Laboratoire National de Santé Publique, MSPP, Port au Prince, Haiti, [4]Population Services International-Haiti, Port au Prince, Haiti

As ***Plasmodium falciparum*** (Pf) incidence in a region declines, strategies for the comprehensive detection of active infections become increasingly laborious and expensive. In addition, current technologies perform poorly for detecting very low density infections, and a paucity of cases creates difficulties in identifying ***foci*** of transmission. The human immune system generates a robust humoral response to many Pf antigens, and IgG production can persist for years following exposure, allowing for a greater historical perspective in assessing transmission. Here, we present comparisons of different analytical methods used for the interpretation of serological data from Haiti, which is thought to be an area of low, but persistent, Pf endemicity. Samples were collected in December 2012 from 5,479 individuals across 62 cluster-based community survey sites. Antibodies against the Pf antigens LSA-1, MSP-1, and AMA-1 were assayed through a bead-based multiplex assay, and data utilized for nationwide spatial analysis of serological intensity. Though the seroresponses of MSP-1 and AMA-1 were found to be independent, each antigen provided similar spatial estimates, showing approximately 20% of the study participants as being seropositive. Estimates for the prevalence of liver-stage antigen LSA-1 antibodies were much lower, with 1% of individuals seropositive. For each of the 62 sites, seroresponses were heterogeneous throughout the nation with a range of 0.3% to 46% persons seropositive within a site. Higher concentrations of seropositive individuals were found within the Central Plateau and along the southern coast of the Ouest Department. When analysis was restricted to persons under 10 years of age, these areas were also shown to contain higher percentages of seropositive children, suggesting stable and persistent transmission. This study gives further rationale for the use of serology to define areas of malaria transmission when parasite rates become low. Future serosurveys in Haiti will look to validate this approach, and provide better resolution in this nation of high Pf geographical heterogeneity.

896

THE SUCCESSION OF MALARIA VECTOR SPECIES IN WESTERN KENYA

Guofa Zhou[1], Edna Ototo[2], Harrysone Atieli[2], Yaw Afrane[2], Andrew Githeko[2], Guiyun Yan[1]

[1]University of California, Irvine, Irvine, CA, United States, [2]Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

The mass distribution of insecticide-treated nets (ITN) together with other interventions during the last decade has led to a decline in malaria and its vector populations. Due to behavioral variation and different insecticide resistance levels among vector species and larval habitat changes, major changes in vector species composition has been reported. However, the extent of species shift and vector community succession is largely unknown. Using data collected from 2001 to 2015, shifts in vector density and species composition were examined in western Kenya. Results showed there was a major population decrease in all malaria vectors after the 2006 mass ITN campaign, and the decline was more pronounced in ***Anopheles funestus***. However, decline in vector population were insignificant after the second round mass ITN distribution in 2011. In western Kenya highlands, species composition changed from 19 : 81 : 0% for ***An. funestus*** : ***An. gambiae*** s.s. : ***An. arabienesis*** in early 2000s, to 10 : 77 : 13% between 2006 and 2008, and then 70 : 27 : 3% in 2014. In the lowland, ***An. funestus*** accounted for 70% of total ***Anopheles*** in early 2000s and reduced to about 50% from 2006 to 2008, and it rebounded to 65% in the last 3 years. ***An. arabiensis*** accounted for about 1% of ***An. gambiae*** s.l, and increased to 40% in 2008 and this proportion remained stable. Surveys in 2014 indicated that more ***Anopheles*** rested in cowshed than in bedrooms and cowshed sampling captured almost equal number of ***An. gambiae*** s.l. and ***An. funestus*** in all sampling sites. Blood meal sources, species PCR identification, surveys for outdoor biting mosquitoes and larval habitats are currently being conducted. Overall, both proportion and density of indoor resting ***An. funestus*** rebounded significantly after 5 yearly of ITN scaling up. This study highlights the limitations of conventional indoor spray catch as a transmission surveillance tool as in the era of intensive use of ITN. Vector control strategies should target refugia of vectors and outdoor biting mosquitoes.

897

DECREASE IN PRESUMPTIVE TREATMENT FOR MALARIA AFTER SCALE-UP OF RAPID DIAGNOSTIC TESTS: RESULTS FROM A NATIONALLY REPRESENTATIVE HEALTH FACILITY SURVEY

Kimberly E. Mace[1], Samuel E. Jean[2], Wilbens Siguineau[2], Alexandre Existe[3], Ito Journel[3], Jean Semé Fils Alexandre[4], Jean Ronald Cadet[5], Michelle Chang[1], Jean Frantz Lemoine[5]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Population Services International/OHMaSS, Port au Prince, Haiti, [3]Laboratoire National de Santé Publique/Ministère de la Santé Publique et de la Population, Port au Prince, Haiti, [4]Centers for Disease Control and Prevention, Port au Prince, Haiti, [5]Programme National de Contrôle de la Malaria/Ministère de la Santé Publique et de la Population, Port au Prince, Haiti

Malaria transmission in Haiti is low and heterogeneous. The national malaria guidelines recommend diagnosis of febrile patients with an approved test, and treatment with chloroquine (CQ) plus primaquine (PQ) to cure illness and reduce ***Plasmodium falciparum*** transmission. Two years after conducting a baseline survey and scale-up of training and rapid diagnostic tests (RDTs), we conducted a national cross-sectional cluster sample survey of health facilities (HF). The sampling frame of all 907 HFs nationwide included data on geolocation and all-cause utilization. Sixty-four HFs were probability sampled, with 32 each from areas with relatively low or high risk, based on a 2011 malaria risk map; HFs with low utilization were under sampled. Survey teams conducted two-day visits from Nov 2014 - Jan 2015; outpatients present on survey days were systematically screened for fever. Post-consultation information was collected from patients and providers on illness history, HF-based test results, and prescribed medications. Gold-standard blood samples were analyzed by Haiti's reference laboratory. Of 64 sampled HFs, 56 were operational. Of 2,048 outpatients screened, 577 (28%) were febrile and attended for a first consultation, of these 451 (78%) consented and completed all survey procedures. Providers ordered a malaria test for 341 (76%) patients; and of these 209 (61%) patients had test results available by the end of the survey day (179 by RDT, 30 by microscopy). The HF-based tests confirmed malaria in four patients (all by RDT) and two of these were treated with CQ and PQ. Altogether, providers prescribed CQ to 26 (6%) patients, 13 were also prescribed PQ. Among those without test results available (n=242) 18 (7%) were prescribed an antimalarial. This is an apparent decrease in presumptive treatment compared to the 2012 results (31%). Malaria is an uncommon cause of fever among Haitian outpatients. Availability of RDTs at HFs has improved since 2012, and presumptive treatment has decreased. Additional effort could promote full implementation of the treatment guidelines.

IMPACT OF THE SCALE-UP OF MALARIA CONTROL INTERVENTIONS IN MALI 2001-2012

Lia S. Florey[1], Kassoum Kayentao[2], Yazoume Yé[3], Erin Eckert[4]

[1]The DHS Program - ICF International, Rockville, MD, United States, [2]Malaria Research and Training Centre, Department of Epidemiology of Parasitologic Diseases, Faculty of Medicine, Pharmacy and Dentistry, University of Sciences, Technics, and Technologies of Bamako, Bamako, Mali, [3]MEASURE Evaluation - ICF International, Rockville, MD, United States, [4]US President's Malaria Initiative, United States Agency for International Development, Bureau for Global Health, Arlington, VA, United States

Enabled by significant increases in funding for malaria control, substantial scale-up of malaria control interventions has occurred over the past decade (2001-2012) in Mali. To assess the impact of this scale-up, an evaluation was conducted using the approach endorsed by the Roll Back Malaria Monitoring and Evaluation Reference Group (RBM MERG). Trends in all-cause childhood mortality (ACCM) were analyzed against trends in coverage of malaria control interventions as well as trends in other factors likely to affect child survival. The evaluation used data from nationally-representative household surveys to estimate intervention coverage and morbidity and mortality for surveys years (2001, 2006, 2010 and 2012) from the highly endemic areas of Mali (excluding Gao, Tombouctou, Kidal, and parts of Mopti). Household ownership of at least one insecticide treated net (ITN) increased from 49% in 2006 to 84% in 2012. Use of ITNs increased between 2006 and 2012 among the general population (21% to 61%), pregnant women (28% to 73%) and children less than five years of age (26% to 69%). The proportion of recently pregnant women receiving at least two doses of sulfadoxine-pyrimethamine for prevention of malaria during pregnancy increased from 4% in 2006 to 20% in 2012. ACCM declined from 225 to 95 deaths per 1,000 live births between 2001 and 2012. The declines of ACCM were greater in 2006-2012 (192 to 95 deaths per 1,000 live births) compared to 2001-2006 (225 to 192 deaths per 1,000 live births) corresponding to the period of rapid roll-out of malaria interventions. Changes in contextual factors such as vitamin A supplementation, diarrhea prevalence, and other socio-economic factors were also measured to develop a complete picture of mortality declines. Existing evidence from this analysis suggests that investments in malaria control interventions have contributed to observed declines in all-cause childhood mortality in Mali between 2001 and 2012.

899

PREVALENCE OF *PLASMODIUM* SPP. AND ANEMIA AMONG SCHOOL CHILDREN IN TWO ECOLOGICAL ZONES IN GHANA

Benedicta A. Mensah, Benjamin Abuaku, Anita Ghansah, James Myers-Hansen, Kwadwo A. Koram

Noguchi Memorial Institute for Medical Research, Accra, Ghana

Malaria remains a public health problem in Ghana. The prevalence of parasitaemia is usually determined by hospital-based surveys. However, a true representation of prevalence of parasitaemia in the population would be among healthy carriers of the malaria parasite in the population. We compare the prevalence of ***Plasmodium*** spp. and anemia among school children in the forest and the coastal zones of Ghana. Cross sectional surveys were conducted in a coastal savanna town (Cape Coast) and a town located in the Forest zone (Begoro) between October and November 2013, representing the end of the peak malaria transmission season. A total of 1037 pupils aged between 6 and 14 years were screened from three randomly chosen basic schools. The overall parasite prevalence was 21% (95% CI: 17%, 24%) and 20% (95% CI: 17%, 24%) in coastal and forest zones, respectively. In the coastal zone three species of ***Plasmodium*** were identified: ***P. falciparum*** accounted for 79% (95% CI: 73%, 86%) of infections whilst ***P. malariae*** accounted for 14% (95% CI: 9%, 20%) and P. ovale accounted for 0.7% (95% CI: -0.7%, 2.0%) of the infections. In the forest zone, two species of ***Plasmodium*** were identified: ***P. falciparum*** and ***P. malariae*** accounted for 75% (95% CI: 68%, 83%) and 22% (95% CI: 15%, 29%) of the infections, respectively. A few mixed infections (3% and 5.5%) were observed in the forest and coastal sites, respectively. Prevalence of asymptomatic parasitaemia was higher in male children than female children (56%; 95% CI: 49%, 63% vs 44%; 95% CI: 37%, 51%; P= 0.004), and was associated with Anemia in children (Odds Ratio = 0.42, P <0.0001) adjusting for study site. There was no evidence of a difference in the mean parasite parasitaemia in all ages groups (F= 1.69, P =0.187) and between the study sites (T= -0.0082, P = 0.9934). We conclude that though malaria parasite prevalence and mean parasitaemia, at the end of the peak transmission season, are same among school children in the coastal and forest zones of Ghana, asymptomatic parasitaemia is associated with gender and anaemia. Malaria interventions in basic schools should focus more on male children.

900

ESTIMATING THE MALARIA ATTACK RATE IN A TANZANIAN MILITARY CAMP. A COMPARISON BETWEEN SUBJECTS FROM IMMUNE AND NON-IMMUNE POPULATIONS FOR FUTURE MALARIA PROPHYLAXIS, VACCINE AND TREATMENT STUDIES

Mercy Chiduo[1], Francis Filbert[1], Charles Mwanziva[2], Lucky Temu[3], Sarah Chiduo[3], David Schnabel[4], George Amoo[5], Lalaine Anova[6], Colin Ohrt[4], Eyako Wurapa[4], Samuel Gesase[1], Yadon M. Kohi[2], Deus Ishengoma[1], Dennis Janga[2]

[1]National Institute of Medical Research, Tanga Research Centre, Tanga, United Republic of Tanzania, [2]Tanzania Peoples Defence Forces, Dar es Salaam, United Republic of Tanzania, [3]Walter Reed Malaria Programme-Tanzania, Dar es Salaam, United Republic of Tanzania, [4]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [5]Amethyst Technologies LLC, Baltimore, MD, United States, [6]ClinicalRM Inc., Hinckley, OH, United States

In Tanzania, malaria is the main cause of both in/out-patient attendance and deaths. Malaria is a major threat to non-immune travellers from malaria-free areas and peace keepers who are deployed to malaria endemic countries. This study is aimed at determining the malaria attack rate in groups from low and high transmission areas at malaria endemic national service (JKT) camps. This study was conducted at the Mgambo JKT camp in the Tanga region of Tanzania and involved military recruits originating from areas of low and high transmission. Consented recruits were screened negative for malaria, enrolled and followed-up biweekly for six months (a total of 12 visits). Blood smears were collected for malaria diagnosis by microscopy and subjects with positive malaria slides (study end point) were treated and censored. Each participant was screened for G6PD deficiency using a fluorescent spot test (FST). Of recruits enrolled (n=508), 67.1% came from low malaria transmission areas and 11.7% had G6PD deficiency. 94.1% completed the 12 follow-up visits or met the study end point. The malaria positivity rate was 43.5 % and there was a trend towards a higher positivity rate among recruits from low compared to those from high malaria transmission areas (46.0% ***vs*** 38.3%, p=0.099). The malaria attack rate was 72 cases/100 with higher rates among recruits from low compared to those from high malaria transmission areas (79 cases/100 ***vs*** 61 cases/100, p=0.08) but the difference was not statistically significant. After adjusting for G6PD deficiency, endemicity and use of bed-nets, the risk of getting a malaria attack was significantly higher among recruits from low transmission areas (OR=1.50, 95% CI =1.04 - 2.17, p=0.029). Recruits from low malaria transmission areas were at a higher risk of malaria due to lower malaria immunity. However, similar parasite positivity and malaria attack rates in the two groups were possibly due to the high malaria transmission in Mgambo and the surrounding area from heavy rains during the study period.

901

AUTOCHTHONOUS MALARIA IN THE ATLANTIC FOREST OF THE RIO DE JANEIRO STATE, BRAZIL

Anielle Pina-Costa

FIOCRUZ, Teresopolis, Brazil

Malaria transmission was considered eliminated from Rio de Janeiro (RJ) in 1968, but some autochthonous sporadic cases are still described. From 2006 to 2014, 14 cases acquired in the state were diagnosed and treated at the National Institute for Infectious Diseases of Fiocruz, in tourists coming from areas covered by the Atlantic Forest. All were vivax malaria cases, with atypical parasites (morphologically different parasites with less numerous merozoites within the schizonts) as compared with the classical ***Plasmodium vivax***. Antibodies (Ab) to all ***P. vivax*** CSP (circumsporozoite protein) variants, with predominance of VK210, were observed in patients. Thirty-six percent of patients were positive for the presence of Ab to the P.malariae/brasilianum CSP and 73 % had positive results for anti ***P. falciparum*** CSP Ab. We estimated the prevalence of ***Plasmodium*** infection by serological and molecular tests in the 220 case-contacting neighbors in an area within a perimeter of five kilometers around the index case. Positive serology for MSP1-19 (Elisa test) ***P. vivax*** in the neighboring contacting-population was around 58%, with titles ranging from 1:100 to 1:3200. All individuals presented, however, as negative in the molecular tests. In all areas where serological and molecular tests were performed we have captured and identified vectors circulating in the locality. Most of them were ***Anopheles*** (***Kerteszia) cruzii*** (Dyar and Knab, 1908) and none was found carrying parasites. Complementarily, we found a death free-living ***Alouatta*** from the Atlantic Forest with positive PCR (***P. vivax***/***P. simium***). These data point to the circulation of ***Plasmodium*** in the areas and, although they can support the hypothesis of autochthonous malaria as a zoonosis in the region, they also raise some questions on the transmission mechanisms: ie; the apparently high number of subjects carrying antibodies contrasting to the reduced number of malaria cases as well as the presence of almost only tourists among patients with symptomatic infection.

902

A PROSPECTIVE COHORT STUDY REVEALS NO ASSOCIATION BETWEEN ABO BLOOD GROUPS AND THE RISK OF UNCOMPLICATED MALARIA

Anna A. Minta[1], Abdramane Traore[2], Lala B. Sissoko[2], Moussa Niagaly[2], Abdrahamane Bathily[2], Tuan M. Tran[3], Shanping Li[3], Ogobara K. Doumbo[2], Safiatou Doumbo[2], Kassoum Kayentao[2], Aissata Ongoiba[2], Peter D. Crompton[3], Boubacar Traore[2]

[1]Laboratory of Immunogenetics, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Johns Hopkins School of Medicine, Rockville, MD, United States, [2]Malaria Research and Training Centre, International Center of Excellence in Research, University of Sciences, Technique and Technology, Bamako, Mali, [3]Laboratory of Immunogenetics, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Although several studies have demonstrated an association between blood group O and reduced risk of severe ***Plasmodium falciparum*** malaria, the relationship between ABO polymorphisms and the risk of uncomplicated malaria remains unclear. To address this knowledge gap, we conducted a prospective cohort study of 510 children aged 3 months to 12 years in Mali during an intense 6-month malaria season. During the study period, ***P. falciparum*** infections and cases of febrile malaria were detected through bi-weekly PCR and weekly active clinical surveillance, respectively. The prevalence of ABO blood groups in this cohort was 25.5% A, 29.4% B, 6.9% AB, and 38.2% O. There was no association between ABO blood groups and the risk of ***P. falciparum*** infection. Multivariate analyses adjusting for confounders of malaria risk revealed no association between ABO blood groups and the time to febrile malaria, the risk of experiencing febrile malaria, or the incidence of febrile malaria. Finally, parasite densities during acute malaria were similar across ABO blood groups. Therefore, unlike sickle cell trait, which has clearly been linked to a reduced risk of both severe and uncomplicated febrile malaria, this study indicates that the protective effects of blood group O are restricted to severe malaria.

903

THE USE OF GPS DATA LOGGERS TO DESCRIBE SPATIO-TEMPORAL MOVEMENT PATTERNS AND CORRELATIONS WITH MALARIA RISK IN AN AREA OF HYPERENDEMIC MALARIA IN NORTHERN ZAMBIA

Marisa A. Hast[1], Mike Chaponda[2], Kelly M. Searle[1], James Lupiya[2], Jailos Lubinda[3], Tamaki Kobayashi[1], Timothy M. Shields[1], Modest Mulenga[2], Frank C. Curriero[1], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Tropical Disease Research Centre, Ndola, Zambia, [3]Macha Research Trust, Macha, Zambia

Human movement has been identified as a potential driver for malaria transmission; however, the importance of this factor in different epidemiologic settings has not been fully examined. Nchelenge District, Luapula Province in northern Zambia has hyperendemic malaria, with a parasite prevalence greater than 50% by rapid diagnostic test (RDT). Participants enrolled in a longitudinal cohort as part of the Southern Africa International Centers of Excellence for Malaria Research (ICEMR) were invited to participate in a population movement study using GPS data loggers. During each bimonthly longitudinal household visit, 12-15 participants aged 13 years and older were asked to carry a logger for one month. Data will be collected for a total of one year starting in August 2014, resulting in at least 80 participants over six data collection periods. GPS devices are motion activated and record GPS coordinates every 2.5 minutes while the participant moves. Following the month of data collection, the loggers were returned and participants answered a questionnaire and provided a finger prick blood sample for malaria RDT, microscopy, and PCR to detect ***Plasmodium falciparum*** DNA. Data were uploaded into ArcGIS and R statistical programs to produce movement tracks and density maps. Analyses were conducted to correlate cases of incident malaria with time spent near the home, use of bed nets, history of indoor residual spraying, and time spent in areas identified to be at high risk of malaria based on risk maps. The relative importance of malaria risk at the household compared with malaria risk in areas of daily movement are compared. To date, 54 participants have contributed over 1,500 days of data comprising 115,000 GPS points. Half of the participants had incident malaria infections after their month of participation, with incidence slightly higher in men (57%) than women (47%). Data collection will be completed in June 2015.

904

PROGRESSIVE AND SUSTAINED DECLINE OF MALARIA BURDEN FOR NINE YEARS AT THE COMMUNITY LEVEL IN NORTHEASTERN TANZANIA

Acleus M. Rutta, Filbert Fransis, Bruno P. Mmbando, Deus S. Ishengoma, Ezekiel K. Malecela, Johari Y. Sadi, Mathias L. Kamugisha, Martha M. Lemnge

NIMR, Tanga, United Republic of Tanzania

Passive Case Detection involving early diagnosis and prompt treatment of malaria was introduced in 2006 in four villages (two in each of the lowland and highland strata) of Korogwe district, North-eastern Tanzania. A significant reduction in the incidence of malaria and parasite positivity rates was previously reported. We present further updates on the burden of malaria in this area with changing malaria epidemiology. In 2006, individuals with history of fever within 24 hours or fever at presentation (axillary temperature ≥37.5°C) were presumptively treated by Community Owned Resource Persons (CORPs) using sulphadoxine/pyrimethamine. From February 2007, individuals aged ≥5years with positive rapid

diagnostic test for malaria (mRDTs) were treated with artemether/ Lumefantrine (AL) while under-fives were treated irrespective of mRDT results. Logistic and Poisson regression were used to assess the changes in parasite positivity and incidence rates. Between January 2006 and December 2014, 21934 cases aged 0 - 98 years were attended whereby 24.6% were under-fives and majority (68.9%) was from lowlands. Overall, 30.9% of the cases had fever at presentation and the positivity rate was 15.5%. Parasite positivity rate was significantly higher in the lowlands compared to highlands (16.6% Vs 13.4%; p<0.001). After adjusting for the effect of year, age and altitude strata, the positivity rate decreased by 78% between 2006 and 2014 (OR =0.22, 95% CI = 0.16 - 0.31) and the incidence rate decreased by 75% (IRR =0.25, 95 % CI =0.18 - 0.34) with a significant decline in lowland compared to highland villages (p<0.001). However, the proportion of cases with fever remained unchanged (>30%). Despite a continued decline in the incidence of malaria and parasite positivity rates, fever cases remained unchanged. Future studies should address causes of persistently high level of febrile illnesses.

905

HIDDEN COST OF INFECTION: MALARIA ACCELERATES TELOMERE DEGRADATION

Muhammad Asghar[1], Victor Yman[1], Klara Sonden[1], Manijeh Vafa Homann[1], Dennis Hasselquist[2], Staffan Bensch[2], Anna Färnert[1]

[1]Karolinska Institutet, Stockholm, Sweden, [2]Lund University, Lund, Sweden

Approximately one half of the global population lives in malaria endemic areas where majority of malaria infections occur in the form of chronic asymptomatic infections. The potential for any long-term effect of such chronic/repeated infections, where individuals either completely recovered or carry asymptomatic infections is poorly understood. We have recently shown accelerated ageing and reduced lifespan mediated through faster telomere degradation in birds with chronic asymptomatic malaria. Great reed warblers that pick up various species of malaria parasites while wintering in the tropics and become asymptomatically infected for life after an initial acute malaria. Although these birds are chronically infected with malaria parasites, we found that these asymptomatic infections reduce lifespan, as well as lifetime number and quality of offspring. Furthermore, these delayed fitness effects were mediated through faster degradation of telomeres, a result supported by additional controlled infection experiments on birds in captivity. In human accelerated telomere degradation has been found in chronic and inflammatory diseases. Whether malaria infections also have effect on telomeres in humans, we have analyzed travelers with single treated ***Plasmodium falciparum*** malaria infections that were repeatedly followed over a year at Karolinska University Hospital in Sweden. We found that malaria infections accelerate telomere degradation in humans even after successful treatment. Furthermore, telomere length restored in these patients one year post infection. Further understanding of dynamics of telomere attrition and restoration in relation to intensity of malaria exposure and chronicity of infections is needed.

906

MALARIA EPIDEMIOLOGICAL STRATIFICATION IN VIETNAM, 2014

Thang D. Ngo[1], Hung X. Le[1], Hung M. Nguyen[1], Thieu Q. Nguyen Q. Nguyen[1], Trung D. Ho[1], Xa X. Nguyen[1], Anh Q. Nguyen[1], Ha S. Dinh[1], Nicholas Martin[2], Colin Ohrt[3], Duong T. Tran[1], The NIMPE Advisory Group Members[1]

[1]National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, [2]Naval Medical Research Centre - Asia, Singapore, Singapore, [3]University of California San Francisco, San Francisco, CA, United States

Malaria stratification is a classification of areas according to the risk of malaria and its level of endemicity. The malaria epidemiological stratification over the last five year period was implemented in all provinces (58) and cities (5) of Vietnam in 2014. The objective of this re-stratification was to identify different levels of malaria endemicity in order to develop more effective interventions for malaria control and elimination, based on the current malaria situation and national plan. Determination of indigenous malaria cases is a prerequisite for classifying each malaria zone. The seven indicators for the zone classification used were 1.) Average number of confirmed cases/1,000 population over the last 5 years, 2.) Presence of at least one of the three major malaria vectors, 3.) Socioeconomic disadvantaged or border commune, 4.) Poor health system, 5.) Drug-resistant parasites, 6.) Chemically-resistant mosquitoes, and 7.) Migratory populations. Each indicator was scored and the sum of the scores was used to define the level of endemicity and priority for interventions. This score was used to characterize each commune (county equivalent) into one of five zones (no malaria transmission, area at risk for reintroduction of malaria, low (>0-1/1,000), medium (1-5/1,000), or high (>5/1,000)). The areas free of malaria included 5,840 communes (52% of communes, 64,541,280 people), while the area at risk of malaria resurgence included 3,448 communes (21,445,395 people). The low malaria endemic areas include 1,095 communes (7,710,946 people); the medium malaria endemic area consists of 529 communes (2,813,221 people) ; the highly malaria endemic areas consisted of 240 communes (1,167,628 people). Based on these numbers 48% communes and 34% of the population are in endemic areas, with only 7% communes and 4% of the population in moderate to high transmission areas. This new stratification will be used to set priorities and target malaria control and elimination efforts to the areas where they are most needed. It will highlight areas where the malaria program needs extra effort and helps to make the best use of limited resources.

907

IMPACT OF ONE VS. TWO ROUNDS OF ANNUAL INDOOR RESIDUAL SPRAYING (IRS) ON MALARIA PARASITAEMIA IN CHILDREN IN NORTHERN GHANA

Benjamin Abuaku[1], Paul Psychas[2], Philip Ricks[3], Collins Ahorlu[1], Peter Mumba[4], David Mensah[1], Sedzro Mensah[1], William Sackey[1], Samuel Oppong[5], Kwadwo Koram[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]University of Florida, Gainesville, FL, United States, [3]United States Agency for International Development, Accra, Ghana, [4]Ghana Africa IRS Project, Abt Associates, Accra, Ghana, [5]National Malaria Control Programme, Public Health Division, Ghana Health Service, Accra, Ghana

The frequency of indoor residual spraying (IRS) is crucial for the effectiveness of IRS and the optimal allocation of malaria control resources. This study was conducted between November 2010 and April 2013 to compare the impact of annual vs biannual pyrethroid IRS in Bunkpurugu Yunyoo District (BYD), in the Northern Region of Ghana, which has high malaria transmission. BYD has a peak malaria season in September-November, at the end of its single rainy season, and a low malaria season in March-April at the end of its dry season. For this study, half of BYD (Area A) was sprayed once a year prior to the rainy season and the other half (Area B) was sprayed prior to both the rainy and dry seasons, using a pyrethroid, alphacypermethrin (Fendona 5 WP, 25mg/m2 application rate) in both areas. IRS impact was measured by peak and low season parasitemia surveys among children under 5 years, starting with the pre-IRS 2010 peak and 2011 low seasons as baselines. Probability proportional to size estimates (PPSE) gave a minimum sample size of 828 children per survey in each IRS area. All selected children were tested for parasitaemia by microscopy, and a questionnaire was used to collect demographic and health information. 826 to 1,022 children in each area were surveyed per round. For peak transmission season, parasitemia prevalence at baseline was marginally lower in Area A compared with B, 49.6% (95% CI: 46.2, 53.1) vs 54.9% (95% CI: 51.9, 57.9), respectively. End-of-study peak season prevalence significantly declined to 44.4% (95% CI: 41.3, 47.6) in Area A whilst peak season prevalence in Area B remained unchanged at 50.7% (95% CI: 47.6, 53.7). For low season, the baseline prevalence in Area A, 31.7 % (95% CI 28.8, 34.8), was significantly lower than in Area B, 39.1% (95%CI 35.6, 42.6). End-of- study low season prevalence

significantly declined in both sites to 24.1% (95% CI: 21.5, 26.9) in Area A and 26.3% (95% CI: 23.6, 28.9) in Area B. There is no consistent evidence that IRS with pyrethroids applied twice a year was more effective than once a year in this district, where there is a short uni-modal transmission season.

908

HIGH PREVALENCE OF MALARIA DESPITE PREVENTION AMONG PREGNANT WOMEN ATTENDING A DISTRICT HOSPITAL IN DOUALA, CAMEROON

Leopold G. Lehman[1], Gaëlle Mbiakop Kemajou[1], Celestin Zam-Ngono[2], Loick P. Kojom Foko[1], Larissa Kouodjip Nono[3], Herve Nyabeyeu Nyabeyeu[1], Arlette L. Ngapmen Yamadji[3], Lafortune Kangam[3], Nicolas Nolla[1], Calvin Tonga[1]

[1]University of Douala, Douala, Cameroon, [2]District Hospital of Cité des Palmiers, Douala, Cameroon, [3]University of Yaounde I, Yaounde, Cameroon

Gestational malaria is still a major health problem in Cameroon despite free delivery of IPT nationwide. Epidemiological data are needed to monitor the effectiveness of the preventive measures undertaken so far. This study aimed at determining an update of the prevalence and determinants of malaria in a District Hospital in Douala; the biggest town of Cameroon. A cross-sectional study was conducted at the District Hospital of Cité des Palmiers in Douala for a three-month period (May - July 2013). Pregnant women were met within the hospital and a questionnaire was administered to collect socio-demographical, midwifery and malaria-related data. In addition Giemsa stained thick film was performed for malaria diagnosis at their admission. A total of 121 pregnant women aged 17 to 42 were included in the study. The overall prevalence of malaria infection was high (81/121; 66.94%) among the women. However, the majority of infections were asymptomatic (67/121; 55.37%) despite the high coverage of IPT (92.6%). IPT was not timely related to routine diagnosis. The rate of ITN ownership was 63.6% and malaria infection varied significantly with respect to parity ($9\chi 2$ = 6.23; p = 0.016). Women living in wooden houses had more mosquito nets and were less infected than those living in block houses. Negative correlations, however not significant were observed between malaria infection and IPT (z = - 1.38; p = 0.16) and also between malaria infection and antenatal consultation (z = -1.41; p = 0.16), More than two-third of pregnant women were infected with malaria despite multiple preventive actions undertaken by the Cameroonian government. The high rate of asymptomatic infection suggests that active case detection could be helpful as well as synchronization with prevention tools like sanitation and the use of contact repellents.

909

MALARIA CHARACTERISTICS AND TRENDS, UNIVERSITY HOSPITAL, TEGUCIGALPA, HONDURAS, 2000-2014

Jackeline Alger, Jorge A. Garcia

University Hospital, Tegucigalpa, Honduras

The University Hospital is the main public health hospital in Honduras. Parasitology Service, Clinical Laboratory Department, performs malaria diagnosis using Giemsa stained thick/thin smears/slide (Mon-Fri, 6 am – 1 pm). Patient registration forms were reviewed with the aim to describe malaria characteristics and trends for the period 2000-2014. A database was prepared from daily/monthly registration reports. Microscopic diagnosis is described as number and average examined blood smears and positive smears by parasite species/year. For the period 2007-2014, epidemiologic and clinical characteristics of positive patients are described, including age, sex, origin of infection, pregnancy status, and therapeutic response. During the 15-year period, 723 annual average requests were analyzed (range 333-1043), including 677 average new cases (301-962), and 30 average post-treatment controls (9-59). A total of 665 malaria cases were diagnosed (44 annual average, range 15-84), 87.5% (582) ***Plasmodium vixax***, 11.4% (76) ***P. falciparum***, and 1.0% (7) mixed infections; 64.1% (426) subjects >15 years old, 20.0% (133) 5-14 age group, 6.6% (44) 1-4 age group and 3.8% (25) <1 year old; 5.6% (37) no age recorded. In 2007-2014, there were 27 cases in pregnant women, average age 21.4 years (14 – 42), 92.6% (25) ***P. vivax***. In 2009-2014, there were 228 malaria cases from which the therapeutic response was evaluated in 127 (55.7%), 118 (51.8%) ***P. vivax***, 8 (3.5%) ***P. falciparum***, 1 (0.4%) mixed infections. The origin of infection was traced to Francisco Morazán 38.6%, other departments 48.7%; Congo, Africa 0.4%; blood transfusion 0.9%, and no information 11.4%. All cases showed good clinical and parasitological response to chloroquine 25 mg/Kg in 48 hours, except one case that required a second cycle. In the last three years, annual cases are below the 15-year period annual average number (44) and are decreasing (40, 26, 15). Because its characteristics and performance in clinical care, academic and research activities, the University Hospital plays an important surveillance and response role, contributing to the activities for malaria elimination in Honduras.

910

THE IMPACT OF FIONET™ TECHNOLOGY ON PASSIVE MALARIA SURVEILLANCE IN TANZANIAN MILITARY HEALTH SYSTEM

Christopher Mswanya[1], Akili Kalinga[2], Lucky Temu[3], Lalaine Anova[4], Eyako Wurapa[5], Colin Ohrt[5], Sarah Chiduo[3], George Amoo[6], Charles Mwanziva[1], Ian Fine[7], Geeta Bhat[7], Dennis Janga[1]

[1]Tanzania Peoples Defense Force, Dar es Salaam, United Republic of Tanzania, [2]National Institute for Medical Research, Tukuyu Research Centre, Tukuyu, United Republic of Tanzania, [3]Walter Reed Malaria Programme-Tanzania, Dar es Salaam, United Republic of Tanzania, [4]ClinicalRM, Hinckley, OH, United States, [5]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [6]Amethyst Technologies LLC, Baltimore, MD, United States, [7]Fio Corporation, Toronto, ON, Canada

Malaria is a major cause of death and illness in Tanzania. In the military health system, malaria surveillance relied on microscopy data; the reliability of malaria microscopy is highly dependent on technician expertise. Recently, malaria rapid diagnostic tests (RDTs) and Fionet™ were deployed to support malaria diagnostics in selected military health facilities. Fionet™ is a digital health system that improves field performance and oversight of rapid diagnostic testing. Fionet™ is a web-based workflow guidance designed for use with standard mobile devices and the Deki Reader™ (DR). It provides step-by-step guidance for performing RDTs. The DR captures a digital record of each RDT performed and allows web-based oversight of RDTs is enabled to provide real time case management. Fionet™ was deployed in eight military health facilities throughout Tanzania. 85% (33648/39585) of RDTs were analyzed and uploaded through Fionet. Fionet enabled real-time data tracking and reporting. 33% and 80% of all data from the sites were uploaded in <1 hour and 24 hours respectively. Prior to Fionet™ implementation, malaria surveillance data typically took 30-40 days to reach TPDF headquarters and did not affect clinical decision-making. Also, remote monitoring enabled managers to instantly correct site personnel, thus reducing errors in preparation and interpretation of test results. Due to the availability of real time data, malaria incidence was determined at each site and the needed supply chain support was more efficient by reducing waste. In addition, collected surveillance data demonstrated which TPDF camps suffered the highest malaria incidence, which supported the selection of study sites for further epidemiological studies through active malaria case detection. Fionet™ has improved diagnostic capacity, real-time malaria data tracking and reporting. It has affected informed decision making positively.

IMPACT OF INTERMITTENT MASS SCREENING AND TREATMENT (IMSAT) ON COMMUNITY MALARIA PARASITEMIA PREVALENCE IN AN AREA OF HIGH TRANSMISSION - KENYA 2013-2014

Aaron M. Samuels[1], Norbert Awino Odero[2], Wycliffe O. Odongo[2], George Okoth[2], John Williamson[1], Kephas Otieno[2], Peter Otieno[2], Ya P. Shi[1], Mary J. Hamel[1], Kim Lindblade[1], S. Patrick Kachur[1], Simon Kariuki[2], Meghna Desai[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya

The asymptomatic malaria infected population contributes significantly to the infectious reservoir. Strategies targeting this population may help to reduce malaria transmission. We implemented a multi-year, community-based, two-arm cluster randomized controlled trial to evaluate the impact of intermittent mass screening and treatment (iMSaT) on malaria parasitemia prevalence in an area with high long-lasting insecticide-treated bednet (LLIN) coverage in Siaya County, Kenya. Villages within 3km of each of 10 health facilities were grouped into two clusters. One cluster was randomly assigned to intervention- the other to control. All residents ≥1 month of age in intervention communities (n>27,000 persons) received three rounds of mass screening with malaria rapid diagnostic tests (RDTs) and all positives were treated. Coverage (percent of intervention population screened) was 73.0% in September 2013, 79.5% in January 2014, and 75.0% in April 2014. Cross-sectional surveys (XSS) were conducted during peak malaria transmission in July 2013 (baseline) and 2014 (post-intervention). In each XSS, twenty compounds from each of twenty clusters were randomly selected from a complete list of compounds. Finger-prick blood samples were tested for malaria by light microscopy. Prevalence ratios (PR) were analyzed using generalized estimating equations. Study population demographics and LLIN coverage and use were similar between arms and surveys. Baseline prevalence (n=1893 residents) in the control and intervention arms were 37.6% (95% confidence interval [CI], 33.3-42.4) and 34.3% (95% CI, 29.3-39.5), respectively. After three rounds of iMSaT, malaria prevalence (n=1934 residents) in the control and intervention arms were 38.7% (95% CI, 34.4-43.6) and 32.0% (95% CI, 26.6-38.4), respectively. After one year of three rounds of iMSaT, the prevalence ratio for the relative change in malaria parasitemia prevalence between the intervention and control communities was 0.91 (95% CI: 0.78-1.06), a relative decrease of 9% (p=0.21). The second year of iMSaT is underway and data from the third XSS will be available by August 2015.

ASSESSING THE FEASIBILITY OF MALARIA ELIMINATION EFFORTS AMONG WORKERS EMPLOYED ON PRIVATE PLANTATIONS IN CAMBODIA

Rebecca Thomson[1], Sochea Phok[2], Abigail Pratt[2], Amanda MacDonald[2], Henrietta Allen[2], Sok Kunthy[3], Sok Chamrouen[3], Kim Daro[3], Sourn Samean[3], Sok Ra[3], Chan Sovottha[3], Nou Panharith[3], Gary Mundy[4], Shunmay Yeung[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Population Services International, Phnom Penh, Cambodia, [3]Partners for Development, Phnom Penh, Cambodia, [4]Population Services International, Bangkok, Thailand

Resistance of ***Plasmodium falciparum*** to artemisinin is a serious global health challenge, and has been increasing in South-East Asia. As malaria prevalence declines in this region, new approaches to target asymptomatic carriers must be adopted to eliminate ***P. falciparum***. Mobile and migrant populations, especially those working in forests and plantations, are considered to be at high risk and pose considerable risk of spreading artemisinin resistant malaria, both within and across borders. We carried out a plantation worker survey in Northeast Cambodia to understand better how to target these groups. Forty plantations were visited in June (dry season) and October (wet season). 4,227 workers were interviewed and had blood samples taken. Plantation workers were classified as temporary or permanent, and individual and plantation level risk factors for malaria infection were analysed. Malaria prevalence was very low: 0.9% in the dry season and 1.1% in the wet season (p=0.11) by polymerase chain reaction. The strongest risk factor was plantation size, with the odds of infection by P.falciparum decreasing as the plantation size increased in the dry season (odds ratio=0.084, p=0.008), and the wet season (OR=0.81, p=0.009). High levels of parasitemia was clustered around certain plantations, with three having prevalence of over 10% in the wet season and one with a 30% prevalence. Migrant workers were no more likely than permanent workers to have malaria in the dry season (0.83% and 0.85%, p=0.904) and more likely to be parasitemic in the wet season, although not significant (1.9% and 0.9%, p=0.109). Forest exposure and previous travel are shown to affect infection in the wet season. Low malaria prevalence on plantations suggests that mass drug administration on plantations is not likely to be the most effective way to target this population. Seasonal targeting of certain workers and on certain plantations may be the best approach.

913

PLASMODIUM VIVAX TRANSMISSION IN AFRICA

Rosalind E. Howes[1], Robert C. Reiner, Jr[2], Katherine E. Battle[1], Peter W. Gething[1], Peter A. Zimmerman[3], David L. Smith[4], Simon I. Hay[5]

[1]Department of Zoology, University of Oxford, Oxford, United Kingdom, [2]Department of Epidemiology and Biostatistics, School of Public Health, Indiana University, Bloomington, IN, United States, [3]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States, [4]Sanaria Institute for Global Health and Tropical Medicine, Rockville, MD, United States, [5]Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom

Malaria in sub-Saharan Africa has historically been almost exclusively attributed to ***Plasmodium falciparum***. The high prevalence of Duffy negativity provided a rationale for excluding the possibility of ***P. vivax*** (***Pv***) transmission. Current diagnostic and surveillance systems are not designed to identify or report ***Pv*** accurately, resulting in a void of routine epidemiological data about its significance in sub-Saharan Africa. Review of varied evidence sources, including traveller infections, community prevalence surveys, local clinical case reports, entomological and serological studies, however, contradicts dogma. Here, these data reports are weighted in a unified framework to reflect the strength of evidence of indigenous transmission they provide in terms of diagnostic specificity, magnitude of individual reports and corroboration between evidence sources. Strong evidence of transmission was available from 12 of the 47 countries evaluated (26%), distributed across West, Central, and Eastern Africa, while four had no evidence of transmission. Approximately 86 million Duffy positive hosts were at risk of infection in Africa in 2015. Analysis of the mechanisms sustaining ***Pv*** transmission across this continent of low frequency of susceptible hosts, found that ***Pv*** prevalence was consistent with transmission among exclusively Duffy positive sub-populations. Finally, reports of apparent Duffy-independent transmission are discussed. While ***Pv*** is evidently not a major malaria parasite across most of sub-Saharan Africa, the evidence-base presented here highlights its widespread low-level endemicity across the continent. An increased awareness of ***Pv*** as a potential malaria parasite, coupled with policy shifts towards the use of combination rapid diagnostic tests and species-specific reporting, will allow a robust assessment of the true public health significance of ***Pv*** in Africa, a parasite currently invisible to most public health authorities, but which can cause severe clinical illness and requires specific control interventions.

914

URBAN MALARIA INCIDENCE AND GEOGRAPHIC CLUSTERING ACROSS AN URBAN-TO-RURAL CONTINUUM: RESULTS FROM A CASE-CONTROL STUDY OF CHILDREN IN BLANTYRE, MALAWI

Lindsay R. Townes[1], Atupele Kapito-Tembo[2], Don P. Mathanga[2], Karl B. Seydel[3], Andrew Bauleni[2], Kondwani Nkanaunena[2], Clarissa Valim[4], Terrie E. Taylor[3], Mark L. Wilson[1]

[1]Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, [2]Department of Community Health, College of Medicine, University of Malawi, Blantyre, Malawi, [3]Department of Internal Medicine, College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States, [4]Department of Immunology and Infectious Diseases, Harvard T. H. Chan School of Public Health, Boston, MA, United States

Urban areas pose challenges to malaria prevention because the location of transmission is often unknown, household-level environmental conditions are highly diverse, and the definition of "urban" is debatable. As part of a case-control study of malaria among under-fives in and around Blantyre City, Malawi, we analyzed disease patterns and risk factors associated with environmental, demographic and infrastructural characteristics. Blantyre (~1.1M pop.) has highly diverse land use/land cover (LU/LC), house density, facilities and services inside its ~225 sq km city limits. Active surveillance at 6 health facilities (HFs) inside and peripheral to the city was undertaken from April 2012 - October 2014. Children with malaria symptoms who were PCR-positive for ***Plasmodium*** infection (cases) were age- and location-matched with one or two PCR-negative children (controls) from the same HF. A total of 202 cases and 353 controls met the eligibility, consent, and matching criteria. Follow-up household visits determined each house location, construction traits, and peri-domestic LU/LC. A standardized questionnaire addressed demographics, malaria prevention, and travel-associated risk. GIS analyses of household location, geographical features, and satellite-image derived LU/LC compared cases and controls, controlling for demographic and behavioral factors. The urban-rural status of each household was classified by measures e.g. census population, house density, peri-domestic agriculture, proximity to infrastructure, and a PCA-derived "urbanicity score." Multivariate statistics demonstrated no simple associations between case-control status and standard definitions of "urban." However, household-level LU/LC and geographic features were highly predictive of malaria risk. Spatial statistical analyses suggested clustering unrelated to governmental urban designations, whereas derived classifications involving LU/LC and other measures were more predictive. Our findings have important implications for household- and community-level malaria risk, and for where malaria control efforts might be most effective.

915

USE OF LONG-READ DEEP-SEQUENCING TO CHARACTERIZE GENETIC DIVERSITY AND PATHOGENIC VARIANTS OF VAR2CSA IN WOMEN WITH PLACENTAL MALARIA

Jaymin C. Patel[1], Steve M. Taylor[2], Christian M. Parobek[3], Nicholas J. Hathaway[4], Kyaw L. Thwai[1], Mwayi Madanitsa[5], Victor Mwapasa[5], Nicaise T. Ndam[6], Feiko O. ter Kuile[7], Jeffery A. Bailey[8], Jonathan J. Juliano[9], Steven R. Meshnick[1]

Placental malaria causes maternal anemia, severe malaria, infant death, preterm birth and low birth weight (LBW), largely owing to ***Plasmodium falciparum*** sequestration in the placenta. The sequestration results from the binding of infected erythrocytes (IEs) to placental chondroitin sulfate A (CSA); this interaction is mediated by ***P. falciparum*** protein VAR2CSA expressed on the surface of IEs. Within VAR2CSA, the ID1-DBL2x-ID2 region both binds CSA with similar avidity as the entire protein as well as elicits cross-reactive immune responses ***in vitro***. Therefore, the ID1-DBL2x-ID2 region is a promising candidate for vaccines against placental malaria. Such a vaccine may be enhanced by the identification of pathogenic variants of VAR2CSA, owing to the great sequence diversity of var2csa genes. However, the extent of genetic diversity of the ID1-DBL2x-ID2 region is incompletely understood, and no pathogenic var2csa genotypes have been described. Using placental and peripheral blood samples from 150 ***P. falciparum*** infected pregnant women in Benin and Malawi, we are conducting a molecular epidemiologic study to use next-generation sequencing technology in order to characterize the genetic diversity of the 1.5kb ID1-DBL2x-ID2 region and identify pathogenic variants that are associated with adverse birth outcomes. Alpha (within group) and beta (between groups) diversity will be compared between pregnant women of differing gravidities and birth weight. Additionally, genetic diversity will be compared between paired peripheral and placental samples from women with malaria at delivery to better understand the role of var2csa in cytoadherence of IE to the CSA and the subsequent sequestration in the placenta. Initial testing of 7 clinical samples from Malawi yielded 15 unique haplotypes occurring at a wide range of frequencies (80-1%), indicating that there exists a large reservoir of quantifiable var2csa variants. By exploiting this diversity using new sequencing technologies and analytic approaches, the results from the study will help elucidate the pathogenesis of malaria in pregnancy and directly inform on-going vaccine development efforts.

916

A DEEP SEQUENCING APPROACH TO ESTIMATE MALARIA COMPLEXITY OF INFECTION IN THE DEMOCRATIC REPUBLIC OF CONGO

Robin H. Miller[1], Nicholas J. Hathaway[2], Oksana Kharabora[3], Kashamuka Mwandagalirwa[4], Antoinette Tshefu[5], Steven R. Meshnick[6], Steve M. Taylor[7], Jeffrey A. Bailey[2], Jonathan J. Juliano[3], V. Ann Stewart[1]

[1]Uniformed Services University, Bethesda, MD, United States, [2]University of Massachusetts School of Medicine, Worcester, MA, United States, [3]University of North Carolina School of Medicine, Chapel Hill, NC, United States, [4]Kinshasa General Hospital (HGK), Kinshasa-Gombe, Democratic Republic of the Congo, [5]Ecole de Sante Publique, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [6]University of North Carolina Gillings School of Global Public Health, Chapel Hill, NC, United States, [7]Duke Global Health Institute, Duke University Medical Center, Durham, NC, United States

In areas of stable malaria transmission, asymptomatic malaria infections can consist of multiple genetically distinct ***Plasmodium falciparum*** strains. These multi-strain ***P. falciparum*** infections can impact malaria transmission dynamics, reduce treatment efficacy, influence clinical outcomes, and facilitate the emergence of novel malaria parasites with increased virulence and drug resistance mechanisms. The number of genetically distinct ***P. falciparum*** strains within a host is defined as the Complexity of Infection (COI). In this study, we utilized a deep sequencing approach designed to detect minor frequency alleles and estimate ***P. falciparum*** COI. We targeted a subset (n=81) of human DNA samples collected as part of the 2007 Demographic and Health Survey (DHS) in the Democratic Republic of Congo (DRC). Additional samples (n=965) were grouped based on geographic locations and pooled together to generate 88 population clusters distributed across the DRC. DNA extracted from each blood sample was utilized as template for PCR amplification of the polymorphic single-copy ***P. falciparum*** apical membrane antigen 1 (***pfama1***) gene. Resulting PCR products were deep sequenced on the Ion Torrent Platform and ***pfama1*** haplotypes were determined via a custom bioinformatics pipeline. Potential confounders, such as age, sex, geographic location, and HIV status were analyzed to determine the impact on the ***pfama1*** haplotypes and COI within a single individual.

917

IN VIVO EFFICACY AND SAFETY OF ARTEMETHER/ LUMEFANTRINE VS DIHYDROARTEMISININ-PIPERAQUINE FOR TREATMENT OF UNCOMPLICATED MALARIA AND ASSESSMENT OF PARASITE GENETIC FACTORS ASSOCIATED WITH PARASITE CLEARANCE OR TREATMENT FAILURE

Celine Mandara[1], Deus Ishengoma[1], Samuel Gesase[1], Esther Ngadaya[2], Janneth Mghamba[3], Peter Mmbuji[3], Sigsbert Mkude[4], Renata Mandike[4], Ritha Njau[5], Ally Mohamed[4], Martha Lemnge[1]

[1]National Institute for Medical Research, Tanga, United Republic of Tanzania, [2]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, [3]Ministry of Health and Social Welfare, Dar es Salaam, United Republic of Tanzania, [4]National Malaria Control Program, Dar es Salaam, United Republic of Tanzania, [5]World Health Organization Country Office, Dar es Salaam, United Republic of Tanzania

Following changes of malaria treatment guidelines in Tanzania in 2006, Artemether/Lumefantrine (AL) was the only ACT which was introduced for treatment of uncomplicated falciparum malaria. However, alternative drugs such as dihydroartemisinin-piperaquine (DP) are urgently required to ensure effective case management.To assess the efficacy and safety of DP and AL for treatment of uncomplicated falciparum malaria and the role of parasite genetic/genomic factors on the treatment outcome among patients treated with these ACTs.This was an open-label, randomized, non inferiority trial that recruited children aged 6 months to 10 years with uncomplicated malaria at two sites of Muheza District Hospital and Ujiji Health Centre in Tanga and Kigoma regions, respectively. Enrolled children were treated with either AL or DP and followed-up for 28 (extended to 42) and 42 (63) days for AL and DP, respectively. Parasite and fever clearance were monitored in the first 72 hours post treatment. The primary outcome was parasitological cure on days 28 and 42 for ALu, and day 42 and 63 for DP. Of the 1094 patients screened, 492 were enrolled with more patients enrolled at Ujiji (n=317) compared to Muheza (n=192). There was no early treatment failure and the crude cure rates on day 28 were 72.2% and 72.0% in patients treated with AL at Muheza and Ujiji, respectively. For the patients treated with DP, the cure rate on day 42 was 77.5.0% at Muheza and 76.5% at Ujiji. With extended follow-up to day 42 for ALu and day 63 for DP, the cure rates were lower in the two groups and at both sites (Muheza, 58.6.0% and 61.6%; Ujiji, 50.0% and 47.1%, for ALu ad DP, respectively). Over 50.0% of patients from Muheza had not cleared parasites after 40hrs post treatment (compared to <10.0% at Ujiji) and only one patient treated with DP at Muheza (1.1%) still had parasites after 72hrs. High parasite clearance for both drugs indicates that there is no tolerance/resistance to artemisinins. However, high rate of treatment failure among patients treated with AL and DP could be due to re-infections which will be corrected after PCR analysis.

918

GENETIC SIGNATURES OF MALARIA SELECTION VALIDATED BY ASSOCIATION WITH CURRENT AND HISTORIC MEASURES OF MALARIA TRANSMISSION INTENSITY

Nuno Sepulveda, Alphaxard Manjurano, Taane Clark, Eleanor Riley, Chris Drakeley

London School of Hygiene & Tropical Medicine, London, United Kingdom

Malaria exerts strong selection pressure on the human genome as evidenced by the congruence of the population prevalence of malaria parasites with sickle-cell trait and other haemoglobinopathies. Proxies of malaria transmission intensity, such as altitude, have also been used to demonstrate genetic associations with malaria. In this study we examined the variation of human genetic polymorphisms as function of three measures of malaria transmission with differing longevity: village altitude as measure of long term malaria transmission, anti-malarial antibody seroconversion rate as a medium term transmission measure and village level parasite prevalence as a measure of current transmission. Samples were collected from 8138 individuals aged 1-45 years resident in 24 villages in north east Tanzania; village altitude ranged from 165 to 1788 above sea level, seroconversion rates from 0.019 to 0.941 person per year and ***Plasmodium falciparum*** parasite prevalence from 17.3 to 96.5%. Genotyping was conducted using Sequenome Massarray for 275 single nucleotide polymorphisms (SNPs) previously associated with protection from malaria; 175 passed a very strict quality check. By analysing the summary data of the villages we showed that alpha-thalassaemia, sickle-cell gene, a specific mutation in CD36 and several SNPs on the G6PD locus were strongly associated with long-term malaria exposure. We also found moderate associations between recent-to-current malaria exposure and several polymorphisms on immune response genes, including IL3, IL13 and TNF. The performed analysis highlights the strength of integrating large and detailed epidemiological studies with high-throughput genotyping technologies, thus providing robust evidence for the long-term genetic selection of sickle cell and alpha-thalassaemia traits and a mutation in CD36 and more recent genetic selection of several immune-related genes.

919

EVOLUTIONARY RATES OF *PLASMODIUM* SPP. GAMETOCYTE EXPRESSED GENES AND THEIR PUTATIVE ROLE AS UNIVERSAL TRANSMISSION BLOCKING VACCINE CANDIDATES

Andreina Castillo[1], Maria Andreina Pacheco[2], Ananias Escalante[2]

[1]Arizona State University, Tempe, AZ, United States, [2]Department of Biology/Institute for Genomics and Evolutionary Medicine, Temple University, Philadelphia, PA, United States

Although efforts to reduce malaria transmission have been highly successful, the development of resistance to antimalarial drugs by the parasite and to insecticides by the vector may hamper their sustainability. In addition, marked differences between transmission patterns and life cycles of the major causal agents (***Plasmodium vivax*** and ***P. falciparum***) increase the complexities that elimination programs are facing worldwide. Among the alternatives considered to overcome these obstacles, transmission blocking vaccines (TBV) have gained interest due to their ability to disrupt transmission and, in some cases, generate lasting immune responses. Given that many proteins are orthologous across the genus, some focus has been given to finding a universal malaria vaccine. In this study, the long term evolutionary trends of 312 genes with gametocyte biased expression were evaluated across 7 ***Plasmodium*** species. Also, 10 known TBVs candidates currently under different stages of development were evaluated. We first estimated the rates of synonymous (Ds) and non-synonymous (Dn) substitutions correcting by time. The difference on the variation of Ds ($F(0.7579)=0.3847$, $p>.05$) and Dn ($F(0.3903)=0.532633$, $p>0.05$) rates was not statistically significant between gametocyte sexes. However, variation of the Dn rate between membrane vs. non-membrane expressed genes regardless of sex was significant, $F(9.1960)=0.002646$, $p>0.05$. Episodic selection was detected on the ***P. vivax*** or ***P. falciparum*** branches in 52 genes. However, a more stringent analysis adding 4 ***Plasmodium*** species detected evidence for episodic selection only on 18 of those 52. Although many genes expressed in the gametocytes are highly conserved, still a few of them are less conserved or even under episodic selection in ***P. vivax*** or ***P. falciparum***. Considering this long-term term evolutionary trends is important for those actively exploring TBV candidates that could elicit cross-reactive immunity between both parasites.

NEXT GENERATION SEQUENCING METHODS FOR THE ANALYSIS OF COMPLEXITY OF INFECTION IN MALARIA PATIENTS IN INDIA

Pavitra N. Rao[1], Swapna Uplekar[1], Sonal Kale[2], Nabamita Bandyopadhyay[2], Prashant K. Mallick[2], Shobhna Mishra[2], Lalitha Ramanathapuram[1], Daniel Hupalo[1], Alex Eapen[3], Ranvir Singh[4], Om Prakash Singh[2], Jane M. Carlton[1]

[1]New York University, New York, NY, United States, [2]National Institute of Malaria Research (Indian Council of Medical Research), New Delhi, India, [3]National Institute of Malaria Research Field Unit, Chennai, India, [4]National Institute of Malaria Research Field Unit, Nadiad, India

Genetically complex malaria infections comprising two or more distinct clones of the parasite ***Plasmodium*** within the host can influence disease phenotypes and outcome, vector transmission, and resistance to antimalarial drugs. Deep-sequencing methods provide high resolution, scalability and sensitivity, and are thus especially suited for the examination of intra-host diversity of malaria infections. We developed an amplicon sequencing protocol for the Ion Torrent sequencing platform in order to evaluate complexity of infection in ***P. vivax*** isolates. Based on SNP incidence and frequency obtained from whole genome sequencing of 200 global field isolates of ***P. vivax***, we selected a panel of five loci in highly polymorphic genes, which includes members of the MSP and SERA multigene families. We carried out a pilot amplicon sequencing run using mixtures of ***P. vivax*** reference strains to assess whether SNP allele frequencies at the selected loci can be used to determine the relative proportion of individual strains in these mixtures. Subsequently we will use this amplicon panel to evaluate the within host diversity of ***P. vivax*** isolates from three epidemiologically different sites in India, namely, Chennai (Tamil Nadu), Nadiad (Gujarat), and Raurkela (Odisha), as part of the Center for the Study of Complex Malaria in India.

921

POLYMORPHISM OF MALARIA VACCINE CANDIDATE MEROZOITE SURFACE PROTEIN 5 (MSP5) IN MALIAN *PLASMODIUM FALCIPARUM* USING PACIFIC BIOSCIENCES AND SANGER SEQUENCING PLATFORMS

Amed Ouattara[1], Mahamadou A. Thera[2], Drissa Coulibaly[2], Elliott F. Drábek[1], Matthew Adams[1], Matthew B. Laurens[1], Amadou Niangaly[2], Youssouf Tolo[2], Mark A. Travassos[1], Joana C. Silva[3], Shannon Takala-Harrison[1], Ogobara K. Doumbo[2], Christopher V. Plowe[1]

[1]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, Baltimore, MD, United States, [2]Malaria Research and Training Center, ICER-Mali, USTTB, Bamako, Mali, [3]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, Baltimore, MD, United States

The highly polymorphic nature of most candidate vaccine antigens may hamper an initially efficacious vaccine's short or long term success in the field. Haplotype prevalence and genetic diversity within vaccine candidate merozoite surface protein 5 (MSP5) were estimated from specimens collected from asymptomatic infections (n=42) and clinical malaria episodes (n=42) in children from Bandiagara, Mali, by Sanger sequencing and Pacific Biosciences (PacBio) single molecule real-time sequencing methods. PCR primers were designed to amplify a 3800 base pair product that encompasses the genomic segment encoding MSP5. Equimolar amounts of each sample amplicon were pooled for multiplex PacBio sequencing. Amplicons were individually assembled for each sample after barcode-based demultiplexing. Using Sanger sequencing methods we identified 92 unique sequences based on chromatogram peak heights. We generated 123 MSP5 sequences by PacBio sequencing with an average, minimum and maximum of 1.4, 1 and 5 sequences per sample, respectively. The average gene coverage by PacBio platform was 97X (range: 9-500) while an average predicted accuracy of 95% (range: 0.33-1) was observed. Overall, sequencing using the Sanger platform cost $82 dollars per sample while PacBio-generated sequence cost $62 per sample. The results from this study show that PacBio sequencing is a cost-effective alternative to Sanger sequencing, and that this third-generation sequencing platform can detect more diversity than that identified using Sanger sequencing.

922

EUPATHDB: AN INTEGRATED GENOMIC DATA RESOURCE FOR EUKARYOTIC PATHOGENS

Susanne W. Warrenfeltz[1], Brian P. Brunk[2], Omar S. Harb[2], Jessica C. Kissinger[1], David S. Roos[2], Christian J. Stoeckert[2], Jie Zheng[2], for the EuPathDB team.

[1]University of Georgia, Athens, GA, United States, [2]University of Pennsylvania, Philadelphia, PA, United States

The Eukaryotic Pathogen Database Resource (http://eupathdb.org) is a free online omics resource that provides a large number of search and analysis tools to the research community. These include: comparative genome analysis, population genetics tools, functional enrichment analysis, data visualization and advanced search capability across a large number of genome sequences and functional datasets. EuPathDB integrates diverse data types (genome sequence/annotation, proteomics, RNA-Seq, metabolomics, population re-sequencing, SNPs, etc.) and applies a standard analysis pipeline to all sequences that generates data

such as domain predictions, orthology profiles and GO term associations. Functional genomics datasets are also analyzed with standard workflows, providing a base for comparing, visualizing and mining data within or across different datasets with only a Web browser. EuPathDB specifically supports eukaryotic pathogens for taxon-specific data mining (AmoebaDB.org, CryptoDB.org, FungiDB.org, GiardiaDB.org, MicrosporidiaDB.org, PiroplasmaDB.org, PlasmoDB.org, ToxoDB.org, TrichDB.org, TriTrypDB.org) as well as cross-taxon inquiries (EuPathDB.org) and orthology inferences across representative organisms from the three kingdoms of life (OrthoMCL.org). Over the next few years EuPathDB will be developing new tools and functionalities that include a private user workspace for primary data analysis, functional analysis tools for result summarization, genome browser and query improvements. The power of EuPathDB lies in the large number of genomes (>224) and integrated functional datasets (>180); sophisticated data mining optimized to support hypothesis driven research; an intuitive graphic web-interface; fast transition between data mining and visualization; and the capacity to mine the details of a single genome-wide dataset or mine across several datasets. EuPathDB provides support via email (help@eupathdb.org), Web demonstrations and help desks, encouraging suggestions for pertinent datasets and new features. Please visit us in the exhibitor hall for a demonstration.

GENETIC DIVERSITY OF VAR2CSA FROM FIELD ISOLATES, BASED ON A COMBINATION OF LONG-RANGE PCR AND SINGLE-MOLECULE SEQUENCING

Antoine Dara[1], Mark A. Travassos[2], Matthew Adams[2], Sarah Schaffer DeRoo[3], Elliott F. Drábek[4], Sonia Agrawal[4], Joana C. Silva[5], Christopher V. Plowe[2], Miriam K. Laufer[2]

[1]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine; Microbiology and Immunology, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]University of Maryland, Baltimore, MD, United States, [4]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [5]Institute for Genome Sciences, University of Maryland School of Medicine; Microbiology and Immunology, University of Maryland School of Medicine, Baltimore, MD, United States

Pregnancy-associated malaria, PAM, a leading cause of maternal anemia and low birth weight, is characterized by the sequestration of ***Plasmodium falciparum***-infected erythrocytes in the placental microvasculature via binding of VAR2CSA, a parasite-encoded protein, expressed on the surface of infected cells. Sero-epidemiological studies suggest that VAR2CSA is a target of naturally acquired immunity, supporting the possibility that VAR2CSA could be a target for a PAM vaccine. However, based on limited data, there appears to be extensive genetic diversity within the var2csa gene that must be taken into account in the design of an effective vaccine. Sequencing the full-length gene from clinical isolates has been challenging due to a low complexity associated with var2csa. We have developed a novel strategy to characterize the extent of var2csa genetic diversity using Single Molecule Real Time (SMRT®) sequencing (Pacific Biosciences). Forty three samples collected from Malawi along with two laboratory strains were used to amplify the full gene in two overlapping fragments of ~5kb each. We successfully sequenced the first fragment spanning the first four domains (DBLpam1-DBLpam3) of the protein. In total 143,603 reads with a median length 2,728 (N50=4566) were generated from one SMRT® cell. After filtering, clustering reads, and removal of chimeric sequences, 98 sequences with an average coverage of 163x and accuracy equal or greater than 99%, including 21 full-length-amplicon sequences of fragment 1, were obtained. Our results showed an extensive polymorphism of N-terminal of var2csa with an average nucleotide diversity of 12%. Of the 4 domains, DBLpam3 was the least variable. Compared with published sequences, Malawian var2csa sequences clustered with 3D7 and FCR3 laboratory reference strains. We are using this approach to sequence the membrane proximal C-terminal region (fragment 2) and characterize the genetic variation of var2csa from parasite from different geographic regions. The findings will provide a framework for strain-transcendent VAR2CSA-based vaccine development.

GENOMIC CHARACTERIZATION OF NF54, THE *PLASMODIUM FALCIPARUM* STRAIN IN THE WHOLE-ORGANISM MALARIA PFSPZ VACCINE

Kara A. Moser[1], Elliot F. Drábek[1], Matt Adams[2], Shay Hampton[2], Amed Ouattara[2], Sushma Nagraj[1], Mark Travassos[2], Claire M. Fraser[1], B. Kim Lee Sim[3], Stephen L. Hoffman[3], Christopher V. Plowe[2], Joana C. Silva[1]

[1]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Sanaria Inc., Rockville, MD, United States

NF54 (Nijmegen Falciparum #54) is the ***Plasmodium falciparum*** (Pf) isolate used in the whole-organism malaria vaccine called Sanaria® PfSPZ Vaccine. This vaccine, composed of radiation attenuated, aseptic, purified, cryopreserved sporozoites, provided 100% protection from homologous controlled human malaria infection (CHMI) in a small safety and efficacy trial using intravenous administration. Clinical trials are underway to replicate these results and to determine efficacy against heterologous CHMI. The annotated genome of NF54 is not yet available, but will be an essential tool to interpret the result of efficacy studies, including the comparison of outcomes between homologous and heterologous CHMI, as well as protection against natural infections. The NF54 genome is likely very similar to that of the reference 3D7 Pf isolate, a clone from NF54. Analyses of publicly available whole-genome sequencing data for NF54, in the form of paired-end 100 bp Illumina reads, reveals the presence of 171 SNPs, of which 36 are non-synonymous, confirming both the close relationship between the two genomes and the presence of a limited number of differences. However, the highly biased genome composition of Pf, together with its considerable repetitiveness, prevents the exhaustive characterization of those differences by read mapping, also an inadequate approach to identify potential genomic regions unique to NF54. In order to extensively characterize its genome, we have cultured NF54 and generated an 18,800 bp insert Pacific Biosciences (PacBio) library. This long-insert library was sequenced in four SMRT cells, with an average of 139,499 reads per cell, and an average mean and maximum read length of 7,433 and 48,513, respectively, for a total of over four gigabases of PacBio data. The genome is currently being assembled; a data set generated in a similar manner for another Pf isolate resulted in a nearly closed 24Mb genome assembly of 40 contigs. The newly generated NF54 assembly will be extensively characterized and compared with clinically relevant strains, including 3D7,as well as the 7G8 clone, currently being used in heterologous CHMI.

NATURALLY ACQUIRED ANTIBODIES TO DUFFY BINDING PROTEIN OF *PLASMODIUM VIVAX* (PVDBP) AND PROTECTION FROM CLINICAL MALARIA IN RURAL AMAZONIA

Vanessa C. Nicolete[1], Sarah Frischmann[2], Susana Barbosa[1], Christopher L. King[2], Marcelo U. Ferreira[1]

[1]Universidade de São Paulo, São Paulo, Brazil, [2]Case Western Reserve University, Cleveland, OH, United States

Plasmodium vivax merozoites recognize specific receptors on the host cell surface to invade their target cells, young erythrocytes known as reticulocytes. One of the major parasite's ligands is the Duffy binding protein (PvDBP), expressed in micronemes, which binds specifically to an erythrocyte membrane glycoprotein known as Duffy blood group antigen/

receptor for chemokines (DARC). Interaction between the cysteine-rich domain II of PvDBP and DARC is crucial for red blood cell invasion; DARC-negative individuals are thus usually refractory to blood-stage infection. Here, we tested whether naturally antibodies to PvDBP conferred protection against clinical vivax malaria among ***P. vivax***-exposed rural Amazonians. We measured IgG antibodies in 1126 plasma samples from 466 individuals (1-7 samples per subject) using a multiplex assay with microspheres conjugated with five different variants of PvDBP (Sal-I, AH, P, O and C). A high proportion of samples tested, ranging from 64% to 85% according to the variant, had IgG antibodies to PvDBP. We found a clear but short-lived boosting by comparing antibody levels in samples collected before and after laboratory-confirmed episodes of ***P. vivax*** malaria. However, survival analysis using multilevel Cox models found no association between high-level antibody response to PvDBP and time to the next laboratory-confirmed ***P. vivax*** malaria episode (hazard ratio = 0.97; $P = 0.86$). We further tested whether the presence of antibodies that are able to block binding of the Sal-I variant of PvDBP to Duffy was associated with clinical immunity and found that 12% of the 564 samples analyzed displayed high blocking activity (≥ 80%) ***in vitro***. Compared with subjects with antibodies displaying low-level (≤ 40%) or no inhibitory activity, those with highly blocking antibodies had a longer time to the next clinical ***P. vivax*** episode, but the difference did not reach statistical significance (hazard ratio = 0.66; $P = 0.32$). We are currently exploring the variant-specificity of blocking antibodies by using additional PvDBP variants in functional ***in vitro*** assays.

GENOME-WIDE COMPARATIVE TRANSCRIPTOME ANALYSES OF VIRULENT AND AVIRULENT RODENT MALARIA PARASITES AND HOST RESPONSES IN THE BLOOD AND SPLEEN PROVIDE MOLECULAR INSIGHTS INTO AN INTIMATE HOST-PARASITE INTERACTION

Jingwen Lin[1], Adam J. Reid[2], Deirdre Cunningham[1], Jan Sodenkamp[1], Sarah Keller-McLaughlin[1], Irene Tumwine[1], Garikai Kushinga[1], Mandy Sanders[2], Matthew Berriman[2], Jean Langhorne[1]

[1]The Francis Crick Institute, London, United Kingdom, [2]Parasite Genomics, Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom

Using fluorescent and bioluminescent parasites, we demonstrate that severe pathology in mice infected with virulent ***Plasmodium chabaudi*** CB strain is associated with greater reticulocyte preference and stronger cytoadherence compared with avirulent AS strain. The reticulocyte preference results in more severe anemia as parasites erode replenishment of erythrocytes, and a more pronounced anemia signature in the host blood transcriptome. Comparative RNA sequencing analysis reveals an association with higher levels of reticulocyte-binding protein transcripts in the CB parasite. Furthermore, genome-wide transcription profiling of mouse blood and spleen during acute blood-stage infection shows an earlier and stronger apoptosis signature with virulent CB infection, whilst a heightened and sustained T cell response signature with avirulent AS infection. Together, these comparative transcriptome analyses elucidate key aspects of host-parasite interactions that shape the outcome of a malarial infection.

927

PD1 MODULATES NEONATAL VΔ2 T CELL RESPONSES TO MICROBIAL ANTIGENS

Haoting Hsu[1], Sarah E. Boudova[2], Godfrey Mvula[3], Titus Divala[3], Randy Mungwira[3], Suchita Chaudhry[1], Christopher Harman[4], Karl Seydel[3], Karl Seydel[5], Miriam Laufer[2], David Pauza[1], Cristiana Cairo[1]

[1]Institute of Human Virology, University of Maryland, Baltimore, MD, United States, [2]Center for Vaccine Development, University of Maryland, School of Medicine, Baltimore, MD, United States, [3]Blantyre Malaria Project, University of Malawi College of Medicine, Blantyre, Malawi, [4]Obstetrics, Gynecology and Reproductive Health, University of Maryland, Baltimore, MD, United States, [5]College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States

In utero exposure to microbial antigens primes the fetal immune system, often with adverse consequences for infant immune responses. Vδ2 cells, a subset of γδ T cells, play important roles in antimicrobial immunity and in the response to BCG vaccination. Their repertoire and responses are altered in neonates prenatally exposed to ***Plasmodium falciparum*** (***Pf***) and these alterations may affect responsiveness to childhood vaccines and susceptibility to later malaria exposure. Our studies focus on the mechanisms for attenuation of Vδ2 function due to ***in utero Pf*** exposure. We hypothesize that PD1, a negative regulator of T and B cell responses critical for maintenance of peripheral and feto-maternal tolerance, is key for neonatal Vδ2 dysfunction. We found that neonatal Vδ2 cells up-regulate PD1 upon activation ***in vitro*** and, unlike their adult counterparts, maintain its expression for up to 28 days. When PD1 is engaged by its ligand PDL1 during T cell receptor stimulation, Vδ2 cell effector functions are decreased. These effects depend on the dose of PDL1 and are positively correlated with the fraction of Vδ2 cells that are PD1+. PD1 expression by neonatal Vδ2 cells is inversely associated with DNA methylation in the PD1 promoter. PD1 mRNA levels are higher in neonatal compared to adult Vδ2 cells at both 14 and 28 days post-stimulation, while mRNA levels of Blimp1, a transcriptional repressor of PD1, are lower in neonatal Vδ2 cells. These differences seem part of a functional program specific for the fetal/neonatal stage of development. Fetal Vδ2 cell function may be regulated by PD1 to prevent excessive inflammatory responses before and shortly after birth. Prenatal stimulation of Vδ2 cells caused by maternal infection may induce prolonged PD1 expression and hinder functional Vδ2 development after birth, thus leading to impaired early immune responses to pathogens and some live vaccines. Our ongoing studies on Vδ2 cell phenotype and function in Malawian newborns with documented prenatal exposure to ***Pf*** will advance our understanding of neonatal immune regulation and help to develop interventions to improve protection of infants against a wide range of pathogens.

ALLELIC FREQUENCY OF INTRONIC SNPS IN HUMAN FC RECEPTOR (FCΓR) GENE DIFFERS AMONG DOGON AND FULANI CHILDREN WITH UNCOMPLICATED MALARIA IN MALI

Daniel Amoako-Sakyi[1], Cherif Mariama[2], Maiga Bakary[3], Amagana Dolo[1], Nébié Issa[2], Marita Troye-Blomberg[4]

[1]University of Cape Coast, Cape Coast, Ghana, [2]Centre National de Recherche et de Formation sur le Paludisme, Ougadougou, Burkina Faso, [3]Malaria Research and Training Center, University of Mali, Bamako, Mali, [4]Department of Molecular Biosciences, The Wenner Gren Institute, Stockholm University, Stockholm, Sweden

Interethnic differences in malaria susceptibility may is influenced by multiple factors including host immunogenetics. Single nucleotide polymorphisms (SNPs) in immunological important molecules, such as Fc receptors (FcγRs) for IgG have been previously studied among Fulani and non-Fulani sympatric tribes to determine if they contribute to

protection. The complex nature of the gene cluster encoding FcγRs and recent reports of genotype-phenotype mismatch in this cluster suggests that other polymorphisms, probably intronic ones, may also influence malaria susceptibility in these populations. The aims of this study were to investigate two intronic SNPs (rs3933769 and rs396991) and a functional SNP (rs1050519) located in the FcγRIIC, FcγRIIA and FcγRIIB genes among Fulani and Dogon tribes living in sympatry in Mali. The study further tested the association of these SNPs with various clinical and immunological indices in 242 Fulani and Dogon children with uncomplicated malaria. All SNPs were genotyped with predesigned TaqMan® SNP Genotyping Assays. The study confirmed known malariometric and immunologic differences between sympatric Fulani and non Fulani tribes. We found the mutant alleles of both the rs3933769 and the rs396991 alleles were less frequent in the Fulani compared to the Dogon ($p < 0.0001$ and $p = 0.0043$). The distribution of the mutant rs1050519 allele was however similar in the two tribes ($p = 0.064$). All SNPs studied were not associated with levels of antibody responses with the exception of rs36991 which was associated with IgG1 ($p = 0.023$) in the Fulani. Carriers of the rs3933769 mutant allele harboured less than half of the parasite burden than those without the mutant allele ($p < 0.0001$). Differences in allelic frequencies between rs3933769 and rs396991 among Fulani and Dogon indirectly suggest that these SNPs could influence malaria susceptibility in the study population. Association of rs3933769 with parasite density is particularly noteworthy.

ALTERED PLATELET COUNTS INFLUENCED LEVELS OF PRO-INFLAMMATORY CYTOKINES OF *PLASMODIUM FALCIPARUM* INFECTED PATIENTS IN A SEMI-URBAN AREA OF NIGERIA

Olusola Ajibaye[1], Akiniyi A. Osuntoki[2], Albert Osaretin Ebuehi[2], Bamidele Abiodun Iwalokun[1], Bassey A. Orok[1], Emmanuel O. Balogun[3]

[1]Nigerian Institute of Medical Research, Lagos, Nigeria, [2]University of Lagos, Biochemistry Department, Lagos, Nigeria, [3]The University of Tokyo, Department of Biomedical Chemistry, Graduate School of Medicine, Tokyo, Japan

Malaria is still a leading global health concern with 3.4 billion people at risk and 198 million clinical cases, sub-Saharan African countries having the highest burden. Our preliminary studies revealed that Pro-inflammatory cytokines are increased in malaria ,however, some hematological parameters were significantly implicated.We therefore hypothesized that some blood components play protective roles in malaria. In 2014,volunteers(613) with a history of fever and forty (40) Uninfected controls were screened microscopically, according to WHO standard, for ***Plasmodium falciparum*** in a cross-sectional study at IJEDE General Hospital. Full Blood Counts (FBC) of participants was determined using Finray hematology Auto-analyzer.Serum levels of TNF-α, Interlukin-1β (IL-1β) and Interlukin-12(IL-12) were determined by capture ELISA while statistical analysis was done using SPSS Version 20. Study protocol was approved by NIMR IRB.A total of 128 patients comprising of 47% males and 53% females with a median age of 10 years were recruited. Malaria prevalence was 20.85% while Haemoglobin, Mean Cell Hemoglobin and Mean Cell Volume were significantly ($P<0.05$) lower in the control group. Thrombocytopenia (Platelets counts < 150 X 109 / L) was prominent in infected participants and was negatively correlated ($r=0.003$) with IL-12. Mean levels of TNF-α, IL-1β and IL-12 were significantly ($P< 0.02$) higher in the test participants than the controls. Increase in Parasitaemia resulted in insignificant increase in TNF-α. Results from this study suggests that hematological indices are key in the immunity against malaria and may modulate disease outcomes and pattern of progression as parasite killing ability of Platelets is related to pro-inflammatory response.

930

MEDIATORS OF MONOCYTE OPSONIC PHAGOCYTOSIS OF *PLASMODIUM FALCIPARUM*

Gloria Tavera[1], Danika L. Hill[2], Christopher L. King[1]

[1]Case Western Reserve University, Center for Global Health and Diseases, Cleveland, OH, United States, [2]Walter and Eliza Hall Institute of Medical Research, Division of Population Health and Immunity and University of Melbourne, Department of Medical Biology, Melbourne, Australia

Antibodies (Abs) mediate naturally acquired immunity (NAI) to blood stage malaria, in part by opsonizing parasites and infected red blood cells for phagocytosis. Thus, immunity to blood-stage malaria requires proper and efficient activation of phagocytosis. Using the THP-1 monocytic cell line, we have recently reported that high levels of merozoite opsonizing antibodies were associated with protection from clinical malaria. Phagocytosis is regulated by both stimulatory and inhibitory surface Fc receptors (FcγRs) on circulating monocytes, and several polymorphisms in FcγRs have been associated with altered malaria disease outcomes. Expression of FcγRs can be regulated by cytokines, and IFNg and IL-4 reciprocally regulate expression of stimulatory and inhibitory receptors, respectively. The influence of monocyte expression levels of various FcγRs receptors on antibody-mediated phagocytosis in malaria is poorly understood. To examine this question, we have tested phagocytosis by the THP-1 cell line of isolated merozoites, and separately, phagocytosis of beads coated with malaria blood-stage antigens that have been opsonized with antibodies from Papua New Guinean individuals. We are currently investigating the impact of knockdown of the stimulatory and inhibitory FcγRs and regulation by IFNγ or IL-4 on phagocytosis. Currently our results are preliminary, however by the time of the meeting we expect to have sufficient results to address this question.

931

PROBING IMMUNE MECHANISMS OF SELECTION OF PARASITES WITH COMMON GENETIC SIGNATURES OVER FOUR TRANSMISSION SEASONS IN SENEGAL

Amy K. Bei[1], Kazutoyo Miura[2], Ababacar Diouf[2], Daniel B. Larremore[1], Daniel E. Neafsey[3], Nicholas Baro[1], Rachel F. Daniels[1], Sarah K. Volkman[1], Ambroise D. Ahouidi[4], Daouda Ndiaye[5], Tandakha Dieye[4], Souleymane Mboup[4], Caroline O. Buckee[1], Carole A. Long[2], Dyann F. Wirth[1]

[1]Harvard School of Public Health, Boston, MA, United States, [2]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, United States, [4]Laboratory of Bacteriology and Virology, Hopital Aristide Le Dantec, Dakar, Senegal, [5]Laboratory of Parasitology and Mycology, Dakar, Senegal

As malaria transmission declines, ***Plasmodium falciparum*** parasite populations display decreased genetic diversity due to emergence of parasites with common genetic signatures (CGS). Previously, we characterized immune responses to one cluster of these highly related parasites and their variant surface antigens (VSA), and observed CGS parasites express similar ***var*** genes, more than expected by chance, and year-to-year variation in immune recognition of VSAs on CGS-infected red cells. Here, we extend these studies to seven different clusters of CGS parasites with different dynamics of emergence, growth, and decline to better understand how their immune reactivity could influence parasite frequencies from year to year over four transmission seasons (2011-2014). We characterized parasites in these seven clusters regarding similarities in their genotypes and virulence gene expression (invasion ligands and ***var*** genes), and addressed whether genetic variation and gene expression are similar within clusters compared to other clusters and controls. We explored the relatedness of parasites within barcode-identified clusters by sequencing the highly polymorphic loci CSP, TRAP, and SERA-2 and observed that parasites within clusters are identical at these loci, but that

each distinct cluster contains unique haplotypes for these loci. As before, we found CGS parasites within clusters express the same ***var*** Ups classes compared to controls, implying that gene expression is also similar within clusters. To probe potential mechanisms of immune selection influencing the dynamics of growth or decline of these clusters, we are currently characterizing the functional humoral immune responses against these parasites by ***ex vivo*** rosetting assays and ***in vitro*** VSA reactivity assays. These experiments should shed light on mechanisms of genotype-specific immune selection over time within the population. These samples provide a unique opportunity to explore common immune responses in patients infected with identical parasites.

932

VAR2CSA: THE SPECIFICITY OF NATURALLY ACQUIRED ANTIBODIES THAT BIND TO THE SURFACE OF CS2 INFECTED ERYTHROCYTES

Elise P. Ngati[1], Yukie M. Lloyd[1], Naveen Bobbili[1], John J. Chen[1], Vanda Koko[1], Maria J. Sanchez[1], Rui Fang[1], Ali Salanti[2], Rose G. Leke[3], Diane W. Taylor[1]

[1]University of Hawaii of Manoa, Honolulu, HI, United States, [2]University of Copenhagen, Copenhagen, Denmark, [3]University of Yaoundé 1, Yaoundé, Cameroon

Placental malaria caused by ***Plasmodium falciparum*** is a major health problem affecting both the mother and fetus. Infected erythrocytes (IE) expressing VAR2CSA on their surface sequester in the placenta by binding to Chondrotin Sulfate A. Previous studies showed that high anti-VAR2CSA IgG levels improve pregnancy outcome, e.g., increase birth weight, reduce anemia, lower placental parasitemia, and prevent drug treatment failures. VAR2CSA has 6 DBL domains. Pregnant women produce antibodies (Ab) that bind to the surface of CSA binding IE. It is not clear if these Ab bind to one or multiple DBL domains. The goal of this study was to determine the specificity of naturally acquired Ab that bind to CS2 IE. In our study, clinical information and archival plasma samples collected between 1996 -2001 at delivery from 1,377 pregnant Cameroonian women living in Yaoundé (low transmission) were used. Since the samples were collected prior to implementation of intermittent preventive treatment and insecticide-treated bed nets, natural immunity determined the presence or absence of placental malaria (PM). Plasma from women who were PM- and PM+ of different gravidities were screened for Ab to full length VAR2CSA (FV2) and other DBL domains using a bead-based multiplex assay. The results identified which DBL domains each woman recognized. Then, a subset of samples was tested for Ab binding to the surface of CS2 IE (express VAR2CSA) and to 3D7 and FVO IE (non CSA-binding phenotypes). IE were incubated with plasma, then anti-human IgG FITC, and the amount of fluorescence per cell surface area was determined by FACS. In the initial study using 25 samples with different levels of Ab to FV2, a significant correlation between Ab to FV2 and cell surface staining intensity was obtained ($r = 0.62$; $p=0.001$: Spearman Correlation). Additional samples are being screened in the cell surface staining assay and levels of reactivity are being compared with the DBL domains recognized by each sample.

933

HIGH AVIDITY ANTIBODIES TO VAR2CSA: ARE THEY ASSOCIATED WITH PROTECTION FROM PLACENTAL MALARIA IN A LOW TRANSMISSION SETTING?

Vanda Koko[1], Naveen Bobbili[1], John J. Chen[1], Elise P. Ngati[1], Maria J. Sanchez[1], Yukie M. Lloyd[1], Rui Fang[1], Ali Salanti[2], Rose G. Leke[3], Diane W. Taylor[1]

[1]University of Hawaii at Manoa, Honolulu, HI, United States, [2]University of Copenhagen, Copenhagen, Denmark, [3]University of Yaoundé 1, Yaoundé, Cameroon

Pregnancy-associated malaria is characterized by the sequestration of ***Plasmodium falciparum*** infected erythrocytes in the intervillous space of the placenta, that is mediated by the binding of parasite membrane protein VAR2CSA with Chondriotin Sulfate A on the surface of placental cells. The presence of ≥ 35% high avidity antibodies (Ab) to VAR2CSA early in pregnancy correlates with the absence of placental malaria at delivery in a high transmission setting. However, very little is known about high avidity Ab to VAR2CSA in low transmission areas, and if one or multiple pregnancies are required to produce such Ab. We therefore looked at a panel of blood samples obtained at delivery between 1995 and 2001 in Yaoundé, Cameroon (low transmission setting). The samples were collected prior to use of chemoprophylaxis (IPT) and bed nets, so natural immunity determined presence/absence of placental malaria. These samples were screened for IgG Ab to Full Length VAR2CSA (FV2) using a bead-based immunoassay and 708 samples were identified for further use in the avidity assay. The percentage of strong binding (high avidity) IgG equals the amount of Ab that remain bound to FV2 after 30 minutes of incubation with 3M NH4SCN. Results showed that ~26% of the 708 women had ≥35% high avidity Ab at delivery. Very few primigravidae had high avidity Ab; and Ab avidity increased significantly between the 1st and 2nd as well as the 2nd and 3rd pregnancies; however, it remained constant thereafter (3rd through 7+ pregnancies). In the dataset, the prevalence of placental malaria (PM) decreased 2-fold with gravidity. After adjusting for age and malaria status, an increase in avidity with gravidity ($P=0.0028$) was found. Avidity increased gradually, with only a 0.9% increase per pregnancy. A higher mean avidity was found in PM-negative compared to PM-positive secundigravidae ($P=0.0319$), but no difference was seen between PM+ and PM- in the other gravidity groups. In summary, even though avidity to FV2 increases with gravidity and PM decreases with gravidity, very few women in this low transmission setting have high avidity Ab.

934

ACUTE MALARIA PREFERENTIALLY ACTIVATES CIRCULATING TFH SUBSET THAT LACKS THE CAPACITY TO INDUCE NAÏVE B CELLS TO PRODUCE IMMUNOGLOBULINS

Nyamekye Obeng-Adjei, Peter Crompton

National Institutes of Health, Rockville, MD, United States

Malaria-specific antibody responses in children are relatively short-lived, leaving them susceptible to repeated bouts of febrile malaria. The cellular and molecular mechanisms underlying this apparent immune deficiency are poorly understood. Recently, T follicular helper (Tfh) cells have been shown to play a critical role in generating long-lived antibody responses. We show that Malian children have resting PD-1+CXCR5+CD4+ Tfh cells in circulation that resemble germinal center Tfh cells phenotypically and functionally. Within this population the PD-1+CXCR5+CXCR3- Tfh cell subset is Th2-polarized and superior to the Th1-polarized PD-1+CXCR5+CXCR3+ subset in providing B cell help. Longitudinally, we observed that acute malaria drives Th1 cytokine responses, and accordingly, the less functional Th1-polarized Tfh subset was preferentially activated and its activation did not correlate with antibody responses. These data provide important insights into the cellular basis of suboptimal antibody responses to malaria in children and establish a link between the quality of Tfh cell responses and the outcome of B cell germinal center responses during a natural infection. These findings also suggest that vaccine strategies that promote PD-1+CXCR5+CXCR3- Tfh cell responses may improve malaria vaccine efficacy in children.

935

PLASMA LEVELS OF INTERLEUKIN-12 IN PATIENTS WITH *PLASMODIUM FALCIPARUM* MALARIA IN IKORODU, LAGOS NIGERIA

Wellington A. Oyibo, Uche Igbasi, **Okechukwu M. Okeagu**, Nnaemeka C. Iriemenam

ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine University of Lagos, Idi-Araba, Lagos, Nigeria

Cytokines are stimulated during malaria infection or the disease itself. Interleukin (IL) 12 is a pro-inflammatory cytokine produced from monocytes/ macrophages and other cell types that is needed in the early defence against malaria. IL-12 plays a central role in regulating innate and adaptive immune responses, and interacts with several other cytokines for increased immunoregulatory activities. The objectives of this study were to determine plasma concentrations of IL-12 in malaria patients and its association with the parasitemia, age, clinical symptoms and anemia in patients with ***Plasmodium falciparum*** malaria in Ikorodu, Lagos Nigeria. Malaria microscopy and blood parameters were carried out using standard protocols and the level of IL-12 in plasma was measured using the Enzyme Linked Immunosorbent Assay (MABTECH AB, Sweden). The concentration of IL-12 in malaria patients ranged from 23.45pg/ml to 99996.98pg/ml. A negative correlation (r = -0.143) was found between the mean levels of IL-12 (7521.69pg/ml) in 144 participants who were microscopy positive and mean parasitaemia (41519.20 p/μL) ($p \leq 0.05$). The levels of IL-12 were high (16352.05 ± 1434.17pg/ml) in patients who presented with symptoms such as fever compared with patients which did not present with fever symptoms. Interleukin (IL) 12 levels were higher in patients who were above 14 years but there was no statistical significant relationship between IL-12 levels and the ages of patients. IL-12 correlated with Hemoglobin levels (r=0.004) but it was not statistically significant. IL-12 was low (2173.66±3225.04pg/ml) in patients with severe anaemia (<8g/dl) and was high (11759.71±21566.09pg/ml) in patient with mild anaemia (8-9.9g/dl). In conclusion, IL-12 in this investigation has been demonstrated to be involved in the immunoregulation of malaria infections and this immunoregulatory activity is improved with aging. This study also confirmed that the tendency for a patient to secrete IL-12 is associated with protection against parasitemia, clinical malaria and anaemia.

936

DELAYED ACQUISITION OF *PLASMODIUM FALCIPARUM* ANTIGEN-SPECIFIC CD4+ T CELLS IN HIV-EXPOSED UNINFECTED MALAWIAN CHILDREN RECEIVING DAILY COTRIMOXAZOLE PROPHYLAXIS

Herbert Longwe[1], Kamija Phiri[1], Nyanyiwe Mbeye[1], Thandile Gondwe[1], Wilson Mandala[2], Kondwani Jambo[2]

[1]University of Malawi, College of Medicine, Blantyre, Malawi, [2]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi

Cotrimoxazole (CTX) prophylaxis, currently recommended in HIV-exposed uninfected (HEU) children as protection against HIV-related opportunistic infections, also has some anti-malarial efficacy.We have recently shown that HEU children have reduced magnitude and breadth of IgG antibody responses to distinct ***Plasmodium falciparum*** merozoite antigens. In this study, we determined the effects of CTX prophylaxis-induced reduction in ***P. falciparum*** exposure on the magnitude and quality of ***P. falciparum*** antigen specific CD4+ T cells in HEU children. Peripheral blood was collected from HEU and HIV-unexposed uninfected (HUU) children at 6, 12 and 18 months of age. Proportion of CD4+ T cells subsets were determined by immunophenotyping. ***P. falciparum*** specific CD4+ T cells responses were measured by intracellular cytokine staining assay. There were no differences in the proportions of CD4+ T cell subsets between HEU and HUU children at all ages. HEU children had lower frequenciesof ***P. falciparum***-specific CD4+ T cells producing IFN-γ ($p = 0.035$) and IFN-γ/ TNF (double producers) ($p = 0.007$) at 12 months after being on CTX prophylaxis for a year compared to HUU children. The study showed that cotrimoxazole prophylaxis-induced reduction in ***P. falciparum*** exposure results in delayed acquisition ***P. falciparum***-specific CD4+ T cell responses in HEU children. This delayed acquisition of ***P. falciparum***-specific CD4+ T cell responses might increase susceptibility to clinical malaria after cessation of prophylaxis.

MAPPING EPITOPES WITHIN INTRINSICALLY DISORDERED PROTEINS OF *PLASMODIUM FALCIPARUM* USING COMPUTATIONAL APPROACHES: IMPLICATIONS FOR IMMUNITY AND VACCINES

Andrew J. Guy[1], Vashti Irani[1], Christopher A. MacRaild[2], Robin F. Anders[3], Raymond S. Norton[2], James G. Beeson[1], Jack S. Richards[1], Paul A. Ramsland[1]

[1]Burnet Institute, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]La Trobe University, Melbourne, Australia

Malaria remains a significant global health burden, with ***Plasmodium falciparum*** responsible for the majority of malaria related deaths. The proteomes of ***Plasmodium spp.*** are predicted to contain a large number of intrinsically disordered proteins, but little is known about their subcellular localisation or immunogenic properties, or their potential as vaccine candidates. We employed several computational algorithms to investigate predicted protein disorder and the impact on adaptive immunity. The proportion of disordered regions was similar for the proteomes of five human and murine ***Plasmodium*** spp. Disordered proteins were shown to be particularly enriched within apical proteins, exported proteins and proteins localised to the parasitophorous vacuole. Tandem repeat regions in proteins have been suggested to be immunodominant, and we found that tandem repeat regions occur predominantly within regions of disorder. Presentation of peptides via MHC class I and II molecules plays an important role in the generation of adaptive immune responses, and we have found that disordered protein regions are predicted to contain relatively few MHC class I and II binding peptides owing to inherent differences in amino acid composition as compared to structured domains. In contrast to MHC binding peptides, linear B-cell epitopes were predicted to be enriched in disordered regions of the malaria proteome, suggesting that recognition of disordered regions by acquired and vaccine-induced antibodies is entirely likely. Several disordered proteins or regions are current vaccine candidates, while a number of others appear to have strong potential for inclusion in multi-antigen vaccine constructs. We will present a newly developed online tool (PlasmoSIP) for the visualisation of protein structural features, predicted immunological features, and known polymorphisms for proteins from ***P. falciparum***. Further study is required to experimentally verify these predicted structural and immunological features and to determine the importance of disordered epitopes as targets of protective immunity.

938

ANTIBODY RESPONSE AFTER CHALLENGE WITH *PLASMODIUM FALCIPARUM* SPOROZOITES BY NEEDLE AND SYRINGE WITH DIFFERENT DOSES AND ROUTES IN MALARIA-NAÏVE AND SEMI-IMMUNE INDIVIDUALS

Gloria P. Gomez-Perez[1], Benjamin Mordmüller[2], Bertrand Lell[2], Joseph J. Campo[3], Marta Vidal[1], Aida Valmaseda[1], Gemma Moncunill[1], Alfons Jimenez[1], Pau Cisteró[1], Diana Barrios[1], Alfredo Mayor[1], Evelina Angov[4], Sheetij Dutta[4], Chetan Chitnis[5], Virander Chauhan[5], Deepak Gaur[5], Eric James[6], Peter Billingsley[6], Kim Lee Sim[6], Sumana Chakravarty[6], Almudena Legarda[1], Stephen L. Hoffman[6], Peter Kremsner[2], Pedro L. Alonso[1], Carlota Dobaño[1]

[1]ISGlobal, Barcelona Ctr. Int. Health Res. (CRESIB), Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, [2]Institut für Tropenmedizin, Eberhard Karls Universität Tübingen and German Centre for Infection Research, Tübingen, Germany, [3]Antigen Discovery, Inc, Irvine, CA, United States, [4]Walter Reed Army Institute of Research, Malaria Vaccine Branch, Silver Spring, MD, United States, [5]International Centre for Genetic Engineering and Biotechnology, New Delhi, India, [6]Sanaria Inc., Rockville, MD, United States

Controlled human malaria infection (CHMI) trials represent an important tool to study the immune response of the human host against ***Plasmodium falciparum*** parasites. We studied the antibody (Ab) response (IgM, IgG, IgG1, IgG2, IgG3 and IgG4) against 21 pre-erythrocytic and erythrocytic ***P. falciparum*** antigens in volunteers from 4 CHMI trials performed with aseptic, purified, cryopreserved ***P. falciparum*** sporozoites (PfSPZ Challenge) in Europe (malaria-naïve individuals) and Africa: 1. Barcelona, Spain (36 volunteers received 2,500 (n=18), 25,000 (n=6) or 75,000 PfSPZ (n=6) by intramuscular injection, and 3,200 PfSPZ (n=6) by direct venous inoculation [DVI]); 2. Tübingen, Germany (24 volunteers received 50 (n=3), 200 (n=3), 800 (n=9) and 3,200 (n=9) PfSPZ by DVI); 3. Lambaréné, Gabon (5 malaria-naïve volunteers, 10 semi-immune volunteers, and 10 semi-immune volunteers with sickle cell trait, received 3,200 PfSPZ by DVI); and 4. Tübingen, Germany (40 volunteers received 3,200 PfSPZ by DVI 10 weeks after being administered different doses of PfSPZ (3,200 (n=9); 21,000 (n=9); 51,000 (n=9)) or placebo (n = 13) under chloroquine prophylaxis, also via DVI. We measured the Ab response at different time points before administration of PfSPZ, at the time of first parasitemia, and at days 35 and 90 after PfSPZ injection. To our knowledge this is the first study to systematically assess the Ab response against a defined set of ***P. falciparum*** antigens in the context of CHMI, as well as the first characterization of the immunoglobulin isotype and subclass pattern. Our results showed that IgM Ab levels peaked at day 35 after PfSPZ CHMI, showing lower levels at day 90, and observed against the majority of ***P. falciparum*** antigens. IgG Ab response on the other hand, peaked at day 90 and it was significant only against a small set of ***P. falciparum*** antigens. Additionally, we observed a PfSPZ Challenge dose-antibody response and different Ab profiles depending on previous malaria exposure, and a consistent Ab response against a defined set of antigens in previously exposed individuals, both naïve and semi-immune, that could be used as markers of ***P. falciparum*** exposure.

939

INCREASING THE POTENCY OF ATTENUATED SPOROZOITE VACCINES WITH A GLYCOLIPID ADJUVANT

Sumana Chakravarty[1], Charles Anderson[2], Moriya Tsuji[3], Andrew Ishizuka[4], Robert A. Seder[4], Stephen L. Hoffman[1]

[1]Sanaria Inc., Rockville, MD, United States, [2]Sanaria Inc. (currently Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD), Rockville, MD, United States, [3]Aaron Diamond AIDS Research Center, New York, NY, United States, [4]Laboratory of Cellular Immunology, VRC, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

The world needs a highly effective malaria vaccine and robust immunity can be induced in humans with ***Plasmodium falciparum*** (Pf) sporozoites (PfSPZ), that invade hepatocytes, but arrest during liver stage development. In recent trials Sanaria® PfSPZ-based vaccines, composed of aseptic, purified, cryopreserved, radiation attenuated PfSPZ Vaccine, or non-attenuated PfSPZ with chloroquine (PfSPZ-CVac) were safe and highly protective. PfSPZ Vaccine protected 100% and 92% of non-immune individuals after 5 doses and 87% after 3 doses in 2 independent trials and provided durable and heterologous (75%) strain protection. PfSPZ-CVac was 100% efficacious in non-immunes. Even under natural exposure settings in Africa, PfSPZ Vaccine provided ~50% protection of semi immune individuals over 6 months. Adjuvants are potent vaccine additives to reduce the number of doses, interval between doses, immunogen quantity/dose, and to prolong efficacy. However, adjuvants are generally not used for live vaccines, nor been shown to improve CD8+ T cell mediated immunity in humans, required to protect against SPZ. In our screens to identify such an adjuvant, a novel glycolipid, 7DW8-5 that binds CD1d, and stimulates iNKT cells, was the only one to demonstrate significant enhancement in a mouse malaria model involving irradiated (irr) ***P. yoelii*** (Py) sporozoites (irrPySPZ). 7DW8-5 enabled reduction in number of doses for 75% protection with irrPySPZ from 3 to just 1 dose administered IV (30/40 protected with, 4/30 without adjuvant), from 4 to 2 doses (70%-100% protection) and even 1 dose (60% protection) given intradermally, with protection lasting for at least 14 weeks. Most importantly, 4 IV doses over 7 days of $2x10^3$ cryopreserved irrPySPZ with and without 7DW8-5 protected 96% (15/16) and 44% (7/16) of mice respectively (p=0.006). In NHPs, 7DW8-5 with PfSPZ Vaccine induced enhanced splenic CD8+ and CD4+ T cells responses. Together, these findings provide strong rationale to combine 7DW8-5 with PfSPZ vaccines, in an accelerated immunization regimen that will vastly improve commercial, clinical, and public health benefits of PfSPZ vaccines.

[1]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States, [2]Global Health Infectious Disease Research, University of South Florida, Tampa, FL, United States, [3]National Center for Parasitology, Entomology, and Malaria Control, Ministry of Health, Phnom Penh, Cambodia, [4]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [5]Department of Parasitology, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil, [6]Departments of Molecular Microbiology and Microbial Pathogenesis, and Biochemistry and Molecular Biophysics, Washington University School of Medicine, St. Louis, MO, United States

Plasmodium vivax (Pv) invasion of reticulocytes requires binding of Duffy Binding Protein (PvDBP) to the Duffy Antigen Receptor for Chemokines (DARC) on erythrocytes for most individuals. About 3.7-8.6% of individuals residing in ***P. vivax***-endemic areas acquire high-binding inhibitory antibodies (BIAbs) (defined as >80% binding inhibition relative to malaria-naïve donor antibodies) to region II of PvDBP (PvDBPII), which correlates with partial protection against ***P. vivax*** malaria. Consequently, PvDBPII is a leading vaccine candidate. However, PvDBPII is polymorphic and whether naturally-acquired or vaccine-induced BIAbs to PvDBPII are strain-transcending is unknown. In initial DARC-binding ELISA studies, we found that naturally-acquired BIAbs from Brazilian and Cambodian individuals show the presence of both strain-specific and strain-transcending BIAbs. To identify which PvDBPII epitopes mediate strain-specific versus strain-transcending BIAbs, we obtained PBMCs from Cambodians with high levels of BIAbs, and sorted single PvDBPII-specific IgG+ memory B cells, PCR amplified their IgG heavy and light chain variable regions, and cloned them into a human IgG expression vector to generate a panel of human monoclonal antibodies (mAbs). From one individual, 13/15 mAbs recognized PvDBPII and 8/10 mAbs blocked binding of PvDBPII to DARC. These 15 mAbs fell into 9 clonal groups. We are now characterizing these mAbs in terms of their ***P. vivax*** strain-specificity, the PvDBPII epitopes they recognize, their affinity for PvDBPII, and their ability to block ***P. vivax*** invasion of reticulocytes ***in vitro***.

941

DYNAMICS OF CIRCULATING T FOLLICULAR HELPER CELLS AND PLASMABLASTS DURING CHEMOPROPHYLAXIS VACCINATION WITH PYRIMETHAMINE AND *PLASMODIUM KNOWLESI* IN RHESUS MACAQUES

Agnes Mwakingwe[1], Irfan Zaidi[1], Sara A. Healy[1], Lynn Lambert[1], Sachy Orr-Gonzalez[1], Dariyen Carter[1], Brandi Butler[1], Sumana Chakravarty[2], Stephen L. Hoffman[2], Patrick E. Duffy[1]

Whole organism ***Plasmodium*** vaccines can induce long-lasting sterile protective immunity. Understanding which components of innate and acquired immunity play a role in conferring sterile immunity will aid in vaccine development. Recent studies with the whole ***P. falciparum*** (Pf) organism product PfSPZ Vaccine showed a correlation between vaccine-induced antibody levels and protection in humans. T follicular helper cells (Tfh) play an integral part in the development of high affinity effector and memory B cells, and studies in influenza vaccine have shown that circulating Tfh cells can predict the development of functional antibodies. The dynamics of Tfh during whole organism vaccination are unknown. We examined this during a Chemoprophylaxis Vaccination (CVac) study in monkeys. Rhesus macaques were vaccinated by direct venous inoculation (DVI) of ***P. knowlesi*** sporozoites (PkSPZ) followed by oral pyrimethamine on days 1, 2 (n=4) or days 2, 3 (n=7) post DVI. Blood samples for Tfh and plasmablasts analysis were obtained on days 0 (day of vaccination), 2, 5, 7, 14 and 27 post DVI. Preliminary results show that levels of circulating plasmablasts and Tfh cells remain at baseline after first vaccination. However after second vaccination, levels of both plasmablasts (p=0.016) and Tfh cells (p=0.016) increase significantly by day 2 post DVI, then return to baseline by day 7. Circulating Tfh undergo a second and sustained rise at day 14 of second vaccination. The initial circulating Tfh rise is observed in the ongoing third and final vaccination. At completion of the study, we will determine if levels and kinetics of Tfh and plasmablasts correlate with antibody levels and can predict development of lasting protective immunity. Since it is now established that the antibody response after immunization with PfSPZ Vaccine is dramatically different in non-immune US and semi-immune African populations, we believe that this approach to studying the development of immunity will be useful for understanding how to optimize immune responses to PfSPZ in all populations.

942

CLODRONATE LIPOSOMES INDUCE PARTIAL DEPLETION OF MONOCYTES AND INCREASE PARASITEMIA IN *PLASMODIUM FALCIPARUM*-INFECTED *SAIMIRI SCIUREUS* MONKEYS

Janaiara A. Cunha, Cesare Bianco-Jr, Marcia C. Andrade, Marcelo Pelajo-Machado, Igor J. Silva, Lilian R. Pratt-Riccio, Evelyn K. Riccio, **Leonardo J. Carvalho**, Claudio T. Daniel-Ribeiro

Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil

Non-human primates of the genera ***Saimiri*** and ***Aotus*** are recommended models for experimental malaria studies, being susceptible to infection by ***Plasmodium falciparum*** and ***P. vivax***. However, splenectomy is usually required to achieve high and reproducible parasitemias. The spleen is a key organ in the immune response to malaria infections and therefore splenectomy is an undesired condition. We asked whether administration of clodronate liposomes (CL), which cause partial depletion of monocytes/macrophages in several organs, including the spleen, would allow the establishment of sizeable and reproducible parasitemias in ***P. falciparum***-infected ***Saimiri sciureus*** monkeys, preventing the need for splenectomy. CL caused marked death of ***Saimiri*** leukocytes ***in vitro***. Groups of 6-9 S. sciureus monkeys inoculated with $1x10^6$ ***P. falciparum***-infected erythrocytes, as well as control monkeys inoculated with saline, received either 0.5 or 1.0mL of CL, intravenously, twice a week starting at the day of ***P. falciparum*** inoculation, with a total of 6-8 injections. While saline-treated monkeys kept parasitemia under control (average 8.1% lasting for over 18 days without need for antimalarial treatment), half of the monkeys receiving 0.5mL LC and 2/3 of monkeys receiving 1.0 mL CL developed high parasitemias (>20%) requiring treatment by day 13. Animals tolerated well CL administration but some showed hepatocyte vacuolization. Although peripheral CD14+ cell counts were not significantly affected by CL administration, ***P. falciparum***-infected, CL-treated animals showed milder splenomegaly compared to infected saline-treated monkeys. Splenic monocyte populations were only partially depleted and were still able to retain hemozoin, showing that the spleens were functional. Partial depletion of Kupfer cells was also observed, with lower levels of ferrous iron, but hemozoin-containing Kupfer cells were still observed in CL-treated animals. These data indicate that CL administration is a viable and effective alternative to surgical splenectomy for malaria studies using ***Saimiri*** monkeys, leading to higher parasitemias with preserved splenic function.

943

HUMORAL IMMUNITY CONTRIBUTES TO CLEARANCE OF ARTEMISININ-RESISTANT PARASITES IN SOUTHEAST ASIA

We have proposed that the ability to clear drug resistant parasites is a phenotype for protective malaria immunity and have found that parasite genetic factors account for only about half of the variation in parasite clearance half-life after artesunate treatment. To assess the contribution of humoral immunity to clearance of artemisinin resistant parasites after artesunate treatment of falciparum malaria, sera from 100 Cambodian, 78 Myanmar, 111 Thailand, and 120 Vietnamese participants in the Tracking Resistance to Artemisinin Collaboration (TRAC) study of artesunate efficacy were probed against two protein microarrays: a customized diversity-reflecting protein microarray and a microarray of 500 reactive ***Plasmodium falciparum*** and ***P. vivax*** antigen fragments. The customized protein microarray included 268 diverse apical membrane 1 (AMA1) fragments, 20 merozoite surface protein 1 (MSP1) fragments, and 30 Rh5 fragments, all based on sequences derived from field samples, as well as 176 fragments of PfEMP1s based on the 3D7 reference genome. Preliminary analyses show that stronger and broader seroreactivity to ***P. falciparum*** antigens was associated with rapid parasite clearance for samples with K13 mutations, particularly with respect to field-derived AMA1 variants. This approach provides a potential way to control for the effects of immunity in assessments of antimalarial drug efficacy.

944

MODELLING MASS DRUG ADMINISTRATION IN MALARIA-ENDEMIC COUNTRIES IN THE PRESENCE OF IMPORTED INFECTIONS

Sheetal Prakash Silal[1], Lisa J. White[2]

[1]University of Cape Town, Cape Town, South Africa, [2]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Mass Drug Administration (MDA) has received renewed interest as a potential tool for the control and elimination of malaria. MDA, the administration of drug therapy to a large segment of the population, has the ability to not only reduce current prevalence, but to decrease onward transmission of the malaria parasite. As the evidence base for MDA is not large, mathematical modelling may be used to simulate the intervention under a variety of epidemiological and logistical conditions to assess the impact of MDA on prevalence and transmission. This paper contributes to the literature by simulating MDA in an open population i.e. in the presence of imported infections. By modelling MDA in high and low transmission settings, with varying levels of imported infections, this paper shows that the impact of MDA in an open population is dampened, particularly in low transmission settings where imported infections originate from areas with higher transmission. In such situations it was found that MDA in the source of imported infections has a larger impact than MDA in the local area of interest. MDA is not a lasting intervention with prevalence reverting to previous levels after 3 years. The presence of vector control may assist with extending this impact. As countries change focus from control to elimination of malaria, the management of imported infections increases in importance. As such the impact of MDA may be lower than expected if imported infections are ignored.

945

GETTING THE LUMEFANTRINE DOSE RIGHT FOR THE TREATMENT OF UNCOMPLICATED MALARIA; A POOLED PHARMACOMETRIC APPROACH

Frank L. Kloprogge[1], Joel Tarning[2], On behalf of[3]

[1]World Wide Antimalarial Resistance Network, Bangkok, Thailand, [2]Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [3]World Wide Antimalarial Resistance Network, AL Pharmacometrics Study Group, Thailand

Artemether-lumefantrine (ARM-LF) is the most widely used antimalarial treatment in the world. Paediatric dosages are available and it is safe for women in the second or third pregnancy. Low cure rates have been reported in pregnant women and under-exposure to LF in these vulnerable populations might increase the risk of resistance development. Objective: To evaluate the pharmacokinetic-pharmacodynamic (PK-PD) properties of LF and conduct in-silico dose optimisations, using a population-based model approach and pooled data from paediatric, pregnant and adult patients from Africa, South East Asia and Oceania. Population PK properties of LF, and demographic and disease-related covariates were evaluated in 1,347 densely sampled patients. Sparsely and densely sampled venous blood, capillary plasma, capillary blood and venous plasma concentration-time data from 595, 190, 840 and 966 patients, respectively, were used for external model validation. Recurrent malaria data in all patients were used for a PK-PD time-to event model and this model was subsequently used for in-silico dose optimisation. Pregnancy affected LF absorption and bodyweight distribution and clearance resulting in lower day 7 concentrations compared to non-pregnant adult patients. Admission parasite biomass correlated with relative bioavailability resulting in lower exposure to LF in more severe patients. LF dosage correlated with relative bioavailability resulting in dose-limited absorption. LF concentration affected the treatment outcome significantly. In-silico simulations were conducted to evaluate the tentative treatment success after a prolonged treatment, intensified treatment and increased dosage for paediatric and pregnant patients. In conclusion, LF concentrations correlated with the

time to recurrent malaria. The in-silico dose optimisations suggest that an intensified treatment is effective and most practical when implemented for paediatric and pregnant patients. Confirming studies evaluating the optimised dose regimens are required to ensure a high efficacy in pregnant patients and young children.

946

OPTIMIZED *PLASMODIUM FALCIPARUM* HEPATOCYTE INFECTION MODEL FACILITATES DRUG AND VACCINE DEVELOPMENT

Rebecca E. Tweedell[1], Elke S. Bergmann-Leitner[2], Dingyin Tao[1], Jonas G. King[1], Tanisha M. Robinson[2], Karen Bingham[2], David E. Lanar[2], Philipp J. Jost[3], Justin A. Boddey[4], Rhoel R. Dinglasan[1]

[1]Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]Walter Reed Army Institute for Research, Silver Spring, MD, United States, [3]Technical University of Munich, Munchen, Germany, [4]University of Melbourne, Parkville, Australia

Malaria is a life-threatening disease that mainly affects children in developing countries, infecting 250 million people and causing over 700,000 deaths per year. ***Plasmodium falciparum*** is the parasite credited with much of the morbidity and mortality. Development of disease in human hosts requires the parasite to invade the liver and replicate in hepatocytes before releasing to the blood stream to cause clinical disease. This liver stage of the infection has proven difficult to study due to the lack of an ***in vivo*** model for ***P. falciparum*** and the challenges of ***in vitro*** studies. ***P. falciparum*** infects primary human hepatocytes, but these cells do not propagate in culture, are in short supply, prohibitively expensive, and result in highly variable infection rates. The human hepatocarcinoma cell line HC-04 is susceptible to ***P. falciparum*** and ***P. vivax*** sporozoite infection but also suffers from poor infection efficiency. Here, we report on the development of a HC-04 monolayer culture platform that results in a 20-fold increase in infection over previous studies. It is well-known that ***in vitro*** culture systems are different from ***in vivo*** systems in many ways, such as nutrient composition, oxygen levels, the presence of signaling molecules, and barometric pressure. We hypothesized that by mimicking the ***in vivo*** conditions as closely as possible in our ***in vitro*** system, we would be able to optimize invasion efficiency of the parasite in the HC-04 cells. We systematically examined variables in our culture model while monitoring ***P. falciparum*** invasion by microscopy in order to determine the optimal culture media and conditions. Additionally, we found that the HC-04 cell line was quite heterogeneous, so we performed dilution sub-cloning in an attempt to isolate a clone that facilitated improved invasion. We successfully identified HC-04.J7, which allowed more efficient invasion by the parasite than did the heterogeneous HC-04 population. Establishment of this method for optimized ***in vitro*** hepatocyte invasion can facilitate future studies of the parasite's mechanism of invasion, as well as allow for the assessment of drug and vaccine candidates.

947

MALARIA TEST POSITIVITY RATES AMONG PATIENTS AT FIVE OUTPATIENT HEALTH CENTERS LOCATED IN AN ENDEMIC REGION IN UGANDA: IRS VERSUS NON-IRS DISTRICTS

Arthur Mpimbaza[1], Ruth Kigozi[2], Asadu Sserwanga[2], Humphrey Wanzira[3], Denis Rubahika[3], Steven S. Yoon[4], Michelle A. Chang[4], Adoke Yeka[5], Kassahum A. Belay[6], Sarah S. Staedke[7], Moses Kamya[8], Grant Dorsey[9], Bryan K. Kapella[6]

[1]Child Health and Development Centre, Makerere University, Kampala, Uganda, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]National Malaria Control Program, Ministry of Health, Kampala, Uganda, [4]President's Malaria Initiative, Atlanta, GA, United States, [5]School of Public Health, Makerere University, Kampala, Uganda, [6]President's Malaria Initiative, Kampala, Uganda, [7]London School of Hygiene & Tropical Medicine, London, United Kingdom, [8]School of Medicine, Makerere University, Kampala, Uganda, [9]University of California San Francisco, San Francisco, CA, United States

In March 2014, the Uganda Malaria Surveillance Project expanded to include five level IV outpatient health centres (HCs) in the Lango sub-region of northern Uganda to monitor the impact of indoor residual spraying of insecticide (IRS). Two of the sites were in districts that received IRS with bendiocarb twice a year since 2010: Apac (Aduku HC) and Kole (Aboke HC) districts. The other three sites were in districts without IRS: Dokolo (Dokolo HC), Amolator (Amolator HC), and Otuke (Orum HC). From March to December 2014, 82,310 patient visits were recorded at the HCs, ranging from 12,960 in Aduku to 22,056in Dokolo. The proportion of patients with suspected malaria ranged from 25-35% in the two IRS districts and 45-58% in the three non-IRS districts. Overall, 87% of patients with suspected malaria underwent laboratory testing, ranging from75% in Amolator to 99% in Aduku and Aboke. Overall, 67% of testing was done using an RDT (as opposed to microscopy), ranging from 22% in Aduku to 94% in Dokolo. The outcome of interest was the test positivity rate (TPR): the proportion of malaria tests positive by RDT or microscopy. TPRs were considerably higher in non-IRS districts (Amolator=57%, Dokolo=63% and Orum=67%) compared to IRS districts (Aduku=19% and Aboke=25%). Prior to bendiocarb spraying in Apac, TPR at Aduku was as high as 58% in 2009, results comparable to current TPRs in non-IRS districts. Upon multivariate analysis using log-binomial regression, patients from non-IRS districts were nearly threetimes more likely to test positive for malaria than those in the IRS districts (RR=2.71, 95% CI 2.59-2.82, p<0.001) after controlling for age and the type of diagnostic test performed. Other than distribution of insecticide treated nets in June of 2014 across all the districts (94% ownership), IRS was the only intervention directly targeting malaria transmission in the region. The higher TPRs in the non-IRS districts compared to the IRS districts in a region of Uganda with historically high transmission highlights the importance of IRS for malaria control in endemic areas.

948

PROJECTED PREVALENCE OF MALARIA IN ALTA VERAPAZ, GUATEMALA FOR THE YEARS 2020 AND 2050 USING GLOBAL CIRCULATION MODELS AND ECOLOGICAL NICHES

Diego Pons[1], Sydney Neeley[2]

[1]University of Denver, Denver, CO, United States, [2]Duke University, Durham, NC, United States

We analyzed a total of 257 confirmed malaria cases (***Plasmodium vivax*** and ***P. falciparum***) for the year 2006 georeferenced at village level in Alta Verapaz, Guatemala. We used a Pearson correlation to validate precipitation (both number of days and daily accumulated rain), mean temperature and maximum/minimum temperatures collected from local weather stations for the same year to used them as potential predictors. After this first approach, we used historical climate data obtained from WorldClim (1950-2000, 30 arc-seconds resolution) and Maximum

entropy (MAXENT®) to generate a baseline map of probabilities of distribution using the georeferenced cases and 19 bioclimatic variables derived from monthly temperature and rainfall. A Jackknife analysis was ran to estimate the standard error associated with each of the variables and a contribution/permutation table was generated leading to the final arrange of variables with high predictive values: annual precipitation, precipitation of the driest month and precipitation of the warmest quarter (AUC = 0.95). We validated our baseline map of probabilities by comparing the variables generated by MAXENT with those from the local weather stations with a statistically significant correlation (α= 0.05) and by comparing the probability outcome per county generated by the baseline map with the actual percentage of cases for the same counties. Using the baseline as a validated framework, we used the predictors to generate a map of probabilities of occurrence of ecological niches at the county level for the IPCC climate change scenarios A1b, A2b, B1 and B2 for the years 2020 and 2050.

ESTIMATION OF AMOUNT OF ARTEMETHER AND LUMEFANTRINE EXCRETED THROUGH BREAST MILK

Jay Prakash Jain[1], Subramanian Ganesan[1], Gilbert Lefèvre[2], Gangadhar Sunkara[3]

[1]Novartis Institutes for Biomedical Research, Hyderabad, India, [2]Novartis Institutes for Biomedical Research, Basel, Switzerland, [3]Novartis Institutes for Biomedical Research, East Hanover, NJ, United States

Artemisinin based combination therapies are widely used and recommended by WHO as first-line therapy for uncomplicated ***Plasmodium falciparum*** malaria in nursing mothers. However, artemether-lumefantrine (AL, Coartem®) is not recommended during lactation (no breast feeding at least up to 28 days post last dose) as the excretion of AL in breast milk has not been studied. Clinical data on dihydroartemisinin (DHA) suggest clinically insignificant amount of DHA is excreted in breast milk (peak concentration: 35 ng/mL) after 200 mg oral artesunate. In the absence of clinical data, amount of AL excreted into breast milk was estimated based on the milk-to-plasma drug concentration ratio (M/P ratio) obtained from preclinical studies. In a pre-postnatal preclinical study there were no developmental changes in rat pups fed exclusively on milk of mothers who received 50 mg/kg/day of AL (7.1 mg/kg artemether, 42.9 mg/kg lumefantrine) up to day 21 of lactation. In rats the M/P ratio was estimated from distribution of radioactivity in mammary gland after oral administration of radiolabelled artemether and lumefantrine. The potential amount of each drug moiety excreted in mother's breast milk in 24 hours was estimated by M/P ratio × maternal plasma Cmax concentration × 150 mL/kg/day (volume of milk consumed per day per kg body weight of infant). The maximum M/P ratios observed over 24 hours for artemether and lumefantrine were 1.04 and 1.3, respectively. Over the recommended six doses of AL, the mean maximum plasma concentrations of artemether and lumefantrine were 186 ng/mL and 25.7 µg/mL, respectively, in malaria patients. Based on the M/P ratio and plasma levels of artemether and lumefantrine, the estimated daily cumulative consumption of artemether and lumefantrine by infants through breast milk following recommended AL doses in nursing mothers is 0.03 and 5.01 mg/kg, respectively, which is ~270 and ~10 fold lower than the recommended daily dose (40 mg artemether and 240 mg lumefantrine dose) for 5 kg body weight infants.

950

TRANSMISSION-BLOCKING ACTIVITY IS A FUNCTION OF OOCYST INTENSITY IN A CONTROL AND TRANSMISSION-REDUCING ACTIVITY OF A TEST IN THE STANDARD MEMBRANE-FEEDING ASSAY (SMFA)

Bruce Swihart[1], Kazutoyo Miura[2], Bingbing Deng[2], Luwen Zhou[2], Thao Pham[2], Ababacar Diouf[2], Timothy Burton[2], Carole Long[2], Michael P. Fay[1]

[1]Biostatistics Research Branch, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, [2]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

For transmission-blocking vaccine development against ***Plasmodium falciparum*** malaria, the standard membrane-feeding assay (SMFA) has been utilized widely to evaluate the functionality of vaccine-induced antibodies. However, there is no consensus whether to use % inhibition in oocyst intensity (transmission reducing activity, TRA), % inhibition in prevalence (transmission-blocking activity, TBA), or both as the main readout(s) of SMFA. We show that TBA is a function of mean oocyst intensity in the control. To establish this relationship, we examined 104 experiments where anti-Pfs25 monoclonal antibody (4B7 mAb) was tested at the same 94 µg/ml dose.The experiments with the 20 lowest control mean oocysts (range: 0.1 - 5.9) were compared with the 20 highest (range: 30 - 74). The TRAs were not statistically significantly different (93 vs. 95, p-value=0.25), but the TBAs were significantly different: 80.0 in the low group vs. 43 in the high group (p-value < 0.001). To address this dichotomy, we developed a model that adjusts TBA estimates to a specified normalizing target control intensity. We used our SMFA data that contained 105 independent feeding experiments with 11,838 mosquitoes to build the model, and two other data sets were utilized to test the model: one set used 4B7 mAb (104 feeds with 14,079 mosquitoes), and another set used polyclonal antibodies against multiple antigens (33 feeds with 6,826 mosquitoes). When observed TBA and model-based TBA (adjusted with control target mean oocyst intensity set to the observed value) were compared, there was a strong concordance between the two TBA values (concordance correlation=92.4 (95CI: [91.3, 93.4]) for 4B7 mAb; 97.6 (95CI: [97.2, 98.0]) for polyclonal) in both data sets. The results indicate that TBA cannot be interpreted without mean number of oocysts in the controls, and TRA and TBA are not independent readouts. Moreover, this study establishes that with appropriate data (i.e., mean number of oocysts in the control and the TRA of a test sample), this model can be used to predict TBA at specific target control oocyst mean values in SMFA.

951

THE ROLE OF HUMAN MOBILITY ON VECTOR-BORNE DISEASE DYNAMICS

Amy Wesolowski, Caroline Buckee

Harvard School of Public Health, Boston, MA, United States

The emergence and continued persistence of various vector-borne diseases into human populations represents a significant global health risk and disease burden. Accurate predictive models identifying changing patterns of spatial vulnerability to both malaria and dengue will be critical to control and elimination measures. Key to defining spatial vulnerability is the role of infected human travelers on disease dynamics. Here we compare and contrast the role of human mobility on two vector-borne disease: malaria and dengue in both Asia and Africa. We find that the type of mobility relevant for transmission is both pathogen and location specific. We show that although the modeling framework varies between diseases, human mobility in combination with transmission suitability maps are able to estimate disease importation to generate fine-scale dynamic risk maps.

952

WHERE TO START MALARIA ELIMINATION: CORE OR FRINGES?

Nakul Chitnis, Allan Schapira, Christian Schindler, Melissa Penny, Thomas Smith

Swiss Tropical and Public Health Institute, Basel, Switzerland

Malaria and some other tropical diseases are currently targeted for elimination and eventually eradication. In many areas where diseases have been eliminated, it is often concluded that it would have been more efficient to focus efforts earlier in the places with the highest disease burden and transmission. These areas remained a threat after transmission was interrupted elsewhere, leading to the need to maintain potentially expensive surveillance activities in peripheral areas after the disease has been eliminated from them. We use a mathematical model to compare the implications of prioritisation choices in reducing overall burden and costs. We consider the implications of various assumptions of the relationships between burden, risk of importation, and the required duration of elimination program to transmission potential to show that (i) when the duration of the elimination program is independent of the transmission potential, burden is always reduced most by targeting high transmission areas first; (ii) the optimal ordering to reduce costs depends on the actual transmission levels; and (iii) in general, when overall transmission potential is low and the surveillance cost per secondary case is low compared to the cost per imported case, targeting the higher transmission area first is favoured.

953

ESTIMATED INCREASE IN MALARIA MORBIDITY AND MORTALITY IN EBOLA-AFFECTED COUNTRIES DUE TO DECREASED HEALTHCARE CAPACITY AND THE POTENTIAL IMPACT OF MITIGATION STRATEGIES

Patrick Walker, Michael White, Jamie T. Griffin, Alison M. Reynolds, Neil M. Ferguson, Azra C. Ghani

MRC Centre for Outbreak Analysis and Modelling, London, United Kingdom

At its peak the Ebola epidemic in West Africa overwhelmed healthcare systems making adequate care for malaria impossible and threatening the gains in malaria control achieved over the previous decade. Using a mathematical model we attempted to quantify the potential additional indirect burden this may have caused. We estimated the number of cases and deaths from malaria in Guinea, Liberia and Sierra Leone from DHS survey data on malaria prevalence and malaria-intervention coverage prior to the Ebola outbreak. We then removed the impact of treatment and hospital care to estimate additional cases and deaths from malaria due to reduced healthcare capacity. In the worst case scenario of malaria care ceasing as a result of the Ebola epidemic, we estimate increases in untreated malaria cases of 45%, 88% and 140% in Guinea, Liberia and Sierra Leone respectively in 2014. This represents 3.5 (95% CrI 2·6-4·9) million additional untreated cases and 10,900 (5,700-21,400) additional malaria-attributable deaths in 2014. As there is a large asymptomatic reservoir of infection in these highly endemic countries we found that the absence of treatment would have only a limited impact upon transmission, suggesting that the additional burden of this worst-case scenario can be scaled according to any intermediate level of health-care capacity when more detailed data of the impact of Ebola upon malaria care are available. Any disruption to ITN delivery during the Ebola epidemic is also likely to have contributed substantially to the additional indirect burden of the disease, although due to the cyclic nature of transmission we found the main impact upon burden due to this factor may not occur until the 2015 transmission season. We found that emergency MDA and ITN campaigns timed to coincide with the 2015 transmission season could largely mitigate any future impact of Ebola on malaria and to substantially decrease the burden of non-Ebola-related febrile patients in affected areas.

954

MODELING THE IMPORTANCE OF THE INFECTIOUS RESERVOIR IN DESIGNING EFFECTIVE MALARIA ELIMINATION CAMPAIGNS

Jaline Gerardin, André Lin Ouédraogo, Kevin A. McCarthy, Philip A. Eckhoff, Edward A. Wenger

Institute for Disease Modeling, Seattle, WA, United States

Elimination of malaria can only be achieved through removal of all vectors or complete depletion of the infectious reservoir in humans. Mechanistic models can be built to synthesize diverse observations from the field collected under a variety of conditions and subsequently used to query the infectious reservoir in great detail. The EMOD model of malaria transmission is calibrated to prevalence, incidence, asexual parasite density, gametocyte density, infection duration, and infectiousness data from nine study sites. The infectious reservoir is characterized by diagnostic detection limit and age group over a range of transmission intensities with and without case management and vector control. The composition of the infectious reservoir by diagnostic threshold is similar over a range of transmission intensities, and higher intensity settings are biased toward infections in children. Recent ramp-ups in case management and use of insecticide-treated bednets reduce the infectious reservoir and shift the composition toward submicroscopic infections. Mass campaigns with antimalarial drugs are highly effective at interrupting transmission if deployed shortly after ITN campaigns. Proper timing of vector control, seasonal variation in transmission intensity, and mass drug campaigns allows lingering population immunity to help drive a region toward elimination.

955

CASE-MANAGEMENT FOR COMPLETE CURE OF *PLASMODIUM VIVAX* MALARIA: A MARKOV COST-EFFECTIVENESS MODEL

Minnie Parmiter[1], Yoel Lubell[2], **Shunmay Yeung**[3]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

Plasmodium vivax elimination, now on the agenda in some regions, requires treatment not only of the blood stage infection but the hypnozoites in the liver that cause relapse. This requires use of primaquine, or another 8-aminoquinoline, which can cause severe haemolysis in patients with Glucose-6-Phosphate Dehydrogenase (G6PD) deficiency, an X-linked enzymatic mutation positively associated with malaria prevalence. In this cost-effectiveness model, we analyse the relative costs, effects and risks associated with three alternative ***P. vivax*** case management strategies: 1. chloroquine only treatment for vivax, 2. chloroquine and primaquine treatment without G6PD testing or 3. chloroquine, G6PD testing and primaquine treatment for those testing normal. Known heterogeneity is explored such as G6PDd prevalence, probability of relapse as a proxy for regional vivax strain and sex-specific risk. The results of this conceptual exploration show that uncertainty surrounding key parameters such as adherence to primaquine, likelihood of severe vivax infection, likelihood of drug-induced haemolysis in G6PD deficient individuals is important for decision making and more data are needed. This analysis shows the potential cost-effectiveness of G6PD test contingent primaquine treatment for many settings, under the chosen baseline assumptions.

956

MODELING AND SENSITIVITY ANALYSIS OF THE EFFICACY OF LONG-LASTING MICROBIAL LARVICIDING ON MALARIA TRANSMISSION IN WESTERN KENYA HIGHLANDS

Ming-Chieh Lee[1], Amruta Dixit[1], Edward A. Wenger[2], Philip A. Eckhoff[2], Guiyun Yan[1]

[1]University of California Irvine, Irvine, CA, United States, [2]Institute for Disease Modeling, Bellevue, WA, United States

Recent studies have showed that rising insecticide resistance and a relative increase in outdoor transmission have greatly hampered the effectiveness of insecticide-treated nets (ITN) and indoor residual spraying (IRS) in further reducing malaria disease burden in Africa. Microbial larvicides have been suggested as a supplemental intervention tool that may tackle outdoor transmission and pyrethroid insecticide resistance. Long-lasting microbial larvicides (LLML) are particularly attractive because they may be potentially more cost-effective. In order to determine the efficacy and cost-effectiveness of EPA-approved LLML in reducing malaria transmission and clinical malaria incidence, the Epidemiological Modeling (EMOD) model for Malaria Transmission developed by Institute for Disease Modeling was employed to determine optimal larviciding strategies. We simulated malaria transmission dynamics using parameters from study sites in western Kenya highlands under several scenarios: 1) LLML as a supplemental tool in the context of different levels of pyrethroid resistance, 2) different killing efficacy of LLML, 3) varying duration of the effective period of larviciding, and 4) resistance to microbial larvicides. The results show the beneficial effect of ITNs and IRS can be gradually being reduced due to increased insecticide resistance and outdoor transmission in the absence of other supplemental interventions. After introducing LLML as a supplemental intervention, EIR in the highland sites can be reduced by up to 95%. Sensitivity analysis found that 50% larval killing efficacy by LLML in combination with ITNs can still lead to an overall 91% reduction in EIR. On the other hand, an 80% killing rate by LLML can lead to an 98% EIR reduction. Re-treatment of aquatic habitats every 5 months or less would lead to consistent reduction in transmission for the default duration of LLML. In summary, the modeling analyses suggest that LLML has the potential to provide significant added benefits to malaria control.

957

MODELING THE EFFECTIVENESS OF POPULATION-LEVEL MALARIA INFECTION DETECTION STRATEGIES FOR OPTIMAL CAMPAIGN SCOPING

Milen Nikolov, Jaline Gerardin, Caitlin A. Bever, Philip A. Eckhoff, Edward A. Wenger

Institute for Disease Modeling, Bellevue, WA, United States

Recent geo-tagged data express significant variation of prevalence and parasitemia, both across spatial regions and sociological units of analysis. Correspondingly, the relative benefits of tools for malaria infection detection - informing drug campaigns planning, execution and outcome analysis - differ across geographical locations and social scales. We investigate the relative effectiveness of infection detection methods in drug campaigns to reduce malaria incidence. Utilizing surveillance and remote sensing data, we re-construct the environmental covariates, vector life cycle, human mobility, and infectious reservoirs at distinct locations characterizing various population units: individuals, households, villages, and districts. We develop a calibrated multi-node spatial model within the EMOD framework accurately capturing the dynamics of malaria transmission and prevalence across hundreds of distinct population units and geographical sites. Within the model, we study five drug campaign strategies: mass drug administration, focal drug administration, mass screen and treat, focal screen and treat, and "snowball" reactive case detection. We evaluate campaign performance over a set of four well-established diagnostics - RDT, PCR from filter paper bloodspots, thick film microscopy, high-volume qPCR - as well as the less commonly used aggregate high-volume qPCR. We derive the optimal combination of infection detection method and campaign strategy for different infectious reservoirs and transmission intensities spanning distinct geographies. In light of ongoing and future malaria elimination efforts comprising regions of greatly varying infectious reservoirs, our results provide a framework for improved drug campaign design via optimal infection detection strategies.

958

CATEGORIZING THE SEASONAL PATTERNS OF MALARIA TRANSMISSION FROM CLINICAL OBSERVATIONS AND SATELLITE SURFACES OF CLIMATE DATA

Caitlin A. Bever, Joshua L. Proctor, Jaline Gerardin, Philip A. Eckhoff, Edward A. Wenger

Institute for Disease Modeling, Bellevue, WA, United States

It is generally accepted that planning of malaria control measures requires proper accounting of local seasonal variation. Where elimination is concerned, it is of even greater importance. That said, many analyses are conducted using gross definitions of transmission intensity, usually in the form of an annual EIR or year-average prevalence, either because more detailed information is unavailable or is difficult to incorporate. Mathematical models have shown that seasonality is an important input to simulations that aim to represent clinical incidence and the impact of interventions that act on either the vector or human populations. In carrying out these analyses, modelers are faced with the need to balance the accuracy of results simulated using spatially and temporally detailed descriptions of seasonality with the efficacy of assuming that large, often arbitrarily defined, regions are similar. We introduce a general framework for assigning regional seasonality profiles in simulations of ***Plasmodium falciparum*** malaria that balances fidelity to observed patterns of clinical data and the computational cost of accurately capturing high resolution climate data. Our approach couples the Temperature Suitability Index (TSI), which quantifies the monthly propensity for transmission across Africa from 2000 to 2012, with the EMOD open-source model of malaria, a mathematical description of the vector life cycle coupled to within-host parasite and immune dynamics. Fourier analysis of the continental TSI data was used to separate latitude-dependent phase shifts from other seasonality characteristics, and dynamic mode decomposition was then applied to identify a basis set of profiles that spans the diversity of observed shapes while limiting redundancy. Finally, a calibration was performed to determine the translation of these profiles into model inputs, in the form of larval habitat descriptions. The broad user base of EMOD can practically leverage this mapping in their own simulations of the disease in sub-Saharan Africa while the seasonality basis set itself can be adapted for use with the wider family of available malaria models.

959

COVERAGE AND EFFECTIVENESS OF MALARIA CASE MANAGEMENT IN SUB-SAHARAN AFRICAN COUNTRIES

Katya Galactionova, Fabrizio Tediosi, Don de Savigny, Thomas Smith, Marcel Tanner

Swiss Tropical and Public Health Institute, Basel, Switzerland

Malaria case management provides individual benefits by curing infection and preventing progression to severe disease as well as community-level benefits by reducing the infectious reservoir and averting emergence and spread of drug resistance. Despite the availability of efficacious drugs, the failure to treat malaria episodes effectively probably contributes much to the still unacceptably high burden of the disease. Many patients with malaria do not have access to or delay appropriate treatment, providers do not always comply with treatment guidelines, and patients do not necessarily receive the correct regimen. Following systems effectiveness literature we propose a framework to identify failures along the service delivery path and quantify their impact on patient outcomes. Populated with data from nationally representative surveys from across SSA countries the model yields important insights for malaria control policy.

Effective coverage, captured as a function of treatment seeking, provider compliance, adherence, and quality of medication remains low. While on average treatment is sought for about 60% of fevers, only 35% of episodes are treated effectively; that is nearly 40% of treatments fail to cure parasitemia. Effective coverage is particularly low in Somalia, South Sudan, Chad, Ethiopia, Central African Republic, and North and South Sudan. The counterfactual analysis indicates the potential improvement in effective coverage that could be achieved by scaling-up each of the service indicators. The analysis highlights the constraints that the downstream factors impose on treatment outcomes. Expanding access to treatment translates into higher levels of effective coverage in settings where other service indicators perform well; switching to a more efficacious treatment regimen can only improve effective coverage if treatment is sought and the drug is taken. This suggests that policy efforts targeting marginal improvements across multiple dimensions of service provision will result in a greater improvement in effectiveness than interventions focused on scaling up only one aspect of malaria case management.

SOCIOECONOMIC-RELATED HEALTH INEQUALITY IN RURAL WESTERN KENYA: EVIDENCE FROM A HOUSEHOLD MALARIA SURVEY ON BURDEN AND CARE-SEEKING BEHAVIOR

Vincent O. Were[1], Meghna Desai[2], Simon Kariuki[1], Peter Ouma[1], Ann M. Buff[3], S. Patrick Kachur[2], Penelope A. Phillips-Howard[4], Feiko O. Kuile[4], Louis W. Niessen[4]

[1]Kenya Medical Research Institute, Center for Global Health Research, Kisumu, Kenya, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Centre for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]United States President's Malaria Initiative, Nairobi, Kenya, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Health inequality is recognized as a barrier to achieving health-related international development goals. Health equality data are essential for evidence-based health planning and assessing the effectiveness of current initiatives to promote equity. Such data have been captured but aren't always analysed or used for managing program efforts. In a malaria endemic site in western Kenya, we examined health inequality data and the societal impact of malaria control initiatives on reducing the equity gap at the micro-level. We analysed data from a malaria cross-sectional survey among 2,719 people in 1,063 households in Siaya County, Kenya in mid-2012. Data were collected on socioeconomic (SES) and demographic factors, history of fever, malaria medication usage, and household expenditure on medications. A composite SES score was created from multiple correspondence analyses of household assets and households were classified as poor (lowest 3 wealth quintiles) or less-poor (highest 2 wealth quintiles). Comparing the two groups, we calculated the odds of diagnostically-confirmed malaria, medication use and care seeking using logistic regression. Medication costs were compared using a generalized linear model. The odds of having malaria was significantly higher in households in the poor category (OR=1.4; 95% CI=1.2-1.7, p=0.001) than less poor. Poor households spent mean of $1.36 (95%CI=0.29-2.42) to purchase malaria medications 2 weeks prior to survey compared to $1.53 (95%CI=1.08-1.98) spent by less-poor households. Poor households spent 13% more to purchase non-recommended medications for malaria. Odds of care seeking and medication usage was lower amongst poor households. In multivariate analysis, the odds of malaria infection were significantly higher in poor versus less-poor households. The data demonstrate the existence of inequalities in malaria indicators between poor and less-poor households in an impoverished rural setting in Kenya. The findings contribute to a strategy for assessing and monitoring micro-level health-equity impact of malaria prevention and control efforts

961

AVAILABILITY OF MALARIA PRODUCTS AT THE LAST MILE: AN ANALYSIS OF FACILITY- AND COMMUNITY-LEVEL LOGISTICS DATA

Naomi Printz

United States Agency for International Development | DELIVER PROJECT, John Snow, Inc., Arlington, VA, United States

Learning Objectives: Participants will describe relationships between supply chain data on malaria commodities at community- and facility-levels, specifically looking at stockout data and consumption data. Community health workers (CHWs) are a major entry point to the health system for detection and treatment of malaria. As a first point of contact and common source of artemisinin-based combination therapy (ACT), consumption at the community level should be included for an accurate picture of health service delivery. Exploring the relationship between consumption at the health facility level and commodity level can better ensure availability of malaria products at the last mile. In 2008, Malawi rolled out a new strategy for integrated community case management of childhood illness to improve treatment given by health surveillance assistants (HSAs), who treat malaria cases in the community with ACTs. As the number of HSAs has increased, overall consumption has significantly increased. Compared with health-facility consumption, community-level consumption accounts for a larger percentage of cases in the dry season and up to 50 percent of overall pediatric case treatment. Health facilities supply products to HSAs. From 2011 to 2014, the number of stockouts increased overall, reflected both in the number of days that HSAs stocked out each month and the percentage of HSAs reporting a stockout of a commodity each month. At the national level, the trend of increasing stockouts among HSAs does not reflect on stockouts at the facility level. Overall facility-level stockouts during the dry season are low; and, in general, have decreased over time. In fact, the percentage of HSAs stocked-out increased significantly in 2013, but the facility-level stockouts of pediatric artemether/lumefantrine declined. Although the percentage of facilities stocked-out has decreased overall, this is not consistently reflected in HSA resupply. When stock is available at the facility level, it does not necessarily correlate to a high order fill rate. For most of 2012 and 2013, order fill rates ranged from around 50 percent to 90 percent, averaging around 65 percent.

962

WHO GOES WITHOUT? AN ASSESSMENT OF GAPS IN MALARIA INTERVENTION COVERAGE USING STANDARDIZED NATIONAL SURVEYS

Cristin A. Fergus[1], Richard Cibulskis[1], Michael Lynch[2], n. Global Malaria Programme, World Health Organizatio

[1]World Health Organization, Grand-Saconnex, Switzerland, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

While there have been impressive increases in the coverage of malaria interventions over the past decade, there are millions that do not receive life-saving services. Gaps in service coverage are evident in all countries that have National Malaria Control Programs. To design programs that fill these gaps, it is important to have a good understanding of the factors responsible for differential coverage levels of insecticide-treated nets (ITNs), Intermittent Preventative Therapy in pregnancy (IPTp), a malaria diagnostic test, and malaria treatment with an Artemisinin-based combination therapy (ACT). Some insight can be gained by examining nationally-representative household surveys (which document the characteristics of people who do not receive services), and by decomposing the explained variance in regression models to identify factors that are associated with gaps in coverage. Across the most recent household surveys, a median: 45% of households do not have an insecticide-treated net (IQR 36-66%), 36% of children do not receive any care for fevers (IQR 28-41%), 78% of febrile children do not receive a diagnostic test (IQR 70-88%), and

43% of pregnant women do not receive at least one dose of Intermittent Preventative Therapy. Poverty, represented by belonging to the lowest wealth quintile, was the strongest factor associated with a household not having an ITN. Other important factors were being in a rural area and a head of household without a formal education. Poverty was also the most important factor associated with a pregnant woman not receiving IPTp. Poverty and living in a rural area were most strongly associated with receiving a diagnostic test, whereas the strongest predictor for not receiving an ACT was low educational attainment, followed by living in a rural area and being poor. To build on the increases of the past decade, it is important to identify and fill specific gaps in intervention coverage. The monitoring of malaria intervention coverage should not only include an assessment of where we have come from, but also identify areas where future gains are possible.

963

USE OF MALARIA SURVEILLANCE DATA TO DRIVE SUPPLY CHAIN DECISION-MAKING TO RESPOND TO MALARIA OUTBREAKS IN THE LAO PEOPLE'S DEMOCRATIC REPUBLIC (PDR)

Claudia Allers[1], Olivier Celhay[2]

[1]United States Agency for International Development | DELIVER PROJECT, John Snow, Inc., Arlington, VA, United States, [2]United States Agency for International Development | DELIVER PROJECT, Vientiane, Lao People's Democratic Republic

Southern Laos experienced a prolonged malaria outbreak in 2013 and 2014, with the highest number of cases reported in a decade in June 2014. The need for a rapid response was critical to ensure that quality malaria rapid diagnostic test kits (RDTs) and artemisinin-based combination therapy (ACT) treatments were available at health facilities to test and treat the surge in malaria cases expected until the end of the rainy season in October. The United States Agency for International Development | DELIVER PROJECT helped plan and carry out an emergency distribution of RDTs and ACTs in the five southern provinces of the country that were the ***foci*** of the outbreak. In the absence of a regular reporting and resupply system, and lack of data on the availability of these critical commodities at provinces and districts, the Centre for Malaria, Parasitology, and Entomology (CMPE) utilized data from the country's Malaria Information System and from sentinel surveillance sites to quantify and target the emergency distribution to those provinces and districts most heavily affected by the malaria outbreaks. Within four months, the project successfully distributed sufficient stocks to the southern provinces where the outbreak was contained.

964

PLASMODIUM CHABAUDI MALARIA IN MICE STRAINS PHENOTIPICALLY SELECTED FOR MAXIMAL OR MINIMAL ACUTE INFLAMMATORY RESPONSE

Bruna Macedo[1], Heitor Franco Andrade[1], Felipe De melo Hermida[1], Marcelo de Franco de Franco[2], Andrea Borrego Borrego[2]

[1]Institute of Tropical Medicine, Sao Paulo, Sao Paulo, Brazil, [2]Institute Butantan, Sao Paulo, Brazil

AIRmax (high) and AIRmin (low) mouse strains diverged in their acute inflammatory response and they were obtained by the bidirectional phenotypic genetic selection, which allows the concentration of alleles of several loci of genes involved in the acute inflammatory response. Rodent malaria models are ideal and useful for the study of immunity and immune response to malaria, especially those with spontaneous control of the infection, as ***Plasmodium chabaudi***. Here, we studied the evolution of ***P. chabaudi*** malaria and some aspects of the immune response min those strains, using as standard BALB/c mice. Parasitemia, serum cytokines and interleukins or their mRNA production by spleen cells were also determined, as well as liver and spleen histology. Groups of mice of each strain were infected ip with 10^6 parasitized erythrocytes. ***P. chabaudi*** CR malaria was more severe and with slower control in phenotypically selected AIRmin with low acute inflammatory response, a fact more intense in early stages of the infection. The spleen enlargement, evaluated by weight and histology, was notable and similar in all strains, without differences, but the limits between white and red spleen pulps was destroyed in latter periods in the 8th and 12th days after infection, due to cell proliferation. The liver showed fewer portals infiltrates in AIRmin models, which was abundant in BALB/c and AIRmax mice, with extra medullary erythropoiesis ***foci*** more intense in AIRmax mice. There are significant increment in mRNA or inflammatory cytokines, as IFNγ e TNFα, in AIRmin mice, with sustained elevated levels and a delay in the increment of regulatory cytokines IL-4 and IL-10. AIRmax mice appear to produce less inflammatory or regulatory cytokines but in a more orchestrated production, as suggested by histology. Our data support that rodent malaria was more severe in acute inflammatory response phenotypically deficient AIRmin mice as compared to BALB/c or AIRmax strains, the latter associated with organized spleen response with lower levels of cytokines. Those data support the participation of acute inflammatory response in the control of blood stages of malaria infection.

965

NEW EFFORTS AIMED AT REPLACING ACTS: THE IDENTIFICATION OF NOVEL, DRUG-LIKE, AND FAST-ACTING ANTIMALARIAL COMPOUNDS FROM A PHENOTYPIC SCREENING

Lourdes Rueda

GlaxoSmithKline, Collegeville, PA, United States

Malaria is a major global infectious disease that causes nearly 700,000 deaths per year, mostly amongst pregnant women and young children. Drug resistance to the most used current tratments (ACTs) is widespread and the last antimalarial introduced into clinical practice was in 1996. Consequently, the next generation of antimalaria drugs is urgently required. Novel chemotypes with new mechanism of action must be identified to deliver new drugs that not only cure the disease, but that could also block the transmission of it. Unfortunately, in the last few years target-based approaches have proven to have limited success in delivering new antimalarial therapies. This fact has forced the antimalarial scientific community to be innovative and to find other ways of identifying new drugs to tackle this disease. Phenotypic screening has become the preferred approach across the antimalarial community for the identification of novel hit series to support these drug discovery efforts. In 2010 we built and published the Tres Cantos Antimalarial Set (TCAMS): 13,533 compounds that are the result of a whole cell screening of nearly two million compounds from the GSK corporate collection. In the last years, TCAMS along with other antimalarial tool sets of compounds have been our source of new hits. Different ways of analyzing, prioritizing and selecting the best molecules have successfully led to deliver different promising series with potential to become the future antimalarial drugs. With a particular focus on fast-acting antimalarial compounds, we selected hits displaying good physicochemical properties and an encouraging developability profile. Hit optimization efforts and additional profiling data around one of these series will be presented.

966

COSTS OF MALARIA TREATMENT BETWEEN PUBLIC, COMMUNITY AND PRIVATE HEALTHCARE PROVIDERS IN SUBSIDIZED INPUT CONDITIONS

Hamidou Niangaly[1], Josselin Thuilliez[2], Alasseini Balam[1], Mahamadou S. Sissoko[1], Ariadna Sanz[3], Abdoulaye A. Djimdé[1], Ogobara Doumbo[1]

[1]Malaria Research and Training Center, USTTB, Bamako, Mali, [2]CNRS-Panthéon-Sorbonne-Paris 1 University, Paris, France, [3]Barcelona Centre for International Health Research (CRESIB) Hospital Clínic - Universitat de Barcelona, Barcelona, Spain

Malaria is one of the main leading causes of healthcare demands in endemic areas. Governments are subsidizing or making free of charge the inputs of fighting against malaria in order to make malaria treatment affordable for their respective populations. Public and private sectors use subsidized and free inputs provided by the government for their customers. The aim of this work was to compare the costs of malaria treatment between public, community and private sectors. In West African Malaria Initiative framework, we carried out a cross-sectional study covering all healthcare center categories in 7 Regions and the Capital city of Mali in 2011. The heads of selected healthcare centers were asked on the fee for medical consultation and the unit cost for the treatment of uncomplicated and severe malaria. For variance comparisons Anova tests were used as appropriate. We surveyed 19, 18 and 16 from the public, community and private healthcare centers, respectively. The average costs for uncomplicated malaria treatment were $4.6, $3.6 and $10.3 (p-value = 0.0031). The treatment of severe malaria was also more expensive within the private sector with $48.2 than public sector with $18.5 or community healthcare providers with $16.7 (p-value = 0.021). When we removed the fees of medical consultation bills the average costs of malaria treatment remained higher in private healthcare providers than public or community providers. There was inequity in the costs of malaria treatment between private, public and community healthcare consumers while all care providers used subsidized malaria control inputs.

GREATER IMPACT AT A LOWER COST: PRIORITIZING SUPPORT TO PATENT AND PROPRIETARY MEDICINE VENDORS FOR INCREASED QUALITY FEVER CASE MANAGEMENT IN EBONYI STATE, NIGERIA

Victor Lara[1], Ogechi C. Onuoha[2], Martin Dale[1], Akin-Kolapo B. Nurat[2], Martin Bell[2]

[1]Population Services International, Nairobi, Kenya, [2]Society for Family Health, Abuja, Nigeria

Recent ACT watch data shows the importance of the private health sector in Nigeria as a provider of antimalarial drugs to patients. This comes with concerns over the correct use of drugs, as well as the overall quality of care offered by Patent and Proprietary Medicine Vendors (PPMVs). Large-scale support systems available for PPMVs are currently incomplete, and often do not emphasize quality of care aspects. Traditionally, improving healthcare providers' quality of care has relied on training and supervision, which includes performance assessments and coaching. This can be expensive, especially when engaging large networks such as PPMVs. Furthermore, introducing real-time observation of case management can also increase costs, especially if all providers are routinely visited. In order to study better ways to allocate available resources to support PPMVs, an integrated community case management project is being implemented in the Ebonyi State of Nigeria by Society for Family Health, MalariaCare and Population Services International. The project uses two data sources to classify providers: (i) case management performance observations to classify providers into three different groups (good, average and poor) and (ii) commodity stock tracking as a proxy of caseload, to separate PPMVs into two groups according to productivity (high= PPMVs accruing 80% of the overall caseload and low= the remaining 20%). The analysis yields a performance vs. productivity matrix that helps prioritize providers for support, focusing first on those with a higher caseload and lower performance. This classification enables a more focused and better-tailored quality monitoring support effort towards those providers who will benefit the most. This innovative approach leads to more cost-effective resource allocation and by targeting providers with the biggest caseload, ensures populations most in need benefit from a better quality case management service.

968

HIGH FOLATE LEVELS ARE NOT ASSOCIATED TO INCREASED RISK OF MALARIA BUT TO REDUCED ANEMIA RATES IN THE CONTEXT OF HIGH DOSED FOLATE SUPPLEMENTS AND SP-IPTP IN BENIN

Violeta Moya-Alvarez[1], Gilles Cottrell[2], Smaila Ouedraogo[3], Manfred Accrombessi[4], Achille Massobodgi[5], Michel Cot[2]

[1]Institut de Recherche pour le Développement, Ecole des Hautes Etudes en Sante Publique EHESP, Paris, France, [2]Institut de Recherche pour le Développement, Université Paris Descartes, Sorbonne Paris Cité, Paris, France, [3]Unité de Formation et de Recherche en Sciences de la Santé, Université de Ouagadougou, Public Health Department, Centre Hospitalier Universitaire Yalgado Ouédraogo, Ouagadougou, Burkina Faso, [4]Institut de Recherche pour le Développement, Cotonou, Benin, [5]Faculté des Sciences de la Santé, Université d'Abomey Calavi, Cotonou, Benin

Gestational anemia is the first cause of morbidity in pregnancy worldwide, and nutritional deficiencies and pregnancy associated malaria (PAM) are its main causes. Therefore, WHO recommends an intermittent preventive treatment in pregnancy (IPTp) of 1500/75 mg sulphadoxine-pyrimethamine (SP) at each antenatal care visit (ANC) to tackle PAM and its effects. WHO also recommends 200 mg ferrous sulfate and 0.4mg folate daily to fight gestational anemia. However, national guidelines in Benin still recommend 5mg per day. SP is an effective anti-folate and, hence, high dose folate supplements might diminish the efficacy of IPTp, especially in the context of some resistance to SP. To evaluate this possible effect, we analyzed hematological and P.falciparum parasite indicators during the entire pregnancy in the context of the MiPPAD clinical trial comparing IPTp regimes of SP and mefloquine. Between 2010 and 2012, 1,005 pregnant women were followed in a prospective longitudinal cohort until delivery in Allada (Benin). At inclusion, socio-demographic status and gyneco-obstetric history were investigated. Extensive medical and biological exams were realized on the occasion of each dose of IPTp and at delivery. Further exams were realized at each unscheduled visit. All patients were treated in case of disease. Random coefficient models assessed the relationship between the different hematological and parasitological measures and other variables. High folate levels and low ***Plasmodium falciparum*** parasite density had a protective effect on gestational anemia in the context of SP-IPTp. Furthermore, high folate levels were not associated with increased malaria risk (measured by blood smear), nor with increased ***P. falciparum*** parasite density. On the contrary, high iron levels were statistically linked to increased odds of PAM and increased ***P. falciparum*** parasite density. Albeit some resistance to SP, benefits of folate are undeniable and do not seem to entail an increased risk of malaria in the context of IPTp with anti-folates and high dosed folate supplements in Benin.

969

IMPROVING PROVISION OF MALARIA SERVICES THROUGH PROVIDER TRAINING IN BURKINA FASO

Ousman Badolo[1], Stanislas Nebie[1], Moumouni Bonkoungou[1], Mathurin Dodo[1], Thierry Ouedraogo[1], Rachel Waxman[1], **William R. Brieger**[2]

[1]Jhpiego, Baltimore, MD, United States, [2]Johns Hopkins University, Baltimore, MD, United States

In 2013, malaria was the main reason for consultation (53.90%), hospitalization (63.20%) and death (49.60%) in health facilities; children under 5 and pregnant women are most affected. Recent revisions to the World Health Organization's (WHO) guidance to maintain effective approaches to defeating malaria, include monthly dosing of intermittent preventive treatment for pregnant women (IPTp), starting from the 13th week of gestation. To align with the latest WHO guidance, the Burkina Faso Ministry of Health, with support from the United States Agency for International Development-funded Improving Malaria Care (IMC) project, revised national malaria guidelines in March 2014. 68 trainers from 9 health regions were trained on the revised national malaria guidelines. From June to September 2014, 744 providers from 524 health facilities in 21 districts (33%) were trained on the prevention and management of malaria cases. To ensure updated guidance reaches all health workers, the training included a module on how to update colleagues in their respective facilities. During supervision visits, most trained providers were using the new guidelines and pregnant women are increasingly receiving the third and higher doses of SP before delivery. In the first six months after the training sessions, pregnant women, who received the third dose of SP (IPTp3) increased from 0% to 12%. Three months later, that proportion rose to 30%. Comparatively, in the remaining 42 districts who received only the copies of the new guideline without training, IPTp3 was 5% nine months after receiving the guidelines. The training sessions contributed to improving the implementation of revised IPTp guidelines and uptake of IPTp 3 and higher better than distribution of the new guidelines alone. As a result the IMC project will scale-up the training in Year 2 to 600 more providers from 464 health facilities, and other partners have also agreed to support the National Malaria Control Program to reach remaining facilities. Challenges in increasing IPTp uptake include commodity distribution and inadequate engagement of private health facilities to update their practices and reporting of SP distribution.

970

NRH: QUINONE REDUCTASE 2 (NQO2) PROTECTS AGAINST HEMOLYTIC TOXICITY INDUCED BY PRIMAQUINE ANTIMALARIAL IN G6PD DEFICIENT HUMAN ERYTHROCYTES

Jagrati Jain[1], Narayan D. Chaurasiya[1], NP Dhammika Nanayakkara[1], Larry A. Walker[1], Babu L. Tekwani[1], James D. McChesney[2]

[1]University of Mississippi, University, MS, United States, [2]Ironstone Separations, Inc, Etta, MS, United States

8-Aminoquinolines (8-AQs), including primaquine (PQ), are important class of anti-protozoal drugs but have limited utility due to hemotoxic effects of one or more metabolites. Hemolytic episodes are of major concern in G6PD deficient populations in states of oxidative stress. Erythrocytes from G6PD deficient Individuals also display depletion of reduced glutathione (GSH) due to compromised capability to produce NADPH. Phenolic metabolites generated through cytochrome P450-dependent pathways appear to be responsible for hemolytic effects of primaquine. The hemotoxic response of the redox active metabolites of PQ could be measured ***in vitro*** by accumulation of methemoglobin and kinetic measurement of increase in oxidative stress. NQO2, a FAD-linked oxidoreductive enzyme, catalyzes mandatory two-electron reduction of quinones to hydroquinones, without accumulating semiquinones and free radicals. Human erythrocytic NQO2 is the only protein target identified for PQ. NQO2 seems to be a detoxification enzyme for quinones. This suggests the role of NQO2 in detoxification of reactive metabolites of PQ in erythrocytes, as redox cycling of quinone and quinone-imine metabolites has been implicated in hemotoxicity of 8-AQs. 5-Hydroxy PQ (5HPQ), and 6-methoxy-8-hydroxylaminoquinoline (MHQ) are among the putative hemotoxic metabolites of PQ. 5HPQ is highly unstable, which is spontaneously converted to 5, 6-orthoquinone (5, 6-o-QPQ) and quinone-imine. 5HPQ and MHQ produce dose-dependent methemoglobin accumulation, oxidative stress and depletion of GSH in G6PD deficient human erythrocytes. The NQO2 inhibitors namely, melatonin, resveratrol and quercetin were tested for their effects on PQ metabolites-induced hemolytic toxicity. The NQO2 inhibitors synergistically increased 5HPQ- and MHQ-induced methemoglobin accumulation, oxidative stress and depletion of GSH in G6PD deficient human erythrocytes. The results suggest a protective role of NQO2 in hemolytic toxicity of PQ. More precise knowledge on interactions of these metabolites with NQO2 should help in understanding the mechanism of PQ-induced hemolytic toxicity.

971

TRANSFORMING THE PRIVATE SECTOR MARKET FOR QUALITY MALARIA CASE MANAGEMENT IN KINSHASA: RESULTS FROM BASELINE SURVEYS AND MONITORING ACTIVITIES.

Stephen Poyer[1], Martin Dale[1], Willy Onema[2], Frederick Persoons[1], Victor Lara[1], Nikki Charman[1], Marcel Lama[2]

[1]Population Services International, Nairobi, Kenya, [2]Association de Sante Familiale, Kinshasa, Democratic Republic of the Congo

Malaria remains one of DRC's foremost public health and development challenges. There were an estimated 11.3 million malaria cases and almost 31,000 malaria-related deaths reported through health facilities in 2013, making the DRC the second most malaria-affected country in the world after Nigeria. With support from DFID, PSI and ASF (PSI's local affiliate) are embarking on one of the most significant malaria control pilot projects in the world today. The capital city, Kinshasa, is home to an estimated 12 million people, all of whom at risk from malaria. 97% of antimalarials are distributed through the private sector in Kinshasa, and yet the quality of that treatment is unacceptably poor. In 2013 only 4% of antimalarials distributed in the private sector were quality-assured artemisinin-based combination therapies (QAACTs), compared to 32% SP and 19% quinine. One of the most important current challenges in malaria control is finding a sustainable and replicable approach to transforming the private sector from a public health threat for malaria sufferers to an opportunity to access affordable, high-quality malaria case management services. Such services include the availability of diagnostic testing and QAACTs at private health facilities and drug shops, the most common private sector sources of care. The project comprises a combination of interventions to target identified market constraints including the high ex-factory price of QAACT, poor supply chain coordination, low consumer demand for QAACT and the poor quality private sector malaria case management. A comprehensive M&E plan guides project learning, course correction and evaluation. Here we present the M&E plan, and baseline results on QAACT price from mystery shopper activities and consumer informed demand and use for QAACT and diagnostic testing from a representative population-based survey. In addition, we present quality of care and rationale treatment outcomes from medical detailing visits and client exit interviews at a subset of private facilities included in an RDT pilot embedded within the wider project.

972

A TALE OF TWO PROVIDERS: DIFFERENCES IN FEVER CASE MANAGEMENT PRACTICES AND PERFORMANCE AMONG PRIVATE CLINICIANS AND PRIVATE PHARMACY PROVIDERS ON THE KENYAN COAST

Purity Njagi[1], Job Makoyo[2], Nancy Njoki[2], Rhoune Ochako[2], Stephen Poyer[1], Cristina Lussiana[1], Martin Dale[1], Stephanie Dolan[1]

[1]Population Services International, Nairobi, Kenya, [2]Population Services Kenya, Nairobi, Kenya

The private health sector is universally recognized as a key player for effective fever case management in malaria-endemic countries. The term 'private health sector' encompasses a variety of providers, with varying competences and behaviours. This inherent heterogeneity of the private health sector is often poorly understood. Population Services International is implementing a project to improve fever case management in the private health sector. In the coastal region of Kenya the project enrols private clinics and pharmacies. In order to better understand differences in provider performance, exit interviews were conducted in Q4 2014 with 534 clients seeking treatment for fever from 86 private clinics and 44 pharmacies. Routine competency assessments were conducted with 75 private physicians and 52 pharmacists in Q3/4 2014. Clients were more likely to be tested for malaria in private clinics than pharmacies (84.1% vs. 39.7%, $p<0.0001$). Overall, 84.9% of 216 malaria test-positive clients received any antimalarial, with no difference between facility types ($p=0.7$). However, test-positive clients were more likely to receive a recommended ACT at pharmacies (86.8%) than they were at private clinics (75.5%, $p=0.06$). Clients at private clinics were twice as likely to receive an antibiotic independently of test outcomes. From the routine assessments 54.4% of pharmacists and 57.7% of physicians scored over 80% when assessed on RDT procedure. Levels of patient counselling were similar in the two groups (pharmacists: 91.5%, physicians: 98.2%). However, no more than one-in-five providers assessed patients for danger signs (pharmacists: 14.1%, physicians: 20.6%). Pharmacists performed worse than physicians in correct fever case management practices (30.9% vs. 42.4%, respectively) and in correct disposal of lancets (24.7% vs. 38.1%, respectively). Provider heterogeneity should be taken into account when conceiving projects within the broad private health sector in order to better define provider profiles and design tailored interventions that improve cost-effectiveness.

973

COSTS ASSOCIATED WITH MALARIA IN PREGNANCY IN THE BRAZILIAN AMAZON

Elisa Sicuri

ISGlobal, Barcelona, Spain

Information on costs associated with malaria in pregnancy (MiP) in low transmission areas where ***Plasmodium vivax*** (Pvivax) predominates is so far missing. This study estimates health system and patient costs of MiP in the Brazilian Amazon. Methods/principal findings: Between January 2011 and March 2012 patient costs for the treatment of MiP were collected through an exit survey at a tertiary referral hospital and at a primary health care centre in the Manaus metropolitan area, Amazonas state. Pregnant and post-partum women diagnosed with malaria were interviewed after an outpatient consultation or at discharge after admission. Seventy-three interviews were included in the analysis. Ninety-six% of episodes were due to Pvivax and 4% to ***Plasmodium falciparum*** (Pfalciparum). In 2010, the total median costs from the patient perspective, were estimated at US$ 45.91 and US$ 216.29 for an outpatient consultation and an admission, respectively. When multiple Pvivax infections during the same pregnancy were considered, patient costs increased up to US$ 335.85, representing the costs of an admission plus an outpatient consultation. Provider direct and indirect costs (overheads) data were obtained from several sources. The provider cost associated with an outpatient case, which includes several consultations at the tertiary hospital was US$ 103.51 for a Pvivax malaria episode and US$ 83.59 for a Pfalciparum malaria episode. The cost of an inpatient day and average admission of 3 days was US$ 118.51 and US$ 355.53, respectively. Total provider costs for the diagnosis and treatment of all malaria cases reported in pregnant women in Manaus in 2010 (N=364) were US$ 17,038.50, of which 92.4% due to Pvivax infection. Conclusion: Despite being an area of low risk malaria transmission, MiP is responsible for a significant economic burden in Manaus. Especially when multiple infections are considered, costs associated with Pvivax are higher than costs associated with Pfalciparum. The information generated may help health policy decisions for the current control and future elimination of malaria in the area.

974

EVALUATION OF A MOBILE PHONE-BASED MALARIA ROUTINE SURVEILLANCE SYSTEM IN AMHARA REGION, ETHIOPIA

Asefaw Getachew[1], Jeff Bernson[2], Belendia Serda[1], Berhane Tesfay[1], Asnakew Yeshiwondim[1], Adem Ahmed[1], Belay Beyene[3], Callie Scott[2], Caterina Guinovart[2], Rick Steketee[2]

[1]PATH, Addis Ababa, Ethiopia, [2]PATH, Seattle, WA, United States, [3]Amhara National Regional State Health Bureau, Bahir Dar, Ethiopia

Ethiopia is a malaria epidemic-prone county learning to transition across the control to elimination continuum in selected districts. Surveillance systems for tracking morbidity and monitoring systems to decide on positioning of anti-malaria commodities based on village level spatiotemporal fluctuations are crucial parts of the program. A rapid reporting system was established in health posts (HPs) in 209 villages in eight districts in Amhara Region, Ethiopia. Community based surveillance assistants (CBSAs) were trained and deployed to report weekly morbidity and commodity data using mobile phones supported by the web-based DHIS2 platform. Reporting includes the counts of seven morbidity and behavioral elements and six commodity data elements. Weekly reporting data were extracted over a 20-month period (September 2013-April 2015). We explored whether reported surveillance data could enable health workers to visualize accurate data to follow the oscillation of morbidity and trigger local response decisions. Across the 209 HPs, the overall report submission rate was 91%; 89% of submitted data was considered complete; and 89% of HPs reported data parameters free of errors. Due to challenges with the DHIS2 system, mobile reporting timeliness could not be captured in the system. In the 209 HPs, the mean weekly rapid diagnostic test (RDT) positivity rate was 30% (weekly range: 13-49%). This initial system assessment demonstrated that for the existing data collection system in rural Ethiopia, it is feasible to use smartphones to report from rural HPs into platforms such as DHIS2 to inform decisions at any level. Data validation procedures are critical to assess and ensure the accuracy of data reported. Factors influencing data quality include the training and follow-up of the CBSA in each HP catchment area, existence and use of job aides, and the number and quality of source documents for reporting cases. Lessons were documented on specific improvements to the rapid reporting system including better measurements of reporting timeliness.

975

MASS WEEKLY FEVER SCREENING, TESTING AND TREATMENT FOR MALARIA IN LOW TRANSMISSION AREAS IN MATAM AND LOUGA REGIONS, SENEGAL

Farba Faye[1], Caterina Guinovart[2], Yakou Dieye[1], Badara Cisse[1], Adama Tall[1], Michael Hainsworth[2], Callie Scott[2], Ruben Conner[2], Mame Sy[3], Doudou Sene[3], Souleymane Ba[3], Elhadji Doucoure[3], Tidiane Thiam[3], Ritu Kumar[2], Michael Kalnoky[2], Moustapha Cisse[4], Fatou Fall[4], Mady Ba[4], Duncan Earle[5], Philippe Guinot[1], Rick Steketee[2]

[1]PATH, Dakar, Senegal, [2]PATH, Seattle, WA, United States, [3]Ministry of Health, Matam and Louga regions, Senegal, [4]Programme Nationale de Lutte contre le Paludisme, Dakar, Senegal, [5]PATH, Lusaka, Zambia

The PECADOM+ strategy (prise en charge à domicile), a weekly active case detection for malaria conducted by community health workers, is ongoing in Southeast Senegal since 2012 and has shown promising results to decrease the malaria burden. The MOH and MACEPA implemented an enhanced PECADOM++ strategy in Kanel, Linguère and Ranérou districts as part of malaria elimination activities conducted in these low-transmission areas during the 2014 transmission season. All households were visited weekly to screen for fever cases and all individuals with a fever or a history of fever in the last 7 days were tested with a rapid diagnostic test (RDT). Positive individuals were treated with dihydro-artemisinin-piperaquine and all individuals in their households were tested and treated if positive (household focal testing and treatment). A quasi-experimental study was conducted in six intervention health post catchment areas, with seven adjacent health posts with similar characteristics selected as controls. Villages within the catchment areas were stratified according to the 2013 incidences of passively detected malaria cases and targeted with different interventions by strata. Those with an incidence ≥5 cases/1000/year received PECADOM++ from October 2014 to January 2015. To evaluate the impact of the interventions, the incidence of passively detected, RDT-confirmed malaria cases at the health posts will be compared before and after the intervention and between intervention and control villages. Preliminary results show that 94% (3100/3304) of households received at least one weekly visit, but the field work was logistically challenging, resulting in inconsistent coverage over time. On average 9% of households had at least one individual with a history of fever each week and 6% of those were RDT-positive (ranging from 2 to 14% by health post). The household focal testing and treatment positivity rate was also 6% (range 0-9% per health post). Final results of the impact evaluation, assessment of geographical clustering of infections over time, characteristics of malaria cases and estimates of implementation costs will be available in mid-2015.

976

SHARED EPITOPES BETWEEN *PLASMODIUM VIVAX* DUFFY BINDING PROTEIN (PVDBP) AND *P. FALCIPARUM* VAR2CSA INDUCE CROSS-REACTIVE ANTIBODIES IN COLOMBIAN POPULATIONS

Sedami Gnidehou[1], Evelyn Medawar[1], Eliana Arango[2], Prachur Shrivastava[1], Albert Jin[1], Jahanara Rajwani[1], Amanda Maestre[2], Michael Good[3], Stephanie Yanow[1]

[1]University of Alberta, Edmonton, AB, Canada, [2]Universidad de Antioquia, Medellín, Colombia, [3]Griffith University, Gold Coast, Australia

Antibodies against the VAR2CSA antigen of ***Plasmodium falciparum*** are associated with improved outcomes of pregnancy-associated malaria. In a recent study, we demonstrated that contrary to what was described in African studies, men and children from Colombia exposed to ***P. falciparum*** and ***P. vivax*** had functional antibodies against VAR2CSA. Here we identified cross-reactive epitopes between VAR2CSA and the Duffy binding protein from ***P. vivax*** (PvDBP). We showed by confocal microscopy that a PvDBP monoclonal antibody generated in mice recognized the VAR2CSA protein expressed by the CS2 ***P. falciparum*** lab strain. Both the PvDBP antibody and anti-VAR2CSA antibodies from an immunized rabbit cross-recognized PvDBP and VAR2CSA proteins by western blot. We identified two peptides within the DBL5ε domain of VAR2CSA that are selectively recognized by sera from Colombian, but not Beninese, men and children. Furthermore, we identified one peptide from PvDBP that shares homology with one of the DBL5ε peptides. Antibodies against these two peptides from different species were highly correlated. Our findings suggest that epitopes from ***P. vivax*** antigens induce antibodies that cross-react with VAR2CSA from ***P. falciparum*** and may be associated with protection against pregnancy-associated malaria.

977

A MALARIA VACCINE FOR TRAVELERS AND MILITARY PERSONNEL

Nimfa Teneza-Mora[1], Joanne Lumsden[2], Eileen Villasante[1]

[1]Naval Medical Research Center, Silver Spring, MD, United States, [2]Henry Jackson Foundation, Rockville, MD, United States

The growth of global travel to potentially malarious regions increases the risk of malaria infection among non-immune travelers. Despite the availability of highly effective malaria protective measures, including chemoprophylaxis, malaria cases among persons who travel from malaria-free countries to endemic areas continue to occur, likely due to suboptimal rates of compliance and other related factors. Two non-immune groups who are at a particularly high risk of acquiring severe malaria infection are international travelers to Africa who visit friends/relatives and military personnel deployed to malaria endemic areas. These two groups would benefit greatly from a vaccine to protect them against malaria infection and constitute a substantial market for such a vaccine. Desirable attributes of a vaccine to protect non-immune travelers and military personnel include a protective efficacy of at least 80% and preferably greater than 90%, adequate level of protection achieved within 14 days of completing the immunization series, durability for at least 6 months, acceptable safety/tolerability profile, and compatibility with current malaria protective measures. Phase 1 clinical studies have shown that a vaccine protective efficacy of at least 80% against controlled human malaria infection (CHMI) was achievable with the RTS,S vaccine with delayed fractional dose and the PfSPZ Vaccine. Clinical studies are being conducted on both vaccine candidates to obtain valuable data on the optimum regimen that affords protection against heterologous strains of ***P. falciparum***, and greater than 6 months durability of protection to support licensure of an effective vaccine for travelers and military members.

978

RELATIONSHIP OF MALARIA PARASITEMIA TO PFAMA-1 VACCINE-INDUCED IMMUNOGENICITY

Matthew B. Laurens[1], Drissa Coulibaly[2], Bourema Kouriba[2], Mark A. Travassos[1], Jason A. Bailey[1], Christopher G. Jacob[1], Amed Ouattara[1], Kirsten E. Lyke[1], Andrea A. Berry[1], Matthew Adams[1], Sheetij Dutta[3], Jozelyn V. Pablo[4], Rie Nakajima[4], Algis Jasinskas[4], Philip L. Felgner[4], Mahamadou A. Thera[2], Ogobara K. Doumbo[2], Christopher V. Plowe[1]

[1]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Malaria Research and Training Center, University of Science, Techniques and Technology, Bamako, Mali, [3]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]Division of Infectious Diseases, Department of Medicine, University of California Irvine, Irvine, CA, United States

Many clinical trials of malaria vaccines have included pre-vaccination curative antimalarial therapy and others have not. The impact of parasite clearance on vaccine immunogenicity for both pre-erythrocytic and erythrocytic antigens is not known. In Phase 2 testing in Malian children, an apical membrane antigen 1 (AMA1) malaria vaccine showed strain-specific efficacy against clinical malaria caused by ***Plasmodium falciparum***, and the increase in anti-AMA1 antibody from baseline

was associated with protection. To evaluate the effect of ***P. falciparum*** asexual parasitemia at vaccination on subsequent immunogenicity, we compared the anti-AMA1 antibody levels at baseline and 30 days after the last vaccination in AMA1 vaccinees positive for asexual parasites by PCR or by microscopy to AMA1 vaccinees negative for parasitemia using an unpaired t test. A subset of 40 vaccinees was also evaluated using a protein microarray that measured seroreactivity to 264 unique AMA1 ectodomain variants at baseline and at 30 days after the last vaccination. Among AMA1 vaccinees with immunogenicity measured, 47/194 had detectable ***P. falciparum*** parasites on vaccination days. Mean anti-AMA1 antibody levels at baseline and 30 days after last vaccination in parasite-positive children were 56.3 µg/mL and 563.2 µg/mL, respectively. In parasite-negative children, these values were significantly lower at 6.0 µg/mL ($p<0.0001$) and 398.8 µg/mL ($p=0.0045$), respectively. Of 40 vaccinees with seroreactivity measured by protein microarray, 11 were parasitemic on days vaccinations were given. Among these 11, seroreactivity against 23 AMA1 variants was higher at baseline than for the 29 participants who were malaria negative ($p<0.01$). At 30 days post-last vaccination when seroreactivity had increased for all variants, no differences in microarray seroreactivity were observed for participants positive vs. negative for malaria at vaccination. These findings suggest that malaria parasitemia at vaccination did not negatively impact, and may have enhanced, humoral immunogenicity for a blood stage vaccine that showed strain-specific efficacy.

979

GENOME-WIDE IMMUNOSCREENING OF ANTIBODIES RESPONSIBLE FOR *PLASMODIUM FALCIPARUM* GROWTH INHIBITORY ACTIVITY OF MALIAN ADULT IGG

Masayuki Morita[1], Eizo Takashima[1], Bernard N. Kanoi[1], Kazutoyo Miura[2], Carole A. Long[2], Takafumi Tsuboi[1]

[1]Ehime University, Matsuyama, Japan, [2]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Residents in malaria endemic area acquire resistance against the disease by repetitive infection with ***Plasmodium falciparum***. Experiments have demonstrated that malaria symptoms in children infected with the parasite can be alleviated by passive transfer of antibodies from malaria semi-immune individuals. This passive transfer provides strong evidence that antibodies have important roles in malaria immunity. Furthermore, antibodies from people residing in a malaria endemic area have been demonstrated to recognize antigens of merozoite, the erythrocyte invasive form of the parasite, and exhibit growth inhibitory activity (GIA) against ***in vitro*** cultured ***P. falciparum***. We therefore hypothesized that identification of antigens responsible for GIA may support the discovery of novel blood-stage vaccine candidates. In this study, we used Malian adult IgGs (n=51) that had GIA against ***P. falciparum*** 3D7 strain ranging from 17 to 84%. Genome-widely selected 1,848 proteins of the 3D7 strain were synthesized by wheat germ cell-free system; a system that can express natively-folded malaria proteins. AlphaScreen, a high-throughput homogeneous system that retains natural conformation of proteins in solution, was modified to detect antigen-antibody reaction. By setting the reactivity cut-off point as mean plus 3SD of the AlphaScreen count of negative control, we selected 905 immunoreactive proteins against Malian IgGs. Of those, we selected 39 antigens which showed significant positive correlations between their reactivity and the GIA. GIA has been attributed to antibodies targeting multiple antigens. Therefore, in addition to the analysis of individual antigens, we statistically analyzed combinations of 3 antigens that could better explain the GIA observed with Malian adult IgGs. To validate this approach, GIA assays were performed with a mixture of 3 rabbit antibodies against ***P. falciparum*** antigens selected by the analysis. The mixture showed higher GIA value than any of individual IgG. From these results, we conclude that our AlphaScreen system is effective to identify novel malaria vaccine candidates.

980

COMPLEX SYNTHETIC MINIGENE VACCINES: AN ALTERNATIVE APPROACH TO ANTIGEN DISCOVERY

Brad Stone, Zachary P. Billman, Arnold Kas, **Sean C. Murphy**

University of Washington Medical Center, Seattle, WA, United States

In the whole ***Plasmodium*** sporozoite model in BALB/c and C57BL/6 mice, we have attempted to modify dosing regimens, intervals, dosages, degree of parasite attenuation and sporozoite species in order to increase the potency of sporozoite-based vaccination. Our efforts continue to show that whole sporozoite hyperimmunization results in 'boostable' CD8 T cell responses to high-abundance, pre-formed antigens and 'unboostable' responses to antigens newly expressed in the liver stage. Since modifications to traditional sporozoite immunization could not dramatically increase diversity the immune repertoire or the intensity of responses against newly expressed liver-stage antigens, we turned to a novel synthetic DNA vaccination approach. We performed proof-of-principle experiments in mice by testing a rapid synthetic "minigene" technology for highly parallel synthesis of multi-antigen ***Plasmodium***-derived DNA vaccines. We utilized microarray-based oligonucleotide synthesis technology and ligation-independent cloning to rapidly synthesize two DNA vaccines, each encoding the complete peptide compliment of 50 secreted or transmembrane ***P. yoelii*** proteins. Using different DNA gene gun vaccination regimens, we induced responses to both known and previously unknown novel antigens. Antigenic responses are being investigated for their ability to protect mice singly or in combination with other DNA vaccine-induced responses. Interestingly, while most but not all DNA vaccine-induced responses can be recalled by later sporozoite exposure, a minority of these responses could be induced by sporozoites alone. The utility of such sub-dominant antigens in multi-antigen vaccines is under evaluation. These data show that rapidly produced, complex experimental DNA vaccines are capable of identifying multiple subdominant T cell antigens. We believe that, with appropriate automation, this approach represents a high-throughput system for discovery of vaccine subunits that cannot be identified by conventional vaccinology approaches.

981

A SYNTHETIC TLR4 AGONIST ENHANCES BI-FUNCTIONAL ANTIBODIES AND MULTI-FUNCTIONAL CD4+ T-CELL RESPONSES AGAINST A *PLASMODIUM FALCIPARUM* MULTI-STAGE PROTEIN VACCINE

Susan L. Baldwin[1], Will Roeffen[2], Susheel K. Singh[3], Regis W. Tiendrebeogo[3], Michael Christiansen[3], Elyse Beebe[1], Christopher B. Fox[1], Randall F. Howard[1], Steven G. Reed[1], Robert Sauerwein[2], **Michael Theisen**[3]

[1]Infectious Disease Research Institute, Seattle, WA, United States, [2]Radboud University Medical Center, Nijmegen, Netherlands, [3]Statens Serum Institut, Copenahgen, Denmark

The development of a multi-stage subunit vaccine targeting both transmission and disease-causing asexual blood stages of ***Plasmodium falciparum*** (Pf) is considered a focus area for malaria vaccine development. We have previously explored a combination vaccine composed of the N-terminal portion of Pf GLURP (R0) genetically fused to the C-terminal 10C fragment of Pfs48/45. Since the GMZ2 vaccine candidate is in advanced clinical development, it was of interest to investigate whether a combination of GMZ2 and Pfs48/45 can elicit an immune response against both transmission and asexual blood-stage parasites. GMZ2 is a hybrid protein consisting of conserved domains of the two asexual blood-stage antigens GLURP27-500 and MSP3212-380 aimed at mimicking pathogen components that induce premunition, a state of NAI against Pf malaria. Here, we have produced the GMZ2.6C chimera between GMZ2 and the 6 Cys-fragment (6C) of Pfs48/45 containing a major epitope for transmission blocking (TB) antibodies.

Fusion molecules containing properly folded 6C were affinity purified using a rat monoclonal antibody. A preclinical study screening of a series of adjuvant formulations (stable emulsions, liposomes, and alum) containing the immune modulators GLA, SLA, and/or QS21 plus GMZ2.6C was performed in C57BL/6 mice to identify a vaccine suitable for further human clinical studies. Those adjuvant formulations containing the synthetic TLR4 agonists GLA or SLA elicited the highest parasite-specific IFA titers, the greatest IFN-γ responses in CD4+ TH1 cells, and the highest percentage of multi-functional CD4+ T cells expressing IFN-γ and TNF in response to GMZ2.6C. GMZ2.6C combined with GLA or SLA formulated with QS21 provided the strongest TB activity four weeks following the last immunization. Furthermore, SMFA activity correlated strongly with the titer of antibodies recognizing sexual-stage parasites as measured in a gametocyte-extract ELISA. Vaccines combining GMZ2.6C with an adjuvant formulated with a synthetic TLR4 agonist show considerable promise, and scale-up manufacturing of the components is underway.

A FRAMEWORK FOR EVALUATING DIFFERENT MALARIA TRANSMISSION BLOCKING VACCINES

Anais Bompard[1], Dari F. Da[2], Sanna Rijpma[3], Serge Yerbanga[2], Thierry Lefevre[4], Sumi Biswas[5], Teun Bousema[3], Anna Cohuet[4], Thomas Churcher[1]

[1]Imperial College, London, United Kingdom, [2]IRSS/IRD, Bobo-Dioulasso, Burkina Faso, [3]Radboud University, Nijmegen, Netherlands, [4]MIVEGEC Université Montpellier, CNRS-Institut de Recherche pour le Developpement, Montpellier, France, [5]The Jenner Institute, University of Oxford, Oxford, United Kingdom

Transmission blocking vaccines (TBVs) against malaria are intended to induce immunity against the stages of the parasites which infect mosquitoes. Used within a community they protect the immediate neighbourhood of vaccinated individuals and could be a key tool for malaria elimination. Various TBV candidates are currently under evaluation. Their efficacy at reducing the number of infectious mosquitoes is dependent both on the level of parasite exposure (measured as the mean oocyst number in the control group, which may vary widely between locations) and on antibody titre (which decays with time between vaccination campaigns). This makes it important to understand the shape of the 3D relationship between efficacy, exposure and titre for each TBV candidate in order to compare them and predict their long term effectiveness in the field using early clinical trial data. Here we present a new mathematical framework for understanding this 3D relationship which takes into account the high variability generated by the membrane feeding assay. A variety of different functional forms are fit to the direct and standard membrane feeding assay data simultaneously for each TBV candidate, in order to generate smooth curves that allow the different candidates (with different titres) to be directly compared. Efficacy estimates from 4 different monoclonal antibodies (Pfs230, Pfs25, Pfs 48/45.1 and Pfs 48/45.5) are generated that allow their respective strengths and weakness in different conditions of malaria exposure and antibody titre to be identified. For example results indicate that pfs230 causes transmission blockade at a lower IgG titre than pfs25 and is more sensitive to changes in parasite exposure. This framework procures a comprehensive, easily accessible method of evaluating TBV candidates and can be combined with Phase II clinical trial data to predict their public health benefit in different field settings.

983

TRANSMISSION BLOCKING ACTIVITY OF ANTIBODIES TO *PLASMODIUM FALCIPARUM* GLURP-PF10C CHIMERIC PROTEIN FORMULATED IN DIFFERENT ADJUVANTS

Will Roeffen[1], Michael Theisen[2], Marga van de Vegte-Bolmer[1], Theo Arens[1], Gorm Anderson[3], Michael Christiansen[3], Sanjay Singh[4], Rajesh Kumar Singh[4], Robert Sauerwein[1]

[1]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands, [2]Statens Serum Institut, Copenhagen, Denmark, [3]University of Copenhagen, Copenhagen, Denmark, [4]Gennova, Pune, India

Plasmodium falciparum (Pf) is transmitted to a human host by bites of infected Anopheles mosquitoes after completion of parasite reproduction and sporogony. Clinical development of vaccines against transmission stages is critical for effective control and eradication of malaria. We generated a chimeric protein composed of ***Pf***-sub-unit fragments Glutamate-rich Protein (R0) fused in frame to a correctly folded fragment of ***Pf***s48/45 (10C). R0-10C was expressed as a recombinant protein in ***Lactococcus lactis*** and purified by affinity-chromatography. The soluble protein generated strong transmission blocking antibodies in rodents as determined in the Standard Membrane Feeding Assay (SMFA). Potency of different adjuvant/R0.10C combinations was tested in mice and rats using Freund's adjuvant, aluminium hydroxide (Alum), Alum with addition of GLA (TLR4-agonists), Stable Emulsion (SE)/GLA and AbISCO-100. All formulations produced high antibody titres recognizing the native Pfs48/45 protein in macrogametes/zygotes. Interestingly, Alum adjuvated combinations were the more potent inducers of transmission blocking antibodies. Moreover, SMFA activity correlated strongly with the titer of antibodies recognizing the native antigen as measured in a gametocyte-extract ELISA. The combined data provide a strong basis for entering the next phase of clinical grade R0-10C production and testing.

984

SCREENING FOR HIGHLY IMMUNOGENIC REGION OF PYGM75, A NOVEL TRANSMISSION-BLOCKING VACCINE CANDIDATE

Mayumi Tachibana, Motomi Torii, Moe Sudo, Takafumi Tsuboi, Tomoko Ishino

Ehime University, Matsuyama, Japan

Malaria transmission-blocking vaccines (TBVs) are intended to induce antibodies that inhibit parasite mating or further development inside mosquito midgut. Thus, TBV-immunized individuals cannot transmit malaria to mosquito vector, which could be one of good strategies to eradicate malaria. The number of candidate antigens for TBV is limited, and up to now, one leading vaccine-candidate, Pfs25, expressing on the ookinete surface is under phase I clinical trial. Thus, we urgently need to discover more vaccine targets. Previously, we reported that a novel male specific protein named PyGM75, is localized to the surface of microgametes in ***Plasmodium*** yoelii and that anti-PyGM75 antibodies had strong transmission-blocking activity. Since genomic database demonstrates that orthologue genes for PyGM75 are existed in human malaria parasites, ***Plasmodium falciparum*** and ***P. vivax***, this could be a promising candidate for TBV development. In this study, our aim is to determine which region of PyGM75 contains suitable epitopes for effective transmission-blocking antibodies. We produced 5 truncated PyGM75 recombinant proteins, excluding transmembrane domain in C-terminal, using wheat-germ cell-free expression system, and designated them as regions I, II, III, IV and V. Region-specific antibodies were collected by affinity purification from anti PyGM75full rabbit serum. Then the transmission-blocking efficiency of purified region-specific antibodies was examined by the membrane-feeding assay. As a result, specific antibodies against region V significantly reduced the numbers of oocysts on the mosquito midgut as efficiently as PyGM75full antibodies. These data suggested that the major epitopes for transmission-blocking antibodies

locate in region V, nearly C-terminal of PyGM75. This study might provide useful information for TMV development targeting to Pf or Pv orthologue of PyGM75.

985

ARE TWO MALARIA TRANSMISSION BLOCKING VACCINES BETTER THAN ONE? SAFETY AND IMMUNOGENICITY OF PFS25M- EPA/ALHYDROGEL® PLUS PFS230D1M- EPA/ ALHYDROGEL® IN MALARIA NAÏVE ADULTS

Sara A. Healy[1], Agnes Mwakingwe[1], Charles Anderson[1], Kelly Rausch[1], David Narum[1], David L. Jones[1], Nicholas MacDonald[1], Daming Zhu[1], Sarah Brockley[1], Joan Aebig[1], Olga Muratova[1], Jen CC Hume[1], Sharon Wong-Madden[1], Erin Gabriel[2], Yimin Wu[1], Patrick E. Duffy[1]

[1]National Institutes of Health, Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [2]National Institutes of Health, Biostatistical Research Branch, Rockville, MD, United States

A vaccine to interrupt malaria transmission would be a valuable tool for local elimination or eradication of this disease. Pfs25 and Pfs230, surface antigens of zygotes and ookinetes in the mosquito stage of ***Plasmodium falciparum***, are currently the lead candidates for a malaria transmission blocking vaccine. A phase 1 clinical trial to assess the safety and immunogenicity of Pfs25 has recently been completed in malaria naïve adults in the US and in malaria-exposed adults in Mali with promising results. Here, we hypothesized that a combination of Pfs25- and Pfs230-based vaccines would enhance functional activity by targeting sequential phases of parasite development in the mosquito. A dose-escalating phase 1 study has been initiated to determine safety and immunogenicity of these vaccines in US adults prior to testing in Malian adults. A total of 35 subjects have been enrolled in the US to receive two doses of Pfs25M-EPA/ Alhydrogel®, two doses of Pfs230D1M-EPA/Alhydrogel®, or simultaneous administration of two doses of Pfs25M-EPA/Alhydrogel® and Pfs230D1M-EPA/Alhydrogel® on Day 0 and on Day 28, escalating between groups. Enrollment within each group was staggered for additional safety, and subjects were enrolled into the simultaneous administration group once each individual dose had been administered and reviewed for safety. Vaccinations have been well tolerated with the majority of the reported AEs being mild (Grade 1) and the most commonly reported AE being local site injection pain. There have been few reported related Grade 2 AEs (local site injection pain, fatigue, hemoglobin decreased) and a few reported mild (Grade 1) laboratory abnormalities. No Grade 3 AEs have been reported. Specific anti-Pfs25 and anti-Pfs230 antibodies and functional activity are scheduled to be completed in the upcoming months.

986

VIRUS LIKE PARTICLES CONTAINING PFS25

Transmission-blocking malaria vaccines which target the sexual-stages of the malaria parasite in the mosquito midgut are widely considered to be an essential tool for malaria elimination. In order to achieve effective transmission-blocking activity high-titer functional antibodies are required against target antigens. We have fused Pfs25 and EGF2, the Pfs25 domain responsible for the majority of transmission blocking antibodies to three virus like particle (VLP) platforms. Genetic fusion to the Hepatitis B surface antigen (HbSAg) and the coat protein of bacteriophage AP205 as well as chemical conjugation to the coat protein of bacteriophage QBeta (Qβ) generated correctly-formed visible particles under electron microscopy (EM). Mice were immunized with a prime-boost vaccination regime using protein-in-adjuvant (Alhydrogel). The poster will present data on immunogenicity and transmission blocking activity.

987

COMPARATIVE ASSESSMENT OF VIRAL VECTORED AND PROTEIN-IN-ADJUVANT PLATFORMS FOR DELIVERY OF TRANSMISSION-BLOCKING VACCINE CANDIDATES AGAINST *PLASMODIUM FALCIPARUM*

Daria Nikolaeva[1], Iona Brian[2], Hugh T. Johnson[2], Alex Fyfe[2], Melissa C. Kapulu[2], Rebecca Dabbs[2], Darren Leneghan[2], Adrian VS Hill[2], Kazutoyo Miura[3], Carole A. Long[3], Simon J. Draper[2], Sumi Biswas[2]

Plasmodium falciparum malaria transmits infection between the human host and mosquito vector via its sexual stages. This transition between drastically different host environments exerts a bottleneck effect, making these stages particularly alluring for transmission-blocking vaccine (TBV) interventions. Indeed, in a vaccination model, antibodies to sexual-stage antigens, ingested in the mosquito blood meal, can inhibit parasite growth in the insect mid-gut as judged by functional ***ex vivo*** experiments such as the standard membrane feeding assay (SMFA). Despite the availability of promising antigenic targets and multiple vaccine delivery strategies, pre-clinical development has lagged in rationally ranking these antigens and platforms in head-to-head comparisons. In this study, the current best-characterized panel of TBV candidates, Pfs230C, Pfs48/45, Pfs28 and Pfs25, were delivered as vaccine antigens in both viral vectored and protein-in-adjuvant formulations to (1) rationally rank the candidates in both delivery platforms and (2) to compare vaccine strategies for each antigen. Recombinant chimpanzee adenovirus 63 (ChAd63) and modified vaccinia virus Ankara (MVA) were generated to express each of the above antigens. The same gene sequences were cloned into a customized plasmid for heterologous protein expression in transiently transfected HEK293 cells followed by affinity-tag purification. Groups of BALB/c mice were immunized in parallel with either a ChAd63-vectored prime followed by MVA-vectored boost or recombinant protein in Addavax™ adjuvant to generate anti-sera for determining antibody immunogenicity. Purified whole IgG from both regimes exhibited a hierarchy of inhibitory activity by SMFA, with anti-Pfs230C and anti-Pfs25 antibodies giving between 99.8 and 100% blockade in both the viral vectored and protein-in-adjuvant delivery platform. This study serves to inform future clinical development by providing the first head-to-head comparative analysis of current leading TBV candidate antigens using two different antigen delivery platforms in the same study.

988

IMMUNOGENICITY OF TWO CHIMERIC RECOMBINANT CIRCUMSPOROZOITE PROTEIN EXPRESSED IN PICHIA PASTORIS CANDIDATES FOR THE DEVELOPMENT OF A GLOBAL VACCINE AGAINST *PLASMODIUM VIVAX*

Tarsila Mendes Camargo[1], Luciana Lima[2], Karina Almeida Caramico[1], Maurício Martins Rodrigues[2], Irene da Silva Soares[1]

[1]University of Sao Paulo, Sao Paulo, Brazil, [2]Federal University of Sao Paulo, Sao Paulo, Brazil

Recently a recombinant vaccine was developed against the deadly ***Plasmodium falciparum*** based on the Circumsporozoite protein (CSP). These optimistic results boosted effort for using the CSP to develop of a vaccine against ***P. vivax***, the most widely distributed malaria worldwide. Toward that goal, we generated two chimeric recombinant proteins

based on the ***P. vivax*** CSP merging the three central repeat regions of the different allelic forms (VK210, VK247 and vivax-like). The full-length (FL) construct contains the fused repeat regions flanked by N- and C-terminal regions. The second construct contains the fused repeat regions and the C-terminal domain. Both proteins were expressed as a soluble form in the supernatant of cultures of the yeast Pichia pastoris. The recombinant proteins were purified by Ni-affinity and ion exchange chromatography, with high yield and purity confirmed by RP-HPLC. Groups of C57BL/6 mice were vaccinated with formulations containing each recombinant protein in the presence of the adjuvants Poly (I: C) or Montanide ISA-720. In all groups of vaccinated mice, high titers of IgG (>106 as measured by ELISA) against all the three allelic variants were observed after three doses. We concluded that both chimeric constructs are interesting candidates to develop a global vaccine formulation against malaria caused by ***P. vivax***.

989

A WHOLE PARASITE VACCINE AGAINST MULTIPLE STAGES IN *PLASMODIUM FALCIPARUM* LIFE CYCLE FOR INTERRUPTING MALARIA TRANSMISSION FROM THE HUMAN HOST TO THE MOSQUITO VECTOR

Tao Li[1], Sumana Chakravarty[1], Minglin Li[2], Abraham G. Eappen[1], Asha Patil[1], Yonas Abebe[1], Yun Wu[2], Adam Richman[1], B. Kim Lee Sim[2], Stephen L. Hoffman[1], Peter F. Billingsley[1]

[1]Sanaria Inc, Rockville, MD, United States, [2]Protein Potential LLC, Rockville, MD, United States

A vaccine that interrupts malaria transmission (VIMT) would be a valuable tool for malaria control and elimination. Sanaria is exploiting its capacity to manufacture ***Plasmodium falciparum*** (Pf) gametocytes under GMP conditions to develop a whole parasite (WP) vaccine against the sexual and mosquito stages (SMS) of Pf, to be used to induce antibodies that interdict parasite transmission from the human host to the mosquito vector. This PfSMS-WP-VIMT approach increases the diversity of antigens presented as compared to subunit vaccine approaches. This should improve the chance of protective coverage due to vaccine and reduce the likelihood of parasite evasion of the immune response and evolution of vaccine resistance. We have purified SMS from an ***in vitro*** cultured mixture of gametocytes, gametes, zygotes and ookinetes, and purified the parasites to significantly reduce the presence of human erythrocytes. Mice were immunized with this enriched-SMS preparation in GLA-LSQ adjuvant (Infectious Disease Research Institute, Seattle, GLA, QS21, liposomes), each receiving 5×10^6 ookinetes per dose by IM injection on days 0, 14, 36 and 57. Anti-sera were collected 2 weeks after the last immunization. The pooled sera from the immunized mice completely (100%) inhibited transmission of parasites to mosquitoes by standard membrane feeding assay (SMFA). A PfSMS-WP-VIMT will be an ideal complement to Sanaria PfSPZ Vaccine, which have shown complete protection against Pf in human volunteers at the pre-erythrocytic stage of the life cycle.

990

MALARIA INFECTION AND GAMETOCYTE CARRIAGE RATE, ASSESSED IN A COHORT OF ADULTS DURING MALARIA TRANSMISSION BLOCKING ASSAY DEVELOPMENT IN BANCOUMANA, MALI

Issaka Sagara[1], Mahamadoun H. Assadou[1], Yimin Wu[2], Merepen A. Guindo[1], Mamady Kone[1], Kourane Sissoko[1], Moussa L. Diakite[1], Sintry Sanogo[1], M'Bouye Doucoure[1], Sekouba Keita[1], Ruth Ellis[2], Sara A. Healy[2], Patrick E. Duffy[2], Ogobara Doumbo[1]

[1]Malaria Research and Training Center, Mali-NIAID ICER, USTTB, Bamako, Mali, [2]National Institutes of Health, Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

For malaria elimination/eradication, transmission blocking tools are key interventions to be integrated in existing control strategies. Epidemiological characterization of transmission reservoirs are being evaluated in targeted populations prior to the start of phase 1 or 2 transmission blocking vaccine clinical trials in order to support study designs and analysis plans. From 2011 to 2014, we have followed a dynamic cohort of adults aged from 18 to 50 years in Bancoumana, Mali, in order to improve assays that support trials of transmission blocking vaccines. After community permission, an individual informed consent was obtained for each volunteer. The study protocol and informed consent document were approved by both National Institute of Allergy and Infectious Diseases/NIH in USA and FMPOS IRB in Mali. The volunteers were screened monthly for malaria parasite and gametocyte carriage. Passive surveillance and care were also provided to volunteers in case of illness throughout the duration of the study. Malaria smears were stained using Giemsa and slides were read by two different readers to assess the presence of malaria parasites.Considering November, the month where parasite carriage peaks, the ***Plasmodium falciparum*** infection rates were: 22.58 (14/62), 25.79 (57/221), 32.94 (28/85), respectively in 2011, 2012 and 2014. Likewise, considering October, the month where the gametocyte carriage peaks, the ***gametocyte carriage*** rates were: 8.57 (6/70), 10.07 (30/298), 6.82 (6/88), respectively in 2011, 2012 and 2014. There were no statistically significant differences seen, for the ***Plasmodium falciparum*** infection rates or for the gametocyte carriage rates, between the different years of the study during the peak months of carriage. Malaria infection and gametocyte carriage rates are sufficiently prevalent in the adult population at this study area to conduct trials that assess the activity of transmission blocking vaccines.

991

EVALUATION OF PROTEIN CONJUGATE NANOPARTICLES FOR MALARIA TRANSMISSION BLOCKING VACCINES

Puthupparampil V. Scaria[1], Christopher Rowe[1], Beth Chen[1], David Jones[1], David Narum[1], Charles Anderson[1], Dariyen Carter[1], Lynn Lambert[1], Elizabeth Fischer[2], Emma Barnafo[1], Andrew Orcutt[1], Kelly Rausch[1], Sarah Brockley[1], Patrick Duffy[1]

[1]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, [2]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Hamilton, MT, United States

Antigen delivery technologies play an important role in enhancing the immunogenicity of antigens and are critical in the development of effective vaccines. The Laboratory of Malaria Immunology and Vaccinology has pioneered the use of protein-protein conjugates for product development, and specifically shown that chemical conjugation of antigens to carrier proteins creates nanoparticles that enhance the antibody response and functional activity of serum after vaccination with the malaria transmission-blocking candidate antigen Pfs25. We sought to evaluate features of our conjugated nanoparticles that might further enhance immunogenicity. In comparative studies of different carriers, conjugation of Pfs25 to Tetanus Toxoid (TT) or CRM-197 induced similar Pfs25 antibody titers when compared to our standard conjugates of Pfs25 to ExoProtein A (EPA). We also explored nanoparticle size, as this may have an effect on the uptake of the antigen complex. Pfs25-EPA conjugates were subjected to fractionation by Size Exclusion Chromatography and different molecular weight fractions were collected and characterized by DLS and electron microscopy. Mice were immunized with fractions with an average diameter of 16, 37, 52 and 73 nm, to evaluate the anti-Pfs25 antibody titer. Immunizations were carried out both formulated on Alhydrogel (AH) and in saline alone. In the absence of AH, conjugates with 16 nm average size gave the highest level of antibody titer. This was not significantly higher than the others except 73 nm. Immunogenicity in other groups did not vary with size. In the presence of AH, average titers of various groups were similar, again with no significant difference between the groups, suggesting that adsorption to the large AH particles may nullify any effects based on the size of individual conjugates. In summary, the use of different established carrier proteins, or of nanoparticles of sizes above 16 nm, did not enhance the immunogenicity of our Pfs25-EPA conjugate vaccines.

992

A NEW SET OF *PLASMODIUM FALCIPARUM* GAMETE-SURFACE REACTIVE MONOCLONALS

Lacy M. Simons[1], Beata Czesny[1], Kathleen A. McGuire[1], Benjamin A. Turturice[1], Christopher M. Wiethoff[1], Kazutoyo Miura[2], Carole A. Long[2], Kim C. Williamson[1]

[1]Loyola University Chicago, Chicago, IL, United States, [2]National Institutes of Health, Bethesda, MD, United States

Monoclonal antibodies (mAb) are valuable tools to identify vaccine candidates as well as assess the structure and function of specific epitopes. These features of mAb have been key to monitoring the production of recombinant vaccine candidates, which can be challenging to generate with native structure using heterologous expression systems. Disulfide-rich, membrane-associated antigens, such as the malaria transmission-blocking vaccine candidates, are particularly difficult to produce. To increase the current library of monoclonal antibodies against transmission-blocking targets in ***Plasmodium falciparum***, we generated a new panel of hybridomas that produce IgG molecules that recognize the surface of intact gametes. An efficient flow cytometry-based immunofluorescence assay (IFA) was developed to screen the 594 hybridomas generated from gamete-immunized mice. From this analysis, 59 hybridomas (10%) produced IgGs that recognized the gamete surface. The target antigens were further evaluated by immunoblot and immunoprecipitation. Supernatants from 39% of the 59 hybridomas recognized a protein corresponding in size to Pfs230, 7% recognized a ~48-45 kDa protein and 24% recognized a ~25 kDa protein. Forty six of the hybridoma supernatants with a range of IFA patterns and antigen reactivity profiles were tested for transmission-blocking activity in a SMFA and 8 have significant transmission-reducing activity (TRA) ($p<0.05$) at 375 µg/ml concentration. IgG from two of the supernatants with TRA recognized a 25 kDa protein and six recognized a protein corresponding in size to Pfs230. This work reconfirms the 3 established transmission-blocking vaccine candidates as immunodominant gamete surface antigens and provides an important toolset of mAb to evaluate the structure and role of specific epitopes. Moreover, the target antigens recognized by 30% of the gamete surface-reactive IgGs remain to be determined and should provide insight into the composition of the external surface of the gamete during fertilization and early zygote development in the mosquito midgut.

993

CHEMICAL PROBE PLATFORMS IDENTIFY TARGETABLE MOLECULES AND PATHWAYS THAT ARE INVOLVED IN *PLASMODIUM* GAMETOCYTE-TO-OOKINETE TRANSITION IN THE MOSQUITO

Rebecca Pastrana-Mena[1], Derrick K. Mathias[1], Jared Balaich[1], Dingyin Tao[1], Michael Delves[2], Rebecca Yee[1], Krithika Rajaram[1], Bryan Jackson[3], Jonas G. King[1], Baldwyn Torto[4], Beatrice Trucchi[5], Woody Foster[3], Luisella Verotta[5], **Rhoel R. Dinglasan**[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Imperial College of London, London, United Kingdom, [3]Ohio State University, Columbus, OH, United States, [4]ICIPE, Nairobi, Kenya, [5]University of Milan, Milan, Italy

Malaria parasite transmission cycles require an obligatory developmental stage in the ***Anopheles*** mosquito vector. In the era of global malaria elimination and eradication, there is emergent emphasis on the development of interventions that break the transmission cycle. While there are several existing antimalarials that have been shown to be effective in blocking the parasite's jump from humans to mosquitoes, to prevent parasite breakthrough resulting from overlapping resistance mechanisms, new pathways that can be targeted by small molecules (and eventually drugs) need to be identified. We used four natural product compounds, two usnic acid derivatives as well as parthenin and parthenolide as chemical probes to explore and identify drug-susceptible pathways during gametocyte-to-ookinete transition. We measured efficacy by a battery of quantitative, functional approaches including high-content fluorescence image capture, imaging flow cytometry and standard membrane feeding assay (SMFA). Two usnic acid (UA) derivatives, BT-122 and BT-37 were extremely potent in blocking ***Plasmodium falciparum*** and ***P. berghei*** zygote-to-ookinete maturation ***in vivo*** and ***in vitro***. We further modified BT-37 with a UV-crosslinking probe and identified its putative targets in zygotes by mass spectrometry. We also observed that parthenin appeared to be more effective in blocking gamete-to-zygote formation than parthenolide; although the latter compound has a more promising pharmacological profile based on Phase I clinical trials. Importantly, we noted that exposure of day 15 stage V gametocytes to parthenin (1 µg/ml) for 24 hours, followed by drug wash out and incubation in parthenin-free culture medium for another 24 hours resulted in the complete blockade of mosquito infection as measured by SMFA. Chemical derivitizations of parthenin are being explored to develop a new crosslinking probe to permit subsequent identification of its candidate target molecules in ***Plasmodium*** stage V gametocytes. We envision that these studies will illuminate the potential mechanism of action that results in the inactivation of this important transmission stage.

994

CAN INSECTICIDE RESISTANCE HINDER COMMUNITY RETENTION AND UTILIZATION OF LONG LASTING INSECTICIDAL NETS?

Samson T. Awolola[1], Adedapo Adeogun[1], Adedayo Oduola[1], Tolu Arowolo[2], Omowumi Bakare[2], Victoria Omoera[2], Bridget Awolola[3], Kazeem Adeneye[1], Jide Idris[2]

[1]Nigerian Institute of Medical Research, Lagos, Nigeria, [2]Lagos State Ministry of Health, Lagos, Nigeria, [3]Golden Race International School, Lekki, Lagos, Nigeria

The use of long-lasting insecticidal nets (LLINs) remains the mainstay for malaria prevention. Although different human behaviors and misconceptions hamper the use of LLINs, the evolution of insecticide resistance is a major threat facing malaria control. Here we investigated LLINs retention, utilization perceived efficacy and bio-efficacy in areas with and without insecticide resistance. A cross-sectional survey was carried out by interviewing household heads in six villages selected based on a priori report on insecticide resistance in the major malaria vector: ***Anopheles gambiae*** s.s. Two villages without resistance were used as control group. Clusters of houses were selected within each village for selection of households. 50 households from each village that had received either permaNet 2.0 or olyset nets in 2013 were randomly chosen from each cluster. 50 used permaNet 2.0 and 50 used olyset nets were collected after 12 months field usage for bio-efficacy tests using standard WHO procedures. A total of 400 household heads were interviewed during the study. Although there was no significant difference in the side effect reported by both groups, the retention rate of LLINs after 12 month of nets distribution was 45% for Olyset and 52% for permanent 2.0, but > 85% in the control group. 20% Olyset nets and 25% permaNet 2.0 were observed to be hanged inside houses when used as proxy indicator for usage in the resistant villages as against 75% in the control group. Bioassay mortality of field strain of Anopheles on LLINs from resistant villages was 22 -38% as against 98% in the control group. While 80-90% respondents in villages without resistance perceived the use of LLIN beneficial, > 50% in the resistant villages found LLIN ineffective with a significant number preferring the use of aerosol. The respondents have little or no knowledge of insecticide resistance but the presence of resistance correlated to net usage in the villages. To maintain the highest level of net usage, resistance tests should be an integral component of LLINs campaign program.

995

THE COMPLEMENTARY ADVANTAGE OF COMBINING SPATIAL REPELLENT TREATED SISAL DECORATIVE BASKETS WITH LONG-LASTING INSECTICIDE TREATED NETS

John M. Paliga, Marta F. Maia, Maggy Sikulu, Fredros O. Okumu, Sheila B. Ogoma

Ifakara Health Institute, Ifakara, United Republic of Tanzania

Spatial repellents (SRs) interfere with host attractiveness of mosquitoes consequently preventing bites and may substantially reduce malaria transmission. The goal of this study was to determine the advantage of combining Transfluthrin treated sisal fiber decorations with long lasting treated nets (LLINs). Efficacy of Transfluthrin treated sisal baskets against malaria vectors that bite in the early evening before humans are protected by LLINs was investigated in experimental huts. The proportion of mosquitoes in experimental huts with Transfluthrin treated sisal baskets and LLINs was compared to huts that had LLINs only using a 3 x 3 Latin square design. Treatments included: 1) untreated sisal baskets and LLINs, 2) 2.5ml Transfluthrin treated sisal baskets and LLINs and 3) 5.0ml Transfluthrin treated sisal baskets and LLINs. One male volunteer was allocated to each hut to conduct human landing catches at 1900hrs-2300hrs and retired to bed until 0600 hours. Mosquitoes were collected from exit traps, the floor and resting surfaces inside huts. Results indicate that 2.5ml and 5.0ml Transfluthrin sisal baskets reduced the proportion of Anopheles arabiensis mosquitoes inside huts by almost three quarters (Relative Rate (RR): 0.26 [0.22, 0.29]; $z = -19.00$, $p < 0.000$ and RR: - 0.31 [0.27, 0.36]; $z = -16.97$, $p < 0.000$) respectively. Both 2.5ml and 5.0ml Transfluthrin baskets treatments prevented more than three quarters of An. arabiensis mosquitoes from biting humans(RR: - 0.17 [0.11, 0.24]; $z = -9.78$, $p < 0.000$). This study shows that combining spatial repellents with LLINs inside huts significantly reduces house entry as well as biting rate of An. arabiensis. This is especially useful where residual malaria transmission occurs in the early evening before people go to bed and are under the protection of LLINs. Nevertheless, there is need to conduct further studies that determine the epidemiological impact of combining spatial repellents with LLINs.

996

WHAT IS THE CONTRIBUTION OF AESTIVATION TO THE PERSISTENCE OF *ANOPHELES* MOSQUITOES AS VECTORS FOR *PLASMODIUM FALCIPARUM* MALARIA?

Gesham Magombedze, Azra Ghani

Imperial College, London, United Kingdom

Plasmodium falciparum malaria, transmitted by the *Anopheles* mosquito, remains a leading cause of death in tropical regions of the world. Despite efforts to drive transmission down, rebound epidemics associated with the persistence of malaria vectors has remained a major impediment to local elimination. One critical area that remains poorly understood is how Anopheles populations survive long dry seasons to re-emerge following the onset of the rains. We developed a matrix population projection model of the mosquito lifecycle to explore the impact of different survival/persistence strategies on the dynamics of the mosquito population. Both longevity and hibernation (mosquito aestivation or adaptive plasticity) allow persistence of the mosquito population through the dry season and can reproduce patterns observed in field data from the Sahel region. We therefore conclude that both may be attributes for vector persistence. We use these results to demonstrate the importance of practical ecological methods to control vectors in both the dry and wet seasons if malaria transmission is to be interrupted.

997

CAREGIVER CHARACTERISTICS AND BED-NET USE AMONG UNDER-FIVE CHILDREN IN RURAL GHANA

Martha A. Abdulai[1], Frank Baiden[2], Lawrence Gyabaa Febir[1], Seeba Amenga-Etego[1], Emmanuel Mahama[1], Seth Owusu-Agyei[1]

[1]Kintampo Health Research Centre, Kintampo, Bar, Ghana, [2]Ensign College of Public Health, Kpong, Er, Ghana

In Ghana, malaria accounts for 44% of outpatient cases and 22% of mortality among children less than five years of age. Mass free distribution of insecticide-treated nets (ITNs) to caregivers with children less than 5 yrs of age is one the interventions in the control of malaria in Ghana. An improved understanding of how caregiver characteristic influences ITN can inform the design of interventions to promote ITN use. Between April and July 2013, we conducted a survey among caregivers of children aged 3-59 months who presented with fever to 18 primary care facilities in five districts in the Brong Ahafo Region of Ghana. Caregivers were asked if their children had slept under an ITN the previous night. The data was analyzed to explore how caregiver socio-demographic and socioeconomic factors influenced ITN use. A total of 4111 caregivers were interviewed. Most (95%) were females. Their average age was 29 years (SD=9). About 37% had no formal education. Presenting children were more likely to have slept under an ITN if their caregivers were least poor (P-value<0.001), had more than one child (P=0.008) and had no formal education (P<0.01). Use was lower among children whose caregivers were between 13-22 years (78.8 %,) compared to carers of 33-42 years (83.0%) (P=0.01). Where it becomes necessary, the characteristics of caregivers can be explored to improve the targeting of ITN distribution and likelihood that they will be used.

998

COMMUNITY KNOWLEDGE, VIEWS AND EXPERIENCES ON OUTDOOR MALARIA TRANSMISSION AND ITS CONTROL IN SOUTHERN TANZANIA

Irene R. Moshi

Ifakara Health Institute, Ifakara, United Republic of Tanzania

The massive applications of Indoor Residual Spraying and Insecticide Treated Nets in Africa have significantly contributed to the reduction of malaria transmission yet residual malaria transmission persists in many parts of Africa, partly driven by mosquitoes that bite people outdoors. It is essential to consider knowledge, perspectives and behavior of people in this transmission before embarking in introduction of outdoor intervention tools. We assessed views, knowledge and experiences of people in rural and peri-urban communities in southern Tanzania, regarding outdoor mosquito bites and malaria prevention. A qualitative cross sectional study was conducted in four villages within the Kilombero Valley in southern Tanzania, using semi-structured interviews and structured observation. A total of 40 participants were selected for interview and participant observations were also conducted in their households. The key areas of focus were; a) explore their knowledge, view and experience on malaria and outdoor malaria transmission b) whether malaria vectors also bite outdoors and whether transmission can also occur, c) means of protection from mosquito bites while they are outdoors performing their daily activities. Majority knew about malaria but little is known on outdoor malaria transmission. Although they regularly experienced outdoor mosquito bites, but most still believed that transmission occurs indoors from midnight. The increasing proportions of outdoor transmission pose risks to these communities and challenge to the control efforts. Malaria is a threat to people and still rated as one among the leading cause of illness. It is also still surprising to them that despite all the efforts and interventions in place, people still suffer from the disease. Majority of use bednets as indoor protection while using long sleeve cloths, smoke from burning leaves or cow dung and cloth to chase mosquitoes away while

outdoors during the evening. In conclusion, community education on outdoor malaria transmission is of vast importance before embarking into provision of outdoor interventions tools

999

ACCEPTABILITY AND PREFERENCE OF INSECTICIDE-TREATED CLOTHING FOR MALARIA PREVENTION AMONG RUBBER TAPPERS IN MYANMAR

Thae Maung Maung[1], **Alison F. Crawshaw**[2], Myat Phone Kyaw[1], Myo Win Tin[2], Nyan Sint[3], Aung Ye Naung Win[4], Olivier Celhay[5], Sarala Nicholas[6], Arantxa Roca-Feltrer[7], Muhammad Shafique[5], Jeffrey Hii[5]

[1]Department of Medical Research- Lower Yangon, Yangon, Myanmar, [2]Malaria Consortium, Yangon, Myanmar, [3]Mon State Health Department, Mawlamyaing, Myanmar, [4]Department of Medical Research-Lower Yangon, Yangon, Myanmar, [5]Malaria Consortium, Bangkok, Thailand, [6]Malaria Consortium, London, United Kingdom, [7]Malaria Consortium, Phnom Penh, Cambodia

Insecticide-treated clothing (ITC) is needed in situations where, for occupation or necessity, people (primarily mobile and migrant populations-MMP) are beyond the reach of core vector control interventions. The success of ITC as a strategy against residual transmission of malaria hinges on acceptability and adherence, as there is limited information to inform policymakers regarding targeted distribution to MMPs. 234 male and female rubber tappers in 16 rubber plantation clusters were enrolled in a two-arm (ITC versus non-treated clothing-NTC) cluster-randomized non-inferiority crossover trial to investigate preference and acceptability of ITC in Mon State, Myanmar. Clusters were randomly allocated to the order of clothing distribution. Quantitative questionnaires and 32 focus group discussions were conducted at baseline and three follow-up intervals. Preliminary findings up to the second follow-up (FU2) revealed high acceptability and adherence to ITC and NTC: in both arms, 94.3% (95% CI: 92.1-97.3*) of respondents at follow-up 1 (FU1) and 96.0% [94.0-98.6] at FU2 reported liking the clothing overall and more than 63% (range 63.0%-83.2%) reported wearing the clothing every night. One explained, "After wearing the [ITC], no other measures are needed. It is perfect." 92.0% [85.4-95.7] of respondents at FU1 and 93.0% [86.3-96.6] at FU2 reported that ITC reduced mosquito bites, compared to 92.2% [85.8-95.8] of respondents at FU1 reporting that NTC reduced mosquito bites and 89.1% [81.5-93.8] at FU2. This unexpected equivalence between the two clothing types may be explained by low mosquito biting pressure during the dry season. The results suggest that ITC could be effective for outdoor malaria prevention among nighttime workers, however, a reassessment of acceptability of ITC versus NTC is needed during the rainy season when mosquito density is higher.*CIs not adjusted

1000

MORTALITY OF *ANOPHELES GAMBIAE* AFTER EXPOSURE TO SULFADOXINE AND PYRIMETHAMINE

Aly Kodio

Malaria Research and Training Center, USTTB, Bamako, Mali

Vector control tools are major component of malaria control/elimination programmes (LLINs, IRS). In recent years, pyrethroid resistance has emerged in many countries and previously endophilic mosquitoes are turning into biting outdoors. The development of new methods of vector control is critical for malaria elimination. We investigated the mortality of ***Anopheles gambiae*** fed on different concentrations of sulfadoxine (S) and pyrimethamine (P) corresponding to physiological concentrations of 3 days (S3 = 61 µg / mL blood, P3 = 154.7 ng / ml), 7 days (S7 = 33.8 µ g / ml, P7 = 66.6 ng / ml) and 14 days (S14 = 14.2 µ g / ml, P14 = 15.7 ng / ml) after an oral dose of sulfadoxine-pyrimethamine. Adults ***Anopheles gambiae*** (N = 1000 per dose) aged at least 5 days and fasted for 24 hours were membran-fed with two solutions, one containing the drug at the above concentrations and one without drug. The number of dead mosquitoes was counted 24 hours, 48 h, and 72 h after feeding. At H24 the mortality rates of ***Anopheles gambiae*** fed on S3, S7, and S14 compared to controls were 12% (n = 455) vs. 2% (n = 487), p <0.001; ; 2% (n = 477) vs. 5% (n = 474), p >0.05; ; 1% (n = 487) vs 1% (n = 487), p >0.05. The mortality rates of mosquitoes fed on each of the pyrimethamine concentrations were similar to the mortality of those fed on controls. We show that Sulfadoxine kills ***An. gambiae*** at day 3 physiological concentrations. The implications of these observations for vector control will be discussed.

1001

THE VITAL ROLE OF VOLUNTEERS IN CONTAINING ARTEMISININ RESISTANT MALARIA: LESSONS FROM WESTERN CAMBODIA

Soy Ty Kheang

University Research Co., LLC, Bethesda, MD, United States

Evidence of artemisinin-resistance in Western Cambodia has drawn national and international attention to contain and eliminate resistant parasites. Cambodian national strategic interventions have relied heavily on health facilities and village malaria workers (VMWs) for early diagnosis and prompt treatment. The Control and Prevention of Malaria Project (CAP-Malaria) conducted a study to assess the contribution of VMWs on case management, focusing on 104 VMWs from 52 villages under 6 health facilities in Samlot District, Battambang Province. A retrospective analysis was done on data retrieved from 2009 to 2014 of malaria cases treated by health facilities and VMWs. The number of malaria cases during this time increased from 1,273 cases in 2009 to 2,127 in 2011 and has since declined to 977 in 2014. During that time, the proportion of malaria cases treated by VMWs increased from 37% in 2009 to 81% in 2014. The results clearly indicate that VMWs have made an enormous contribution to the detection and treatment of malaria in Western Cambodia where artemisinin resistance has been documented.

HOW NET CARE AND REPAIR INFLUENCE NET DURABILITY IN SÈMÈ-KPODJI COMMUNE, SOUTHERN BENIN

Andre T. Houtoukpe[1], PADNET TEAM, Luis Benavente[2], Matt Worges[2], Manzidatou Alao[1], Liscovich Ademikpo[1]

[1]MCDI, Cotonou, Benin, [2]MCDI, Silver Spring, MD, United States

In Benin, The Center for Entomologic Research of Cotonou (CREC) conducted studies on bed net durability that showed low net retention and integrity after 6 months of use in 4 communes randomly selected at national level with perennial (2communes) and seasonal (2communes) transmission. Some net manufacturers are improving fabric durability and others are increasing bio efficacy, but these strategies are more likely to succeed if communities become successfully engaged in net care and repair. The project to advance the durability of long-lasting insecticide treated bed nets (PADNET) is investigating community-based interventions that prolong the useful life of nets. PADNET used an experimental design with two intervention groups =cohorts: C1 -Behavior Change Communication (BCC) on net durability, C2 -BCC+ bed net repair kits, and C3 - a control group. The monitoring measured between a quite number, two main indicators of LLINs durability, the survivorship: Deltamethrin retention and physical integrity through proportional Holes Index pHI. Households received in Jan-Feb 2014 one of two different types of nets both deltamethrin treated and, labeled "A" and "B". In November 2014, 9 months after net distribution, we conducted a monitoring round By net type and cohort: Retention of nets "A": C1=94%, C2=92%, C3=90%. Retention of nets "B": C1=93%, C2=93%, C3=85%. Percentage of nets "A" without holes: C1=96%, C2=94%, C3=96%. Percentage of "B" nets without holes C1=91%, C2=95%, C3=97%. Average (Avg.) proportional hole index (pHI) for nets "A": C1=13.2, C2=25.4, C3=48.6. Avg. pHI for nets" B": C1= 35.1 C2=11.3, C3=51.5. After 9 months of intervention, for nets used by children, pregnant women or the remaining household

members There were statistically significant differences between the "B" brand cohorts for retention (X^2 =3.77 p= 0.004) and also in net holes found (X2 = 8.9 p= 0.012).

1003

USE OF A TABLET-BASED CAMPAIGN INFORMATION MANAGEMENT SYSTEM TO PLAN, MANAGE AND MONITOR LLIN DISTRIBUTION ON BIOKO ISLAND THROUGH MASS TOP-UP CAMPAIGN

Guillermo Garcia[1], Thomas Stabler[1], Jose Osa Osa Nfumu[1], Telesforo Eyegue Abuy[1], Restituto Mangue Avue[1], Jeremias Nzamio Mba Eyono[1], Teobaldo Babo[1], Marcos Mbulito Ivanga[1], Lucas Ondo Nze Nchama[1], Rosa Patricia Richard Ateme[1], Bruce MacLeod[2], Andrew Taylor[2], Benjamin Heasly[2], Nathan Lienhardt[2], Dianna B. Hergott[3], Luis Segura[1], Christopher Schwabe[3]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]University of Southern Maine, Portland, ME, United States, [3]Medical Care Development International, Silver Spring, MD, United States

Between December 2014 and June 2015, the Bioko Island Malaria Control Project (BIMCP) set out to distribute 150,000 LLINs to 220,000 people through a door-to-door mass top-up campaign. In order to efficiently plan, implement, and monitor the distribution, the BIMCP used a tablet-based Campaign Information Management System (CIMS) that contains a georeferenced listing and mapping of all households by community and an ODK-based form to record within each household the number of sleeping areas, the supply of existing LLINs, and the number of new LLINs provided (based on the top-up quantity calculated by the CIMS to ensure 1 LLIN per sleeping area). At the end of each distribution day, data collected by all field workers was synchronized to a main server, and then analyzed to track the quantity of LLINs distributed, determine community coverage, assess daily distributor productivity, and map the exact location of houses that had not yet received nets. Through the use of the CIMS, field teams were able to quickly locate houses that needed nets, achieve very high supply coverage, improve distribution efficiency particularly during mop-up days when targeting houses that had not yet received nets, and track in real time the cumulative coverage achieved. In addition, use of the CIMS reduced the cost and burden of paper-based data collection and processing, improved turnaround time for analysis and reporting, and improved the quality of data through incorporation of validation rules and data input constraints. Between December 2014 and March 2015, 87,633 nets had been distributed to 35,017 households. Complete coverage and distributor prodcutivity data will be presented, as well as an analysis of impact of the CIMS on distribution. It is anticipated that the CIMS will be used to plan, manage and monitor keep-up efforts planned through antenatal clinics, child immunization clinics and through annual distributions to all primary school attenders.

1004

ANTIBIOTIC RESISTANCE PATTERNS AND β-LACTAMASE IDENTIFICATION IN *E. COLI* ISOLATED FROM YOUNG CHILDREN IN RURAL LIMPOPO, SOUTH AFRICA: THE MAL-ED COHORT

Alicia DeFrancesco[1], Nicoline Tanih[2], Amidou Samie[2], Richard Guerrant[3], **Pascal Bessong**[2]

[1]Harvard University, Cambridge, MA, United States, [2]University of Venda, Thohoyandou, South Africa, [3]University of Virginia, Charlottesville, VA, United States

Antibiotic resistance is a growing problem worldwide. Mechanisms of resistance vary, and can confer resistance to multiple classes of antibiotics. In this study, we sought to characterize the antibiotic resistance profiles of E. coli isolates obtained from stool samples. These samples were collected from children between the ages of 4 to 12 months who were participants in the MAL-ED study at the South Africa research site. We isolated 87 E.coli samples (clones) from 65 individual participants, all of which were subjected to the disk diffusion assay to determine resistance. We characterized the minimum inhibitory concentration of antibiotics in a subset of strains as well as the mechanism by which these strains were resistant to β-lactam antibiotics. Our results revealed high resistance rates to co-trimoxazole (54.02%), penicillin (47.13%), and tetracycline (44.83%) in our isolates, and indicated that the β-lactamase TEM-1 is a prevalent source of β-lactam resistance. We also identified two isolates with the extended-spectrum β-lactamase CTX-M-14.

1005

ENTEROAGGREGATIVE *E. COLI* (EAEC) IN PATIENTS WITH TRAVELERS' DIARRHEA, COMMUNITY ACQUIRED DIARRHEA AND NON-DIARRHEAL GASTROINTESTINAL ILLNESS

Bradley A. Connor[1], Susan Lucak[1], Maryna Rogova[2], Olga Whyte[2]

[1]Weill Cornell Medical College, New York, NY, United States, [2]New York Center for Travel and Tropical Medicine, New York, NY, United States

Enteroaggregative E. coli (EAEC) is a diarrheal pathogen epidemiologically linked to residence in a developing country or international travel. The finding of EAEC in travelers unassociated with diarrhea has been documented and certain genetic markers seem to predict risk for developing diarrheal disease. As most U.S. clinical laboratories have historically not tested for this microbial pathogen, local epidemiology is largely unknown. With the advent of culture independent diagnostic techniques such as high throughput multiplex DNA extraction PCR technology, we have been able to identify a broad array of enteric pathogens in patients with travelers' diarrhea, community-acquired diarrhea, as well as in patients in whom stool aspirates were obtained at the time of colonoscopy for screening or for non-diarrheal gastrointestinal complaints. Stool specimens obtained between May 2014 and March 2015 were analyzed with the BioFire FilmArray multiplex platform. Of 394 stool specimens, 40 (10%) tested positive for EAEC making it the most common microbial finding of the 22 pathogens tested for with this assay. Of the 40 positive specimens, 20 (50%) were from patients who traveled, 17 (42.5%) were from patients who acquired EAEC in the community, and 3 (7.5%) were obtained from patients at the time of colonoscopy. Of the 40 specimens which tested positive for EAEC, 19 (47.5%) were positive for co-infecting pathogens. Enteropathogenic E. coli (EPEC) was the most common co-infecting pathogen and was detected in 14 (35%) of specimens positive for EAEC. Using culture independent diagnostic techniques we have found EAEC to be more common than previously recognized, especially in community acquired diarrhea and in patients in the community without diarrhea. Further studies and characterization of clinical symptoms related to EAEC are needed to more fully understand this pathogen.

1006

EVIDENCE THAT CHILDHOOD UNDERNUTRITION IS CAUSALLY RELATED TO IMPAIRED DEVELOPMENT OF THE GUT MICROBIOTA

Laura V. Blanton[1], Mark Charbonneau[1], Sathish Subramanian[1], Michael Barratt[1], Olga Ilkayeva[2], James Bain[2], Michael Muehlbauer[2], Christopher B. Newgard[2], Indi Trehan[3], Mark Manary[3], Kathryn Dewey[4], Ken Maleta[5], Per Ashorn[6], Jeffrey I. Gordon[1]

[1]Center for Genome Sciences and Systems Biology, and Center for Gut Microbiome and Nutrition Research, Washington University School of Medicine, St. Louis, MO, United States, [2]Sarah W. Stedman Nutrition and Metabolism Center and Duke Molecular Physiology Institute, Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC, United States, [3]Department of Pediatrics, Washington University School of Medicine, St. Louis, MO, United States, [4]Department of Nutrition, and Program in International and Community Nutrition, University of California, Davis, Davis, CA, United States, [5]College of Medicine, University of Malawi, Blantyre, Malawi, [6]Department for International Health, University of Tampere School of Medicine, Tampere, Finland

We have tested the hypothesis that perturbations in postnatal development of the gut microbiota are causally related to childhood undernutrition. Applying machine-learning methods (Random-Forests) to fecal bacterial 16S rRNA datasets generated from samples collected during the first three postnatal years from healthy Malawian twins, we identified age-discriminatory bacterial strains. The relative abundances of these strains were used as microbial signatures to define microbiota maturity in Malawian infants/children with varying degrees of undernutrition compared to healthy controls of the same chronological age. Infants/children with undernutrition have immature microbiota. Transplantation of 19 fecal microbiota samples from donors with healthy growth phenotypes and with varying degrees of undernutrition (defined by anthropometry) into young germ-free mice consuming a Malawian diet, and 16S rRNA analysis of recipient animals' fecal microbiota as a function of body mass gain revealed that the age-indicative taxa are growth indicative. Co-housing young coprophagic mice shortly after receiving microbiota from healthy versus undernourished infants demonstrated invasion of age/growth indicative taxa from the former into the latter's microbiota, prevention of growth faltering, and altered host metabolic phenotypes. We have established that impaired development of the gut microbiota is a factor in the pathogenesis of childhood undernutrition and that the developing microbiota is a target for disease treatment and prevention.

1007

WHAT DOES CLIMATE CHANGE MEAN FOR DIARRHEAL DISEASES?

Antarpreet Jutla[1], Rita Colwell[2]

[1]West Virginia University, Morgantown, WV, United States, [2]University of Maryland, College Park, MD, United States

Environmental association of diarrheal diseases is well documented and inspite that diseases such as cholera, Shigella, rotavirus etc continue to be a global public health threat. The uncertainty in environmental processes affecting diarrheal diseases can significantly be affected by changing climate at different temporal and spatial scales-either through amplification of hydroclimatic cycle or by enhanced variability of large scale geophysical processes. Using cholera as key signature diarrhea diseases, the goal of this study was to understand intricacies on conditions that may impact outbreak of cholera across tropical regions. Our previous research categorized cholera into two forms: epidemic (sudden and unexpected) and endemic (persistent over time). Endemic cholera in Bengal Delta region of South Asia, as an example, has a unique pattern of two seasonal peaks and are associated with asymmetric and episodic variability in river discharge. The first cholera outbreak in spring is related with intrusion of bacteria laden coastal seawater during low discharge seasons while cholera occurring in fall season is hypothesized to be associated with high river discharge that aids in cross-contamination of water resources, thus leading to second wave of disease, primary in the inland regions. On the other hand, epidemic cholera in several inland regions of Africa were strongly associated with anomalous conditions of temperature followed by precipitation. Using simulations from three global climate models (GCM) and combination of data mining technique that includes support vector regression, we will show that endemic cholera is expected to increase in the deltaic coastal regions. Several parts of Africa are prone to sudden and unexpected cholera outbreaks in the next 50 years.

1008

ASSOCIATION OF ENTERIC PATHOGENS WITH POOR GROWTH IN CHILDREN IN A RURAL DISTRICT OF PAKISTAN

Najeeha Talat Iqbal[1], Furqan Kabir[1], Tauseef Akhund[1], Shahida Mumtaz Qureshi[1], Jie Liu[2], Jennie Ma[2], Kamran Sadiq[1], Molly Hughes[2], Syed Asad Ali[1]

[1]Department of Paediatrics and Child Health, Aga Khan University, Karachi, Pakistan, [2]Division of Infectious Diseases, University of Virginia School of Medicine, Charlottesville, VA, United States

Malnutrition in early childhood has adverse effects on long term physical and cognitive growth of individuals. Environmental Enteropathy (EE), characterized by villous blunting, improper permeability and lymphocytic infiltration of small intestinal mucosa, is considered to be an important factor in the development of malnutrition. Major determinants leading to EE include poor diet, hygiene and frequent enteric infections. However, little is known about the contribution of individual enteric pathogens (both symptomatic and asymptomatic) towards the development of EE and the resulting long term growth compromise. A total of 328 children were enrolled in a prospective study in a rural district of Sindh, Pakistan to test novel biomarkers of EE. Stools specimen from the enrolled children were collected at 6 and 9 months of age, and were tested for enteric pathogens using high throughput TACMann Low Density Array (TLDA). Logistic regression was carried out to determine association of stool pathogens at 6 and 9 months of age with malnutrition and growth faltering at 12 and 18 month of age. We found that the presence of ***Campylobacter*** [1.95(1.10-3.47);p=0.02], ETEC [2.33 (1.22-4.44); p=0.01] and ***Giardia*** [1.93 (1.12-3.32); p=0.02] at 6 month stool samples was associated with higher odds of stunting at 12 month. Whereas presence of ***Campylobacter*** [1.79 (0.92-3.48);p=0.09] and Sapovirus [2.04 (0.89-4.70);p=0.09] at 9 month stool sample were associated with stunting (HAZ <-2.0) at 18 month. However, infection with ***Cryptosporidium*** [0.36 (0.18-0.71);p=0.003], ***Shigella*** [0.43 (0.19-0.99); p=0.05] and Adenovirus [0.27 (0.08-0.89);p=0.03] were associated with lower risk of stunting at 18 and 12 month respectively. Our data suggests that certain pathogens like ***Campylobacter, Giardia*** and ETEC may play a disproportionately important role in causing malnutrition. This finding needs to be confirmed by other studies of similar design.

1009

VIRULENCE GENES OF ENTEROAGGREGATIVE *ESCHERICHIA COLI* (EAEC) AND THEIR ASSOCIATION WITH DIARRHEA IN CHILDREN

David Durand[1], Carmen A. Contreras[2], Susan Mosquito[1], Joaquim Ruíz[3], Thomas G. Cleary[4], Theresa J. Ochoa[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Nacional Autónoma de México, Mexico City, Mexico, [3]ISGlobal, Barcelona Ctr. Int. Health Res., Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, [4]University of Texas School of Public Health, Houston, TX, United States

Enteroaggregative ***Escherichia coli*** (EAEC) are a group of enteric pathogens that causes acute and persistent diarrhea among children, human HIV-infected patients, and travelers to developing countries. EAEC pathogenesis involves adherence to intestinal mucosa, elaboration

of enterotoxins and cytotoxins, and induction of mucosal inflammation involving several virulence genes. However, the pathophysiology of EAEC infection is not completely understood. In this study we analyzed 18 virulence genes associated with aggregative adherence, biofilm, dispersin, and toxins in 172 well characterized EAEC strains (aggR+) isolated from stool samples of 97 children with diarrhea and 75 healthy controls, from a passive diarrhea surveillance study in peri-urban communities in Lima, Peru. 81 different genetic profiles were identified; 56 profiles among diarrhea samples and 44 among control samples. The most frequent was aggC+aatA+aap+shf+fyuA+, present in 19% of all strains. Of all genes evaluated, the most frequent were aatA (CVD 342) present in 159 strains (92%), followed by fyuA in 157 (91%) and aap in 149 (87%). When co-infection cases were not considered and EAEC strains were analyzed as a single pathogen, only pic was found more frequently in diarrhea than in control samples (64% vs. 44%, $p<0.05$), and was associated with prolonged diarrhea (≥ 7 days) (83% vs. 50%, $p<0.05$). In summary, EAEC strains isolated from children living in endemic countries are highly heterogeneous. Further studies are needed to elucidate the exact role of each virulence factor and its association with diarrheal episodes.

1010

IMPACT OF SOCIOECONOMIC STATUS ON ANTIMICROBIAL RESISTANCE PATTERNS OF ENTERIC PATHOGENS ISOLATED FROM BANGLADESHI CHILDREN WITH DIARRHEA

Randon J. Gruninger[1], Margaret Carlson[1], M.A. Malek[2], Eric J. Nelson[3], Emily Sydnor Spivak[1], A.S.G. Faruque[2], Daniel T. Leung[1]

[1]Division of Infectious Diseases, University of Utah, Salt Lake City, UT, United States, [2]Centre for Nutrition and Food Security, International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Department of Pediatrics, Stanford University, Palo Alto, CA, United States

Antimicrobial resistance is a global problem affecting countries of all income levels. Knowledge of how socioeconomic status affects antimicrobial resistance patterns could critically inform interventions targeting this problem in low-income countries. The objective of this study is to determine differences in antimicrobial resistance patterns of enteric pathogens between high- and low-income patients presenting for care at a diarrheal hospital. We used data collected from 2009 to 2012 by the diarrheal disease surveillance system at the icddr,b Dhaka Hospital to examine the relationship between socioeconomic status and antimicrobial resistance patterns of enteric pathogens. We identified children ≤5 years of age who presented with diarrhea and had ***Shigella*** spp. (***Shig***, n=163) or ***Salmonella*** spp. (***Salm***, n=43) isolated from stool culture. We found that 47% (76/163) of ***Shig*** isolates were resistant or had reduced susceptibility (R/RS) to ciprofloxacin, and 33% (14/43) of ***Salm*** isolates had R/RS to ciprofloxacin. We calculated family income as the combined reported income of the patient's father and mother. We found that children from families in the top income quartile were more likely to have ***Shig*** R/RS (27/41 61%) than those who came from families in the bottom income quartile (14/43, 31%, P = 0.002). In the smaller group with ***Salm*** infection, we also found that those in the top income quartile had higher rates of R/RS (6/12, 50%), compared with those in bottom quartile (5/17, 29%, P = 0.26), but the difference was not statistically significant. We also found that patients who lived in homes with brick walls were more likely to have ***Salm*** with R/RS (12/25, 48%) than those living in corrugated tin walls (1/14, 7%, P = 0.009). In this preliminary analysis, we show that children from wealthier families have an increased risk of antimicrobial resistant enteric bacteria. We plan to complete a multivariable regression model analysis to include factors such as presence of domestic animals, education level, and household property ownership, and anticipate that results will be available at time of presentation.

1011

ARCOBACTER SPP. VIABILITY IN STOOL SAMPLES OF HUMANS AND ANIMALS (PIGS AND CATTLE)

Rito Zerpa[1], Jorge O. Alarcon[1], Percy Lezama[2], Cesar Condori[3], Lilian Patiño[4], Edwin Correa[5]

[1]Instituto de Medicina Tropical "DA Carrion", UNMSM, Lima, Peru, [2]Frigorífico La Colonial SAC, Lima, Peru, [3]Frigorífico Yerbateros, Lima, Peru, [4]Instituto Nacional de Salud del Niño, Lima, Peru, [5]Universidad Peruana Cayetano Heredia, Lima, Peru

Arcobacter spp. is currently considered emerging zoonotic pathogen. Not found reports about its viability in fecal samples of humans and animals such as cattle and pigs. In this study we report the feasibility of ***Arcobacter spp.*** mixed in fecal samples with physiological serum (FS) in sealed plastic vials at room temperature for a period of one year. We study 100 samples positive for ***Arcobacter*** spp., 4 human fecal samples and 96 fecal samples from animals obtained from colon freshly slaughtered cattle, 48 pigs and 48 cattle. Samples were mixed with FS in plastic vials with screw cap and seal. Monthly plantings are made for the isolation of ***Arcobacter*** with filter method on Columbia blood agar plates, incubated in microaerophilic with the method of the ***Klebsiella***, the plates were sealed with rubber bands without talc obtained from latex gloves, Incubated at 28 ° C for 24 to 48 hours and phenotypically identified only. During the first 10 months the feasibility of ***Arcobacter spp***. was shown in 100% of samples; at 11 and 12 months was found feasible the organism in 95% of samples. Therefore, ***Arcobacter spp.*** viability remained one year between 95% to 100% in fecal samples mixed with FS.

1012

THE ROLE OF VIRULENCE-RELATED GENES IN THE PATHOGENESIS OF MALNUTRITION ASSOCIATED WITH ENTEROAGGREGATIVE *ESCHERICHIA COLI* INFECTION: THE MAL-ED CASE-CONTROL STUDY SITE IN FORTALEZA, CEARA, BRAZIL

Ila F. Lima[1], Alexandre Havt[1], Marjorie M. Guedes[1], Marco A. Clementino[1], Pedro H. Medeiros[1], Álvaro M. Leite[1], Alessandra F. Moura[1], Noélia L. Lima[1], Richard L. Guerrant[2], Aldo A. Lima[1]

[1]Federal University of Ceara, Fortaleza, Brazil, [2]University of Virginia, Charlottesville, VA, United States

Enteroaggregative ***Escherichia coli*** (EAEC) infection is associated with intestinal inflammation and it leads to childhood malnutrition and growth impairment. This case-control study investigated the association of EAEC virulence-related genes (VRGs), isolated or combined, with malnutrition in Brazilian children. A total of 125 children positive for EAEC, 66 malnourished (WAZ<-2) and 59 nourished (WAZ>-1), had their stool samples analyzed by five multiplex-PCRs targeting 20 DNA sequences encoding VRGs. The EAEC HilA homolog (eilA) was the most frequently detected (78%, 98/125). The presence of AAF/II fimbria assembly unit gene (aafC) was associated with malnutrition among the tested samples (P=0.01, OR=6.33, 95%CI=1.35-29.63). This association was stronger in the absence of agg4A gene (P=0.005, OR=11.60, 95%CI=1.45-92.91). The isolated absence of aafC was significantly correlated with nourished children carrying EAEC, as well as in combination with two sets of genes: 1) Presence of enteroaggregative immunoglobulin repeat protein (air, P=0.04, OR=0.45, 95%CI=0.22-0.94); and 2) Absence of air, agg3A, sigA (***Shigella*** IgA-like protease homolog), aafA and shiA (shiA-like inflammation suppressor) (P=0.02, OR=0.20, 95%CI=0.05-0.79). The presence of sigA in the absence of aafC, air, agg3A, and aafA was sufficient to associate this combination of genes with malnourished group (P=0.001, OR=10.36, 95%CI=1.28-83.63). These results are consistent with the heterogeneity of VRG profiles of EAEC in malnourished versus nourished children. The data also showed that aafC, alone or in combination with other VRGs, were associated with malnourished children and their absence were protective in nourished children.

We have previously developed a customized TaqMan Array Card (TAC) that enables sensitive and quantitative detection of a wide range of enteropathogens. The card was customized to test for 36 pathogens and controls using 57 molecular targets, including 8 G (VP7 gene) and 6 P (VP4 gene) targets for genotyping rotavirus A (RVA). In this work we deployed the technology to 4 WHO Global Rotavirus Network Laboratories and tested stool samples from RVA EIA- positive (n=396) and RVA EIA-negative (n=681) diarrheal cases collected from 11 countries. Using quantitative cutoffs for diarrhea association that we have determined previously, five countries showed rates of Norovirus GII of at least 15% with Ct values indicating that it was a probable cause of diarrhea. Three of five African countries showed rates of Cryptosporidium of at least 12% with Ct values indicating a probable cause of disease. Country-specific results included: Myanmar (n=121) revealed high rates of adenovirus 40/41 (45%) and norovirus (21%, both GI and GII); from Melbourne (n=185), the RVA negative specimens (n=108)revealed >5% rates of adenovirus, ***B. fragilis, C. difficile***, norovirus, and sapovirus; from Brazil (n=303), >10% rates of adenovirus, enteroaggregative ***E. coli***, enterovirus, and ***Giardia***. The RVA typing results from the card matched the networks' standard testing results in most cases, however the sensitivity of the TAC assay was lower than the networks' nested PCR/electrophoresis assay. Additional optimization may be necessary before these card-based genotyping assays are deployed in surveillance activities. Operationally we learned that best results required well-maintained specimens, and correlations with RVA enzyme immunoassay and genotyping were better when specimens were retested prior to the use of the card versus archived results. In summary, this technology can be deployed to yield information on a range of diarrheagenic pathogens and allow geographic comparisons throughout the world.

We are developing an anthrax vaccine intended to be distributed for public use without refrigeration, self-administered orally, durably protective following a one-week immunization regimen, safe, and well tolerated. We integrated a codon-optimized, protective antigen (PA) gene of ***Bacillus anthracis*** (plus extracellular secretion machinery) into the chromosome of the licensed, oral, live-attenuated typhoid fever vaccine Ty21a to form Ty21a-PA-01 and demonstrated excellent expression of PA. We produced the vaccine in a 10 L fermenter; foam-dried, vialed and characterized the dried product, which retained ~50% viability for 20 months at ambient temperature. Sera from immunized animals had high levels of anti-PA antibodies and anthrax lethal toxin-neutralizing activity. Immunized mice were fully protected against intranasal challenge with ~5 LD_{50}s of Sterne spores, and immunized rabbits were protected against aerosol challenge with 200 LD_{50}s of ***B. anthracis*** Ames spores with significant correlation between protection and threshold antibody titers by both ***in vitro*** assays.

STAPHYLOCOCCUS AUREUS IN BOTSWANA: PREVALENCE, RISK FACTORS, ANTIBIOTIC RESISTANCE, AND MOLECULAR EPIDEMIOLOGY

Rebecca Susann Fischer

Baylor College of Medicine, Houston, TX, United States

Carriage of ***Staphylococcus aureus***, an opportunistic pathogen of concern in Africa and elsewhere, is a primary risk factor for disease. Understanding carriage risk factors is critical for identifying who is at greatest disease risk. Individuals with HIV suffer more severe ***S. aureus*** disease and are at risk of treatment failure and death. Despite the high HIV burden, data on ***S. aureus*** carriage in southern Africa are sparse. To describe ***S. aureus*** nasal carriage in Botswana, we evaluated outpatients in and around Gaborone. From March-June, 2013, 473 adults (404 HIV+ /69 HIV- and 56 children (<18 yrs) (14 HIV+/42 HIV-), had 2 nasal swabs, 4 weeks apart, and interviews about health status and potential risk factors. Carriers (≥1 swab positive for ***S. aureus*** by standard microbiologic techniques) were classified as intermittent or persistent carriers. We tested antibiotic susceptibility to 19 antibiotics and performed ***spa***-typing of isolates. ***S. aureus*** nasal carriage prevalence was 39.3%, of which 36.0% was persistent; 3.97% had MRSA, but none persistently. Rural patients (Prevalence Ratio [PR] 2.19, p<0.01), those in households with ≥1 child (PR 1.36, p=0.06), or with viremia (>399 copies/mL) (PR 1.88, P=0.02) were more likely to be persistently carriers. HIV+ participants were less likely to have MRSA (p=0.049), while children (PR 1.9, p<0.01) and those with eczema (PR 5.72, p=0.001), asthma (PR 3.8, p=0.037), or a history of tuberculosis (PR 3.26, p=0.03) or pneumonia (PR 3.6, p=0.03) had more MRSA. Resistance was low to TMP-SXT (10.6%) but high to cloxacillin (87.0%). Persistent carriers harbored more resistance,

and 14.2% of carriers were multiply resistant. A large genotypic diversity was present, including new ***spa***-types (analysis ongoing). Rural and large households and children with HIV are high-risk ***S. aureus*** carriage groups, and adults with viremia are more likely persistent reservoirs. Children and outpatients with comorbidities or history of respiratory disease are major MRSA risk groups. Cloxacillin resitance is noteworthy, as it is the empiric antistaphylococcal. Our findings may guide indicators of carriage risk in a clinic setting.

1016

ISOLATION AND CHARACTERIZATION OF BROAD SPECTRUM BACTERIOPHAGES WITH LYTIC ACTIVITY IN *STAPHYLOCOCCUS AUREUS* METHICILLIN RESISTANT (MRSA) STRAINS

Luis A. Estrella[1], Javier Quinones[1], Mathew Henry[1], Biswajit Biswas[1], Vishwesh Mokashi[1], Ninfa Teneza-Mora[2], Eric Hall[2]

[1]Naval Medical Research Center, Frederick, MD, United States, [2]Naval Medical Research Center, Silver Spring, MD, United States

Infections by antibiotic resistant ***Staphylococcus aureus*** are common on the clinical and community settings. Bacteriophages (phages) are prokaryotic virus that infect and multiply using bacteria as a host. In an effort to develop an alternate therapy against MRSA infections, we used our collection of nosocomial and community acquired MRSA strains to identify phages with lytic activity. We have isolated and identified eight ***S. aureus*** phages from various environmental sources and tested for their lytic activity against 170 MRSA isolates. The results indicate that these phages are highly virulent and can effectively prevent the growth of 95% of the MRSA isolates. Phage K was previously isolated as a broad spectrum phage with lytic activity against ***S. aureus*** and was available from American Type Culture Collection (ATCC). Testing of phage K against our MRSA collection showed that it can prevent the growth of 81.7% of the isolates. One of our phages designated as SA0414$^{\Phi}$1 in our laboratory was further analyzed by electron microscopy. Results indicate that like phage K, SA0414$^{\Phi}$1 belongs to the ***Myoviridae*** family of virus. The eight phages were characterized via restriction endonuclease digestion and protein profile and determined to be distinct from one other and from phage K. Furthermore, minimal inhibition concentration (MIC) assay indicates that combination of the phage K, with three of our isolates have an enhanced phage-mediated lytic effect on MRSA strains. These results indicate that these phages combination can produce a cocktail preparation which can be used to treat ***S. aureus*** infections in human wounds.

1017

QUANTIFYING THE INDIRECT EFFECTS OF *HAEMOPHILUS INFLUENZAE* TYPE B VACCINATION IN CHILDREN UNDER 5 YEARS-OLD

Anwesha Majumder, Brian Wahl, Maria Knoll

Johns Hopkins University, Baltimore, MD, United States

Haemophilus influenzae type b (Hib) is a significant cause of meningitis and pneumonia among children under 5 years. A conjugate vaccine has been available since the mid-1980s, leading to disease reductions well above what would be expected from direct protection of the vaccine alone. This indicates indirect effects provide substantial protection against Hib disease. Indirect effects are rarely investigated because it requires large, cluster randomized trials; instead we used pre-post vaccine introduction studies to model the effects. Three methods to perform this analysis were identified in the literature. Wolfson, et al. described a method to compare the observed disease reduction to the reduction expected only from direct effects, resulting in an indirect effect multiplier based on vaccine coverage. Samandari, et al. estimated a multiplier for the number of people effectively protected by vaccination using vaccine coverage and incidence rates before and after vaccination. Lastly, Adegbola, et al. used average ages of infection and vaccination to calculate an alternative estimate of direct protection from vaccination. Eleven studies were used for the Wolfson and Samandari methods and three were used for the Adegbola method. All three methods suggest a robust indirect effect against Hib disease, with > 90% disease reduction predicted at only 70% coverage. Indirect effects were more influential at lower vaccine coverage, as vaccinating one child protected anywhere from two to six others. Direct effects dominated at vaccine coverages above 60%. Validating these results against an infectious disease theoretical framework and a study that examined indirect effects on an individual level confirmed the accuracy of our results. Predicted protection varied between the methods, but all demonstrated the importance of indirect effects at low vaccine coverage. These results can be used to better estimate the expected disease reduction prior to beginning a vaccine program and can impact policy decisions regarding vaccination. The models used in this analysis can also be applied to other vaccines, such as pneumococcal conjugate vaccine.

MARKED IMPROVEMENT OF *NEISSERIA MENINGITIDIS* CARRIAGE DETECTION USING PCR AFTER OVERNIGHT BROTH CULTURE WITH PARALLEL QUANTIFICATION USING FILTER PAPER SAMPLES

Olivier Manigart[1], Jacinta Okeakpu[2], Aderonke Odutola[2], Sheikh Jarju[2], Ebenezer Foster-Nyarko[2], Kanny Diallo[3], Anna Roca[2], Beate Kampmann[2], Umberto D'Alessandro[2], Martin Antonio[2], Caroline Trotter[4], James Stuart[5], Brian Greenwood[5]

[1]London School of Hygiene & Tropical Medicine and MRC, The Gambia Unit, London and Fajara, United Kingdom, [2]Medical Research Council, The Gambia Unit, Fajara, Gambia, [3]Centre pour le développement des vaccins, Bamako, Mali, [4]University of Cambridge, Cambridge, United Kingdom, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

Conventional methods used to detect pharyngeal carriage of ***Neisseria meningitidis*** (Nm) involve multiple tests which are time consuming, expensive and a source of potential errors. There is a need to develop better methods for large-scale studies. Prior to field surveys, we demonstrated on spiked samples that Todd-Hewitt broth (THB) was optimal for the overnight growth of Nm prior to direct PCR after DNA extraction. We demonstrated also that blots on filter paper can be used to detect a few copies of Nm DNA. 1000 school-children aged 10 to 18 years were sampled once with 3 different swabs and detection of carriers was compared using three different methods randomly chosen: (i) plating on Thayer-Martin selective medium and testing by conventional microbiology; all suspected Nm were confirmed by PCR. (ii) seeding in THB and, after overnight culture, processing using the same PCR (iii) compression of the swab on filter paper and processing after DNA concentration by the same PCR. Conventional microbiology detected 57 Nm carriers. Most of these (84%) were also detected after THB culture and 44% were detected on filter papers. In comparison, direct PCR after DNA extraction of THB samples detected 139 carriers, an improvement of 243%. Filter papers detected 54 carriers, 53 of which were also detected through broth culture and 25 by conventional microbiological methods. DNA copies from a first central filter paper punch varied between 1 and 25,000 DNA copies. 26 among the 57 Nm carriers (46%) detected by the conventional method were non-groupable on genogrouping and the capsule null intergenic region was identified, whereas 62% of the Nm identified from broth culture were non-groupable as were 30% obtained from filter papers. No genogroup A Nm was detected; one fifth of the capsulated bacteria were genogroup W, followed by X, B and Y in decreasing prevalence. For large-scale studies, where standardized methods are needed, simple molecular detection after broth overnight culture in an appropriate medium allows improved detection of Nm. We also demonstrated the feasibility of using filter paper followed by quantitative PCR for carriage studies.

1019

SERUM BACTERICIDAL ANTIBODIES AGAINST GROUP W *MENINGOCOCCI* IN NIGERIAN HOUSEHOLDS

Rahamatou Boukary[1], Ali Mahamane[2], Lesley Mabey[3], Daniel Holme[3], Helen Findlow[3], James Stuart[4], Maria Nascimento[4], Jean-Marc Collard[2], Caroline Trotter[5], Olivier Manigart[4], Ray Borrow[3], Brian Greenwood for the MenAfriCar Consortium[4]

[1]CERMES and Public Health England, Niamey and Manchester, Niger, [2]Centre de Recherche Médicale et Sanitaire CERMES, Niamey, Niger, [3]Public Health England, Manchester, United Kingdom, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]University of Cambridge, Cambridge, United Kingdom

The African Meningococcal Carriage Consortium (MenAfriCar) was established in 2009 to study the epidemiology of meningococcal carriage across the African meningitis belt. The Centre de Recherche Médicale et Sanitaire (CERMES) in Niger was one of the seven African research centres within MenAfriCar. In 2010 and 2011, following cross-sectional carriage surveys, households in which a carrier was identified were recruited and followed up for 6 months. In Niger, 61 households, including 466 individuals were recruited, although not all consented to a blood sample. Blood samples collected at the first household visit were tested for serum bactericidal antibody (SBA) activity to group W (strain M01 240070; W:NT:P1.18-1,3 cc22). A validated complement-mediated SBA assay, utilising baby rabbit complement was used. Serum from 330 individuals was tested for SBA activity against group W. SBA titres were analysed overall, and by carrier status. The overall SBA geometric mean titre (GMT) was 18 (95% CI 13,24) and GMTs did not vary significantly by age or sex. There were 31 index carriers of a group W meningococcus; GMTs in this group were significantly higher (350, 95% CI 138, 890) than in individuals who were not carriers (13, 95% CI 10,18; p<0.001) at the time the blood sample was taken. Individuals in the same household as group W index carriers, but who were not carriers themselves, had similar SBA titres to individuals in households without a group W carrier. Fifty-three individuals who were not index carriers acquired group W meningococci during the 6 month follow-up period; GMTs at baseline were modest in this group (15, 95% CI 7,35) but not significantly different to individuals who did not carry group W at any time (13, 95% CI 9, 18). Thus, while we can observe a clear immunological response to group W carriage, we are not able to elucidate a correlate of protection against group W carriage.

1020

MENINGOCOCCAL CARRIAGE IN NORTHERN GHANA

Isaac Osei on behalf of the MenAfriCar Consortium

Navrongo Health Research Centre and London School of Hygiene & Tropical Medicine, Navrongo and London, Ghana

The African Meningococcal Carriage Consortium (MenAfriCar) was established in 2009 to study the epidemiology of meningococcal carriage across the African meningitis belt. The Navrongo Health Research Centre in northern Ghana was one of the seven African research centres within MenAfriCar. Three cross-sectional carriage studies were undertaken in 2010, 2011 and 2012, in both urban and rural areas, with a target sample of 1000 participants in each area and survey. A total of 5209 oropharyngeal swabs were collected and tested for the presence of meningococci. The overall carriage prevalence of ***Neisseria meningitidis*** was 3.7%, but prevalence increased with each survey. Most meningococci (79%) were genogroup W. Factors associated with carriage included age, with the highest prevalence in 5-14 year olds, and sex with males having a higher prevalence of carriage than females. In 2010, blood samples were collected from a sub-set of participants to allow sero-epidemiological investigations. The seroprevalence of meningococcal serogroup-A specific IgG antibodies was determined by ELISA in 765 age-stratified samples. The overall geometric mean concentration (GMC) was 9.09 (95% CI 8.29, 9.97) and 87% of participants had antibody concentrations above 2ug/ml. Antibody concentrations were higher in the urban compared to rural area and increased with increasing age. In 2011 and 2012, households in which a carrier was identified were recruited and followed up for 6 months. Twenty-three households and 167 individuals were studied and the patterns of transmission among these households will be described. Studies of carriage, such as this, are central to understanding the epidemiology of meningococcal infection in the African meningitis belt.

DOES *STAPHYLOCOCCUS AUREUS* NASAL COLONIZATION INDUCE T-CELL AND INFLAMMATORY CYTOKINE RESPONSES? EVIDENCE FROM MILITARY TRAINEES AT HIGH-RISK FOR *S. AUREUS* COLONIZATION AND DISEASE

Danett K. Bishop[1], Lauren H. Nagy[1], Katrina Crawford[2], Eugene V. Millar[2], Jeffrey B. Lanier[3], Carey D. Schlett[2], Natasha Law[3], Nimfa Teneza-Mora[1], Michael W. Ellis[2], Eric R. Hall[1]

[1]Naval Medical Research Center, Silver Spring, MD, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]Martin Army Community Hospital, Fort Benning, GA, United States

Staphylococcus aureus is a major cause of skin and soft tissue infection (SSTI). Colonization of the anterior nares, the reservoir for ***S. aureus***, is thought to be a risk factor for SSTI. Numerous studies have shown that both humoral and cellular immunity are involved in the host response to SSTI. By contrast, few studies have evaluated the host immune response to colonization among individuals without SSTI, and none to our knowledge have evaluated the impact of colonization on distributions of T-cell subsets and pro-inflammatory cytokines in serum. From 4/2013-12/2014, we conducted a case-control study of SSTI among US Army Infantry trainees, a group known to be at increased risk for ***S. aureus*** colonization and disease. Trainees presenting to the medical clinic for non-infectious conditions (e.g. musculo-skeletal injury) were recruited as healthy controls. A nasal swab and blood sample was collected at the time of enrollment. Swabs were processed by standard methods to assess colonization status. T-cell populations in peripheral blood were assessed by flow cytometry. Serum concentrations of pro-inflammatory cytokines were assessed by 25-plex Luminex panel. Forty-seven participants without SSTI were included in the analysis. Of these, 20 (42.5%) were colonized with ***S. aureus***. The proportion of $\gamma\delta$ T-cells was higher among colonized as compared to non-colonized individuals ($p<0.01$). Moreover, proportions of Th1-cells ($p<0.05$) and $\gamma\delta$ T-cells producing IFN-γ ($p<0.01$) were higher among colonized vs non-colonized individuals. There were no differences between groups with respect to proportions of IL-17 producing T-cells ($p=0.30$). Colonized individuals also had higher serum concentrations of pro-inflammatory cytokines, specifically IFN-γ ($p=0.004$), MCP-1 ($p=0.01$), IL-1RA ($p=0.02$), Eotaxin ($p=0.03$), and MIP-1α ($p=0.05$). Concentrations of IL-17 did not differ between groups ($p=0.14$). In conclusion, these findings suggest that nasal acquisition of ***S. aureus*** elicits a systemic immune response, namely an induction of pro-inflammatory cytokines and proliferation of Th1 and IFNγ-secreting cells.

1022

GLOBAL ELIMINATION OF LEPROSY BY 2020: ARE WE ON TRACK?

David J. Blok, Sake J. de Vlas, Jan Hendrik Richardus

Erasmus MC, Rotterdam, Netherlands

Annually more than 200,000 new leprosy cases are registered. This number has been fairly stable in the past 8 years. WHO has set a target to eliminate leprosy globally by 2020.The aim of this study is to investigate whether this is feasible given the current control strategy. We focus on three endemic countries, India, Brazil and Indonesia, which together account for nearly 80% of all leprosy cases. We used the existing individual-based model SIMCOLEP to predict future trends of leprosy incidence given the current control strategy in each country. SIMCOLEP simulates life histories of individuals, structured in households, and the

natural history of infection with M. leprae. Current control consists of passive case detection, some active case detection, and multidrug therapy (MDT). Also, BCG vaccination of infants against tuberculosis is known to be effective against leprosy. Predictions of leprosy incidence were made for each country as a whole and for one high-endemic region in each country: Chhattisgarh (India), Para (Brazil) and Madura (Indonesia). Data for model quantification came from the National Leprosy Elimination Program (NLEP, India), SINAN database (Brazil) and the Netherlands Leprosy Relief (Indonesia). Our projections of future leprosy incidence all show a downward trend. In 2020, the country-level leprosy incidence has decreased to 6, 7 and 4 per 100,000 in India, Brazil and Indonesia, respectively, meeting the elimination target of less than 10 per 100,000. However, elimination may not be achieved in the high-endemic regions. The leprosy incidence in 2020 is predicted to be 17, 19 and 24 per 100,000 in Chhattisgarh, Para and Madura, respectively. Although it seems that country-level elimination is reached by 2020, leprosy is likely to remain a problem in the high endemic regions, which account for most of the cases in a country. We therefore conclude that elimination may only be reached by 2020 with additional control measures.

1023

CO-INFECTION OF GONORRHEA AND CHLAMYDIA AMONG PATIENTS ENROLLED WITHIN A STI SURVEILLANCE STUDY IN GHANA

Naiki Puplampu[1], Eric Behene[1], Helena Dela[1], Shirley Nimo-Paintsil[1], Kwesi Addo[2], Edward Owusu Nyarko[3], Cynthia Kwakye[4], Nehkonti Adams[1]

[1]Naval Medical Research Unit - 3, Ghana Detachment, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [3]Ghana Armed Forces Public Health Division, Accra, Ghana, [4]Ghana Health Service, Accra, Ghana

Gonorrhea and chlamydia are the most prevalent bacterial sexually transmitted infections (STI) and they often coexist. Common manifestations of these diseases include urethritis in men and cervicitis in females. This study provides data on co-infections collected during June 2012 and November 2014 in five health facilities in Accra and Sekondi/Takoradi. Eligible patients presenting with dysuria and or genital discharge were consented and enrolled. After enrolment, urine samples were obtained and tested by nucleic acid amplification test (NAAT) for ***Neisseria gonorrhea*** and ***Chlamyia trachomatis***. Gram stain and culture for ***N. gonorrhea*** was also performed. A total of 679 specimens were tested. Males and females enrolled were 313 and 361 respectively One hundred and seventy-two cases (25.3%) were positive for gonorrhea and 72 (10.6%) for chlamydia. There were 18 co-infections (2.7%). Among patients who tested positive for gonorrhea, 10.4% were positive for chlamydia. Males who tested positive for gonorrhea were 39.3% and females 13.6%. Only 16 males were co-infected, however, for those between 25 and 31 years of age, 9 of 57 (15.7%) with ***N. gonorrhea*** also tested positive for chlamydia. Co-infection among females in the same group was 2 of 22 (9.1%). For patients who tested positive for chlamydia, 25% of them tested positive for gonorrhea. Symptoms seen in co-infections were as follows; dysuria (61.1%), genital discharge (83.3%), malodorous urine (16.7%), genital ulcers (5.6%) and genital warts (5.6%). Co-infection rates were higher among males than females. Males who tested positive for chlamydia were 13.7% and females 8.0%. Gonorrhea infection rates for chlamydia positive cases were higher in males (37.2 %) than in females (6.9%). The majority of patients with co-infections presented with genital discharge. Genital ulcers and warts observed in co-infected patients could be indicative of STIs caused by viral and other bacterial pathogens which may warrant further surveillance of other STIs in Ghana.

ISOLATION OF BACTERIOPHAGES SPECIFIC FOR *ACINETOBACTER BAUMANNII*, A PROSPECTIVE ALTERNATIVE THERAPY AGAINST MULTI-DRUG RESISTANT BACTERIA

Nathanael D. Reynolds[1], Paul Rios[1], Ricardo Abadie[1], Claudio Rocha[1], Mark P. Simons[1], Miguel Lopez[1], Adriana Meza[1], El Mohammady Hanan[2], James M. Regeimbal[3], Luis A. Estrella[3], Matthew S. Henry[3], Rae Heitkamp[4], Amanda Roth[4], Amy Zale[4], Biswajit Biswas[3], Nimfa C. Teneza-Mora[3], Eric R. Hall[3]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]U.S. Naval Medical Research Unit - 3, Cairo, Egypt, [3]U.S. Naval Medical Research Center, Silver Spring, MD, United States, [4]Walter Reed Army Institute of Research, Silver Spring, MD, United States

Antimicrobial resistant organisms complicate the successful treatment of wound infections and are a threat to both military and civilian populations. The U.S. Naval Medical Research Center (NMRC) along with the Naval Medical Research Unit No. 6 (NAMRU-6), Peru and NAMRU-3, Egypt, has initiated development of phage therapy as an alternative therapeutic strategy against multi-drug resistant bacterial infections. To provide proof of concept and to generate a viable bacteriophage therapy, we focused on isolation of phage specific to ***Acinetobacter baumannii*** due to the recent mergence of carbapenemase expression and multi-drug resistance that is becoming commonplace in wound and nosocomial infections. Because of capsular phase variation and the highly variable surface phenotype associated with ***A. baumannii*** strains, it is important to generate a robust library of different ***A. baumannii*** phage specific to different receptors that can be compounded into an effective therapeutic cocktail. To generate the phage library, environmental water samples were collected from different sites in Frederick, Maryland, Lima and Iquitos, Peru, and Cairo, Egypt. Using a standardized diversity set of ***A. baumannii*** isolates, we screened each of the water samples for the presence of ***A. baumannii***-specific phage with phage isolates obtained from 9% of water sources tested in Frederick, 50% in Lima, 31% in Iquitos, and approximately 50% in Cairo. All purified phage isolates were sent to NMRC for further characterization and sequencing. Once completely characterized, a cocktail of broad spectrum phage against a large variety of ***A. baumannii*** strains will be generated for evaluation in pre-clinical trials. These preliminary findings demonstrate high success rates of identifying bacteriophage from common environmental water sources providing initial feasibility to generate phage cocktails for alternative therapies against drug-resistant bacteria.

1025

ZOONOTIC CESTODES OF WILD AND DOMESTIC CANIDS IN SOUTHERN KAZAKHSTAN

Aida Abdybekova[1], Ahmetzhan Sultanov[1], Aziza Zhumabayeva[1], Zhanna Shapiyeva[2], Daniyar Toksanbayev[3], Christine M. Budke[4], Paul R. Torgerson[5]

[1]Kazakh State Veterinary Research Institute, Almaty, Kazakhstan, [2]Scientific Practical Center for Sanitary Epidemiological Expertise and Monitoring, Almaty, Kazakhstan, [3]Kazakhstan National Scientific Center for Surgery, Almaty, Kazakhstan, [4]Texas A&M University, College Station, TX, United States, [5]University of Zurich, Zurich, Switzerland

Cystic echinococcosis (CE) and alveolar echinococcosis (AE) caused by the zoonotic cestodes ***Echinococcus granulosus*** and ***E. multilocularis***, respectively, are considered neglected tropical diseases by the World Health Organization and other international entities. Both ***Echinococcus*** species primarily use domestic and/or wild canids as definitive hosts. Humans are at risk of becoming infected via the ingestion of parasite eggs shed in the feces of an infected definitive host. In order to obtain information on the frequency of infection in wild and domestic canids, field surveys were conducted from 2008-2012 in 3 regions (Almaty, Zhambyl, and South Kazakhstan) of southern Kazakhstan. In total, 41 wolves (***Canis lupus***), 128 red foxes (***Vulpes vulpes***), 60 jackals (***Canis aureus***), 39 corsac foxes (***Vulpes corsac***), and 101 stray dogs were evaluated via necropsy

of the intestinal tract. ***E. granulosus*** was identified in 6.9% (7/101) of dogs and 19.5% (8/41) of wolves while ***E. multilocularis*** was found in 4.7% (6/128) of red foxes, 2.6% (1/39) of corsac foxes, and 2.0% (2/101) of dogs. Neither parasite was found in jackals. Findings from this study indicate that there is an ongoing zoonotic risk from both ***E. granulosus*** and ***E. multilocularis*** for the population of southern Kazakhstan.

THE EXPRESSION AND POSSIBLE ROLE OF TH1/TH2/TH9/TH17/TREG TRANSCRIPTION FACTORS IN LIVER TISSUES FROM HEPATIC ALVEOLAR ECHINOCOCCOSIS PATIENTS

Heng Zhang, Tuerhongjiang Tuxun, Shadike Apaer, Hai-zhang Ma, Amina Aierken, Ren-yong Lin, Hao Wen

First Affiliated Hospital of Xinjiang Medical University, Urumqi, China

Human alveolar echinococcosis continues to be a major public health issue in China. The role and expression profile of T helper cell subsets in the hepatic lesion in hepatic alveolar echinococcosis patients are still not quite clear. In this study, we are aiming to investigate the expression and effect of T-bet / GATA-3 and Foxp3 / RORrt in liver tissue from alveolar echinococcosis patients, and then reflect the function and effect of the cell Th1/Th2 and Th17/Treg in AE. All liver tissues were selected from 14 patients with hepatic AE who were treated and divided into 3 groups: lesion tissues (L group), para-lesion tissues (P group) and liver tissues (N group). The mRNA expression of T-bet / GATA-3 and Foxp3 / RORrt were measured by real-time PCR (qRT-PCR). For statistical analysis,interquartile test and Spearman correlation were used. Both T-bet and GATA3 mRNA levels were significantly higher in group L than those in group N. There was no significant difference in those between group L and group P. However, there was significant difference in those between group P and group N. While, the expression of GATA-3 and T-bet mRNA were positively correlated in different liver tissue. As for the Foxp3 and RORrt mRNA expressions, the hepatic Foxp3 levels were significantly higher in group L than that in group P and group N. However, there was no significant difference in those between group P and group N. Meanwhile, RORγt mRNA expression in group P were also significantly higher than that in group N. Significant difference was found between group L and group N. The expression of RORγt and Foxp3 mRNA were positively correlated in different liver tissues. Th9 related transcription factor PU.1 mRNA levels elevated in group L and group P with statistical significance when compared to group N. The increased expression of Th1/Th2/Th9/Th17/Treg transcription factors in different hepatic tissues from human alveolar echinococcosis may indicate a close involvement of T cell subsets during the process of parasitic granuloma formation in alveolar echinococcosis patients.

1027

THE POSSIBLE ROLE OF TLR2 AND TLR4 WITH THEIR RELATED TRANSCRIPTION FACTORS/CYTOKINES IN INTRAPERITONEALLY INFECTED MICE WITH *ECHINOCOCCUS MULTILOCULARIS*

Shadike Apaer, Tuerhongjiang Tuxun, Heng Zhang, Hai-Zhang Ma, Amina Aierken, Ren-Yong Lin, Hao Wen

First Affiliated Hospital of Xinjiang Medical University, Urumqi, China

The crosstalk between host and parasite ***Echinococcus.multilocularis (E.m)***, which causes alveolar echinococcosis (AE), is highlighted by the immune response. Toll-like receptor (TLR) 2 and 4 are known to play crucial role in other parasitic infections. Therefore, in this study, we explored the expressions of TLR2 and TLR4 with related cytokines in ***E.m*** infected mices. 24 subjects were enrolled and divided into three groups: ***E.m*** infection with CMC (***E.m*** + CMC, n=8) group, ***E.m*** infection with albendazole (***E.m*** + ABZ, n=8) group, and controls with CMC (C + CMC, n=8) group. The splenic cells and peritoneal exudates cells were prepared and real-time fluorescent quantitative reverse-transcription polymerase chain reaction (qRT-PCR) and enzyme linked immune-sorbent assay (ELISA) analyses were carried out to detect the levels of TLR2, TLR4 and a series of transcription factors and cytokines. The mRNA expression levels of TLR2 and TLR4 and relative transcription factors and cytokines including GATA-3 , IFN-γ and IL-10 in splenocytes were significantly increased in ***E.m***+CMC group comparing with both ***E.m***+ABZ and C+CMC group. Simultaneously, T-bet mRNA expressions were elevated in ***E.m***+ABZ and C+CMC group compared to ***E.m***+CMC group. In addition, T-bet / GATA3 ratios were elevated in ***E.m***+ABZ group when comparing with ***E.m***+CMC group and were higher in C+CMC group than those in ***E.m***+CMC group. The concentration levels of IFN-γ, IL-10, and IL-5 in abdominal exudates cells as well as splenocyte supernatants were extremely lower, interestingly, they were found to be significantly elevated after stimulating with Con A for 36h, resulting in higher concentrations in ***E.m***+CMC group comparing with both ***E.m***+ABZ and C+CMC group. TLR2 mRNA expressions in splenic cells had a positive correlation with splenocyte IL-10 concentration levels. The present study provided evidence on the possible role of TLR2 in the process of immune tolerance during ***E.m*** infection. Further, our study also suggests that albendazole treatment might reverse the immune tolerance situation and improve parasite clearance process.

1028

DEVELOPMENT OF A SIMPLE IDENTIFICATION OF HUMAN *TAENIA* SPECIES BY USING MULTIPLEX LAMP AND DOT-ELISA

Agathe Nkouawa, Akira Ito, Yasuhito Sako

Asahikawa Medical University, Asahikawa, Japan

Differential detection of ***Taenia solium*** from ***T. saginata*** and ***T. asiatica*** is a key strategy for the control and prevention of human cysticercosis in endemic areas. For this purpose, we have recently developed a sensitive and specific LAMP assay targeting the mitochondrial cytochrome c oxidase subunit 1 (cox1) gene and have showed its usefulness. However, to achieve differential identification, three reaction mixtures containing ***T. solium***-, ***T. saginata***- and ***T. asiatica***-primer set separately per one specimen must be set up, which is complicated and time-consuming. In this study, we developed a simple identification of human Taenia species by using multiplex LAMP (mLAMP) and dot-ELISA. FIP primers of ***T. solium***, ***T. saginata*** and ***T. asiatica*** labeled with FITC, DIG and TAMRA, respectively, and biotin labeled-BIP primers were used in mLAMP. mLAMP assay succeeded in specific amplification of each respective target gene in single tube. Furthermore, LAMP product from each species was easily distinguished by using dot-ELISA with antibody specific for FITC, DIG or TAMRA. This method specifically identified cysticerci, proglottids and eggs of Taenia from endemic areas. mLAMP in conjunction with dot-ELISA will make real-time identification of human ***Taenia*** species in the field more practicable.

FIRST TIME SEROLOGICAL EVIDENCE OF *TAENIA SOLIUM* LARVAL INFECTION IN ORANG ASLI COMMUNITIES - THE ABORIGINES FROM MALAYSIA

Priyadarshi Soumyaranjan Sahu[1], Yvonne A. Lim[2], Romano Ngui[2], Rohela Mahmud[2]

[1]International Medical University, Kuala Lumpur, Malaysia, [2]University of Malaya, Kuala Lumpur, Malaysia

Till today Malaysia is being presumed to be non-endemic for ***Taenia solium*** cysticercosis. Being a Muslim majority country, pork consumption by Muslims is prohibited. While considering non-Muslim communities in Malaysia who are pork eaters, possibility of its underlying prevalence is a matter of concern. Though there may be strict regulations in pig farming practice particularly in Peninsular Malaysia, however, the true estimate of the underlying prevalence, and risk factors of its transmission in this country remains unexplored. We initiated this study to understand the scenario on the native populations of Malaysia; 'Orang Asli' communities are known as aborigines of Malaysia who are underprivileged and also well

known to be carriers of many different parasitic infections. But the possible burden of ***T. solium*** cysticercosis was never explored in these aborigines. By using a commercial IgG-ELISA kit, the sera from a total of 522 randomly chosen Orang Asli individuals including either genders (age range between 1 to 68 years) were screened for ***T. solium*** larvae specific antibodies. A total of 3.8% subjects were diagnosed positive for anti-Cysticercus antibodies (95% CI: 2.5% - 5.8%; $\chi 2=17.8$; $p<0.05$). The prevalence of antibody positivity ranged between 0.9% (Semelai subgroup) to 9.9% (Orang Kuala subgroup). Statistical significance was observed between the low income status of family and seropositivity for cysticercosis ($p=0.041$) based on univariate analysis. Study findings indicated exposure to ***T. solium*** larval infection might have occurred in the aborigine communities in Peninsular Malaysia. For the first time our study findings could highlight that cysticercosis is an under recognized public health problem in Malaysia. Its actual prevalence can be estimated if a larger population is targeted in this country including both Peninsular and East Malaysia. Also a public health surveillance program must verify further on the risk factors for this neglected parasitic disease transmission either among the natives or imported from neighbouring endemic countries of Southeast Asia.

MOLECULAR DETECTION OF TAENIID CESTODE EGGS IN DUNG BEETLES FROM ENDEMIC AREA TO PORCINE CYSTICERCOSIS

Ana M. Vargas-Calla[1], Luis A. Gomez-Puerta[1], Monica Pajuelo[2], Maria T. Lopez-Urbina[1], Hector H. Garcia[2], Armando E. Gonzalez[1]

[1]Universidad Nacional Mayor de San Marcos, Lima, Peru, [2]Universidad Cayetano Heredia, Lima, Peru

The complex taeniasis/cysticercosis by ***Taenia solium*** is an important zoonotic disease mainly in development countries. The adult ***T. solium*** tapeworm localizes in the small intestine of humans, the definitive host. The eggs of ***T. solium*** are eliminated into gravid proglottids with the faeces, and then they are ingested by pigs, the intermediate host. Dispersal of cestode eggs of the Taeniidae family can occur in various manners, resulting in different ways in which they can be ingested by the corresponding host. The aim of this study was to confirm molecularly the presence of ***T. solium*** eggs in dung beetles collected from environmental, to confirm they are potential vectors of porcine cysticercosis. In this study, dung beetles were collected from 3 endemic villages of porcine cysticercosis in Piura, Peru. Dung beetles were collected in 41 different geographic point. For molecular study, we used a pool sample from each geographic point, each pool contained between 3 to 10 beetles. The DNA of the 41 pools was extracted using the FastDNA spin kit for soil DNA extraction according manufacture protocol. Then, mitochondrial cytochrome c oxidase subunit I (COXI) gene was amplified to identify occurrence of tapeworm. Finally, the positive samples were sequenced to know the species of tapeworm. Fifteen positive samples were obtained to PCR amplification. Two pools were compatible to ***T. solium*** and 3 pools were compatible to ***T. hydatigena***. Our findings suggest that the dung beetles likely to play a role in the dynamic of transmission of cysticercosis by ***T. solium*** and ***T. hydatigena*** in the endemic areas.

1031

GENERATION AND CHARACTERIZATION OF A PROLIFERATING *TAENIA CRASSICEPS* CELL LINE

Jaeson S. Calla[1], Miguel A. Orrego[1], Hector H. Garcia[2], Siddhartha Mahanty[3], Cristina Guerra-Giraldez[4], Theodore E. Nash[3], Cysticercosis Working Group in Peru[5]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto Nacional de Ciencias Neurologicas and Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [4]Facultad de Ciencias y Filosofia. Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Other, Lima, Peru

Neurocysticercosis, caused by the larval stage of the flatworm ***Taenia solium***, is the most frequent helminth brain infection in humans and the most common cause of adult onset seizures worldwide. ***Taenia crassiceps***, a closely related tapeworm, is a useful model for ***T. solium*** infection and has the advantage of supplying large numbers of larval cysts that multiply in mice following passage of cultivated cysts. We used ***T. crassiceps*** larvae to isolate, identify and grow neoblasts, the only platyhelminth-specific proliferating cells. Neoblasts have been studied in free-living planaria and later in cestodes like Echinococus. To isolate neoblasts, ***T. crassiceps*** (ORF strain) larval cysts were harvested from female BALB/C mice 8-10 weeks after intraperitoneal inoculation. These were washed, physically disrupted and placed at 27ºC in RPMI 1640 (with fetal calf serum, amino acids, mercaptoethanol and antibiotics) for one week before digestion with 1% trypsin and agitation. After cultivation and further growth, individual cells were isolated by limiting dilution and allowed to proliferate. Growth was enhanced by culture under a 5% N2 atmosphere and by addition of Concanavalin A, gonadotropin or b-estradiol, each at 1 µg/ml. Proliferation was confirmed by BrdU uptake, observed by immunofluorescence and immunohistochemistry assays detecting incorporated BrdU. Cells were maintained in serial passage over several months and grew at doubling time of 4.5 hr. These cells contained ***T. crassiceps*** antigens as determined by immunoblots and reactivity only against ***T. crassiceps*** infected mouse serum. Cells were cryopreserved using RPMI with 10% DMSO or 10% glycerol with full recovery of viable neoblasts. Since these are the only cells proliferating in cestodes and they show ***T. crassiceps*** antigens, they fulfill the definition of neoblasts. The successful isolation and ***in vitro*** culture of ***T. crassiceps*** neoblasts as a stable cell line with remarkable proliferating capacity allows for systematic studies on the development and biology of a helminthic parasite, including the search for novel drugs, and provides the basis for similar assays in ***T. solium***.

1032

DESCRIPTION AND PREDICTORS OF NEUROCYSTICERCOSIS CYST EVOLUTION AND RESOLUTION: A CYST-LEVEL ANALYSIS

Michelle A. Montgomery[1], Katarzyna Wyka[1], Arturo Carpio[2], Denise Leslie[3], Howard Andrews[4], Emilia Bagiella[4], W. Allen Hauser[5], Elizabeth A. Kelvin[1]

[1]CUNY School of Public Health, New York, NY, United States, [2]School of Medicine, University of Cuenca, Cuenca, Ecuador, [3]MRI Diagnostics, Valhalla, NY, United States, [4]Department of Biostatistics, Mailman School of Public Health, Columbia University, New York, NY, United States, [5]Gertrude H. Sergievsky Center, College of Physicians and Surgeons, Columbia University, New York, NY, United States

Neurocysticercosis (NC) is an infection of the central nervous system by the larval stage of the pork tapeworm. In the human brain, NC cysts evolve through three distinct phases, the active phase in which the parasite is viable, the transitional phase in which the parasite is degenerating and is targeted by the host's immune system, and in some cases the parasite leaves a calcified cyst instead of resolving completely. Almost all research on NC describes the cysts at the patient level, presenting summaries of the cyst burden within patients (e.g. number or presence of cysts in a

phase or location). To date, these analyses have been unsatisfactory in explaining the different patterns of cyst evolution between patients. In this study we disaggregated data from the patient to the cyst level for 62 patients who had 1 or 2 NC cysts in the active or transitional phase who were participating in a randomized clinical trial of albendazole treatment in Ecuador 2001-2003. We describe the evolution of 73 cysts from baseline to months 1, 6 and 12 through serial imaging and look at possible predictors of complete cyst resolution, cyst calcification and phase trends over time. By month 12, 59.4% of the cysts had completely resolved. Cysts in the parenchymal region of the brain and those in the transitional phase at baseline were more likely to have resolved completely by 12 months. Cysts in patients who developed new cysts (either due to new infection or cysts becoming newly apparent on imaging due to decreased inflammation) were also more likely to have resolved by 12 months. Age and gender, presence of calcified cysts at baseline, number of cysts at baseline and treatment group had no impact on cyst resolution by month 12. The associations were similar after adjusting for covariates and taking clustering into account using generalized estimating equations. Host immune response to cysticercosis varies widely across individuals, as well as between different cysts within the same individual. Understanding the patterns and predictors of cyst evolution within as well as between individuals may help us better identify treatments for those in whom current options are not working.

1033

EOSINOPHILIA IS NOT ASSOCIATED WITH NEUROCYSTICERCOSIS: RETROSPECTIVE ANALYSIS OF CASES SEEN AT THE NATIONAL INSTITUTES OF HEALTH 1985-2015

JeanAnne Ware, Theodore E. Nash

National Institutes of Health, Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Neurocysticercosis (NCC) has been generally cited as a parasitic infection associated with eosinophilia, but little evidence has been published to establish this relationship. A retrospective analysis was done of 106 patients with confirmed neurocysticercosis referred to NIH for evaluation and treatment between 1985 and January 2015. Historical records from referring providers, and from NIH were reviewed to identify the earliest available eosinophil count at the time of diagnosis. Eosinophilia was defined as an absolute eosinophil count ≥ 500/mm3. Patients with current or recent corticosteroid use (within two weeks) were excluded from further analysis (31%). The remaining cases (73) were reviewed for medical history including type of NCC, presence of a viable cyst(s) at diagnosis, current and past surgical and medical treatments and evidence of concurrent parasitic infections as judged by stools for ova and parasites and serologies for ***S. stercoralis*** (performed in most) and other helminthes when indicated. In this cohort, only 2 had an absolute eosinophilia of 500/mm^3 at the referring hospitals but were likely due to strongyloidiasis based on positive serology. The advantage of this study is the low likelihood of confounding eosinophilia due to migrating gastrointestinal helminthes not commonly endemic in the U.S. and routine serologic testing for ***Strongyloides stercoralis***, a common cause of occult eosinophilia in immigrants. Limitations include treatment prior to referral to NIH in many and incomplete historical records for some patients seen prior to 2000. In summary eosinophilia in patients with NCC was rare and when present could be attributable to other helminth infections.

1034

COMMUNITY-BASED SURVEILLANCE AND TREATMENT TO CONTROL TRANSMISSION OF *TAENIA SOLIUM*

Seth E. ONeal[1], Luz Maria Moyano[2], Viterbo Ayvar[2], Sandra Olaya[2], Ricardo Gamboa[2], Percy Vilchez[2], Ruth Atto[2], Claudio Ecca[2], Victor Benavides[2], Robert H. Gilman[3], Armando E. Gonzalez[4], Hector H. Garcia[5], For The Cysticercosis Working Group in Peru[5]

[1]Oregon Health & Science University, Portland, OR, United States, [2]Center for Global Health Tumbes, Tumbes, Peru, [3]Bloomberg School of Public Health, Baltimore, MD, United States, [4]Universidad Nacional Mayor de San Marcos, Lima, Peru, [5]Universidad Peruana Cayetano Heredia, Lima, Peru

Taenia solium is a common zoonosis and a leading cause of preventable epilepsy worldwide. Focusing screening and treatment for taeniasis within households located around pigs that are heavily-infected with cysticercosis can reduce parasite transmission over time. This control approach, known as ring-strategy, reduced the seroincidence in pigs by 41% over one year in a prior study. The objective of this on-going randomized community trial is to apply ring-strategy in a community-based approach to evaluate whether control gains can be replicated by villagers working in coordination with the local Ministry of Health. This approach requires significant community collaboration and capacitation including formation of a functioning surveillance and response system at the local level. We randomized 4 villages (pop. 1117) to intervention and 3 villages (pop. 1287) to control. The intervention consists of villager surveillance for infected pigs followed by Ministry of Health response including case investigation and presumptive treatment of humans and pigs in nearby households. The seroincidence of cysticercosis is monitored serially as the outcome over a period of one-year. We collaborated with the Ministry of Health so that local health workers could provide treatment of humans and pigs in response to disease reports. We trained 33 healthcare workers in case investigation, diagnosis and treatment, and another 12 health promoters to promote and document cysticercosis reports from residents. Collaboration with the Ministry of Education provided access to primary and secondary classrooms where students were given interactive instruction regarding cysticercosis prevention and surveillance. This collaboration also facilitated treatment of children at the schools provided parent consent. Twelve cases of porcine cysticercosis were reported within the first 6 months of the study resulting in presumptive treatment of 249 humans and 169 pigs in at-risk households. The final effect of the program on pig seroincidence in the intervention communities versus control will be presented at the 2015 ASTMH meeting.

1035

IDENTIFICATION, ISOLATION, CULTURE AND CHARACTERIZATION OF *TAENIA SOLIUM* PROLIFERATING CELLS

Miguel Angel Orrego Solano[1], Cristina Cristina Guerra-Giraldez[1], Carla Cangalaya[1], Jaeson Calla[1], Siddhartha Mahanty[2], Theodore Nash[2], Hector H. Garcia[3], Cisticercosis Working Group in Peru

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]Cysticercosis Unit, Instituto Nacional de Ciencias Neurologicas., Lima, Peru

Proliferation, regeneration and differentiation in flatworms are functions restricted to a particular group of cells, called neoblasts, which are also involved in the enormous plasticity typical of planarians. Despite some diferences at the morphologic and genetic level, neoblasts are also found in parasitic flatworms and are the only proliferating cells in platyhelminths. These cells have been identified in and isolated from Echinococcus and ***Taenia crassiceps***. We identified proliferating cells in ***T. solium*** cysts collected from an infected pig; neoblasts were identified by their ability to replicate and incorporate bromodeoxyuridine (BrdU), detected with

a BrdUspecific monoclonal antibody. Cells were extracted from cysts by digestion with trypsin followed by limiting dilution cultures, proliferating cells were abundant in the neck of the parasite, and were more evident after bile-induced evagination of the cysts. Their identity as neoblasts was confirmed after incubation with BrdU. ***In vitro*** growth of isolated neoblasts was enhanced with different supplements and incubation at two temperatures. Plates were incubated in the presence of 5% N2. Proliferating cells in stable cell cultures have been achieved. T solium neoblasts reacted with sera from pigs naturally infected with ***T. solium***, and not with sera from healthy pigs gave in immunohistochemical assays. Given the urgent need for novel, more effective and faster cysticidal drugs without deleterious side effects, efficient and scalable ***in vitro*** systems are essential to perform systematic testing and further research. Therefore we utilized the neoblast to test new compounds for cytotoxicity as a first step towards development of therapeutic agents.

1036

CORRELATION OF EVANS BLUE STAINING AND GADOLINIUM ENHANCEMENT IN MAGNETIC RESONANCE IMAGING OF PIGS NATURALLY INFECTED WITH *TAENIA SOLIUM*

Carla Marcia Cangalaya[1], Javier Bustos[2], Juan Calcina[3], Ana Vargas[3], Armando Emico Gonzalez[3], Cristina Guerra Giraldez[1], Siddhartha Mahanty[4], Teodhore Nash[4], Hugo Hector Garcia[2], Cysticercosis Working Group in Peru[5]

[1]Universidad Peruana Cayetano Heredia, Facultad de Ciencias y Filosofía, Lima, Peru, [2]Unidad de Cisticercosis, Instituto Nacional de Ciencias Neurológicas, Lima, Peru, [3]Facultad de Medicina Veterinaria, Universidad Nacional Mayor de San Marcos, Lima, Peru, [4]Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [5]Peru, Lima, Peru

How well Evans blue (EB) extravasation into the brain correlates with MRI studies employing gadolinium (Gd) enhancement was analyzed in pigs harboring brain cysts of ***Taenia solium***. Previous experiments documented that after intravenous injection of EB, there was increased leakage of the dye into the cyst capsules that was associated with the enhanced presence of pericystic inflammation. Twelve naturally infected pigs were injected with EB two hours prior to evaluation by coronal, sagittal and axial T1-weighted, Gd-enhanced magnetic resonance imaging (T1-MRI), after which the animals were euthanized and their brains analyzed. Histological examination allowed for classification of pericystic (capsular) inflammation as minimal, moderate or extensive, according to kind and distribution of immune cells. Ten-mm coronal sections of each brain were photographed and cyst capsules were scored according to absence or presence of EB (0 or 1: clear or blue capsules) and distribution of the color per cyst (EB categories were 0: 0%; 1: up to 50% of the capsule was blue; 2: over 50% of the capsule was blue; 3: 100% of the capsule was blue). The open access software packages IMAGE J and R were used for bidimensional analysis of MRI images, which were normalized, assigned spacial sectors and converted to 3-D data. The occurrence and spacial distribution of Gd enhancement (GE) were determined for each capsule identified on MRI using continuous normalized histogram values from 0 (black) to 256 (brightest). GE scores had a 100% success and sensitivity for discriminating between the presence of EB in clear (mean: 40.46) and blue capsules (mean: 64.03) (Student's t test; $p<0.001$); the cutoff value for GE was 42.5. According to EB distribution per capsule, 0% of blue had statistically lower GE from the other three categories (Bonferroni corrected Anova; $p<0.01$). Distribution of Gd correlated with the presence and distribution of EB and both correlated with the severity of the inflammation as observed histologically. These data demonstrate that EB staining can be a surrogate for Gd enhancement in MRI and may be applied to study inflammation in the pig model of NCC.

1037

THREE-DIMENSIONAL DISTRIBUTION OF *TAENIA SOLIUM* CYSTS IN PORCINE NEUROCYSTICERCOSIS

Carla Cangalaya[1], Cristina Guerra-Giraldez[1], Javier Bustos[1], Armando E Gonzalez[2], Siddhartha Mahanty[3], Theodore E Nash[3], Hector H Garcia[1], Cysticercosis Working Group in Peru

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]National Institutes of Health, Bethesda, WA, United States

Neurocysticercosis (NCC) is the common major cause of seizures in Latin America. The symptoms of NCC depend on different characteristics, among them the anatomical location of the cysts. In domestic pigs, the middle or rostral cerebral artery has 10 main branches on the surface of the cortex, 7 of which are oriented towards the occipital lobe. In order to know if cysts are distributed following the vascular network at the central nervous system, we analyzed the three-dimensional spatial point pattern distribution of 414 ***Taenia solium*** cysts in the brains of 15 naturally infected pigs. Photos of coronal brain sections were used to obtain the X, Y, Z coordinates of the center of each cyst with the ImageJ program. The coordinates were corrected by the size and center of each brain to normalizate the data. We analyzed the distribution patterns of each cyst through the Ripley's K function, G-function and F-function for three-dimensional data, using the statistical program R and Spatstat library. The spatial point pattern was categorized in three main classes, namely aggregation (defined by a distribution with the shortest distances between cysts), regularity and complete spatial randomness (CSR), according to the interpretation of functions graphs. Aggregation of cysts was confirmed only if indicated by the three functions. Cyst distribution in the occipital, parietal and frontal lobe followed an aggregation pattern in 100%, 10% and 22% of pigs, respectively. Only in the temporal lobe the distribution pattern observed was random in all pigs studied. Parenchymal cysts follow a CSR distribution in 20% of the pigs and the other 80% follow a regular distribution. The meningeal and corticomeningeal cysts showed aggregation in 20% of the pigs studied, and the zones with the highest aggregation (i.e., the shortest distance between cysts) followed the branching of the rostral cerebral artery in 4 temporal branches oriented to the occipital lobe. According to these results we confirm that the distribution of cysts in the brain tends towards aggregation following the distribution of blood vessels.

1038

IN VITRO CULTURE ASSAY AND *IN VIVO* RAT NEUROCYSTICERCOSIS MODEL TO STUDY DIFFERENCE BETWEEN *TAENIA SOLIUM* AND *T. SAGINATA*

Nancy Chile[1], Sandra Palma[1], Manuela Verastegui[1], Noelia Angulo[1], Beth Jessy Condori[1], Edson Bernal[1], Alejandro Florentini[1], Robert H. Gilman[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Johns Hopkins University, Baltimore, MD, United States

Why can larval-stage ***Taenia solium*** infect humans while larval-stage ***T. saginata*** does not have this ability? It has not yet been answered. The aim of this work was to use an ***in vitro*** culture assay and a rat neurocysticercosis model to study and compare the development of ***T. solium*** and ***T. saginata*** from oncosphere to cysticerci. In the first experiment ***T. solium*** and ***T. saginata*** activated oncospheres were cultured in INT–407 intestinal cells for up to 180 days in order to evaluate the difference in the morphology during the development. Both of them developed to postoncospheral stage and the morphology was similar up to 60 days of culture, then ***T. solium*** postoncospheral stage started to die and ***T. saginata*** grew for up to 180 days and developed to cysticerci. In the second experiment, we inoculated rats, intracranially, with oncospheres and postoncospheral stage of ***T. solium*** and ***T. saginata***. Rats that were infected with ***T. solium*** oncosphere and postoncospheral stage developed neurocysticercosis whereas rats infected with ***T. saginata***

oncosphere and postoncospheral stage did not develop neurocysticercosis. In conclusion, an ***in vitro*** assay could permit in the future to compare the molecules and proteins that are expressed by ***T. solium*** and ***T. saginata***. An ***in vivo*** model could permit in the future to study at which moment ***T. saginata*** loses the ability to cause neurocysticercosis.

1039

TRANSMISSION DYNAMICS OF *TAENIA SOLIUM* AND CYSTICERCOSIS IN PIGS AND HUMANS IN BURKINA FASO

Ashley L. Sword-Buster, Helene Carabin

University of Oklahoma Health Sciences Center, Oklahoma City, OK, United States

A transmission dynamics model of ***Taenia solium*** and the resulting infections of taeniasis and cysticercosis is explored using a mixed model which combines both density dependence and a frequency dependent Who Acquires Infection From Whom matrix similar to those used to model sexually transmitted infections. This approach aims to address the differences in the way that pigs acquire infection versus the way that humans become infected and the interaction between the two in a way that, to our knowledge, has yet to be addressed. This model assumes that a pig's likelihood of acquiring infection is dependent on the density of the human population, and that seasonality plays an important role in the rate that porcine cysticercosis is acquired. The model also assumes the contact of humans with infected meat; and then subsequently each other; is not homogeneous. Individuals of a lower socio-economic status are modeled to be more frequently in contact with infected meat, as well as additionally at higher risk for spreading the disease through contamination to others following food preparation. Verification of the model using serum samples from pigs and humans testing for cysticercosis and taeniasis collected from Burkina Faso will allow for not only the verification and more complete understanding of the transmission dynamics of this disease, but also the feasibility of this novel modeling approach.

INJECTIONAL ANTHRAX AMONG HEROIN USERS: A VIEW FROM THE AMERICAS

Varun Gopinath[1], **David Adams**[2]

[1]ASU, Savannah, GA, United States, [2]ASU/Medical College of Georgia, Savannah, GA, United States

Anthrax is caused by ***Bacillus anthracis***, a Gram-positive, rod-shaped bacterium that is the only obligate pathogen in the large genus ***Bacillus***. The disease can manifest in four forms including: cutaneous, inhalational, gastrointestinal, and, more recently, injectional. "Injectional anthrax is a form of anthrax infection that is receiving increasing attention after a single strain caused an outbreak in Europe left over 130 infected and at least 19 individuals dead." Cases involving this new form of anthrax involve people who inject drugs (PWIDs) who have been found to use anthrax-contaminated heroin. "Important differences between cutaneous and injectional anthrax have included an increased risk of shock and a higher mortality rate despite antibiotic therapy (<1% versus 34% respectively)." Literature on the European outbreak highlight the belief that natural contamination of the heroin supply occurred as it was transported and/or processed through anthrax endemic regions of the Middle East. Surveillance of the illicit heroin supply for future anthrax contamination is therefore of concern. The United Nations Office on Drugs and Crime (UNODC) estimates that in 2011 a total of 14.0 million (range: 11.2 million to 22.0 million) people injected drugs worldwide, which corresponds to 0.31 per cent (range: 0.24-0.48 per cent) of the population aged 15-64." These people are potential at-risk individuals for injectional anthrax. This study will specifically look into the possibility of anthrax contamination of the illicit heroin supply within North America using the European outbreak as a model. The importance of this study comes from the fact that North America has a large percentage of the world's PWIDs, having 2 million people vulnerable to a lethal form of anthrax infection. As there is gap in the literature as to how anthrax contamination could affect other illicit heroin markets other than Europe, this hypothetical piece views the possibility of anthrax contamination within North American PWIDs.

1041

ETIOLOGY OF PEDIATRIC FEVER IN WESTERN KENYA: A CASE-CONTROL STUDY OF FALCIPARUM MALARIA, RESPIRATORY VIRUSES, AND STREPTOCOCCAL PHARYNGITIS

Jeremiah Laktabai[1], Wendy Omeara[2], Joshua Mott[3], Kabura Wamburu[3], Barry Fields[3], Janice Armstrong[1], Steve Taylor[4], Charles McIntyre[2], Reeshi Sen[2], Diana Menya[1], William Pan[4], Brady Nicholson[5], Christopher Wood[4], Thomas Holland[6]

[1]Moi University, Eldoret, Kenya, [2]Duke University, Durham, NC, United States, [3]Centers for Disease Control and Prevention, Nairobi, Kenya, [4]Duke Global Health Institute, Durham, NC, United States, [5]Durham Veterans Affairs Medical Center, Durham, NC, United States, [6]Duke University Medical Center, Durham, NC, United States

In Kenya, >10 million episodes of acute febrile illness are treated annually among children under five. Most are clinically managed as malaria without parasitological confirmation. There is an unmet need to describe pathogen-specific etiologies of fever. We enrolled 370 febrile children and 184 healthy controls. We report demographic and clinical characteristics of patients with ***Plasmodium falciparum***, group A streptococcal (GAS) pharyngitis, and respiratory viruses (influenza A&B, respiratory syncytial virus, parainfluenza types 1-3, adenovirus, human metapneumovirus), as well as those with undifferentiated fever. 79.7% of febrile children were treated for malaria. However, ***P. falciparum*** was detected infrequently in both cases and controls (14/268 [5.2%] vs. 3/133[2.3%],p=0.165), whereas 41%(117/282) febrile children had a respiratory viral infection, compared to 24.8%(29/117) controls (p=0.002). Only 9/515(1.7%) children had streptococcal infection. Of febrile children, 22/269(8.2%) were infected with >1 pathogen, and 102/275(37.1%) had fevers of unknown etiology. Respiratory viruses were common in both groups, but only influenza or parainfluenza was more likely to be associated with symptomatic disease (attributable fraction 67.5% and 59%, respectively). Malaria was over-diagnosed and over-treated. Few children presented to the hospital with GAS pharyngitis. An enhanced understanding of carriage of common pathogens, improved diagnostic capacity, and better-informed clinical algorithms for febrile illness are needed.

1042

THE PREVALENCE OF ANAEMIA IN CHILDREN UNDER FIVE YEARS OLD LIVING IN THE AREA OF INTERVENTION OF THE AMAZON HOPE MEDICAL PROGRAM, PERÚ

Ronald Ramirez[1], Oscar M. Linárez[1], Tom Wingfield[2]

[1]Union Biblica Peru and Amazon Hope Medical Project, Iquitos, Peru, [2]Universidad Peruana Cayetano Heredia, Lima, Peru and Imperial College London, London, United Kingdom

The Amazon Hope medical boat health program offers primary medical care and health promotion to 167 communities of the Peruvian Amazon in four of its river regions (Amazonas, Tigre, Puinahua, and Ucayali). The subsistence farming and fishing communities in these regions have high rates of poverty and infant morbidity, including diarrhoeal disease and stunted growth. Despite this, there is limited research on anaemia and parasite infection in the area. We aimed to assess the prevalence of anaemia in children from rural Peruvian Amazonian communities who access care from the Amazon Hope medical boat. 1421 children in the study site were randomly selected to participate. Inclusion criteria were being a child from 6 to 59 months whose guardian gave informed consent to participate. All consenting participants underwent a haematocrit analysis undertaken by a laboratory technician aboard the Amazon Hope. Anaemia was defined as a haematocrit percentage <33%. Prevalence of anaemia in participants was high (89%), regardless of gender. The highest prevalence of anaemia was found in children aged between 6-11 months

(96.9%) followed by 12-33 months (90.8%). The prevalence of anaemia in children aged two, three, and four years was 86.6%, 87.4%, and 83.7% respectively. The Rio Tigre had the highest rate of anaemia (93%) followed by the Ucayali (90%), Puinahua (89%) and Amazonas (83%). This study demonstrates a previously undocumented high prevalence of anaemia in the children of isolated Peruvian Amazonian communities attending a medical boat clinic. The reasons behind this high prevalence are likely to be inter-related with the extreme poverty found in the region, which can cause: poor nutrition (including iron deficiency) and high burden of gastrointestinal parasites. Interventions are required to combat this previously unidentified health need and thus prevent associated long-term sequelae such as stunted growth and impaired immunity.

1043

LOW-COST SYSTEM FOR PERFORMING A WHITE BLOOD CELL COUNT AND 3-PART DIFFERENTIAL AT THE POINT-OF-CARE

Catherine E. Majors, Michal Pawlowski, Tomasz Tkaczyk, Rebecca Richards-Kortum

Rice University, Houston, TX, United States

The ability to perform a white blood cell (WBC) count and differential is an important laboratory diagnostic test. However, the current methods for performing a WBC count and differential in high-resource settings are not feasible for use in low-resource settings due to high cost and infrastructure requirements. There is a particular need for affordable tools to measure the WBC count and differential at the point-of-care in such settings. To meet this need, we developed a portable microscope and disposable cartridge that can be used at the point-of-care to perform a WBC count and 3-part differential using 20 uL of blood obtained from a fingerprick. The device is inexpensive, can be deployed at the bedside, and results are available within 60 seconds. The cartridge, which is composed of a glass slide, a layer of transfer tape, and a glass cover slip with laser cut inlet and outlet ports, contains a well in which acridine orange is pre-dried. Blood from a fingerstick is drawn into the well via capillarity and WBCs are stained with acridine orange, staining nuclei green and granules red. The cartridge can then be imaged using a portable fluorescence microscope; the image is analyzed automatically to report the WBC count and the percentages of granulocytes, monocytes, and lymphocytes to the user in less than one minute. This is achieved by a novel image analysis program that identifies the WBCs in the field of view and classifies them into the WBC subtypes based on the red and green pixel intensity within each cell. Preliminary results from testing the cartridge and microscope device with 9 normal capillary samples have shown promising results with all samples tested falling within ±15% the true WBC value. Further, the differential data also correlates strongly with the true values with an overall R-squared value of 0.85. We estimate that, at production scale, the portable microscope can be developed for under $800 and the cartridge device for less than $0.50.

1044

EPIDEMIOLOGY OF REINFECTION BY LEPTOSPIROSIS IN NEW CALEDONIA: A FIVE-YEAR PROSPECTIVE STUDY

Gilles Guerrier

Hôpital Cochin, Université Paris Descartes, Paris, France

In endemic areas, recurrent episodes of leptospirosis remain scarcely described. The objective of the study was to assess incidence, characteristics and risk factors of reinfection by leptospirosis in a large at-risk population. We performed a longitudinal study to capture patients admitted for leptospirosis more than once over a 5-year period (2007-2011) in New Caledonia. Of 716 episodes of confirmed leptospirosis recorded among 707 individuals, 9 cases of reinfection (incidence rate 1.3%) were identified. All recurrent episodes occurred in adults who presented with fever (100%), jaundice (100%), conjunctival suffusion (55%), headache (78%), and myalgia (78%). Renal function impairment was noted in 5 (55%) cases. No Weil disease nore fatality case were observed. The mean time elapsed between the two episodes was 23 months. The serogroup was identified in 8 recurrent cases and was similar to the previous episode in 6 (75%) cases. There was no difference in behavioural changes after the first infection between people experiencing recurrent episodes and the other. Although recurrent episodes of leptospirosis appeared to be rare and non severe, prompt administration of standard antibiotic therapy is required in reinfection. Similar environmental factors for both reinfected and non reinfected patients suggest the potential role played by individual factors in the physiopathology of the disease. However, reinforced public health campaigns should help preventing both infection and reinfection to occur.

1045

FIRST ESTIMATES OF THE DISEASE BURDEN OF PODOCONIOSIS IN ETHIOPIA

Kebede Deribe[1], Jorge Cano[2], Melanie J. Newport[1], Nick Golding[3], Rachel L. Pullan[2], Heven Sime[4], Abeba Gebretsadik[4], Ashenafi Assefa[4], Awoke Misganaw[5], Amha Kebede[4], Asrat Hailu[6], Maria P. Rebollo[7], Oumer Shafi[8], Moses J. Bockarie[9], Abraham Aseffa[10], Mohsen Naghavi[5], Simon I. Hay[3], Richard Reithinger[11], Fikre Enquselassie[12], Simon J. Brooker[2], Gail Davey[1]

[1]Brighton and Sussex Medical School, Brighton, United Kingdom, [2]Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, [4]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [5]Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States, [6]School of Medicine, Addis Ababa University, Addis Ababa, Ethiopia, [7]Task Force for Global Health, Decatur, GA, United States, [8]Federal Ministry of Health, Addis Ababa, Ethiopia, [9]Centre for Neglected Tropical Diseases, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [10]Armauer Hansen Research Institute/ALERT, Addis Ababa, Ethiopia, [11]RTI International, Washington, DC, United States, [12]School of Public Health, Addis Ababa University, Addis Ababa, Ethiopia

Ethiopia has the highest burden of podoconiosis globally, yet the geographical distribution and burden of the disease is poorly understood: no up-to-date, nationwide survey data were available and the appropriate measure of disease burden has yet to be defined. A commonly used standardized measure of disease burden is the disability-adjusted life years (DALYs) metric which combines years lost due to premature mortality (YLLs) and years lived with disability (YLDs). Currently there are no YLDs or DALYs estimates for podoconiosis. We report the results of a recent nationwide mapping of podoconiosis in Ethiopia, plus additional work providing estimates of YLDs for podoconiosis - both provide an estimate for the population at risk and the disease burden of podoconiosis in Ethiopia, and will be the first ever countrywide estimate of disease burden due to podoconiosis. Our analyses are based on data arising from the integrated mapping of podoconiosis and lymphatic filariasis (LF) conducted in 2013, supplemented by data from an earlier mapping of LF in western Ethiopia in 2008-2010. Data are available for 141,238 individuals from 1,442 communities in 775 districts from all regional states in Ethiopia. The proportion of people with podoconiosis was 4.0 % (95% CI; 3.9-4.1%) overall and ranged from 0% to 8.6% in regional states. Using boosted regression tree modelling and a suite of environmental variables we estimated that 34.9 million people are at risk of podoconiosis in Ethiopia. Using the Bayesian meta-regression method, DisMod-MR, employed by the Global Disease Burden (GBD) 2010 study, we estimate the YLDs due to podoconiosis. Results will be reported on the number of people affected with podoconiosis in Ethiopia, and YLDs will be calculated as prevalence of podoconiosis by age, sex and weighted by disability weights for lymphoedema. Estimates of uncertainty will be presented at all stages of the analysis. Finally, we will compare the YLDs for podoconiosis with other priority health problems in Ethiopia and discuss the implications for policy and planning.

1046

CANDIDA AND BACTERIA RELATED VAGINITIS AMONG FEMALE SENIOR HIGH STUDENTS IN NAVRONGO, GHANA

Eunice Essel, Yaw Frimpong Mensah, Seth Asamoah

Department of Applied Biology, University for Development Studies, Navrongo, Ghana

Vaginal candidiasis affects most females during their lifetime, with approximately 50% having two or more episodes. Most cases are caused by ***Candida albicans*** (85%-90%). It is the second most common cause of vaginitis. On the other hand, Bacterial vaginosis is an imbalance of the vaginal bacterial microbiota and its etiology is still unknown. It is a common condition afflicting mostly women in their reproductive age. The study was conducted to assess the incidence of ***Candida*** and bacteria related vaginitis among female senior high students. Seventy-two high vaginal swabs were obtained from consenting students for laboratory analysis and a structured questionnaire administered to assess symptoms, risk factors and demographic information. Methods employed in laboratory analysis included wet mount, whiff test, clue cell test, pH test, Gram staining and culture. The results revealed 40% (29) of participants were infected with ***Candida*** vaginitis while 14% (10) were diagnosed with bacteria vaginosis. Lactobacilli which are supposed to be a normal flora in a healthy vagina were isolated in only 29% (21) of the participant who were between the ages of 14 to 22 years. For symptoms, 100% (72) of the participants had vaginal discharge. 68% (49), 63% (45) and 18% (13) had itching, irritation and burning sensation respectively. Among the risk factors sexual activity recorded the highest 76% (55), 61% (44) douched and 32% (23) were on antibiotics. The incidence of ***Candida*** vaginitis especially is high in the study population and this may be due to few participants having Lactobacilli isolated from their vagina and may also explain the incidence of bacteria vaginosis.

1047

'IT COULD BE VIRAL BUT YOU DON'T KNOW, YOU HAVEN'T DIAGNOSED IT': CHALLENGES IN MANAGING NON-MALARIA PEDIATRIC FEVERS IN THE LOW TRANSMISSION SETTING OF MBARARA DISTRICT, UGANDA

Emily White Johansson[1], Freddy Eric Kitutu[1], Chrispus Mayora[2], Stefan Swartling Peterson[1], Henry Wamani[2], Helena Hildenwall[3]

[1]Uppsala University, Uppsala, Sweden, [2]Makerere University, Kampala, Uganda, [3]Karolinska Institutet, Stockholm, Sweden

In 2012, Uganda initiated nationwide deployment of malaria rapid diagnostic tests (mRDT) as recommended by revised national guidelines. The shift from presumptive malaria treatment of pediatric fevers to test-based management has great potential to improve quality fever care. Yet studies show common mRDT non-compliance, which has spurred calls to deploy mRDT as part of enhanced training packages that include integrated fever management protocols. An understanding of how health workers currently manage non-malaria fevers and challenges faced in this work should also inform efforts. A qualitative study was conducted in the low-transmission area of Mbarara District in Uganda where most fevers are not due to malaria. In-depth interviews with a purposive sample of 20 health workers at lower level clinics focused on mRDT perceptions, strategies to differentiate non-malaria fevers, influences on clinical decisions, desires for additional diagnostics, and dilemmas faced in this work. Differential diagnosis strategies included studying fever patterns, taking histories, assessing symptoms, and analyzing contextual factors (e.g. child's age or home environment). If no alternative cause was found, malaria treatment was often prescribed despite a negative result. Other reasons for malaria over-treatment included mRDT mistrust; mRDT misperceptions ('for RDTs to become positive it might take like three days [from illness start]'); caregiver demands and system constraints, notably working alone without opportunity to confer on difficult cases. Many health workers expressed uncertainty about how to manage non-malaria fevers, feared doing wrong and patient death, worried caregivers would lose trust, or felt unsatisfied without a clear diagnosis. Enhanced support is needed to improve mRDT adoption at lower level clinics that focuses on how to manage non-malaria fevers. This includes facilitating peer-learning networks, correcting mRDT misperceptions, building trust in negative results, and reinforcing integrated care initiatives (IMCI/iCCM) to improve mRDT compliance, rational drug use and quality fever management.

1048

COMPARING THE USE OF PERSONAL PROTECTIVE MEASURES FOR MOSQUITO-AVOIDANCE DURING TRAVEL TO REGIONS WITH DENGUE OR CHIKUNGUNYA ACTIVITY, AND REGIONS ENDEMIC FOR *PLASMODIUM FALCIPARUM* MALARIA

Tahaniyat Lalani[1], Mark D. Johnson[2], Anuradha Ganesan[1], Heather Yun[3], Jamie Fraser[1], Edward Grant[1], Timothy Burgess[4], Robert G. Deiss[1], David Tribble[1]

[1]Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Naval Medical Center - San Diego, San Diego, CA, United States, [3]San Antonio Uniformed Services Health Education, Fort Sam Houston, TX, United States, [4]Walter Reed National Military Medical Center, Bethesda, MD, United States

The recent outbreak of chikungunya in the Caribbean highlights the importance of personal protective measures (PPM) in preventing mosquito-borne febrile illnesses that lack effective treatment. We compared the use of PPM in Department of Defense beneficiaries traveling to areas in the Caribbean with dengue or chikungunya activity, to those traveling to areas of Africa with high ***Plasmodium falciparum*** endemnicity. Individuals presenting to 4 US military travel clinics were prospectively enrolled. Participants completed a post-travel survey documenting the use of PPM, and the frequency and timing of mosquito bites. Participants traveling to regions in Africa with high malaria endemnicity (***P. falciparum*** parasite rate [PfPR2-10] > 35%) or regions in the Caribbean with minimal or no risk of malaria, but with documented chikungunya or dengue activity were included. Compliance with PPM was defined as frequent or daily use of insect repellant on skin, and use of a repellant on clothes. Multivariate regression was performed to evaluate factors associated with PPM compliance. Between 2010 and 2015, 1723 enrolled travelers completed a post-travel survey, of which 186 traveled to highly-endemic malarious regions of Africa, and 148 traveled to regions in the Caribbean with chikungunya or dengue activity. A significantly greater proportion of participants traveling to malaria-endemic regions reported seeing mosquitoes (87% vs 56%) and experiencing mosquito bites (65% vs. 47%). Travelers to the Caribbean reported mosquito bites during the day more frequently than travelers to malaria-endemic regions (76% vs. 39%) ($p < 0.05$ for all comparisons). Compliance with PPM was associated with travel to areas with chikungunya or dengue activity (24% vs. 13%; OR: 1.58 [95% CI 1.05-2.39]), and travel for a military mission (49% vs. 8%; OR: 5.52 [95% CI: 3.11-9.79]) on multivariable analysis. Overall, we observed poor compliance with PPM in travelers, although compliance was significantly higher in travelers going to areas with dengue/chikungunya activity. Additional studies and interventions aimed at improving compliance with PPMs are needed.

1049

USE OF ELECTROCARDIOGRAM TO EVALUATION SAFETY OF ANTIMALARIAL DURING POST LICENSURE SURVEILLANCE IN AFRICA-MODELLING OF PATIENTS ECG

Abdunoor M. Kabanywanyi[1], Rita Baiden[2], Ali Ali[3], Muhidin K. Mahende[4], Abraham Oduro[5], Tinto Halidou[6], Margaret Gyapong[7], Ali Sie[8], Esperanca Sevene[9], Eusebio Macete[9], Seth Owusu-Agyei[10], Bernhards Ogutu[2], Alex Adjei[7], Guillaume Compaoré[8], Innocent Valea[6], Isaac Osei[5], Abena Yawson[10], Martin Adjuik[2], Raymond Akparibo[2], Mwaka Athmani[1], Salim Abdulla[1], Fred Binka[11]

[1]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [2]INDEPTH Network, Accra, Ghana, [3]Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, [4]Ifakara Health Institute, Rufiji, United Republic of Tanzania, [5]Navrongo Health Research Centre, Navrongo, Ghana, [6]Nanoro Health Research Centre, Nanoro, Burkina Faso, [7]Dodowa Health Research Centre, Dodowa, Ghana, [8]Nouna Health Research Centre, Nouna, Burkina Faso, [9]Centro de InvestigaçãoemSaúde de Manhiça, CISM, Manhiça, Mozambique, [10]Kintampo Health Research Centre, Kintampo, Ghana, [11]INDEPTH Network, University for Health and Allied Sciences, Accra, Ho, Ghana

Current use of Dihydroartemisinin/piperaquine [DHA/PQP] for the treatment of uncomplicated malaria infection in vulnerable groups with cardiogenic problem requires more supportive safety data. One of the most outstanding side effect of DHA/PQP is its negative electrocardiographic (ECG) effect on heart rhythm through prolongation of the QT intervals. There is at present scarce toxicity data of ECG to warrant greater use of DHA/PQP in cardiogenic arrhythmic predisposed individuals. PQP is the fat soluble part of DHA/PQP that is responsible for belated ventricular depolarization hence QT prolongations. We conducted an ECGs safety assessment at baseline before intake of DHA/PQP and during subsequent doses as well on day seven in a 7 months multicentre antimalarial study. Laboratory analyses included haematology, biochemistry and population pharmacokinetics. We hereunder report a descriptive details of the QTc intervals changes during the trial together with modelling of QTc outcome using a linear mixed model. Overall 1315 patients gave consent of which only 1002 (76.2%) were eligible. A comparison of mean QTcf at baseline (383.3 ms) and during subsequently follow up records was 395.1 before drug intake and 402.3 after drug intake on day 3 and the resultant QTcf on day 7 was restored to baseline of 387.3 ms. Mean QTcf in patient from Ghana was significantly higher compared to other three countries (Burkina Faso, Tanzania and Mozambique). In a multivariate model a unit increase in total bilirubin and body mass index was associated with a decrease for nearly 10% and 50% of mean QTcf intervals respectively. Plasma drug concentration on day 3 and day 7 was recorded preliminary results is expected before ASTMH in October. This study demonstrated DHA/PQP is not cardiogenic unsafe in children and adults at normal dose with uncomplicated malaria in Africa.

1050

A CLINICAL PREDICTION MODEL OF IN-HOSPITAL MORTALITY DERIVED FROM PATIENTS ADMITTED WITH ACUTE INFECTION TO A REGIONAL REFERRAL HOSPITAL IN MBARARA, UGANDA

Kacie J. Saulters[1], Arjun Shankar[1], Albert Majwala[2], Richard Ssekitoleko[2], Mary Auma[2], Susan Adakun[2], Abigail Flower[1], Laura E. Barnes[1], Christopher C. Moore[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]Mbarara University of Science and Technology, Mbarara, Uganda

Clinical early warning scores (EWS) used in resource-rich settings (RRS) to predict mortality due to sepsis may not be applicable to resource-limited settings (RLS) due to a lack of laboratory infrastructure and population differences. Therefore, we created a prediction model of in-hospital mortality for use in RLS based on data from patients admitted with suspicion of infection to Mbarara Regional Referral Hospital (MRRH) located in Southwestern Uganda. We imputed missing data (range<0.5-30%) for temperature, white blood cell count (WBC), hemoglobin, platelets, and lactic acid using a k-nearest neighbors algorithm. We used multivariable logistic regression with 10-fold cross validation to create the model. We compared our model to the Modified Early Warning Score (MEWS) and CRB-65 which have been validated in RRS. The study included 1089 patients with a median (IQR) age of 34 (27-45) and which was 47% female. There were 755 (69%) HIV-infected patients with a median (IQR) CD4 count of 80 (20-201). Tuberculosis was suspected or confirmed in 67%, 36% had suspected meningitis, and 35% had a suspected pulmonary source. In-hospital mortality was 26% and 30-day mortality was 61%. Median (IQR) length of hospital stay was 6 days (3-10). Glasgow coma score ($p<0.0001$), respiratory rate ($p<0.001$), temperature ($p<0.001$), mean arterial pressure ($p=0.001$), WBC ($p=0.001$), hemoglobin ($p=0.001$), and lactic acid ($p=0.001$) were associated with increased mortality in the multivariable model. The AUC for the model without laboratory values was 0.70 and improved slightly to 0.71 with laboratory values. The AUC was 0.66 for MEWS and 0.64 for CRB-65. The AUC for a model that included HIV sero-status (n=992) was 0.77. In conclusion, our derived clinical model showed good ability to predict in-hospital morality in this special population of alarmingly young and critically ill patients. Improved predictive models for mortality from critical illness in RLS are needed to accelerate early interventions and improve morbidity and mortality in this population.

ADMISSION EEG FINDINGS IN AFRICAN CHILDREN WITH CEREBRAL MALARIA ARE ASSOCIATED WITH MORTALITY, MORBIDITY, AND MALARIAL RETINOPATHY

Douglas G. Postels[1], Xiaoting Wu[1], Chenxi Li[1], Karl B. Seydel[1], Peter Kaplan[2], Terrie E. Taylor[1], Robert Opoka[3], Youssef Kousa[1], Gretchen L. Birbeck[4], Chandy H. John[5]

[1]Michigan State University, East Lansing, MI, United States, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Makerere University, Kampala, Uganda, [4]University of Rochester, Rochester, NY, United States, [5]Indiana University, Indianapolis, IN, United States

The spectrum and implication of electroencephalographic (EEG) findings in children with cerebral malaria (CM) has been described in case reports and small case series, but to date there has been no large study assessing these findings in children in more than one site or comparing findings in children with and without malarial retinopathy . In the present study we characterized and compared admission EEG findings in Malawian and Ugandan children with CM, identified EEG factors associated with mortality or adverse neurological outcome in survivors, and compared EEG findings in patients of differing malarial retinopathy status. We reviewed admission EEG tracings from 281 hospitalized children with clinical CM, 122 from Uganda and 159 from Malawi, admitted between December 2008 and January 2012. Tracings were interpreted by neurologists blinded to the patient's outcome and retinopathy status. The risk of death was lower in those with EEG vertex waves (odds ratio (OR)= 0.15, 95% confidence interval (CI): 0.03, 0.87), higher maximal voltage, and higher average background frequency. EEGs with an increased proportion of epochs with spindles were associated with a lower likelihood of death. A generalized voltage attenuation to painful stimulation decreased the odds of death compared to those with no EEG reaction to stimulation (OR= 0.33, 95%CI: 0.11, 0.98). The presence of electrographic seizures was not associated with mortality but was associated with an increased odds of a neurologic deficit in survivors at discharge (OR= 12.5, 95%CI: 2.8, 56.2). Children with malarial retinopathy were more likely to have EEG variability, absence of spindles, and a non-attenuated reaction to painful stimulation (all $p < 0.05$). Specific EEG findings in children with CM are associated with mortality, neurologic deficits, and the presence of malarial retinopathy. In pediatric CM, brain pathways associated with death likely differ from those associated with neurologic morbidity in survivors.

1052

REPRODUCTIVE HEALTH: BURDEN OF SEXUALLY TRANSMITTED INFECTIONS IN MACHALA, ECUADOR

Abigail G. Fessler[1], Saurabh Mehta[1], Efraín Beltrán-Ayala[2], Anita L. Arichábala Wilches[2], Anna M. Stewart-Ibarra[3], Julia L. Finkelstein[1]

[1]Cornell University, Ithaca, NY, United States, [2]Ministry of Health, Machala, Ecuador, [3]SUNY Upstate Medical University, Syracuse, NY, United States

Over one million people acquire a sexually transmitted infection (STI) every day worldwide. Sexually transmitted infections are a major threat to public health in Latin America. The objective of this analysis was to examine the burden of sexually transmitted infections, including viral, protozoan, and bacterial infections, in Machala, Ecuador, a coastal city located in southern Ecuador. A total of 398,919 records were analyzed from a citywide epidemiological database of patient clinic visits in Machala, Ecuador, in 2014. Binomial regression was used to examine the associations of sexually transmitted infections with socio-demographic factors. There were a total of 1,432 cases of sexually transmitted infections in Machala in 2014. Viral infections, including herpes, hepatitis B, HIV, and human papillomavirus (HPV), were the most commonly reported, comprising 46.8% of the total STI cases, followed by protozoan (38.1%) and bacterial (15.1%) infections. Trichomoniasis, HIV, and herpes accounted for more than half of all cases of sexually transmitted infections. Although the burden of syphilis was relatively low, it accounted for 86.6% of bacterial infections. Women had a two-fold greater risk of presenting with sexually transmitted infections, compared to men (RR: 1.91, 95% CI: 1.71-2.12, p<0.0001); the risk was even higher for women of reproductive age (15-49y) (RR: 5.50, 95% CI: 4.75-6.36, p<0.0001), compared to women of other age groups. Although men had a lower risk of presenting with a sexually transmitted infection (p<0.05), they had a three-fold greater risk of HIV infection (RR: 3.10, 95% CI: 2.48-3.89, p<0.0001), compared to women. The burden of sexually transmitted infections is relatively high in coastal Ecuador, particularly among women of reproductive age. Future surveillance efforts are needed among women of reproductive age that integrate sexually transmitted infection screening with reproductive and perinatal health care in this setting.

1053

IDENTIFICATION OF *RICKETTSIA* SPP INFECTION IN PATIENTS WITH CLINICAL SUSPICION OF LEPTOSPIROSIS: APPLICATION OF MOLECULAR TECHNIQUES IN A CASE SERIES

Doris E. Gómez-Carmago[1], Pedro Blanco[2], Gustavo Mora-García[1], Margareth Paternina[2], Libardo Caraballo[2]

[1]Universidad de Cartagena, Cartagena, Colombia, [2]Universidad de Sucre, Sincelejo, Colombia

Leptospirosis is a public health problem on the Colombian Caribbean Coast. In Cartagena, a major city in this region, this disease is endemic with high annual lethality. In clinical practice, differential diagnosis of leptospirosis with others icteric febrile syndromes is crucial to an appropriated therapeutic approach. Nevertheless, high complexity hospitals employ only serological test to confirm suspicious cases, with an elevated frequency of undetermined results. Therefore, the aim of this study was to apply molecular techniques in patients under leptospirosis suspicion. It was carried out a case series study with adults in 2013 last trimester. Patients with clinical manifestations and positive/undetermined results in serological test for leptospirosis were included. We used Polymerase Chain Reaction to detect ***Leptospira spp*** from blood samples with specific primers that amplify a DNA segment from the ***lipl32*** gen. A total of 9 patients were included (3 women, 6 men). IgM test for leptospirosis was positive in 5 subjects and undetermined in 4 others. A 423pb product was expected, however only 3 samples showed an amplicon of 358pb. When those DNA fragments were sequenced, none of them were part of ***Leptospira spp***. genome. Thereafter, samples were amplified for ***Riskettsia spp.*** by nested PCR for the ***OmpB*** gene. Seven samples were positive (420pb amplicon). These samples were also positive for ***Rickettsia spp*** 17KDa gene (230pb amplicon). According to these results, in spite of high clinical suspicion in a scenario were physicians are familiarized with leptospirosis, lacking of specific tests could lead to misdiagnosis. On this particular situation, considering that therapeutic approaches between leptospirosis and rickettsiosis are mainly divergent, a permanent protocol for differential diagnosis would be a major advance in reducing diseases burden. Also, this case series study revealed an apparently silent public health threat by rickettsiosis.

1054

CHIKUNGUNYA FEVER IN THE CARIBBEAN: CLINICAL FINDINGS FROM GRENADA

A. Desiree LaBeaud[1], Trevor Noel[2], Donald Jungkind[2], Katherine Yearwood[2], Paul Fields[3], Susana Widjaja[2], George Mitchell[4], Monika Simmons[5], Dolland Noel[2], Satesh Bidaisee[2], Todd Myers[5], Calum Macpherson[2]

[1]Stanford University, Stanford, CA, United States, [2]St. George's University School of Medicine, St. George's, Grenada, [3]Windward Islands Research and Education Foundation, St. George's, Grenada, [4]Ministry of Health, St. George's, Grenada, [5]Naval Infectious Diseases Diagnostic Laboratory, Silver Spring, MD, United States

Chikungunya virus (CHIKV) made its debut in the Americas during a large outbreak in the Caribbean from 2013-2014. The tri-island nation of Grenada was severely affected. The objective of this study was to evaluate the demographic features and presenting symptoms of those patients with suspected and/or confirmed CHIKV infection in Grenada. Patients with fever (>38.0°C) and symptoms consistent with CHIKV were enrolled at health facilities throughout Grenada. Survey data and serum samples were collected. Sera were tested for CHIKV and dengue virus using real-time PCR and for anti-CHIKV IgM by ELISA. Sera from 493 suspected cases were collected from mid-July until early October 2014 from Grenada, Carriacou, and Petit Martinique. Sixty-six percent were female and the mean age was 37.3 (range 0.1-92) years. The most common reported symptoms included joint pain (89%), fever (88%), myalgia (66%), headache (54%), chills (50%), and rash (43%). On exam, petechia (5%), gingival bleeding (2%), hematuria (1%), bruising (1%), and epistaxis (1%) were also noted. Of the 487 sera tested by both PCR and IgM ELISA, 87% (N=425) had a positive test: 22% (N=94) were PCR positive, 66% (N=282) were IgM positive, and 12% (N=49) were positive for both. Those positive by PCR had 2.2 days of illness vs. 8.1 days if positive by IgM (p<0.001). No DENV was detected by PCR in any sample. Confirmed CHIKV cases (aged 0.1-89 years) were more likely to present with fever, rash, joint swelling, joint pain, and chills (p<0.05) than those who tested negative. Grenada suffered an explosive CHIKV outbreak in 2014. IgM testing detected 78% of test positive patients while PCR detected only 34%. Fever, rash, joint swelling, joint pain, and chills were associated with CHIKV disease. Hemorrhagic signs were rare.

1055

SEROPREVALENCE STUDY TO IDENTIFY AGE OF GROUPS THAT ARE MOST AT RISK OF DENGUE INFECTION IN PIEDECUESTA, AN ENDEMIC MUNICIPALITY OF COLOMBIA

Maria I. Estupiñan Cárdenas[1], Isabel Rodriguez Barraquer[2], Victor M. Herrera Galindo[1], Milena Zaraza Moncayo[1], **Luis A. Villar Centeno**[1]

[1]Centro de Investigaciones Epidemiológicas, UIS., Bucaramanga, Colombia, [2]Johns Hopkins University, Baltimore, MD, United States

Dengue has become an important public health problem because of its increased burden and geographic expansion over the last years. Taking into account that a vaccine may become available shortly, it is critical to characterize the transmission dynamics of the virus at local scales in order to design appropriate vaccination policies. The purpose of this study was to estimate the age-specific dengue seroprevalence in the population of

Piedecuesta, Santander, Colombia, and to explore risk factors for infection. Between July and October 2014, we conducted a household based cross-sectional survey among 1037 individuals aged 2 to 40 years living in 40 randomly selected locations in urban Piedecuesta. In addition, we also enrolled 246 indviduals living in rural "veredas". Participants were asked to answer a questionnaire that included demographic, socioeconomic and environmental questions and to provide a 5ml blood sample. Sera were tested using the IgG indirect ELISA (Panbio) kit to measure past infection by dengue. The average age of participants was 20.73 years (CI 95%=20.12; 21.33). The overall dengue seroprevalence was 69.8% (CI 95%= 67.43122; 72.45949), but was significantly higher in urban (81%) as compared to rural (22.3%) locations. Age was a major predictor of seropositivity, consistent with endemic circulation of the virus. We estimate that on average, 11% (95%CI 8%-16%) of susceptible individuals are infected by dengue each year. Preliminary analyses also suggest that health insurance, occupation and migration are risk factors for infection in both rural and urban settings. Additional analyses will explore other factors associated with seropositivity. These results show that Piedecuesta is an endemic area of DENV transmission, with large heterogeneities between urban and rural settings. Findings from this study will inform the design of a prospective cohort study among children between 2 and 15 years of age. Enrollment for this study is expected to be completed by late 2015, and follow-up will continue for 2.5 years.

1056

CLINICAL COMPARISON OF RETINOPATHY-NEGATIVE AND RETINOPATHY-POSITIVE CEREBRAL MALARIA

Chandler Villaverde[1], Ruth Namazzi[2], Robert O. Opoka[2], Chandy C. John[3]

[1]Warren Alpert Medical School at Brown University, Providence, RI, United States, [2]Global Health Uganda, Kampala, Uganda, [3]Indiana University, Bloomington, IN, United States

Cerebral malaria (CM), defined as coma in an individual with ***Plasmodium falciparum*** on blood smear and no other defined cause for coma, is the most severe and lethal complication of ***P. falciparum*** malaria. A classic malaria retinopathy is seen in some (retinopathy-positive, RP) children but not others (retinopathy-negative, RN), and is associated with increased parasite sequestration. It is unclear whether RN CM is a severe non-malarial illness with incidental parasitemia or a less severe form of the same malarial illness as RP CM. Understanding the clinical differences between RP and RN CM may help shed light on the pathophysiology of malarial retinopathy. We compared clinical history, physical exam, laboratory findings, and outcomes of RP (n=170) and RN (n=91) children admitted to Mulago Hospital, Kampala, Uganda. Compared to RN children, RP children presented with a longer history of illness, as evidenced by longer duration of coma before presentation (p=0.021), time since first convulsion (p=0.047), and time since last meal (p<0.001). In addition, RP children presented with physical exam and laboratory findings indicative of more severe disease and organ damage when compared to RN children, including higher levels of respiratory distress, pallor, and jaundice; elevated creatinine, BUN, and BUN/Cr ratios; and lower hemoglobin levels. The hospital course of RP children was complicated by longer coma duration (p<0.001) and a greater transfusion burden (p<0.001) than RN children. Mortality did not differ significantly between RP and RN children (14.1% vs 8.8%, p=0.21). RP CM is associated with a longer history of illness and greater evidence of end-organ damage than RN CM. The data suggest that RP and RN CM may reflect the spectrum of illness in CM, and that RN CM could be an earlier, less severe form of disease.

1057

TREATING CHAGAS DISEASE IN SPAIN: THE EXAMPLE OF A "NON-NEGLECTED" TROPICAL DISEASE IN A NON-ENDEMIC COUNTRY

Miriam Navarro[1], Sonia Tarragona[2]

[1]Fundación Mundo Sano, Madrid, Spain, [2]Fundación Mundo Sano, Buenos Aires, Argentina

Population from endemic areas of ***Trypanosoma cruzi*** represents in Spain around two million people. Thus, Spain is the most affected country of Chagas disease in Europe, and the second globally in terms of infection among migrants (after US). Several estimations launch a figure between 45,000 and 65,000 migrants infected with ***T. cruzi*** living in Spain. Healthcare access was universal for all people in Spain. Nevertheless, since a Royal Decree launched in September 2012, barriers of access to the health system have been enhanced, and many migrants are currently in a situation of vulnerability. Benznidazole (the first-line treatment option for Chagas disease) shortage occurred at the end of 2011 could have made Chagas disease a neglected tropical disease also in developed countries. We describe the process and results of the re-availability of benznidazole in Spain, a non-endemic country of Chagas disease. Database with the requested orders of benznidazole from the Spanish hospitals, managed by Fundación Mundo Sano and the laboratory that imports the drug from Argentina, was analyzed. The drug started to be produced by a different laboratory in Argentina in 2012. Since November 2012, benznidazole is available in Spain as foreign medication, through the Spanish Drug Agency (Agencia Española de Medicamentos y Productos Sanitarios). Fundación Mundo Sano is contributing since then to facilitate the access to the treatment. Globally, 134 healthcare centers in Spain have requested this drug for their patients. In the first 4 months of the re-availability of the drug in Spain, around 900 treatments were given (1,738 bottles of 100mg and 12 of 50mg). From November 2012 to February 2015, around 3,450 treatments were administered to patients with Chagas disease (6,703 bottles of 100mg and 228 u. of 50mg). Fifty-eight percent of the treated patients are living in four regions of Spain: Catalonia, Madrid, Murcia and Valencia. These data show how Spanish healthcare professionals are attending a Neglected Tropical Disease in a non-endemic country, contributing to its visibility.

1058

INTERRUPTION OF LYMPHATIC FILARIASIS FOLLOWING MASS DRUG ADMINISTRATION IN NORTHEASTERN TANZANIA: TRANSMISSION ASSESSMENT SURVEYS (TAS) IN LUSHOTO AND MUHEZA DISTRICTS, TANGA

Upendo J. Mwingira

NIMR, Dar es Salaam, United Republic of Tanzania

Lymphatic filariasis (LF) is one of the major tropical diseases affecting people living in poverty. It is estimated that LF infects 120 million people in more than 80 countries throughout the tropics and sub-tropics. One third of those infected live in India, one third in Africa and the remainder in South Asia the pacific and the Americas. Mapping was done in 2000 in Lushoto and Muheza and Circulating Filarial Antigen (CFA) prevalence was 10% and 62% respectively. Tanga region has been implementing consecutive Ivermectin Mass Drug Administration (MDA) for Onchocerciasis control since 2000 while Ivermectin and Albendazole MDA for LF have been conducted since 2004 with reported coverage of above 65%. Pre-Transmission Assessment survey conducted in 2012 revealed that, Muheza had CFA prevalence of 1.6% and Lushoto was 0.3% and these results warranted Transmission Assessment Survey.A community-based household survey was conducted in Lushoto per WHO -TAS guideline. A cluster-sampling approach was employed and children aged 6-7 years old were sampled in 78 hamlets. For Muheza district, since the school attendance rate appeared to be above 75%, sampling was done in schools. Children of Grade 1 and 2 were recruited for the study.

A blood sample was collected from each child, from finger-prick using a 100-microlitre capillary tube and tested with ICT. Children found positive for CFA were traced to their home for night (between 2100 and 2300 hours) blood collection for further evidence of filarial infection. Data were immediately entered in a mobile smart phones loaded with a simple survey questionnaire. In Muheza; A total of number of children enrolled for study was 1664, from 33 schools and 13-tested positive for CFA (0.78%). Mf count was done to all 13 cases and non-was found positive. For Lushoto;a total of 1843 children of 6-7 years old children were tested and non tested positive for CFA. These findings warrant both districts of Muheza and Lushoto to stop MDA according to the WHO guidelines as they indicate interruption of Disease transmission.

1059

LYMPHATIC FILARIASIS MASS DRUG ADMINISTRATION IN SEVEN COMMUNES IN AND AROUND METROPOLITAN PORT-AU-PRINCE, HAITI, MARCH MAY 2014: HAS COVERAGE BEEN ATTAINED?

Maximilian P. Nerlander[1], Alaine K. Knipes[1], Valery Madsen Beau de Rochars[2], Carl R. Fayette[3], Franck Monestime[3], Luccene Desir[4], Abdel N. Direny[3], Mary Claire Worrell[1], Dismer Amber[1], Kristen Renneker[5], Brian Chu[5], Ryan E. Wiegand[1], Ezra Barzilay[1], LeAnne Fox[1], Jean F. Lemoine[6], Patrick J. Lammie[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]University of Florida, Gainsville, FL, United States, [3]Interchurch Medical Association World Health, Port-au-Prince, Haiti, [4]University of Notre Dame/Hopital St. Croix, Léogane, Haiti, [5]The Task Force for Global Health, Decatur, GA, United States, [6]Haitian Ministry of Health/National Malaria and Lymphatic Filariasis Control Programs, Port-au-Prince, Haiti

Lymphatic Filariasis (LF) is a parasitic infection endemic to Haiti causing lymphedema and hydrocele. The World Health Organization called for LF elimination using at least five yearly rounds of mass drug administration (MDA) using Albendazole and Diethylcarbamazine with >65% coverage of the population at risk. Achieving good coverage in urban settings is challenging. In May 2014, Port-au-Prince (PAP) completed its third MDA and two nearby communes completed their fourth. The study objectives were to assess MDA coverage and knowledge, attitudes and practices (KAP) of the population regarding LF MDA. Five communes inside and two communes outside PAP were selected using a two-stage cluster sample design. Thirty clusters per commune were selected with probability proportional to estimated size with 10 households per cluster. A coverage questionnaire was administered to everyone age ≥2, and a KAP questionnaire was administered to one randomly selected household member age ≥18. Results were weighted according to cluster and household size and analyzed using SAS 9.3. Out of 5145 individuals, 74% (95% CI 72-76) reported having swallowed medication during the 2014 MDA. Coverage was 72% in females and 76% in males (p<.0101). Coverage was highest in the rural communes (Grand Goâve 81%) and Petit Goâve 79%) while Pétionville in the metro area had the lowest (64%). Top reasons for noncompliance were drug safety concerns (20%) and not being present (15%) or aware (9%) of MDA and losing the pills (7%). KAP results revealed that 9% of participants knew LF elimination requires 5 years of MDA. The commonest routes for community notification of MDA were radio, TV, megaphone and health workers. Potentially useful but unexploited messaging routes include community meetings, church meetings and public health officials. Results indicate that except for Pétionville, the 2014 MDA achieved satisfactory coverage in both urban and rural settings. Increased awareness of the duration of MDA campaigns may reduce inconsistent participation. Use of newly identified routes of communication for awareness of the MDA campaigns may assist in improving future compliance.

1060

HOW LONG WILL IT TAKE TO ERADICATE LYMPHATIC FILARIASIS? A MODEL-BASED ASSESSMENT ON THE IMPACT OF SCALING UP MASS DRUG ADMINISTRATION PROGRAMS

Randee Kastner, Chris Stone, Peter Steinmann, Fabrizio Tediosi

Swiss Tropical and Public Health Institute, Basel, Switzerland

Lymphatic filariasis (LF) is a neglected tropical disease primarily prevalent in poor populations in 73 countries. LF is caused by ***Wuchereria bancrofti***, ***Brugia malayi*** or B. timori transmitted by a variety of mosquito genera. Infection with the filarial nematodes can damage the lymphatic vessels, leading to lymphedema, hydrocele and elephantiasis. Administration of albendazole with ivermectin or diethylcarbamazine (DEC) has been shown to reduce circulating microfilariae (MF) to levels that cannot sustain transmission. For this reason, LF is one of six diseases considered to be potentially eliminable. Accordingly, in 1997 the World Health Assembly adopted Resolution WHA 50.29, which calls for the elimination of LF as a public health problem, and in 2000, the World Health Organisation (WHO) established the Global Programme to Eliminate Lymphatic Filariasis (GPELF). However, current efforts appear to aim for elimination in some but not all endemic areas. With the 2020 goal of elimination looming, we set out to develop plausible scale up scenarios to reach elimination and eradication. We predict the duration of MDA necessary to reach local elimination for a variety of transmission archetypes using an existing model of LF transmission and consider implications of rapid scale up. We define four scenarios that differ in their geographic coverage and rate of scale up. For each scenario, country specific simulations and calculations were performed that took into account the pre-intervention transmission intensity, different vector genera, drug regimen, previously achieved coverage, previous progress towards elimination, and programmatic delays. Our results indicate that eliminating LF by 2020 is uncertain. If MDA programmes are drastically scaled up and expanded, the final round of MDA could be delivered by 2029. However, if the current rate of scale up is maintained, the final round of MDA may not occur until 2050. While rapid scale up of MDA will decrease the amount of time required to reach eradication, it may also propel the programme towards success, as the risk of failure is likely to increase with increased programme duration.

1062

MONITORING COVERAGE OF LYMPHATIC FILARIASIS MASS DRUG ADMINISTRATION (MDA) IN TANZANIA

Deogratias Damas[1], Paul Erasto[2], Maria Chikawe[3], Cecilia Uisso[3], Upendo Mwingira[3]

[1]IMA World Health, Dar es Salaam, United Republic of Tanzania, [2]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, [3]Tanzania Neglected Tropical Disease Program, NTD Secretariat, Dar es Salaam, United Republic of Tanzania

Successful interruption of the transmission of lymphatic filariasis through mass drug administration (MDA) is dependent on achieving a high rate of annual consumption of preventive chemotherapy (PCT) among at-risk populations. Currently, WHO estimates that 5 years of MDA, achieving 65% coverage can result in disease elimination in most populations. Inadequate coverage rates result in continued disease transmission, and likely additional years of MDA. Thus, the Tanzania Neglected Tropical Diseases Control Program (TZNTDCP) closely monitors MDA coverage. In October 2014 the TZNTDCP carried out an integrated Albendazole and Ivermectin MDA campaign in 16 regions of Tanzania jointly with the national immunization program. A post-MDA coverage survey was conducted in nine randomly selected regions to compare success of campaign styles, validate coverage rates reported by PCT distributors, determine age and gender specific coverage, and determine reasons for noncompliance among community members. Coverage rates ranged from 81% to 52%, with the lowest rate of coverage occurring in Dar es Salaam. Most regions achieved over 65% coverage. Lack of compliance in all regions was primarily associated with absence during the dates of

the MDA, and lack of awareness about the campaign. Coverage rates reported by the survey varied from rates reported by PCT distributors, reflecting both under- and over-reporting. An important limitation for reported coverage is imperfect census data. Further, in Dar es Salaam, PCT distribution centers included transit centers for day laborers, many of whom are not city residents. MDA coverage among different age groups was not statistically significant, however, women were more likely to have received PCT in almost every district in each region. Survey findings provided valuable information that TZNTDCP will use to tailor MDA campaigns in coming years to achieve higher coverage rates in low-performing districts, including intensified pre-campaign education where lack of awareness limited participation, and finding innovative ways to reach people, especially men, who are temporarily absent during campaigns.

1063

SHRINKING THE LYMPHATIC FILARIASIS MAP: A NEW TOOL TO ASSESS ACTIVE TRANSMISSION OF LF DURING MAPPING

Upendo Mwingira[1], **Heven Sime**[2], Sonia Pelletreau[3], Michael Deming[4], Maria Rebollo Polo[4], Katherine Gass[4]

[1]Ministry of Health Tanzania, Dar salaam, United Republic of Tanzania, [2]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Task Force for Global Health, Decatur, GA, United States

The Global Program to Eliminate Lymphatic Filariasis (GPELF) recommends mapping to determine if each district, or implementation unit (IU), requires mass drug administration (MDA) based on the presence of active filarial transmission. Current guidelines require that 2 sites be selected per IU and within each site a convenience sample of 100 adults be tested for antigenemia. The presence of 1 or more positives in either site is interpreted as an indicator of potential transmission, prompting MDA at the IU-level. While this strategy has worked well in high-prevalence settings, imperfect diagnostics, the limited geographical representation of just two sites within an IU, and the fact that a single antigenemia positive adult may not provide evidence of disease transmission, have raised concerns about its use in low-prevalence settings. A statistically rigorous re-mapping strategy was designed. Schools are selected by either systematic or cluster sampling, and within each selected school, children (9-14 years old) are sampled systematically. Children are tested for antigenemia, and the number of positive results is compared against a critical value to determine whether the prevalence of LF is likely below a threshold of 2%. It was applied to 14 IUs in Ethiopia and Tanzania that had qualified for MDA during mapping. In 13 IUs, the number of antigen-positive identified in the remapping surveys was below the critical cutoff, suggesting that in these IUs transmission of LF is not ongoing. In one IU, 10 positives were identified, suggesting that there is on-going transmission and MDA should be initiated. Whereas the current guidelines would have recommended MDA in all 14 IUs based on the traditional strategy, the results of the new strategy suggest that only 1 has on-going transmission. In low-prevalence settings where initial mapping results are uncertain, this inexpensive, rigorous and representative re-mapping strategy may help to generate data on LF transmission to guide programmatic decisions, enabling the GPELF to focus resources where they are truly needed to achieve global LF elimination by 2020.

1065

ASSESSING THE PREVALENCE OF LYMPHATIC FILARIASIS THROUGH SENTINEL AND SPOT CHECK SITES IN TANZANIA

Andreas Nshala[1], Maria Chikawe[2], Mwele Malecela[3], Irene Mremi[3], Upendo Mwingira[2]

[1]IMA World Health, Dar es Salaam, United Republic of Tanzania, [2]Tanzania Neglected Tropical Disease Program, NTD Secretariat, Dar es Salaam, United Republic of Tanzania, [3]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania

Lymphatic filariasis (LF) is endemic in all districts in Tanzania putting over 47 million people at risk of infection. The causative agent, ***Wuchereria bancrofti***, is spread by vector mosquitos, particularly anopheles spp. Control efforts have largely focused on interruption of transmission through mass drug administration (MDA) and vector control. Along the coastal belt, initial mapping reported infection levels (circulating filarial antigen, measured by ICT tests) up to 68%. With over 6 rounds of Ivermectin (IVM) and Albendazole (ALB) MDA, infection levels have started to go down. Two communities from each of the 38 implementation units, which have had over five rounds of IVM and ALB MDA, were selected for the assessment. Approximately 300 people aged 5 years and above were selected and tested for circulating filarial antigen (CFA) for Wulchereria Bancrofti using ICT cards. All ICT positives were followed up and night blood was tested for microfilaraemia using a counting chamber technique. Of the 38 districts surveyed, 31 districts had CFA prevalence between 0-1%, and 7 districts had CFA Prevalence of 2.0-3.7%. These results are in line with expectations following six or more rounds of IVM and ALB MDA. Infection levels have been significantly reduced. Districts with higher baseline prevalence (Morogoro and Tanga regions) reported higher than expected CFA level. This may due to higher baseline/pre-intervention LF infection levels, and or sub-optimal MDA coverage in certain areas.

1066

LYMPHATIC FILARIASIS IN UGANDA: PROGRESS TOWARDS ELIMINATION TARGETS

Gabriel K. Matwale[1], Ambrose Onapa[2], Alexis Serna[3], Edridah M. Tukahebwa[1]

[1]Ministry of Health, Kampala, Uganda, [2]RTI International, Kampala, Uganda, [3]RTI International, Washington, DC, United States

Uganda launched its Lymphatic Filariasis (LF) Elimination program in 2002, in line with World Health Assembly resolution of 1997, with a strategy of annual Mass Drug Administration (MDA) to all at-risk populations with ivermectin and albendazole, co-administered. The first MDA covered 2 highly endemic districts in northern and eastern Uganda, with an eligible population of 1 million, achieving ~75% program coverage. Plans to scale up MDA to 8 districts in 2003 did not materialize due to civil war, instability due to cattle rustling in the north and Eastern regions and lack of funds. In 2004, MDA covered 5 districts and then 10 districts in 2005. In 2007, LF joined other vertical MoH Programs in an integrated program under the umbrella of Neglected Tropical Disease Control Program, funded by United States Agency for International Development. As a result of this program, LF mapping was completed by 2008 and MDA scaled up to 38 districts. By 2010, all 54 LF endemic districts were covered under MDA and to date, all endemic districts have had 3 or more MDAs. Maintenance of effective coverage of 65% is still a challenge, especially in the post-conflict districts in the north. Impact assessments indicated dramatic reductions in both antigenemia and microfilariae prevalence. Transmission Assessment Surveys (TAS), based on WHO protocol, commenced in 2012 in 6 districts. In each evaluation unit, at least 1550 individuals, either aged 6-7 years in communities or primary one and two in schools where feasible were examined for circulating filarial antigens (CFA) using Immunochromatographic Test (ICT) cards. CFA positivity ranged from about 0.06% to 0.6%. From 2014 to 2015, TAS surveys were done in 27 districts, where positivity for CFA ranged from 0% to 0.1%, with many districts registering 0% CFA. Current data indicate that LF transmission

in more than 33 districts has been interrupted, and these districts are eligible for stopping MDA. WHO Regional Program Review Group recently approved the stopping of MDA in 16 districts and more districts are under the same consideration. PELF Uganda is optimistic that by or before the year 2020, most of the evaluation units would have achieved elimination target of CFA below 1%.

1067

SPATIAL CLUSTERING OF FILARIASIS AND RISK FACTORS ANALYSIS IN BENGO PROVINCE, ANGOLA

Miguel Brito[1], Rossely Paulo[2], Thomas R. Unnasch[3], Robert Novak[3], Benjamin Jacob[3], Michelle Stanton[4], David Molyneux[4], Pedro Van-Dumen[5], António Martins[6], Louise Kelly-Hope[4]

[1]CISA - Health Research Centre in Angola/ESTeSL, Caxito, Angola, [2]CISA - Health Research Centre in Angola, Caxito, Angola, [3]College of Public Health, Department of Global Health, University of South Florida, Florida, FL, United States, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Health Ministry Angola, Luanda, Angola, [6]Director Provincial de Saude, Caxito, Angola

The implementation of lymphatic filariasis (LF) and onchocerciasis elimination programmes in areas where ***Loa loa*** is co-endemic is problematic because individuals with heavy ***L. loa*** infections may develop severe adverse events when treated with ivermectin. This has implications for mass drug administration campaigns and alternative strategies may be required. The aim of this study was to determine the distribution of filariasis and associated risk factors in Bengo Province using rapid field survey methods including clinical observations, serology and molecular analysis. RapidEye (5m resolution) satellite data was also employed to provide the foundation for empirical information on vector and parasite populations. A total of 1616 individuals were surveyed in 22 villages across peri-urban and rural areas during August- September 2014. A total ***L. loa*** prevalence of 6.2% using the Rapid Assessment Procedure for loiasis (RAPLOA) was observed, with village prevalence ranging from 0 to 18%. Molecular analysis of blood samples for ***L. loa*** is under analysis with Real Time PCR, and the results will be presented. No positive infection of LF were found by the rapid ICT card or Real Time PCR. However, 13 lymphoedema (0.8%) and 16 hydrocele cases (1.7%) were observed. For onchocerciasis, an overall prevalence of 4.7% was found using the Ov16 ELISA, with village prevalence ranging from 0 to 35%. Regarding intervention use, a low bed net ownership (46.1%) was reported, with only 33.8% sleeping under a bed net the previous night. There was little or no evidence of ivermectin consumption for onchocerciasis. When asked about the main ***L. loa*** vector Chrysops spp. 12.1% of individuals could identify the fly by a photo. Individuals with loiasis were twice as likely, and males with loaisis were four times as likely to recognize the fly, than those without. Filariasis is endemic at different prevalences and spatial patterns throughout the region, and the presence of ***L. loa*** suggests that alternative strategies for elimination are required, which may include scaling up vector control with key information on the best targets directed by local community knowledge.

1069

"RIVER EPILEPSY" IN DEMOCRATIC REPUBLIC OF THE CONGO? PREVALENCE OF EPILEPSY SYMPTOMS IN A ZONE ENDEMIC FOR ONCHOCERCIASIS, KATANGA PROVINCE, 2015

Moise A. Mussa[1], **Karen D. Cowgill**[2], Robert Colebunders[3], Floribert Tepage[4], Michel Mandro[5], Anne Laudisoit[6]

[1]Universite de Lubumbashi, Lubumbashi, Democratic Republic of the Congo, [2]Seattle University, Seattle, WA, United States, [3]Institute of Tropical Medicine, Antwerp, Belgium, [4]Programme National de Lutte contre l'Onchocercose, Ministère de la Santé Publique, Buta, Democratic Republic of the Congo, [5]University of Bunia, Bunia, Democratic Republic of the Congo, [6]University of Antwerp, Antwerp, Belgium

Nodding syndrome is a particular type of epilepsy epidemic in some regions of South Sudan and east Africa. Its cause is unknown, but epidemiological data suggest an association with onchocerciasis. Increased levels of epilepsy have been observed in other regions endemic for onchocerciasis, and nodding syndrome may be only one manifestation along a continuum of onchocerciasis-associated neurological syndromes. A surveillance system for epilepsy cases in different onchocerciasis-endemic regions is planned to be rolled out in the Democratic Republic of the Congo (DRC) in 2015. The relationship between prevalence of epilepsy, degree of onchocerciasis endemicity, and ivermectin coverage will be investigated. In April 2015, we conducted a pilot study in the health zone of Kafubu, outside the city of Lubumbashi in Katanga province, DRC. We surveyed 500 households with 2359 people. Reported ivermectin uptake since annual MDA started in 2006 ranged between 26 and 46%. There were 63 (2.7%) cases consistent with epilepsy (reporting either a previous diagnosis of epilepsy, or 2 or more episodes of loss of consciousness with or without incontinence or drooling; absence seizures; convulsions; or sudden-onset, brief auditory, visual, or olfactory hallucinations). Mean age of these cases was 16.9 years, and mean age of onset was 6.4 years; 54% were female. Four of the 63 cases consistent with epilepsy also reported nodules consistent with onchocerciasis. The results of this pilot study indicate that the prevalence of reported epilepsy in this onchocerciasis endemic region in the DRC is well above the WHO average prevalence estimate of 4-10 per 1000, and also suggest the need to strengthen ivermectin distribution programs and epilepsy care in this region. Determining how much of this high prevalence of epilepsy is due to "river epilepsy" -- epilepsy caused by onchocerciasis -- will require laboratory testing and the exclusion of cysticercosis and other potential causes.

1070

AN IMPLEMENTABLE AND SUSTAINABLE QUALITY ASSURANCE PROGRAM FOR OV16 SEROLOGY-BASED RAPID TESTS

Roger B. Peck, Dunia Faulx, Allison Golden, Eric J. Stevens, Lindsay Yokobe, Gonzalo J. Domingo, Tala de los Santos

PATH, Seattle, WA, United States

The availability of an Ov16 serology-based rapid test has highlighted important issues around uptake and appropriate use. Confidence in the testing process, including test quality, performance, and accurate results, are important factors to consider when national onchocerciasis control and elimination programs (NOCPs) use test results for action. A quality assurance (QA) program will help to assure NOCPs that the tests are functioning as intended, results are of high quality, and additionally provide an opportunity for feedback to the test manufacturer. Six modules have been developed to support a QA program: 1. Operator training to familiarize those involved in the testing process with the proper use of the test; 2. Operator proficiency to qualify trained individuals to conduct the test; 3. Quality assessment to demonstrate performance with country-specific samples, as necessary; 4. Lot testing to confirm that the tests perform as intended when received in-country from the manufacturer; 5. Quality control to increase confidence that the test system is working as

intended at the point of use; and 6. Post-market surveillance to monitor the performance of the product during routine use. The QA program is intended to be utilized by and implemented completely or by module with NOCPs in conjunction with test manufacturers and other key international stakeholders. Early adopters of Ov16 serology-based rapid testing have piloted modules of the QA program. Test users were trained by a variety of mechanisms including in-person training, remote training by teleconferences and/or video conferences, and QA program material review. Feedback from QA program implementers has indicated that the methods are acceptable. The feedback is also used to iteratively improve the QA program and will seed future implementation. Implementation of the QA program or modules by NOCPs should be simultaneous with the adoption of Ov16 rapid testing. The elements and reagents required for such a QA program are presented here. Stakeholder support for the QA program and reliable availability of the sample panels and supplemental materials are needed to make it sustainable.

1071

SCREENING CASCADE FOR DISCOVERY PROGRAMS AIMING AT THE IDENTIFICATION OF NEW MACROFILARICIDE AGENTS FOR TREATMENT OF ONCHOCERCIASIS

Simon Townson[1], Sabine Specht[2], Suzanne Gokool[1], James Metz[3], Sujatha Gopalakrishnan[3], Dale Kempf[3], Coralie Martin[4], Achim Hoerauf[5], Thomas von Geldern[3], Ivan Scandale[6]

[1]Northwick Park Institute for Medical Research, London, United Kingdom, [2]Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany, [3]AbbVie, Chicago, IL, United States, [4]Parasitologie Comparée et Modèles Expérimenteaux, Paris, France, [5]Institute for Medical Microbiology, Immunology and Parasitology, University Hospital of Bonn, Bonn, Germany, [6]Drug for Neglected Diseases initiative, Geneva, Switzerland

Existing medicines to treat filarial infections primarily kill microfilaria and temporarily sterilize adult nematodes. There remains an urgent need to design and develop modern anti-filarial treatments that are cidal to adult worms (macrofilaricides). Recently, a small pipeline of new drug candidates has been created by PDPs, academic groups and pharmaceutical companies. Given the attrition rate in drug discovery and development, it is important to strengthen the pipeline by adding new chemical entities into the drug development pathway. To identify compounds with such potential, DNDi has accessed commercial libraries and worked with companies to access focused libraries from their drug discovery programs. These libraries were evaluated through a screening cascade encompassing three steps: phenotypic screen against Onchocerca spp, determination of ***in vivo*** ADME, and proof of principle testing in murine models using L. sigmodontis. Through this process, several existing drugs and advanced clinical candidates were identified for potential repurposing as antifilarial agents. These include compounds that have activity against several human kinase targets, as well as a set of nitroheterocyclic molecules. This strategy has also been adapted to the screening of pharma collections. A prioritized subset of the AbbVie compound collection was clustered based on structure, and sampled for screening against adult ***Onchocerca gutturosa*** worms. Back-screening of hits, facilitated by cheminformatic analysis, led to a dramatically improved second-round hit rate. Several of the primary hits have demonstrated ***in vivo*** activity. The combination of structure activity relationships and ***in vivo*** proof of principle identified three distinct chemical series. These novel anti-filarial scaffolds will be advanced to hit expansion and lead optimization studies.

1072

IN VITRO ANTIFILARIAL ACTIVITIES AND METABOLOMIC PROFILING OF EXTRACTS OF *DANIELLIA OLIVERI* AND *PSOROSPERMUM FEBRIFUGUM*

Melanie Abongwa[1], Fidelis Cho-Ngwa[2], Godfred A. Ayimele[2], Moses Samje[2], Smith B. Babiaka[2], Ann Perera[1], Adrian J. Wolstenholme[3], Richard J. Martin[1], Alan P. Robertson[1]

[1]Iowa State University, Ames, IA, United States, [2]University of Buea, Buea, Cameroon, [3]University of Georgia, Athens, GA, United States

Subcutaneous filariasis (onchocerciasis) caused by ***Onchocerca volvulus***, and lymphatic filariasis caused by ***Brugia malayi*** are among the neglected tropical diseases predominant in the developing world. These infections cause debilitating pathologies, including blindness, severe skin itching and lymphedema. Currently, the approved drugs for treatment of filariasis; ivermectin, diethylcarbamazine and albendazole, are only microfilaricidal. Effective control is therefore hindered by the lack of macrofilaricides, leaving the adult worms, which may live for over 15 years. Additionally, the repeated use of ivermectin, diethylcarbamazine and albendazole has generated concerns of resistance development. Clearly, there is the need for the development of new drugs that will be effective against the macrofilariae, while more effective microfilracidal compounds are also desirable. In an endeavor to contribute to the search for new antifilarial drugs, we screened extracts of the plants; ***Daniellia oliveri and Psorospermum febrifugum***, for activity against both macrofilariae and microfilariae of ***O. ochengi***, the best known animal model of ***O. volvulus***; and adult ***B. malayi***, using ***in vitro*** quantitative biochemical and motility assays. Extracts of ***D. oliveri*** and ***P. febrifugum*** were effective in killing both ***O. ochengi*** and ***B. malayi*** adult worms, and also ***O. ochengi*** microfilariae. Remarkably, the active extracts of these plants had IC_{50s} as low as 4µg/mL, and the majority of them showed little or no toxicity on N27 rat neuronal cells. Metabolomic profiling of active extracts using GC-MS revealed identifiable peaks for compounds which can be isolated and further tested for enhanced activity. Based on our findings, ***D. oliveri and P. febrifugum*** have potential as sources of lead compounds for the development of novel antifilarial drugs. Presently, we are investigating the effects of our most promising extracts on the motility of ***Caenorhabditis elegans***, a model for parasitic nematodes, using the WormLab system. Results obtained will be combined with mutagenesis studies in ***C. elegans*** to elucidate the mode of action of our filaricidal extracts/compounds.

1073

EFFECTS OF TEMPERATURE AND HUMIDITY ON THE STABILITY OF DRY BLOOD SPOTS: EVALUATION OF ANTIBODY REACTIVITY AND COLOR

Circe McDonald[1], **Vitaliano A. Cama**[2]

[1]IHRC, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

Dried blood spots (DBS) are an inexpensive and robust format to preserve blood specimens for public health evaluations and surveys, including programmatic monitoring and evaluation of neglected tropical diseases. DBS have been demonstrated to preserve antibody reactivity for long periods; however, procedures to determine the specimen quality in DBS are not always available or performed. We conducted a 12-month DBS antibody stability study using a reference control for lymphatic filariasis (LF). DBS cards were split into groups and exposed to 4°C, 25°C or 37°C, and low (<40%) or high (>99%) humidity. DBS were collected biweekly and stored frozen until all samples were analyzed. At the end of 12 months, all DBS were eluted and simultaneously analyzed for IgG antibody responses against 7 antigens: Bm14, Bm33, Wb123 and BmR1 for LF, and ***Streptococcus***, ***E. coli*** toxin, and ***Tetanus*** toxoid. Additionally, coloration of the eluted DBS was quantified using image analysis. DBS kept at 37°C and 27°C under high humidity conditions lost all detectable antibody reactivity by days 56 and 112, respectively. DBS stored at 37°C and 25°C

under low humidity conditions had decreased reactivity at 101 and 154 days, respectively, with total loss of reactivity by 264 and 364 days, respectively. Meanwhile, DBS stored at 4°C had minor losses in reactivity, with greater reductions seen with exposure to high humidity. Color of eluted DBS was measured using colorimetric RGB codes; values closer to 255 in each channel correlated with higher antibody reactivity. This study shows the importance of storage at low temperature conditions and the key role of desiccants when refrigeration is not immediately available, In addition, it illustrates the potential use of color analyses of eluted DBS as a simple surrogate method for specimen quality control.

1074

COMBINATION OF CONVENTIONAL PARASITOLOGICAL DIAGNOSTIC METHODS AND QPCR ASSAYS FOR DETECTING *ONCHOCERCA VOLVULUS* INFECTIONS

Melanie Lloyd[1], Rebecca Gilbert[1], Nathalie Tebao Taha[2], Gary J. Weil[1], Aboulaye Meite[2], Ilunga M. Kouakou[2], Peter U. Fischer[1]

[1]Washington University School of Medicine, St. Louis, MO, United States, [2]Ministry of Health and Social Welfare of Côte d'Ivoire, Abidjan, Côte D'Ivoire

Commonly used methods for diagnosing ***Onchocerca volvulus*** infections (microscopic detection of microfilariae in skin snips and nodule palpation) are insensitive. Improved methods are needed for monitoring and evaluation of onchocerciasis elimination programs and for clinical diagnosis of individual patients. We have developed a sensitive probe-based qPCR assay for detecting ***O. volvulus*** DNA, and this assay was tested with samples collected from an endemic area in eastern Côte d'Ivoire. The new test was evaluated with dried skin snip pairs from 369 subjects and compared to routine skin snip microscopy and nodule palpation results from the same individuals. Onchocerciasis prevalence for these samples by qPCR, skin snip microscopy, and nodule palpation were 56.9%, 26.0%, and 37.9%, respectively. Furthermore, the combination of all three tests produced an infection prevalence of 72.9%, which was significantly higher than the 53.1% detected by microscopy plus nodule palpation without qPCR. The qPCR assay was also compared to conventional PCR: while qPCR did not detect significantly more positive individuals, the limit of detection of the qPCR assay was 100-fold lower than that of conventional PCR. In conclusion, the new qPCR assay could be a useful tool for detecting residual ***O. volvulus*** infections in human populations as prevalence decreases in areas following community-directed treatment with ivermectin.

1075

A NOVEL BIPLEX RAPID TEST FOR THE SIMULTANEOUS DETECTION OF *WUCHERERIA BANCROFTI*- AND *ONCHOCERCA VOLVULUS*-SPECIFIC ANTIBODIES: A NEXT GENERATION INTEGRATED SURVEILLANCE TOOL

Allison L. Golden[1], Cathy Steel[2], Dunia Faulx[1], Roger Peck[1], Eric J. Stevens[1], Lindsay Yokobe[1], Jeffrey Wellhausen[1], Gonzalo J. Domingo[1], Tala de los Santos[1], Thomas B. Nutman[2]

[1]PATH, Seattle, WA, United States, [2]National Institutes of Health, Bethesda, MD, United States

In recent years, there has been a global push for an integrated approach to neglected tropical disease (NTD) control and elimination. In Africa, there is the opportunity to integrate programs for onchocerciasis and lymphatic filariasis (LF) due to similarities regarding surveillance activities, control mechanisms, and programmatic overlap. To facilitate the integrated surveillance activities for onchocerciasis and LF, PATH and NIAID are collaborating to develop a biplex rapid diagnostic test that detects IgG4 antibodies against both the Ov16 antigen, specific for ***Onchocerca volvulus***, and the Wb123 antigen, specific for ***Wuchereria bancrofti***. Concurrent to the 2014 launch of an Ov16-only antibody detection rapid test, a proof-of-concept onchocerciasis/LF biplex test prototype has been developed. Laboratory data using well-characterized clinical specimens indicate the sensitivity and specificity to be 92.6% and 96.0%, respectively for Wb123 and 90.3% and 98.1%, respectively for Ov16, similar to the performance of the Ov16-only test. The technology has been transferred to a commercial manufacturing partner for optimization. Early beta prototypes are undergoing further performance evaluation and stability studies to ensure a field-ready test. Supplemental materials that have been developed include a human monoclonal IgG4 antibody positive control for Wb123 and user-friendly training materials for use by field teams. The test and supplemental materials will be used in product verification and field validation, leading up to activities in support of programmatic use of the test.

1076

IN VIVO FILARIASIS MODEL PREDICTS HIGH DOSE RIFAMPICIN CAN ACHIEVE RAPID ELIMINATION OF WOLBACHIA FROM FILARIAL NEMATODES

Ghaith Aljayyoussi[1], Hayley Tyrer[1], David Waterhouse[1], Jill Davies[1], Louise Ford[1], Joseph Turner[1], Sabine Specht[2], Achim Hoerauf[2], Mark Taylor[1], Steve Ward[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University Hospital Bonn Germany, Bonn, Germany

The Anti-Wolbachia (A•WOL) programme aims to find safe macrofilaricides for lymphatic filariasis and onchocerciasis through targeting the Wolbachia bacterial endosymbiont. Doxycycline demonstrates proof of concept to achieve depletion of Wolbachia leading to macrofilaricidal activity when administered for a period of 4-6 weeks. The prolonged period of treatment and exclusion of key target groups (pregnancy and children <8) restricts the widespread scale-up of doxycycline for use in elimination programmes. The A•WOL programme aims to identify new drugs and regimens that can reduce the treatment period to 7 days or less and be used in currently restricted groups. In this study we show that clinically relevant high doses of rifampicin can lead to Wolbachia elimination rates from adult worms that are several times faster than elimination rates achieved by doxycycline. Using systemic dose escalation studies in the A•WOL mouse screening model we show that Rifampicin can achieve >90% Wolbachia elimination in time periods of 7 days or less resulting in marked macrofilaricidal activity at later stages. Using pharmacokinetic/pharmacodynamic (PK/PD) modelling and mouse-human bridging analysis, we show that high doses of rifampicin, which could be safely administered to eligible populations should reduce treatment times to 7 days or less. Clinical trials are planned to test these findings in human lymphatic filariasis and onchocerciasis.

1077

ESTABLISHMENT OF A DISEASE MODEL OF LYMPHATIC FILARIASIS

Belinda M. Jackson, So Young Kim, Shalini Jaiswal, Colin M. Wilson, Jessica Scott, Scott Jones, Bernard J. Dardzinski, Edward Mitre

Uniformed Services University, Bethesda, MD, United States

In this study, we sought to establish the small mammal model of lymphatic filariasis (LF) initially developed in the 1980s. Ferrets were infected with 150 L3 stage ***Brugia malayi*** or ***Brugia pahangi*** larvae by subcutaneous injection into the right footpad. Blood was drawn every two weeks for white blood cell differential counts and microfilaria quantification. With both ***B. malayi*** and ***B. pahangi*** microfilaremia began at 12-14 weeks after infection with a mean peak of 85 mf/ml and 300 mf/ml, respectively. Eosinophilia developed at 12 weeks. Animals were euthanized four months post infection and dissections were performed to localize adult worms. The mean number of adults recovered was 13 for ***B. malayi*** and 16 for ***B. pahangi***. 85% of recovered worms were located in the lymphatics draining the injected limb; most of the other worms were found in the lymphatics of the opposite leg. While there were no differences in adult worm numbers between male and female

ferrets, females exhibited greater numbers of microfilariae and less peripheral eosinophilia. Subcutaneous Evans Blue dye (injected into both legs one hour prior to euthanasia) demonstrated expanded networks of tortuous and dilated lymphatic vessels on the side of the initial infection. Motile worms were observed within these vessels. To visualize changes in lymphatic function over time, we developed an 18F-FDG PET/CT lymphography protocol using the Siemens Inveon Multimodality scanner for imaging. With this technique, we are able to assess both lymphatic anatomy and functionality. Preliminary results support those of the Evans Blue studies, demonstrating aberrant anatomy and disrupted lymphatic flow. Histology and immunology studies are also in progress. In conclusion, we have successfully re-established the small mammal disease model of lymphatic filariasis. We expect it will be a robust model for 1) testing the efficacy of new antifilarial medications, 2) ensuring new antifilarial medications do not worsen clinical disease, 3) evaluating novel means of decreasing lymphatic disease morbidity in LF, and 4) understanding the mechanisms by which lymphatic dysfunction occurs in LF.

1078

TYLOSIN ANALOGS AS ANTI-FILARIAL AGENTS. PART A: MEDICINAL CHEMISTRY OPTIMIZATION AND CANDIDATE SELECTION

Thomas von Geldern[1], Kelly Johnston[2], Rachel Clare[2], Kennan Marsh[1], Junli Ma[1], Deanne Stolarik[1], Howard Morton[1], Louise Ford[2], Joseph Turner[2], Sabine Specht[3], Achim Hoerauf[3], Stephen Ward[2], Dale Kempf[1], Mark Taylor[2]

[1]AbbVie, North Chicago, IL, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]University Hospital, Bonn, Germany

Onchocerciasis and lymphatic filariasis (LF), diseases resulting from filarial nematode infections, together affect nearly 150 million people worldwide, with over 1.5 billion at risk. These diseases create an enormous burden of morbidity and lost productivity, in addition to the social stigma associated with their clinical manifestations. Current treatment options (ivermectin, albendazole, and diethylcarbamazine, alone or in combination) focus on eliminating microfilaria and temporarily sterilizing adult worms, but do not clear the infection. New agents with macrofilaricidal activity are needed. Many filarial nematodes, including those responsible for onchocerciasis and LF, carry an obligate symbiont, the bacterium ***Wolbachia***. Anti-***Wolbachia*** therapy using doxycycline has demonstrated clinical benefit by clearing adult worms; however, the developmental toxicity of this agent and the long treatment courses required for efficacy limit its scale-up for programmatic use. Through a screen of a representative sample of the AbbVie anti-infectives collection, we identified the veterinary antibiotic tylosin A (TylA) as a potent anti-***Wolbachia*** agent. ***In vivo*** testing confirmed that this agent is an effective macrofilaricidal agent; however, the pharmacokinetic properties of TylA make it unsuitable for oral administration. We have prepared a set of over 150 analogs of tylosin, optimizing anti-***Wolbachia*** activity as well as drug exposure upon oral delivery. During the course of these structure-activity studies, potency has increased by over 1,000-fold, while oral drug levels have improved by as much as 40-fold. The optimized analogs A-1535469 and A-1574083 are highly effective in several models of filarial worm infection, meeting Target Product Profile regimens of less than 7 days. Their efficacy and safety profiles make them attractive candidates for therapeutic use, and they are currently being advanced toward clinical evaluation.

1079

FEASIBILITY STUDIES TOWARDS A VIRTUAL SKIN BIOPSY FOR ONCHOCERCIASIS

Lieven Stuyver[1], Jon Holmes[2], Ole Lagatie[1], Andrew Freeman[3], Michel Boussinesq[4], Simon Townson[3]

[1]Janssen Diagnostics, Beerse, Belgium, [2]Michelson Diagnostics, Maidstone, United Kingdom, [3]Northwick Park Institute for Medical Research, London, United Kingdom, [4]Institut de Recherche pour le Développement, Montpellier, France

The gold standard test for onchocerciasis diagnosis is the skin biopsy procedure, including removal of around 2 mg of skin, incubate in standard saline at rt for 24 hours, and count microfilariae (mf) under light microscopy. Although the skin snip is highly specific, its sensitivity can be limited in case of low microfilaridermia. Skin biopsies are invasive, painful, require sterilization of equipment and examination by experienced microscopists. In this study, we evaluated optical coherent tomography (OCT) as a non-invasive alternative to generate a virtual biopsy in an artificial setting. Onchocerca lienalis mf kept in culture on a monkey kidney feeder cell line were examined in three successive steps, using two visualization techniques: light microscopy (control) and VivoSight multi-beam dermatological OCT (Michelson Diagnostics, UK). First, O. lienalis mf were placed in 20 µL on a Petri dish and imaged, conclusively demonstrating that the mf could be imaged by OCT at the limit of the device's resolving power. Next, O. lienalis mf were placed in 20 µL medium at the surface of a sample of human abdominal skin (4cm x 4cm) collected from surgery (Tissue Solutions, UK). It was found to be impossible to find the mf in-situ using optical microscopy. However, a parasite could be seen in the OCT images and positively identified from its characteristic wriggling motion, illustrating that a parasite could be detected based on motion, but not because of optical contrast against the skin tissue. Finally, mf were injected in the upper dermis (250 - 310 µm under the skin surface). After 30 min at 37°C, the skin sample was imaged with Dynamic OCT. The algorithm successfully picked out the areas in the skin where movement was seen, demonstrating that the mf had migrated from the injection site into the tissue of the dermis. These initial results show promise for the technology to be developed into a practical method for the field diagnosis and quantitation of Onchocerca microfilaria present in a skin tissue in-vivo. The imaging processing could be further enhanced to automatically count the number of individual parasites.

1080

A VISUAL ISOTHERMAL NUCLEIC ACID AMPLIFICATION ASSAY FOR DIAGNOSIS OF ONCHOCERCIASIS IN HUMANS

Andy K. Alhassan[1], Nathan A. Tanner[1], Kwadwo F. Kyeremeh[2], Mike Y. Osei-Atweneboana[2], Yinhua Zhang[1], Thomas C. Evans, Jr.[1], Clotilde K. Carlow[1]

[1]New England Biolabs, Ipswich, MA, United States, [2]Council for Scientific and Industrial Research-Water Research Institute, Accra, Ghana

Onchocerciasis or "river blindness" is a parasitic infection caused ***Onchocerca volvulus***. The standard method to diagnose infection relies on the detection of microfilariae in human skin biopsies. This technique lacks sensitivity particularly when samples are collected from drug-treated individuals. Nucleic acid-based tests provide specificity and sensitivity however the currently used assays, such as polymerase chain reaction (PCR), and real-time PCR assays are difficult to implement in low resource settings. Loop-mediated isothermal amplification (LAMP) is a one-step, nucleic acid amplification technique that can be performed under isothermal conditions. Its simple visual detection format, and no need for equipment or post amplification processing, offer considerable advantages over PCR in the field. In the present study a LAMP assay targeting the genus-specific O-150 repeat sequence was developed. Amplification was detected by measuring turbidity through real-time monitoring using a turbidimeter, or visually using either hydroxylnaphthol blue (HNB) or a newly developed pH sensitive dye. The performance of LAMP and PCR

were evaluated using human skin snips spiked with varying concentrations of ***O. volvulus*** genomic DNA or unrelated filarial DNAs. Both PCR and LAMP (regardless of detection method used) assays were highly specific. However, higher levels of sensitivity were achieved in LAMP assays detecting DNA equivalent of less than one parasite within 60 minutes. Of the various LAMP detection methods evaluated, the pH sensitive dye provided easier discrimination between positive and negative results and the color remained stable. In summary, we have developed a rapid and highly specific and sensitive LAMP assay to detect ***O. volvulus*** infection in humans. Colorimetric visualization of amplification using a pH sensitive dye facilitates its use in less equipped laboratories and in rural settings. The test has the potential to be developed further as a field tool to assist in the management of control programs.

1081

MNSODTG MICE EXHIBIT IMPROVED HEART AND MITOCHONDRIAL FUNCTION DURING CHRONIC CHAGAS DISEASE

Jianjun Wen

University of Texas Medical Branch, Galveston, TX, United States

We observed that mitochondrial reactive oxygen species (mtROS) plays very important roles in the pregression of chagesic disease. In this study, we utilized genetically-modified mice to scavenge mtROS to investigate the impact of improved ROS scavenging capacity on heart function in Chagas disease. C57BL/6 mice (wild-type, MnSODtg, MnSOD+/-) were infected with ***Trypanosoma cruzi*** (Tc***)***. Chronically infected mice (≥120 days post infection, dpi) exhibited a substantial decrease in heart tissue MnSOD gene expression, MnSOD protein level, MnSOD enzyme activity and antioxidant level; decrease of heart dysfunction via lower of stroke volume (SV), cardiac output (CO), ejection fraction (EF), fractional shorting (FS) and left ventricular posterior wall of systolic, and increase of end-systolic/diatolic volume (ESV/EDS) and left ventricular internal diameter of systole(LVID;s); enhancement of hypertrophy by increase of left ventricular septum (IVS), left ventricular mass (LV mass) and areas duo to augmentation of collagen expressions. One of our novel observations was that sarco/endoplasmic reticulum Ca2+-ATPase (SERCA2) lost its role of maintenance of low cytoplasm free calcium and mediated calcium uptake to intracellular store in Tc-induced chronic chagasic disease. Studies of fresh heart slices using O2K confirmed that Tc diminished heart mitochondrial function like decrease of oxygen flux and respiratory control ratio (RCR), which were caused by enhancements of ROS. Chronically infected MnSODtg mice exhibited a marginal decline in Tc-induced heart function, heart hypertrophy, mitochondrial dysfunction. In conclusion, overexpression of MnSOD inhibited Tc-induced oxidative damage od heart tissue, suggesting that enhancing the mitochondrial ROS scavenging capacity was beneficial in controlling the inflammatory and oxidative pathology, and cardiac remodeling responses that are hallmarks of chronic Chagas disease.

ENHANCING PGC-1A ACTIVITY IMPROVES HEART FUNCTION THROUGH ACTIVATING MITOCHONDRIAL BIOGENESIS AND INHIBITING INFLAMMATORY PATHWAYS IN CHAGAS DISEASE

Xianxiu Wan, Jianjun Wen, Koo Sue-jie

The University of Texas Medical Branch, Galveston, TX, United States

Chronic chagasic cardiomyopathy (CCM) is presented with ventricular hypertrophy and contractile dysfunction that can lead to heart failure. I have found that a substantial decline in mitochondrial biogenesis and SIRT1/PGC-1α activity ensue in chronic chagasic mice. It was evidenced by the decline in mitochondrial DNA content as well as mRNA levels of mitochondrial encoded genes and mtDNA replication machinery. Further, the activity of SIRT1 (required for PGC-1α activation) was decreased and associated with decreased nuclear levels of PGC-1-regulated NRF1 transcription factor in chagasic hearts. The mitochondrial size and number were also reduced in chagasic heart, determined by electron microscopy. Therefore, we hypothesized that enhancing the SIRT1/PGC-1α activity by SIRT1 agonist would improve heart function through activating mitochondrial biogenesis and inhibiting inflammatory pathways in Chagasic disease. Mice were infected with ***Trypanosoma cruzi***, and beginning at day 90 post-infection (pi), treated with resveratrol (SIRT1 agonist) or metformin (AMPK agonist, can enhance SIRT1 activity) for 21 days; and then heart function was monitored at 150 days pi. We found that treatment with resveratrol partially attenuated the heart dysfunction (stroke volume, cardiac output, ejection fraction, heart rate) and cardiac hypertrophy in chagasic mice. These benefits were associated with improved expression of the mitochondrial DNA encoded genes and mtDNA content though the expression of genes involved in mtDNA replication was not improved. Treatment with metformin was not significantly beneficial in improving the CCM outcomes. The partial beneficial effects of resveratrol could be due to inefficient activation of SIRT1 or delayed start of the treatment. We plan to treat mice with SIRT1 agonist SIRT1720 (10 fold more active than resveratrol) during the indeterminate phase of ***T. cruzi*** infection in next set of experiments. This study will improve our understanding of the molecular and immune mechanisms of chagasic heart disease and will provide a novel treatment for chronically-infected chagasic patients.

1083

HISTOPATHOLOGICAL AND ULTRASTRUCTURAL FINDINGS IN SKIN BIOPSIES OF PATIENTS WITH EARLY AND LATE CUTANEOUS LEISHMANIASIS INDUZED BY *LEISHMANIA (VIANNIA) BRAZILIENSIS*

Maíra G. Saldanha[1], Sérgio Arruda[1], Edgar M. Carvalho[2]

[1]Fundação Oswaldo Cruz, Salvador, Brazil, [2]Serviço de Imunologia. Complexo Hospitalar Universitário Professor Edgard Santos. Universidade Federal da Bahia, Salvador, Brazil

Cutaneous leishmaniasis (CL) is the most frequent clinical form of leishmaniasis, which affects the skin and is an important health problem in Brazil. ***Leishmania (V.) braziliensis*** infection induces a large spectrum of lesions that clinically may manifest as a single skin lesion localized, generally in uncovered parts of the body, initialized with a papule until the development of an ulcer or which may regress spontaneously. Patients with early cutaneous leishmaniasis (ECL) have 46% failure to standard treatment, while the cure rate for patients with late cutaneous leishmaniasis (LCL) is until 90%. We aim to investigate the cellular inflammatory aspects in situ biopsies of human infection by ***L. braziliensis*** in ECL while papule comparing them with LCL. We describe tissue cells from inflammatory infiltrate different stages of infection and feature the immune response based on histophatological and ultrastructural analysis, as well the total extent of inflammation and cellular profile, changes in the epidermis and dermis, amount and quality of amastigotes. Hyperkeratosis is more frequent in ECL while giant cells were observed during the classical ulcer. Macrophages and lymphocytes were the predominant cells in the ulcers of localized CL and the inflammation increased with diseases evolution. By other hand, the quantity of amastigotes decreased with the time of disease. Some parasites righteous were viewed by transmission electron microscopy. Although the attempt of the macrophages to kill some Leishmania in the earlystage, we also observed the development strong inflammatory response with extensive cellular infiltrate and other histological changes that may be involved with pathogenesis and progress lesion in CL, also may contribute to treatment failure.

1084

TRYPANOSOMA CRUZI REDOX NETWORK AS A VIRULENCE FACTOR: ROLE OF TRYPAREDOXIN PEROXIDASE IN THE PATHOGENESIS OF CHAGAS DISEASE

M. Paola Zago[1], M. Dolores Piñeyro[2], Andrea Mesias[1], Carlos Robello[2], Nisha J. Garg[3]

[1]Experimental Pathology Insititute CONICET, Salta, Argentina, [2]Pasteur Institute, Montevideo, Uruguay, [3]Department Microbiology and Immunology, University of Texas Medical Branch, Galveston, TX, United States

The aim of our study is to gain insight the involvement of ***Trypanosoma cruzi*** redox system in the pathogenic mechanism of Chagas disease. Many groups have attributed to this pathway a role in the evasion of the host innate immune response. Previously, we described the up regulation of enzymes of this network, particularly tryparedoxine peroxidase (TXNPx), in trypomastigotes of DTUI isolates. In order to characterize its participation in the cellular response to infection, we employed a site-directed mutagenesis approach to construct the active site mutants of cytosolic (CPX^{C52S}, CPX^{C173S}) and mitochondrial (MPX^{C81S}, MPX^{C204S}) isoforms of TXNPx. The pRibotex plasmid encoding the cDNAs for mutant TXNPx isoforms was electroporated into Sylvio X10/4 and transfectants were selected under drug pressure (250-400µg/ml G418). Overexpression of the mutant proteins and the wild type protein in the transfectants was confirmed by western blotting with specific antibodies against CPX and MPX isoforms. Also, the differential peroxidase activity of the recombinant parasites was detected with the Peroxidase Assay Kit (Invitrogen). Evaluation of viability by Alamar Blue®, revealed that ***T. cruzi*** expressing mutant isoforms of CPX and MPX were significantly more sensitive ($p<0.05$) to oxidizing species, e.g. H_2O_2 and $ONOO^{\bullet-}$, when compared to the wild type parasites or ***T. cruzi*** transfected with CPX wild type isoform. ***In vitro*** infection studies in RAW macrophages showed that intracellular replication of $Syl.MPX^{C81S}$ and $Syl.CPX^{C173S}$ determined by qPCR was decreased, compared to that noted for SylWT and Syl.CPX ($p<0.01$). This capability was associated with their inability to prevent intracellular ROS accumulation (measured by H_2DCF-DA probe) and oxidants released into the culture media (Amplex red and Griess assays). In summary, we demonstrate that via TXNPx decomposition of macrophage derived free radicals, ***T. cruzi*** ensures its survival and persistence in the host. Further characterization of the mutants' biological behavior by murine infection is ongoing, and these data will be presented in further support of TXNPx role in the pathogenesis of Chagas disease.

DIVERSITY OF *TRYPANOSOMA CRUZI* INFECTION IN PATIENTS CO-INFECTED WITH HIV AND CHAGAS DISEASE

Natalie M. Bowman[1], Daniel Clark[2], Jeong Choi[3], Gerson Galdos Cardenas[4], Mauricio Dorn[5], Omar Gandarilla[6], Enzo Fortuny[6], Anne Palumbo[6], Lisbeth Ferrufino[6], Leny Sanchez[7], Louisa Messenger[4], Jorge Flores[5], Roni Colanzi[8], Steven Meshnick[1], Caryn Bern[9], Robert H. Gilman[4], Jonathan J. Juliano[1]

[1]University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, [2]Vanderbilt University, Nashville, TN, United States, [3]University of California Davis, Davis, CA, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [5]Hospital San Juan de Dios, Santa Cruz, Plurinational State of Bolivia, [6]AB PRISMA, Santa Cruz, Plurinational State of Bolivia, [7]Universidad Peruana Cayetano Heredia, Lima, Peru, [8]Universidad Catolica Boliviana, Santa Cruz, Plurinational State of Bolivia, [9]University of California San Francisco, San Francisco, CA, United States

Chagas disease, caused by the protozoan ***Trypanosoma cruzi***, can cause severe neurological syndromes in immunocompromised patients such as those infected with HIV. We characterized the genetic diversity of ***T. cruzi*** infection in several HIV-infected Bolivian patients with high-level parasitemia. Samples were derived from HIV-positive patients recruited into epidemiological studies of HIV/Chagas disease coinfection in Cochabamba and Santa Cruz, Bolivia. DNA was extracted from whole blood or guanidine-preserved samples, and ***T. cruzi*** infection was confirmed with RT-PCR. We used high-fidelity nested PCR to amplify a 327-base pair fragment of the TcSC5D gene, which has been used for strain typing, and amplicon deep sequenced the region using an Ion Torrent PGM. We determined multiplicity of infection and genotyped the strains of ***T. cruzi*** using deep sequencing and conventional restriction fragment length polymorphism (RFLP) methods. Sequences were clustered to predict genotypes using a heuristic clustering algorithm. Within-host and within-population diversity indices were calculated using EstimateS and/or QIIME. We have shown that deep sequencing of ***T. cruzi*** from clinical samples is possible and explored the diversity of ***T. cruzi*** infections in HIV-infected patients, which may have implications for the pathogenesis of the disease in this population. Future studies will examine parasite diversity in a larger sample size and compare ***T. cruzi*** strains found in blood and cerebrospinal fluid.

1086

CEREBRAL VASCULATURE AND COGNITIVE IMPAIRMENT IN ACUTE *TRYPANOSOMA CRUZI* INFECTION

Umaru Barrie, Brandi Freeman, Herbert Tanowitz, Mahalia Desruisseaux

Albert Einstein College of Medicine, Bronx, NY, United States

The brain is sheathed with a blood-brain barrier (BBB) system, which tightly regulates the passage of substances from the blood to the Central Nervous System. Certain organisms, however, including ***Trypanosoma cruzi***, are able breach this selectively permeable unit. Damage to the cerebral vasculature and the BBB are important features tied to neurological impairments in Chagas disease (CD). Endothelin-1 (ET-1) has been shown to mediate BBB permeability, inflammation, and vascular tone, thus may be important in the pathogenesis of ***T. cruzi*** infection. ET-1 reduces the expression of angiopoietin-1 (Ang-1), a growth factor that promotes endothelial quiescence and expression of tight junction proteins responsible for maintaining BBB integrity. We postulate that ET-1 contributes to the pathogenesis of neuro-CD by disrupting BBB integrity and potentiating endothelial activation and inflammation. C57BL/6 mice were infected with 10,000 trypomastigotes of the Tulahuen strain of ***T. cruzi*** to induce experimental CD (ECD). Cognitive function, degree of illness, and levels of inflammatory mediators were assessed in the brains of ***T. cruzi*** infected mice and controls. Acute ECD caused an increase in parasitemia, which correlated with blood glucose as well as the level of illness as determined by a decrease in rapid murine coma and behavior scale (RMCBS). Object recognition and placement tests revealed significant impairments in the visual and spatial memory of infected mice. These deficits were associated with elevated levels of pro-inflammatory cytokine IL-1β and cell adhesion molecules, E-selectin and ICAM-1. Ang-1 has been shown to suppress these molecules on endothelial cells, whereas Ang-2 promotes their expression. qRT-PCR performed on whole brain homogenates revealed elevated levels of ET-1 in the brains of ***T. cruzi*** infected mice in conjunction with decreased Ang-1, resulting in an increased ratio of Ang-2 to Ang-1. An imbalance in the angiopoietin system illustrates endothelial dysfunction and cerebral vasculature disruption, which may contribute to the neurological impairments and activated endothelium observed in ECD.

1087

INHIBITORS OF NA+, K+-ATPASE AND RELATED ION ANTI-PORTER FUNCTIONS AS NEW ANTILEISHMANIAL DRUG LEADS

Surendra K. Jain[1], Ilias Muhammad[2], Larry Walker[1], Babu Tekwani[1]

[1]National Center for Natural Products Research, Department of BioMolecular Sciences, School of Pharmacy, University of Mississippi, University, MS, United States, [2]National Center for Natural Products Research, School of Pharmacy, University of Mississippi, University, MS, United States

Visceral leishmaniasis, caused by protozoan parasite ***Leishmania donovani,*** is fatal if left untreated. Extreme toxicity, increasing resistance of the parasite to currently available drugs and absence of a suitable vaccine necessitate the discovery of new anti-leishmanial drugs. The Na^+-K^+-ATPases and related anti-porter functions may be necessary for survival of the leishmania parasite in extreme acidic environment of phagolysosomal vacuoles in macrophages. A P-type ion-motive ATPase, with predicted function as a potassium and/or sodium efflux pump, has been identified in ***Leishmania donovani*** genome. Random screening of a library of natural products has indicated Na^+,K^+-ATPase or related ion transports as potential antileishmanial drug targets. To validate this, a few selected standard inhibitors namely, N-ethylmaleimide, omeprazole, ouabain, amiloride, bufalin, quercetin, oleandrine, digoxin, mansonin, sanguinarine, cinobufagin and procillaridin A, known to inhibit Na^+,K^+-ATPases or proton pumps, were evaluated ***in vitro*** against different forms of ***L. donovani*** namely, promastigotes, axenic amastigotes and intracellular amastigotes growing in differentiated THP1 human acute monocytes cells. The inhibitors were also tested for cytotoxicity against differentiated THP1 cells. Except omeprazole and amiloride, all inhibitors showed highly potent and selective anti-leishmanial effect on intracellular amastigotes, with no significant effect on promastigotes and axenic amastigotes. Bufalin, a cardiotonic steroid was the most active inhibitor with IC_{50} value in sub-nano molar range. This selective action of inhibitors indicate essential role of Na^+,K^+-ATPase and related proton transporters in survival of intracellular ***L. donovani*** amastigotes. Further analysis of selective susceptibility of intracellular amastigotes, molecular/functional characteristics of leishmanial Na+,K+/H+-ATPase and their role in leishmania growth and survival would be useful in identification of selective leads, devoid of cardiotonic functions as potential novel antileishmanial drug leads.

1088

LEISHMANIA SPECIES IDENTIFICATION BY HIGH RESOLUTION MELTING ANALYSIS (HRMA) IN PERU

Nyshon M. Rojas Palomino, Gloria S. Minaya Gómez, Aidé C. Sandoval Juárez, Omar Cáceres Rey

Instituto Nacional de Salud, Lima, Peru

Leishmaniasis is a disease characterized by the presence of different clinical manifestations depending on ***Leishmania*** species. Our aim was develop of a High Resolution Melting Analysis (HRMA) for the identification of ***Leishmania*** species, amplifying a region of minicircles of kDNA which presents polymorphism. Two hundred and thirteen DNA samples from skin biopsy of the lesion from patients confirmed with the disease and the following reference strains: ***Leishmania (Viannia) braziliensis, L. (V.) peruviana, L. (V.) guyanensis, L. (Leishmania) amazonensis and L. (L.) mexicana*** were evaluated. 10 ng/ul of DNA and the following primers: OL1: GGGGAGGGGCGTTCTGCGAA and OL2: CCGCCCCTATTTTACACCAACCCC were used in a Real-time PCR protocol using 1X of Eva Green dye in a Rotor Gene Q thermocycler (Qiagen®). The thermal cycling profile was: Initial denaturation at 95°C by 5 min followed by 35 cycles of denaturation at 95°C x 10s, annealing at 55°C x 30s and an extension at 72°C x 10s. Finally, the temperature was increased 1°C between 75 to 90°C. The HRMA analysis was done using Rotor Gene Q Software v2.1.0. This method allowed identifies five different pattern curves corresponding to each one of the reference Leishmania strains. The samples evaluated were identified as ***L. braziliensis*** (52), ***L. peruviana*** (59), ***L. guyanensis*** (54), ***L. amazonensis*** (29), ***L. lainsoni*** (15) and ***L. mexicana*** (4). Twenty six samples (12%) were confirmed by partial sequencing of cytochrome B gene using GeneBank/DDBJ/EMBL databases. Of these samples, we found four discordances between HRMA and sequencing of Cyt B gene: Two strain of ***L. braziliensis*** which were identified previously as ***L. guyanensis***; one strain of ***L. amazonensis*** and ***L. guyanensis***, were identified both as ***L. (V.) braziliensis*** by HRMA respectively. It is necessary the evaluation of this HRMA with a greater number of samples to determine the real power of this technique as an identification method of ***Leishmania*** species.

1089

IMMUNO-ENZIMATIC EVALUATION OF THE TCTASV PROTEIN FAMILY OF *TRYPANOSOMA CRUZI* AS A TOOL TO DIAGNOSE NATURAL INFECTION OF DOGS FROM ENDEMIC AREAS

Noelia Floridia-Yapur[1], Valeria Tekiel[2], Anahí Alberti D' Amato[3], Mercedes Monje Rumi[3], Juan José Lauthier[3], Nicolás Tomasini[3], Paula Ragone[3], Patricio Diosque[3], Rubén Cimino[1], Julio Nasser[1]

[1]Instituto de Investigaciones en Enfermedades Tropicales, San Ramón de la Nueva Orán, Salta, Argentina, [2]Instituto de Investigaciones Biotecnológicas "R. Ugalde", IIB-Intech, UNSAM-CONICET, Buenos Aires, Argentina, [3]Unidad de Epidemiología Molecular, Instituto de Patología Experimental, CONICET, Universidad Nacional de Salta, Salta, Argentina

Chagas disease, produced by ***Trypanosoma cruzi***, affects millions of people worldwide. High incidences of human infection and vector transmission are still reported in endemic regions like the Gran Chaco, due to partial success of triatomine control programs. In this area, dogs represent important reservoirs of the parasite in domestic environments. Canine infection correlates with the risk of transmission to humans, therefore, proper methods to detect the parasite in dogs are needed. The novel TcTASV protein family (subfamilies A, B, C) has no orthologs in other species and is differentially expressed in bloodstream trypomastigotes, suggesting that these antigens could be useful to diagnose ***T. cruzi*** infection. The aim of this study was to assess the antibody response to TcTASV-A, B and C proteins in dogs naturally infected with ***T. cruzi*** using ELISA. We produced a representative member of each subfamily (Ags: A, B and C) with a GST-tag, and GST. Three groups of sera were evaluated. GI: 30 healthy dogs from non-endemic area, with negative ELISA-epimastigote protein extract (ELISA-HT); GII: 35 infected dogs from Chaco, ELISA-HT positive; and GIII: 35 infected dogs with positive ELISA-HT that also had ***T. cruzi*** detection by xenodiagnoses and/or PCR. Each sample was tested in duplicate against TcTASV antigens individually or combined and against GST (background control). Sensitivity (Se), Specificity (Sp), AUC ROC and Kappa Index (KI) were estimated for all assays, considering GI and GIII as controls. A-ELISA and C-ELISA, obtained the highest sensitivities: 65.7% and 74.3%, with 0.83 and 0.86 AUC ROC, respectively, indicating high accuracy of these tests. All assays were 100% Sp, except for B-ELISA (50%) that also had a poor reactivity in GII and GIII sera. The ELISA with the A+C mixture obtained 94.3% Se and 0.99 AUC ROC, proving that the combined use of these antigens has desirable diagnostic performance that could be useful to detect the infection in dogs in endemic regions. The mean OD in GIII samples was significantly higher than in GII samples, in C-ELISA and A+C-ELISA, suggesting that TcTASV-C antigen could have a role in the acute phase of infection.

1090

QUANTIFICATION OF MACROPHAGE MARKERS NEOPTERIN AND CHITOTRIOSIDASE ACTIVITY TO MONITOR VISCERAL LEISHMANIASIS TREATMENT RESPONSE

Antonia E. Kip[1], Jan H. Schellens[2], Jos H. Beijnen[1], Thomas P. Dorlo[3]

[1]Antoni van Leeuwenhoek Hospital/Slotervaart Hospital, Amsterdam, Netherlands, [2]Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands, [3]Pharmacometrics Group, Uppsala University, Sweden

As a 6 month follow-up is required to establish final cure, pharmacodynamic (PD) biomarkers are potentially useful to monitor treatment response in visceral leishmaniasis (VL), but have not been identified yet. ***Leishmania*** parasites replicate within host macrophages, thereby increasing the overall macrophage biomass, decreasing again with waning parasitic infection. Neopterin and chitotriosidase activity are markers of macrophage activation and their potential use as PD markers in VL was evaluated in this analysis. Plasma samples were collected from VL patients in Sudan and Kenya, receiving 2 different treatments: (i) combination therapy (liposomal amphotericin B, L-AmB + miltefosine) or (ii) miltefosine monotherapy. Neopterin was quantified by ELISA (133 samples, 31 patients) and chitotriosidase activity by an enzymatic fluorescent assay (116 samples, 29 patients), during and after treatment. All values are reported as mean ±95% CI. Baseline neopterin levels were elevated (90.6±11.4 nmol/L) compared to normal (<10 nmol/L) and decreased during treatment to 35.9±13.1 nmol/L for combination and 23.3±8.05 nmol/L for monotherapy. On day 7, neopterin concentrations halved for the combination therapy, while for monotherapy they only started to decrease after day 7. Mean neopterin concentrations one day after L-AmB infusion were significantly higher for cured (124±30.1 nmol/L) than for relapsed patients (79.3±14.3 nmol/L, P<0.01), indicating neopterin levels exhibit a prognostic value for the combination therapy. The initial surge in neopterin in cured patients, could imply an instant immunomodulatory effect of L-AmB. The baseline mean chitotriosidase activity was 317±169 nmol/mL/hr, with large between-subject variability, and decreased in response to both treatments. 1-month follow-up activity increased significantly in relapsing patients (n=10), while cured patients (n=9) retained stable levels (P<0.001), compared to end of treatment. However, a chitotriosidase deficiency-rate of 26.3% was found in Kenyan patients (~5% in Caucasians,) which causes chitotriosidase activity to lack sensitivity as a biomarker.

1091

EFFECTIVENESS OF ORAL PENTOXIFYLLINE PLUS SODIUM STIBOGLUCONATE THERAPY VERSUS SODIUM STIBOGLUCONATE MONOTHERAPY IN MUCOSAL LEISHMANIASIS: A RETROSPECTIVE COHORT

Fatima Rosario Concha Velasco

Regional Direction of Health, Cusco, Peru

Treatment failure in mucosal leishmaniasis occurs in 7-30% of patients treated with antimonials. Pentoxifylline is a xanthine oxidase inhibitor with anti-inflammatory effects that if it is used in addition to antimonials may improve the effectiveness of mucosal leishmaniasis therapy. The aim of the study was to determine the effectiveness of sodium stibogluconate therapy plus oral pentoxifylline compared to sodium stibogluconate monotherapy in mucosal leishmaniasis. Data was collected retrospectively from clinical records of consecutive patients treated and with complete follow-up at a reference center in Lima, Peru. Sodium stibogluconate was administered intravenously at 20mg per kg of body weight per day and pentoxifylline was administered orally at 400 mg 3 times daily. Effectiveness was defined as clinical cure with complete reepithelization of the mucosal tissue and absence of inflammatory activity 180 days after 30 days of treatment. Treatment assignment depended on pentoxifylline availability without random assignment. A retrospective cohort analysis was conducted calculating crude and adjusted relative risks (RR) of treatment effectiveness using a robust Poisson regression. A total of 234 eligible patients were enrolled and 205 (90%) were evaluated at six months. Combined therapy and monotherapy groups were only different by sex (proportion male: 78% versus 91%, p=0.022). Effectiveness of monotherapy and pentoxifylline combined therapy was 61% (85/139) and 79% (52/66), respectively (p=0.011). The difference remained significant (RR: 1.34, 95% confidence interval: 1.10-1.56, p=0.002) after adjusting for severity and sex. Adjusting for therapy, better effectiveness was observed when the oral mucosal was also affected compared to nasal tissue only, without a significant interaction between therapy and oral tissue involvement. In conclusion combined therapy of sodium stibogluconate plus oral pentoxifylline is more effective than sodium stibogluconate monotherapy for mucosal leishmaniasis. Randomized, experimental trials may give additional validity to this finding.

1092

BACTERIAL CELLULOSE BIO-CURATIVES CONTAINING DIETHYLDITHIOCARBAMATE (DETC) FOR THE TOPICAL TREATMENT OF CUTANEOUS LEISHMANIASIS CAUSED BY *LEISHMANIA BRAZILIENSIS*

Fabiana S. Celes[1], Eliane Trovatti[2], Ricardo Khouri[1], Johan Van Weyenbergh[3], Sidney J. Ribeiro[2], Valéria M. Borges[1], Hernane Barud[2], Camila I. de Oliveira[1]

[1]Centro de Pesquisas Gonçalo Moniz - FIOCRUZ BA, Salvador (BA), Brazil, [2]Instituto de Química, Universidade Estadual Paulista, Araraquara (SP), Brazil, [3]Rega Institute for Medical Research, Department of Microbiology and Immunology, K.U. Leuven, Leuven, Belgium

Leishmaniasis remains a worldwide public health problem. The limited therapeutic options, drug toxicity and reports of resistance reinforce the need for the development of new treatment options. Herein, we tested a topical formulation of bacterial cellulose (BC) membranes containing Diethyldithiocarbamate (DETC), a superoxide dismutase 1 inhibitor. Exposure of leishmania-infected murine macrophages to BC-DETC resulted in a dose-dependent killing of intracellular parasites, without pronounced toxic effects to host cells. Parasite killing was associated with decreased SOD1 activity paralleled by the increased production of superoxide and pro-inflammatory mediators. Topical application of BC-DETC to dermal lesions significantly decreased ear thickness and parasite load at the infection site. Additionally, expression of IFN-γ and TNF-α, was down modulated in situ as well as in recall responses employing draining lymph node cells. BC-DETC also decreased parasite load following exposure to human macrophages infected with ***Leishmania braziliensis***, an effect reversed in the presence of anti-oxidants. These results highlight the feasibility of using BC-DETC as a topical formulation for chemotherapy of cutaneous leishmaniasis caused by ***L. braziliensis***.

1093

REPURPOSING OF FINGOLIMOD FOR THE TREATMENT OF HUMAN AFRICAN TRYPANOSOMIASIS

Amy J. Jones, Graeme Stevenson, Vicky M. Avery

Eskitis Institute for Drug Discovery, Brisbane, Australia

Human African trypanosomiasis (HAT) is a parasitic disease caused by the protozoan parasites ***Trypanosoma brucei rhodesiense*** and ***T.b. gambiense***. Currently prevalent in 36 sub-Saharan countries the disease inflicts a significant degree of morbidity and mortality accounting for the loss of over 560,000 disability adjusted life years each year. An estimated 20,000 cases of HAT occur annually, nearly all of which are fatal without adequate treatment. However, treatment of HAT is currently reliant on a small number of drugs nearly all of which have poor safety profiles and complicated, prolonged administration schedules. New drugs are desperately needed for HAT. The high-throughput screening of an inhouse compound library containing licensed drugs and compounds that had reached the late stages of clinical development led to the identification

of Fingolimod (Glienya®) as a promising lead compound for HAT. Fingolimod is an orally available drug currently licensed for the treatment of relapsing multiple sclerosis (MS). The compound exhibited an IC_{50} of 0.59 µM against ***T.b. brucei*** with a selectivity index (SI) of 17 against the mammalian cell line HEK293. Importantly the compound also displayed potent activity against the human infective subspecies, ***T.b. rhodesiense*** and ***T.b. gambiense*** with IC_{50} values of 0.69 and 0.021 µM, respectively. Fingolimod is cidal in action with ***T.b. brucei*** parasites being eliminated within 48 hours following exposure to the minimum inhibitory 90 (MI90) concentration. Disappointingly, Fingolimod exhibited no in-vivo activity in acute or CNS murine models of HAT. These poor in-vivo results led to the evaluation of commercially available analogues of Fingolimod and the initiation of a medicinal chemistry program in order to produce analogues of Fingolimod with in-vivo trypanocidal activity. In this presentation the identification of Fingolimod is discussed along with the results obtained to date against ***T. brucei*** spp and the steps taken to optimise and progress the drug along the drug discovery pipeline for HAT.

1094

USING A CONSENSUS TECHNIQUE TO IMPROVE THE METHODOLOGY OF CLINICAL TRIALS ASSESSING TREATMENTS FOR CUTANEOUS LEISHMANIASIS (CL)

Astrid Erber[1], Liliana Lopez Carvajal[2], Byron Arana[3], Trudie Lang[1], Piero Olliaro[4]

[1]University of Oxford, Oxford, United Kingdom, [2]Universidad de Antioquia, Medellin, Colombia, [3]Drugs for Neglected Diseases Initiative, Geneva, Switzerland, [4]UNICEF/UNDP/WB/World Health Organization Special Programme for Research and Training in Tropical Diseases, Geneva, Switzerland

The term Cutaneous Leishmaniasis (CL) includes a variety of disease manifestations caused by ***Leishmania*** species in the old and the new world. Despite an estimated 0.7-1.3 million new cases each year, CL is not life-threatening and is not assigned a high burden of disease; however, it causes visible, generally long-lasting lesions leaving potentially life-long scars. There are few treatment options, and recommendations have a weak evidence base: systematic published reviews pointed to a lack of methodological standardization in the conduct and analysis of clinical trials of CL interventions. In order for both current and newer treatments to be adequately assessed, standardised trial methodologies are needed which can be applied generally, while allowing the flexibility required to cover the diverse disease manifestations. This would provide clinical investigators with guidance for the design, conduct, analysis and report of future clinical trials of CL treatments, including the definition of measurable, reproducible and clinically meaningful outcomes. A guidance document is available. To further broaden the base for consensus, we involve a range of stakeholders (researchers, care-providers (physicians, nurses) and patients) to define key methodological questions regarding whom to treat and how to measure treatment effects (core eligibility criteria, core outcome measures). An iterative online Delphi-type consensus methodology is used. A call for expression of interest in February 2015 was answered by around 120 researchers and care-givers. Additional input is being sought from patients via interviews (56 applications received; selected candidates will also receive specific training in patient interviews). CL is used as a case-study to assess whether the key stakeholders can be identified and encouraged to collaborate using an innovative, participatory approach. The project is in progress; results from the first two Delphi rounds will be presented.

1095

DETECTING *TRYPANOSOMA CRUZI* ANTIGENS WITH NANOPARTICLES

Elisabeth S. Attupina Figueroa[1], Edith S. Malaga Machaca[1], Robert H. Gilman[2], Remo Gonza Luque[1], Maritza Calderon Sanchez[1], Alessandra Romero[1], Noelia P. Angulo Surca[1], Holger Mayta[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Chagas disease, caused by the protozoan parasite ***Trypanosoma cruzi***, is one of the major health problems affecting the Latin American population. The World Health Organization estimates that approximately 16 to 18 million people are chronically infected, and 120 million are at risk of contracting the disease. Currently there is no gold standard test for the diagnosis of Chagas disease, and immunological diagnosis is based on the detection of anti-***T. cruzi*** antibodies. However, these tests have poor specificity and have been known to cross react with other endemic diseases. Moreover, the efficacy varies depending on the genetic makeup of both the parasite and the human population studied, and even despite successful treatment and parasite eradication, the immunologic tests may remain positive. Alternatively, antigen detection tests may provide a solution to these issues, as they are able to directly detect the presence of the parasite in a sample. This work aims to develop a screening test for the detection of ***T. cruzi*** antigens. For this purpose we have developed specific antibodies against a panel of ***T. cruzi*** antigens (membrane, flagella, and excretory/secretory proteins), from rabbits, chickens and alpacas. The purified antibodies have been evaluated by Western blot, and have shown different banding patterns, even when presented with the exact same antigen. These antibodies will next be tested in an ELISA format. We plan to perform a pilot study using nanoparticles in an ELISA platform to increase the conventional assay's sensitivity in samples from chronic Chagas disease patients. One goal of this work is to determine the potential of this antigen detection test to be used as a rapid diagnostic test (RDT) that can be transferred to laboratories in endemic areas as a way to reliably detect and thereby treat Chagas disease.

1096

AN IMAGE-BASED, HIGH THROUGHPUT ASSAY FOR PROFILING THE ACTIVITY OF SELECTIVE INHIBITORS AGAINST *TRYPANOSOMA CRUZI* FROM THE MMV MALARIA BOX COLLECTION

Melissa L. Sykes, Vicky M. Avery

Eskitis Institute for Drug Discovery, Griffith University, Brisbane, Australia

Treatment of Chagas disease caused by ***Trypanosoma cruzi*** is limited to drugs with known side effects and questionable efficacy against the chronic phase of the disease. The search for more effective, less toxic drugs is imperative for improved treatment of ***T. cruzi*** infection. To identify new compounds with anti-***T. cruzi*** activity, a high throughput, image-based assay was developed to visualise the effect of compounds against the intracellular amastigote life cycle stage. A prototype of the Medicines for Malaria Venture (MMV) Malaria Box containing 641 molecules, with previously demonstrated activity against ***Plasmodium falciparum***, was screened against ***T. cruzi***. The activity of compounds against the parasite and the host cells were estimated in one well by the use of fluorescent markers. Compounds with an IC_{50} value of <10 µM and a selectivity index of >10 were considered for further evaluation. Nine molecules with activity against ***T. cruzi*** amastigotes were identified. Of these, six compounds had previous reported activity against ***T. cruzi***, supporting the use of this assay, whilst three remaining compounds were not reported in the literature. These were evaluated for activity against the mammalian cell line HEK293, and against ***T. cruzi*** trypomastigotes in whole cell viability-based assays utilising the redox dyes, Resazurin and PrestoBlue, respectively. Lack of activity in these assays suggested selective activity against amastigotes

with IC_{50} values of 1.2 and 1.7 μM and 3.6 μM and selectivity indices of 59 and 42 and 21, respectively toward the parasite over 3T3/ HEK293 cells. As compounds did not remove 100% of parasites from host cells at the EC_{100}, modification of the image-based assay was undertaken to determine the clearance of parasites following removal of compound, important for the chronic phase of the disease. The incubation time was separately extended, to determine efficacy over time. These 3 structures, from different chemical classes, serve as chemical starting points for ***T. cruzi*** research.

1097

PROBING A SMALL MOLECULE SCAFFOLD TO IDENTIFY NOVEL INHIBITORS OF *TRYPANOSOMA BRUCEI, TRYPANOSOMA CRUZI,* AND *LEISHMANIA DONOVANI*

Jeannie Moore Stubblefield, Alexis M. Gross, Charlie R. Boyle, Nicoletta Guglielmi, Scott Handy, Anthony L. Newsome

Middle Tennessee State University, Murfreesboro, TN, United States

Three of most devastating Neglected Tropical Diseases - African Trypanosomiasis, Chagas Disease and the Leishmaniases - are caused by vector-borne, flagellated protozoa. An estimated 30,000 people are infected and up to 70 million are at risk of developing African Trypanosomiasis (also known as African Sleeping Sickness,) which is caused by ***Trypanosoma brucei***. ***Trypanosoma cruzi*** is the causative agent of Chagas Disease, which affects an estimated 7-8 million people. Although Chagas is primarily classed as a disease of poverty endemic to Latin and South America, it is considered an emerging disease in the United States. The Leishmaniases, which are caused by various subspecies of ***Leishmania,*** affect an estimated 10-12 million people in almost 100 countries. All three can be extremely debilitating and even fatal if untreated. However, current drug therapies have issues with toxicity and there are growing concerns about developing resistance. There is an urgent need to develop new drugs that are safer and more effective to treat these devastating diseases. In this study, derivatives of a small molecule with known antimicrobial properties were synthesized and screened for inhibitory activity against the bloodstream form of ***T. brucei***. Compounds were also screened against a rat skeletal myoblast line (L6) and macrophages differentiated from a human monocyte line (THP-1) to gauge cytotoxicity. Compounds with low toxicity were further screened against the intracellular forms of ***T. cruzi*** and ***L. donovani***. These screens identified several novel compounds with IC_{50} values in the low micromolar range and low cytotoxicity that have potential to be developed into new drug therapies for these diseases.

1098

COST-EFFECTIVENESS OF DIAGNOSTIC-THERAPEUTIC STRATEGIES FOR PEDIATRIC VISCERAL LEISHMANIASIS IN MOROCCO

Albert Picado[1], Nabil Tachfouti[2], Sergi Alonso[1], Adil Najdi[2], Chakib Nejjari[2], Elisa Sicuri[1]

[1]ISGlobal, Barcelona, Spain, [2]Sidi Mohamed Ben Abdillah University, Fes, Morocco

Visceral leishmaniasis (VL) is a neglected parasitic disease that is fatal if left untreated. VL is endemic in Morocco and other countries in North Africa were it mainly affects children from rural areas. In Morocco, the direct observation of ***Leishmania*** parasites in bone marrow aspirates is used to diagnose VL and antimonials (Sb for 20 days) is the first line of treatment. In this study we evaluate the cost and cost-effectiveness of alternative diagnostic-therapeutic strategies for pediatric VL in Morocco. In particular we evaluate the use of liposomal amphotericin B (L-AmB), the safest and most efficacious anti-leishmanial drug. A decision-analysis model was used to estimate the cost-effectiveness of using RDT and/or short course L-AmB to manage VL pediatric cases in Morocco compared to the current clinical practices. Incremental cost-effectiveness ratios (ICERs), expressed as cost per death averted, were estimated by comparing costs and effectiveness of the alternative algorithms with the current practices. This study shows that using RDT and/or implementing short course L-AmB treatments would be cost-effective in the Moroccan context according to the World Health Organization (WHO) criteria. In particular, if L-AmB is purchased at a preferential price (18 US$ per vial) the use of this drug to treat pediatric VL cases would be less expensive than antimonials. The results of this study should encourage the implementation of RDT and/or short course L-AmB treatments for pediatric VL in Morocco and other countries in North Africa facing similar challenges.

1099

IGG PRODUCTION, CIRCULATING IMUNE COMPLEXES AND IGG AVIDITY MATURATION DURING EXPERIMENTAL HAMSTER VISCERAL LEISHMANIASIS

Camila Aparecida de Carvalho[1], Thiago Fidelis Ferrão[2], Heitor Franco de Andrade Jr.[2]

[1]Tropical Medicine Institute/ Biomedical Sciences Institute at University of São Paulo, São Paulo, Brazil, [2]Tropical Medicine Institute, São Paulo, Brazil

Visceral leishmaniasis (VL) is a neglected disease according World Health Organization, with about 300,000 cases and 20,000 deaths annually. Hypergammaglobulinemia is found in VL but is not associated to effective control of the disease. Circulating immune complexes (CIC) were associated with hypergammaglobulinemia and we showed that CIC could interfere in the positivity of serology in infected hamsters, dogs and humans. Widely used in epidemiology, serology does not distinguish active disease and may be inconclusive due to the presence of CIC. We study ***Leishmania*** CIC during experimental infection in hamsters and its impact in conventional serology. Serum samples from ***L. (L.) infantum chagasi*** infected hamsters were collected at 15, 30, 45, 60 and 90 days after $5x10^7$ amastigote infection. For detecting IgG and its avidity and CIC we used solid phase conventional ELISA with or without 6M Urea washing (cELISA), an antigen capture ELISA assay using anti promastigote rabbit IgG in solid phase and a biotinylated anti ***Leishmania*** rabbit IgG as conjugate (DAC) and a dissociative pH shock ELISA, which is performing by diluted sample brought at pH 2,5 added to well, followed by neutralization, reaction and subsequent conjugate incubation (dELISA). Using cELISA specific IgG showed gradual increase, with higher levels found after 30 days of infection. Detection of circulating antigen by DAC and the IgG increment in dELISA identified positive CIC samples in most periods of infection. Highest frequency of positive samples was found at 30 days of infection (28% and 54.1%, respectively). ELISA IgG avidity showed the same proportion of high-avidity antibodies in all periods of infection, suggesting absence of avidity maturation of anti-***Leishmania*** IgG antibodies. The association of these results indicates that during the experimental VL in hamsters, CIC were present and interfere with conventional serology, and could be also associated to immunopathology due to the absence of antibody avidity maturation. Antibodies and circulating immune complexes could be involved in the establishment of ineffective immune response associated to B cell activation in experimental VL.

A SIMPLE COLORIMETRIC ASSAY FOR HIGH-THROUGHPUT SCREENING OF POTENTIAL DRUG COMPOUNDS AGAINST INTRACELLULAR AMASTIGOSTES OF *LEISHMANIA*

Henk Schallig, Erika Van den Bogaart, Gerard Schoone

Royal Tropical Institute, Amsterdam, Netherlands

There is a pressing need to identify new drugs (leadcompounds against ***Leishmania*** parasites as current medication is old, often toxic and failing due to resistance. Critical to the search for new anti-leishmanial drugs (or lead compounds) is the availability of high-throughput screening (HTS) methods to test chemical compounds against the relevant stage for disease pathogenesis, the intracellular amastigotes. Recent progress in automated microscopy and genetic recombination have produced powerful tools for drug discovery. Nevertheless, a simple and efficient

test for measuring drug activity against ***Leishmania*** clinical isolates is lacking. At KIT Biomedical Research (Parasitology Unit), we have developed a quantitative colorimetric assay, whereby the activity of a ***Leishmania*** native enzyme is used to assess parasite viability. Enzymatic reduction of disulphide-trypanothione, monitored by a microtiter plate reader, was used to quantify the growth of ***Leishmania*** parasites. An excellent correlation was found between the optical density, as measured at 412nm, and the number of parasites inoculated. Pharmacological validation of the assay was performed against the conventional AlamarBlue® method for promastigotes or standard microscopy for intracellular amastigotes. The activity of a selected-compound panel, including several anti-leishmanial reference drugs, demonstrated high consistency between the newly developed assay and the reference method, and corroborated with previously published data. Quality assessment with standard measures confirmed the robustness and reproducibility of the assay, which performed in compliance with HTS requirements. This simple and rapid assay provides a reliable, accurate method for screening anti-leishmanial agents, at high-throughput. The basic equipment and manipulation required to perform the assay makes it easy to implement, simplifying the methodology for scoring inhibitor assays.

BENZNIDAZOLE-RELATED ADVERSE DRUG REACTIONS IN BRAZILIAN PATIENTS WITH CHAGAS DISEASE

Carlos H. Moreira[1], Noemia B. Carvalho[2], Rosário Q. Ferrufino[2], Cristina M. Guastini[2], José Ângelo L. Lindoso[3], Léa C. Oliveira[4], Erika R. Manuli[5], Marcela Souza[5], Ester C. Sabino[6]

[1]Institute of Infectology Emilio Ribas, Laboratory of Parasitology, Tropical Medicine Institute of São Paulo, University of São Paulo, São Paulo, Brazil, [2]Division of Infectious Diseases, Hospital das Clinicas de São Paulo, School of Medicine, University of São Paulo, São Paulo, Brazil, [3]Institute of Infectology Emílio Ribas, Laboratory of Seroepidemiology, Tropical Medicine Institute of São Paulo, University of São Paulo, São Paulo, Brazil, [4]Laboratory of Medicine laboratorial, Hospital das Clínicas de São Paulo, School of Medicine, University of São Paulo, São Paulo, Brazil, [5]Laboratory of Parasitology, Tropical Medicine Institute of São Paulo, University of São Paulo, São Paulo, Brazil, [6]Laboratory of Parasitology, Tropical Medicine Institute of São Paulo, University of São Paulo, São Paulo, Brazil

There are only two drugs approved for the treatment of Chagas disease: benznidazole (BZN) and nifurtimox. Both present a wide spectrum of toxicity. BZN is the only one available in Brazil and the response rate and adverse drug reactions (ADRs) are extremely variable. There are few studies describing in details the ADRs during the treatment of adult patients with BZN. We have established a prospective cohort study that followed 93 ***Trypanosoma cruzi*** infected adults, (age between 18 - 65 years), with the chronic indeterminate form of the disease, with mild to moderate cardiac or digestive involvement, without advanced forms during BZN treatment (5mg/kg/day, up to 300mg/day for 60 days). Patients were evaluated in 3 schedules visits for adhesion and ADRs (approximately 15th, 30th and 60th day after treatment initiation). They were informed to call a dedicated line if they presented with ADRs, and they received prompt medical evaluation if needed. Of the 93 patients, 63 (67.7%) informed at least one ADR and 18 (19.4%) had to interrupt the treatment (4 temporally and 14 permanently). The majority of ADRs, 57 (90.5%) occurred during the first 15 days of treatment, 22 (34.9%) patients related ADRs on schedule visit day 30. The most frequent ADRs were related to skin (47%), gastrointestinal (47.6%) and peripheral nervous system (31.7%). ADRs were less common among individuals receiving a proton pump inhibitor, omeprazole (p=0.0002), OR=0.02 (CI 0.001-0.45), and more common among individuals using hydrochlorothiazide (p=0.047), OR=4.5, (CI 0.97-21.5). ADRs were not associated with age, gender, skin color, education and comorbidities, such as diabetes and hypertension. The ADRs symptoms disappeared after BZN interruption and the administration of drugs to manage the skin manifestations and gastrointestinal symptoms. Two patients with severe ADRs were hospitalized in the emergency for less than 24hs to receive intravenous glucocorticoids. There was no fatal event in this cohort. In conclusion, ADRs are common during BZN treatment, but they can be manageable with orientation and easy access to the physicians.

1102

CLINICAL AND HISTOPATHOLOGICAL CHARACTERISTICS OF CUTANEOUS LEISHMANIASIS IN A GROUP OF MILITARY PERSONNEL IN SRI LANKA

Nuwani H. Manamperi[1], Charisma S. Fernando[2], Nishantha Pathirana[3], Wimaladharma Abeyewickreme[1], Vipula C. de Silva[2], Nadira D. Karunaweera[2]

[1]University of Kelaniya, Ragama, Sri Lanka, [2]University of Colombo, Colombo, Sri Lanka, [3]Sri Lanka Army Medical Services, Colombo, Sri Lanka

Cutaneous leishmaniasis (CL) is a newly established vector-borne parasitic disease in Sri Lanka. Military personnel have an occupational risk for CL due to being stationed in endemic areas and exposure to vectors outdoors. This study describes the clinical and histopathological features of CL in a group of military personnel. Thirty five patients with smear positive for ***Leishmania*** amastigotes were included, their data analyzed for clinical features and skin biopsies processed routinely for histology, examined at a conference microscope and classified into 4 groups using modified Ridley criteria for Leishmaniasis as: I-parasitized macrophages with variable lymphocytes and plasma cells; II-parasitized macrophages with lymphocytes, plasma cells and ill formed histiocytic granulomata; III-a mixture of macrophages (with or without parasites), lymphocytes, plasma cells and epithelioid granulomata; IV-epithelioid granulomatous response with a few lymphocytes and plasma cells but no amastigotes. Lesions were categorized by duration, as acute (< 6 months) or chronic (≥ 6 months). Study group composed of all males with a mean age of 32.6 years (range 22-47) and lesion duration of 5.6 months (range 1-24). Number of lesions varied from 1 to 6 with majority (71.4%, n= 25) having a single lesion. Nodular (37.1%, n=13) and nodulo-ulcerative (25.7%, n=9) lesions in upper limbs (68.6%, n=24) was the commonest presentation. Twenty nine (82.9%) of the biopsies were positive also by histology. Twenty two (62.9%) were acute and 13 (37.1%) chronic. Group I, II, III and IV patterns were seen in 14 (40%), 12 (34.3%), 5 (14.3%) and 4 (11.4%) respectively and 9 (40.9%), 9 (40.9%), 2 (9.1%) and 2 (9.1%) of acute lesions and 5 (38.5%), 3 (23.1%), 3 (23.1%) and 2 (15.4%) of chronic lesions respectively. Necrosis was not seen in any of the lesions. Majority in this group of military personnel with CL had single lesions affecting the upper limbs and sought treatment within 2 years of appearance of lesions. The histological picture varied from diffuse infiltration of parasitized macrophages admixed with chronic inflammatory cells to ill-formed histiocytic granulomata.

1103

EVALUATING THE COST-EFFECTIVENESS OF DIFFERENT SCREENING STRATEGIES FOR HUMAN AFRICAN TRYPANOSOMIASIS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Paul R. Bessell[1], Crispin Lumbala[2], Pascal Lutumba[3], Sylvain Baloji[2], Sylvain Biéler[4], Joseph M. Ndung'u[4]

[1]Epi Interventions Ltd., Edinburgh, United Kingdom, [2]PNLTHA, Kinshasa, Democratic Republic of the Congo, [3]University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [4]FIND, Geneva, Switzerland

Human African trypanosomiasis (HAT), caused by the protozoan ***Trypanosoma brucei gambiense*** is a neglected tropical disease that is endemic in many areas of sub-Saharan Africa. Interruption of transmission requires the early diagnosis and treatment of cases among suspects that are identified using a screening test. Screening for HAT has been performed using the card agglutination test for trypanosomiasis (CATT), but recently, rapid diagnostic tests (RDTs) have been developed that, unlike CATT, are thermostable and do not require electricity. In a clinical

trial carried out in the Democratic Republic of the Congo (DRC), the SD BIOLINE HAT RDT had a higher sensitivity, but a lower specificity than CATT in active screening (by mobile teams) and passive screening at healthcare facilities. This study estimates the cost-effectiveness of using the RDT and CATT in different algorithms and diagnostic infrastructures. Data on HAT prevalence and performance of diagnostic tests were collected during the RDT clinical trial. These data informed a stochastic epidemiological model incorporating the number of people presenting for screening, infection rates, the number of cases detected at screening, and the number subsequently confirmed and cured. Into this we incorporated the costs incurred when screening was done by CATT or by RDT in passive or active screening. The RDT was the most cost-effective screening test, costing 406 and 394 USD per case cured in active and passive screening respectively, cheaper than CATT by 131 USD in active and 118 USD in passive screening. Sensitivity analysis demonstrated that these conclusions were robust to a number of assumptions, and that the results could be scaled to smaller or larger healthcare facilities and a range of prevalences of HAT. By analyzing the cost-effectiveness of different screening tests in different diagnostic settings, we have provided valuable information on diagnostic options to the HAT control program in DRC. Crucially, the RDT remains the most cost-effective test as prevalence declines and HAT nears elimination. We conclude that the RDT should be recommended as the routine screening test in the DRC.

1104

ENZOOTIC TRANSMISSION AND ECOLOGY OF ARBOVIRUSES IN SYLVATIC REGIONS OF KENYA

Gillian Eastwood[1], Rosemary C. Sang[2], Scott C. Weaver[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Centre for Virus Research, Kenya Medical Research Institute, Nairobi, Kenya

Prompted by the re-emergence of chikungunya virus [CHIKV] originating in Kenya in 2004 (which subsequently spread into the Indian Ocean and beyond, with adaptation to transmission by Aedes albopictus), we investigated potential enzootic sources of CHIKV and similar arboviruses in East Africa that could lead to similar spillover events of medical or veterinary importance. Sylvatic cycles e.g. circulation between non-human primates and arboreal Aedes spp. mosquitoes, are hypothesized based on studies in West Africa and Asia. By sampling sylvatic mosquito vectors at multiple forest sites across Kenya, and potential vertebrate reservoir hosts (including recent surveys of non-human primates) at two regions (coastal and western Kenya), we assessed possible ***foci*** for outbreak scenarios and evidence for enzootic circulation of arboviruses. Virus detection methods and serological assays were used to screen for infection in 1187 pools of mosquitoes of 43 species, and for antibody presence in 41 rodents (2 species) and 77 non-human primates (4 species), as well as in banked primate samples. We discuss isolation of viral agents, and seroprevalence for o'nyong nyong virus, dengue (1-4) and chikungunya viruses, as well as characterization of vector species diversity. Understanding of the enzootic ecology of arboviruses, and where human contact with sylvatic pathogen cycles occur, is critical to limit future disease outbreaks.

1105

MIXED METHODS SURVEY OF ZOONOTIC DISEASE AWARENESS AND PRACTICE AMONG ANIMAL AND HUMAN HEALTHCARE PROVIDERS IN MOSHI, TANZANIA

Helen L. Zhang[1], Kunda W. Mnzava[2], Sarah T. Mitchell[3], Matayo L. Melubo[2], Tito J. Kibona[2], Joanne P. Sharp[4], Rudovick R. Kazwala[5], Sarah Cleaveland[6], John A. Crump[3], Jo E. Halliday[6]

[1]Duke University Medical Center, Durham, NC, United States, [2]Nelson Mandela African Institute of Science and Technology, Arusha, United Republic of Tanzania, [3]Centre for International Health, University of Otago, Dunedin, New Zealand, [4]School of Geographical and Earth Sciences, University of Glasgow, Glasgow, United Kingdom, [5]Sokoine University of Agriculture, Morogoro, United Republic of Tanzania, [6]Institute of Biodiversity, Animal Health and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom

Zoonotic diseases are common yet under-recognized causes of morbidity in northern Tanzania. We conducted a mixed methods study to assess healthcare provider knowledge, perceptions, and practices about endemic zoonoses in the formal animal and human healthcare sectors. We administered a questionnaire with questions on knowledge, local cases, and testing for zoonoses to 52 human health practitioners and 10 livestock health providers in Moshi, Tanzania. We also conducted 61 post-questionnaire interviews to discuss a previous study that demonstrated that bacterial zoonoses are common among febrile patients in this region. Sixty (96.8%) of the 62 questionnaire respondents had heard of brucellosis, 26 (41.9%) of leptospirosis, and 20 (32.3%) of Q fever. Respondents in the animal sector were more likely to have heard of leptospirosis than those in the human sector (Odds Ratio: 7.3, 95% Confidence Interval: 1.3-77.6, p=0.013). There was no statistically significant difference between sectors in awareness of brucellosis or Q fever. The zoonoses that respondents reported seeing cases of included brucellosis (19, 30.6%), rabies (13, 21.0%), and anthrax (9, 14.5%). No respondents reported cases of leptospirosis or Q fever. Nineteen (38.0%) of the 50 human sector providers who were aware of brucellosis gave details of a human brucellosis diagnostic test available locally, and one gave details of tests for leptospirosis (5.6%) and Q fever (6.7%). One (10.0%) animal sector respondent gave details of an animal brucellosis diagnostic test available locally, and none described tests for leptospirosis or Q fever. During interviews, few respondents were surprised by the high human health burden of bacterial zoonoses, and many agreed that it was consistent with local livestock keeping practices. Several respondents highlighted an absence of knowledge of zoonoses among both healthcare providers and the general public, and many cited a lack of testing facilities for diagnosis of zoonoses. These findings reveal clear differences in knowledge of different zoonoses and a need for improved diagnostic capacity for multiple zoonoses in northern Tanzania.

1106

EXPRESSION OF CATHEPSIN L-LIKE AND ENOLASE FROM *TAENIA SOLIUM* IN THE BACULOVIRUS SYSTEM FOR DIAGNOSIS OF HUMAN NEUROCYSTICERCOSIS

Nancy León Janampa

Cayetano Heredia University, Lima, Peru

Abstract: Neurocysticercosis (NCC) is the main cause of adult epilepsy in developing countries. It is caused by the infection of ***Taenia solium*** larvae in the central nervous system. The available immunodiagnostic test is the Western Blot test composed by 7 partially purified lentil-lectin glycoproteins; with sensitivity of 40-60% for patients with single cyst NCC. In the search for new antigens for immunodiagnostic, we have expressed ***T. solium*** cathepsin L-like and enolase with their respective posttranslational modifications in the baculovirus-insect cell expression system (BES). Cathepsin L-like gene and enolase were anotaded from the ***T. solium*** genome. Coding sequences were cloned in both pFastBac

HT and E. coli DH5alpha. The gene rearrangement was made in the baculovirus genome (bacmid) in E. coli DH10 Bac. Bacmids were used for production of viral particles, and these were used for cathepsin L-like and enolase expression in Sf9 cells. Western blot with polyclonal rabbit antibodies specific for cathepsin L and Enolase was made to verify the expression of the proteins. We expressed cathepsin L (27 kDa) and enolase (52 kDa) of ***T. solium*** in BES. Expression was confirmed by western blot with specific rabbit polyclonal antibodies (1/5000) for cathepsin L-like and enolase. The BES is efficient to express low levels of cathepsin L-like enolase and its posttranslational glycosylation. This was suggested by a 5 kDa difference between the molecular weights of the proteins expressed in BES and expressed in E. coli BL21 DE3 pLys. Lower titers of antibodies to recognize and cathepsin L-like and enolase suggest that they are highly antigenic. Also, in the next three months we will evaluate the usefulness of recombinant proteins in the diagnosis using sera from patients with NCC.

1107

RISK OF ZOONOTIC DISEASE TRANSMISSION IN WORKERS WITH WILDLIFE CONTACT: CHINA

Corina Monagin[1], Blanca Paccha[2], **Neal Liang**[1], Sally Trufan[3], Huiqiong Zhou[4], De Wu[4], Changwen Ke[4], Bradley S. Schneider[1], Peter Rabinowitz[3]

[1]Metabiota, Inc., San Francisco, CA, United States, [2]Yale University, New Haven, CT, United States, [3]University of Washington, Seattle, WA, United States, [4]Guangdong Provincial Center for Disease Control and Prevention, Guangzhou, China

Wildlife zoonoses are a significant source of emerging infectious disease, but much remains unknown the factors driving species jumps of pathogens at the human animal interface. Here we report on a longitudinal cohort study conducted in Guangdong, China, to characterize the transmission of pathogens with pandemic potential in highly exposed human populations at the human-animal interface. The study was conducted in 12 prefecture level locations in Guangdong, targeting high-risk individuals- primarily hunters, persons working in wet markets and restaurant workers who process bushmeat. A risk factor/exposure survey was constructed and administered to these workers following informed consent and enrollment. Serology testing was performed at baseline for evidence of past infection with hanta virus, SARS CoV, and novel Bunyavirus. Follow up serology was performed on a subset of the cohort as well as close contacts of individuals testing positive on initial baseline serology. Bivariate and multivariate analysis was performed to examine association of reported risk factors with infection status. In our survey, cooks or kitchen workers were the most commonly reported occupation (reported by approximately one third of participants), while approximately 17% engaged in agriculture, 8% worked as butchers. However, hunters were rarely reported. Our data shows an overall low seropositivity to Hantavirus, SARS CoV, or new Bunyavirus (less than 1%), but higher positivity rate among certain subgroups such as butchers (approximately 10%). When reported tasks were analyzed, ever butchering a wild animal was associated with an elevated risk of seropositivity (approximately 5%), while ever hunting was associated with a lower rate (approximately 1%). Our results indicate that working as a butcher appears to be associated with an increased risk of infection with wildlife pathogens. Targeted educational programs for prevention, monitoring of high risk populations and comprehensive evaluation of sick persons with wildlife contact appears warranted.

1108

PREVALENCE OF *MYCOBACTERIUM BOVIS* INFECTION IN CATTLE FROM WESTERN KENYA

Eric Ogola[1], Anita L. Michel[2], Jennifer R. Verani[3], Godfrey M. Bigogo[1], Elkanah S. Otiang'[1], Linus O. Otieno[1], Joel M. Montgomery[3], Darryn L. Knobel[4]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]University of Pretoria, Onderstepoort, South Africa, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis

Bovine tuberculosis is a zoonotic disease with worldwide distribution affecting a broad range of mammalian hosts.It is caused by the bacterium ***Mycobacterium bovis*** causing pulmonary tuberculosis in cattle,leading to chronic debilitation and coughing,and the potential for systemic spread to other organs.In humans, ***M. bovis*** infection results mainly in extra-pulmonary tuberculosis especially among HIV positive and immune-compromised individuals. Asembo,Western Kenya, is an area with an estimated HIV prevalence of 16%. However there are limited data about the prevalence of ***M. bovis*** in cattle in Asembo.In livestock hosts, the single intradermal comparative cervical tuberculin test (SICCTT) detects infection with ***M. bovis*** before the onset of clinical disease. To determine the prevalence of cattle reacting to a SICCTT in Asembo, a cross-sectional survey was conducted among herds in 64 compounds randomly chosen from 33 villages. SCCITT was performed;animals were classified as reactors if their M bovis tuberculin reaction was 4mm greater than an avian tuberculin reaction. We tested 258 cattle from 64 herds and observed an individual cattle and herd-level prevalence of 1.6% (4/258) and 6.3% (4/64), respectively. Three of the four reactors were females. The median age of the reactors was 60 months, compared with 54 months for non-reactors. All reactors had been within their herds for more than 12 months, and 2 (50%) were born in their current herds, compared with 218/254 (85.8%) and 89 (35%) respectively of the non-reactors. All reactors (4/4, 100%) were herded together with other ruminant species. Among the non-reactors,213/254(83.9%) were commingled with other ruminant species. All households with reactor-cattle (100%) as well as 57/60 (95%) with non-reactor cattle also kept chickens. Similar studies from African countries have reported a prevalence range of 0.9-21%, with a higher prevalence in regions with high cattle: human ratio. This is within the range observed in the current study. This study demonstrates that ***M. bovis*** is present among cattle in a high-HIV burden area in Western Kenya, indicating a threat to both cattle and human health.

1109

AN EPIDEMIOLOGICAL APPROACH TOWARDS MASSIVE BOTULISM OUTBREAK IN CATTLE FARMS IN SOUTH KOREA

Wooseog Jeong, Oun-Kyong Moon, Hachung Yoon, Do Soon Kim, Yongsang Kim

Animal and Plant Quarantine Agency, Anyang, Republic of Korea

Botulism (types A to G) is neuroparalytic disease caused by a toxin produced by anaerobic bacteria ***Clostridium botulinum***. The bacteria are commonly present in the environment and become highly toxic in decaying vegetable compound and animal carcasses. Diagnosis is determined based on clinical signs and compatible history because standard confirmatory laboratory tests are not useful due to low sensitivity. The aim of this study is to provide knowledge on the recent outbreak of Botulism in Pocheon and Yeoncheon, Gyeonggi-do between August 2011 and July 2012 which specifically occurred in 24 cattle farms causing 431 cattle deaths. Further to this, possible risk factors were examined to find out the cause of the outbreak that the findings could be applied to establish bio-security policies. ***C. botulinum*** toxins were detected in 5 farms among 24 farms. Toxin type B and D detected farms were 1 and 2 respectively. Toxin type B and D, type B, C and D were detected at the same farm each. ***C. botulinum*** type D was confirmed in poultry litter specimens from 2 of 15 poultry farms situated nearby the affected

farms. With the consideration of diagnostic difficulty in detection of the bacteria, it is hard to ignore possibilities that other test negative poultry farms might be actually affected in real. From the fact that large number of livestock farms, agricultural farms using animal feces, burying livestock carcasses around the farms, and factories dealing with food leftover and livestock feces are densely populated in Pocheon, the area is assumed to have been already polluted with the toxin. The long rainy season (52 days, precipitation of 1,318mm), intensive heavy rain (675mm for 4 days) and flood then seemed to act as a carrier of potential risk elements from the environment to the farms. It was the first official diagnosis of ***C. botulinum*** in South Korea.

1110

BAT EXPOSURE RISK TO THE INDIGENOUS POPULATION OF THE PERUVIAN AMAZON

Julia S. Ampuero[1], Erik Jhonston[2], Christian Albujar[1], Jorge Gómez[3], Víctor A. Laguna-Torres[3], Sergio Recuenco[4]

[1]U.S. Naval Medical Research Unit - 6, Callao, Peru, [2]Direccion Regional de Salud Loreto, Iquitos, Peru, [3]Ministerio de Salud del Perú, Lima, Peru, [4]National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States

Surveillance activities have provided recent evidence that multiple ***Chiroptera*** (bats) species in Asia, Africa, and America serve as reservoirs for previously unrecognized pathogens affecting domestic animals and humans. Community education and enhanced surveillance activities among these at-risk populations are necessary to identify the level of exposure due to contact between bats and humans. This study aimed to examine the frequency of bat exposures among indigenous and non-indigenous populations, and describe the knowledge, attitudes, and practices of individuals with regard to possible bat exposure in Peru. This study was a collaborative effort between the Centers for Disease Control and Prevention, the Peruvian Ministry of Health, and the Virology and Emerging Infectious Department of the U.S. Naval Medical Research Unit No. 6 in Peru (NAMRU-6). A participant questionnaire gathered information about any history of bat exposures (e.g. bites, scratches, skin contact), actions taken following a bat exposure, perceived risk towards bats, and knowledge of bat-borne zoonotic diseases. The study population was comprised of residents from two rural villages around Iquitos, the largest city in the Peruvian Amazon (non-indigenous), and four riverside indigenous communities in Datem del Marañon province in Loreto, Peru. A venous blood sample was taken from the respondent from each household as well as anyone else in the household who claimed to have been exposed to bats. During four nights in each community, we captured ***Chiroptera*** using 6-20 mist nets around houses and caves near the villages. We found that the indigenous populations had more bats exposures (391/790, 49.5%) than the non-indigenous population (25/154, 16.2%). Riverside communities, indigenous, and non-indigenous populations had more bats exposure than the roadside community, 48.7% (407/836) and 8.3% (9/108) respectively. Three genuses of vampire bats reported in the amazon region were captured (***Diphylla, Diaemus***, and ***Desmodus***) primarily in the indigenous communities. Laboratory analyses will be conducted to determine the role of bats in the transmission of bat borne diseases.

1111

PREVALENCE AND DISTRIBUTION OF *ANGIOSTRONGYLUS CANTONENSIS* (CHEN, 1935) IN RATS AND FRESHWATER SNAILS OF MUÑOZ, NUEVA ECIJA, PHILIPPINES

Ma. Angelica A. Tujan, Vachel Gay V. Paller

University of the Philippines Los Banos, Los Banos, Philippines

Angiostrongylus cantonensis or rat lungworm is the major cause of eosinophilic meningitis in humans. Humans can be infected through ingestion of infected mollusks, paratenic hosts such as shrimps, crabs, or frogs, and vegetables which may be contaminated with infective stage. This study was conducted to determine the prevalence of ***A. cantonensis*** in rats and freshwater snails of Muñoz, Nueva Ecija, Philippines. Rats and freshwater snails were collected from both residential and agricultural areas in five selected barangays of Muñoz, Nueva Ecija. Rat tissues, e.g. heart and lungs, and snails were examined and subjected to artificial digestion for parasite collection. Results revealed that 30.62% of the rats examined were positive with ***A. cantonensis***. ***Rattus norvegicus*** and ***R. tanezumi*** showed prevalence of 45.83% and 28.65%, respectively. Also, prevalence was compared between sexes and age groups, however, only the latter showed significant difference among ***R. tanezumi*** ($P < 0.001$), e.i., adults, sub-adults, and juveniles showed prevalence of 57.14%, 44.62%, and 8.70%, respectively. Meanwhile, out of 781 freshwater snails belonging to eight different species, only ***Pomacea canaliculata*** (1.50%) and ***Melanoides maculata*** (1.12%) from irrigations and rivers were infected with larval stages (L3). This study revealed that rat species ***R. norvegicus*** and ***R. tanezumi*** and snail species ***P. canaliculata*** and ***M. maculata*** are susceptible hosts for ***A. cantonensis***. Furthermore, analysis of the host distribution showed an overlap in their habitats between residential and agricultural areas. Their presence on and near human settlements indicates risks of transmission to humans. The present study can be used in promoting public health awareness regarding rats and snails that can serve as sources of infection for both humans and other animals.

1112

IMPROVING RISK MAPPING FOR VECTOR-BORNE, ZOONOTIC DISEASES

Freya Shearer, Catherine Moyes

University of Oxford, Oxford, United Kingdom

Geospatial mapping of infectious diseases is important for targeting and assessing various public health activities. By combining information on locations where diseases have been recorded with geographic data on environmental and socioeconomic covariates known to affect disease transmission using machine-learning models, niche modelling can generate fine-resolution, evidence-based risk maps for a variety of diseases of public health importance. To understand spatial variation in risk for diseases with reservoirs in multiple host species, transmitted by multiple vector species, we need to develop this mapping approach further. For spatial epidemiology to capture the full complexity of these disease transmission systems, it is important to consider the niches and distributions of all component species. Prime examples of human diseases involving multiple vector and animal reservoir species include a number of important arboviruses and ***Plasmodium knowlesi*** malaria. Japanese encephalitis, West Nile fever and yellow fever all have reservoirs in multiple animal species and are transmitted by a wide range of mosquito genera. ***P. knowlesi*** is a malaria parasite found in wild monkey populations which is transmitted to humans via anopheline mosquitoes. It is the most common cause of clinical malaria in high transmission regions of Malaysia. Using a boosted regression tree modelling framework, species distribution maps were produced for putative reservoir and vector species of ***P. knowlesi*** malaria. Methods were developed to account for various sources of bias in the available data. These maps were used to assess whether distribution maps of putative reservoir and/or vector species explain the distribution of ***P. knowlesi*** infections in humans. A consensus map incorporating the distributions of multiple vector and reservoir species was subsequently generated and used as a covariate for disease occurrence mapping of ***P. knowlesi*** malaria. The application of this approach to investigate variation in risk from arboviruses with multiple reservoirs and vectors is discussed, and preliminary results for key arboviruses are presented.

1113

DIRECT BLOOD ANALYSIS OF *BARTONELLA BACILLIFORMIS* MULTI LOCUS SEQUENCE TYPING FROM PATIENTS WITH OROYA'S FEVER DURING A PERUVIAN OUTBREAK

Maria J. Pons[1], Cláudia Gomes[2], Willmer Silva-Caso[1], Joaquin Ruiz[2], Juana Del Valle-Mendoza[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]ISGlobal, Barcelona Ctr. Int. Health Res., Hospital Clínic - Universitat de Barcelona, Barcelona, Spain

Bartonella bacilliformis is the etiological agent of Carrion's disease, which is a neglected disease, affecting Mountain Andean valleys. This disease in absence of antibiotic treatment presents a high mortality during the acute phase (Oroya's Fever) between 44-80%. The second phase is characterized by the development of dermal eruptions, known as "Peruvian wart". Asymptomatic carriers also has been described in the population from endemic areas (0.5-40%). ***B. bacilliformis*** is a fastidious slow growing microorganism, being difficult and cumbersome to culture and isolate from clinical sources. Then, the available data about phylogenetic relationship in clinical samples are really scarce, but suggesting high variability. The aim of the study was to perform direct blood analysis of ***B. bacilliformis*** Multi Locus Sequence Typing (MLST) from diagnosed patients with Oroya fever. Almost the majority of the samples (8 out of 10) were collected during an outbreak in 2009 in Cajamarca. All samples were confirmed by PCR for B.bacilliformis. In addition 2 collection strain were included. Phylogenetic relationship was performance by CLUSTAL W. A total of 8 blood samples isolated during a Carrion outbreak in the period March-April 2009 in Cachachi (Cajamarca) in Northern Peru were analyzed. One blood sample was added in 2011 from Condebamba (Cajamarca), only 50Km of distance and finally another blood sample from Sihuas (Ancash), 500 Km of Cachachi in the center of the country. All strains from the outbreak belong to the same ST group, ST1. The strain of Condebamba is closely related to ST1, and finally the strain of Ancash is belonging to ST4. The collection strains from Pasteur Institute isolated in 1941 and 1949 belong to ST3. The present study demonstrate that the direct blood MLST PCR is a technique useful for application apply in the phylogenic characterization of this fastidious microorganism's endemic from Andean regions. In this study, we demonstrate that the Cajamarca outbreak of Oroya's fever is caused by the same Sequence Typing group, it might suggest that variability of strains from a region is not as variable as previously described.

1114

INFLUENCE OF DAIRY PRODUCTION PRACTICES ON RISKS FOR BOVINE VACCINIA EXPOSURE IN CATTLE: BRAZIL

Iara A. Borges[1], Andrea M. McCollum[2], Erna G. Kroon[1], Giliane D. Trindade[1], **Mary G. Reynolds**[2]

[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

Vaccinia-like viruses have been observed in natural circulation in Brazil since 1965. Outbreaks of bovine vaccinia (BV) have been recurrent in agricultural areas of the country for the last 15 years. A genetically diverse set of vaccinia-like strains have been recovered during these outbreaks and from related biological surveys aimed at virus discovery. Some strains have been observed to persist in specific regions for years and even decades. The purpose of this study was to identify environmental features of dairy farms or farming practices that are associated with risk for bovine exposure to vaccinia-like viruses. To accomplish this we collected sera from a cohort of domestic bovine (N=745) in an area with a history of outbreaks in order to assess associations between the environmental features and work practices of farms and virus exposure in bovines. Over the course of eight field visits which took place during June 2010--February 2012, 18 dairy farms within Minas Gerias state, Brazil, were visited by investigators. The properties surveyed during this study varied both in size and relative sophistication. A standardized data-collection instrument was used to record information from each property (i.e., cattle feed, utilization of mechanized ***vs.*** manual milking, pasture characteristics, presence of other domestic animals, water sources, non-domestic animals seen on property, etc.) Forty-eight presumptive predictor variables were assessed for association with ***Orthopoxvirus*** sero-status using univariate logistic regression methods; 10 were found to be significantly associated (p-value ≤ 0.050). A subset of these variables (relating to farming practices and to the presence of other domestic animals on the property) were determined to be independently associated with virus exposure in bovines.

1115

NOVEL ABUNDANT HEMOTROPIC PARASITISM OF NIGERIAN DOGS

Anise Happi[1], Jane Sykes[2], Christy Petersen[1]

[1]University of Iowa, Iowa City, IA, United States, [2]University of California, Davis, Davis, CA, United States

Dogs are an understudied reservoir host in Nigeria to potentially recognize blood-borne parasitic diseases that could be zoonotically transmitted to human. Most ill dogs brought to the University of Ibadan Veterinary Teaching Hospital (UIVTH) are tick-infested and anemic. Due to resource limitations, light microscopy (LM) is the only diagnostic means used in UIVTH for detection of haemoparasites. Quantitative PCR (qPCR)-based assays have been reported to a the gold standard for accurate diagnosis of haemoparasitism among others. In this study, we used LM and qPCR-based assays on 117 blood samples from dogs brought to the UIVTH for detection of haemoparasites. In addition, next generation sequencing was performed on positive samples for characterization of detected parasites. Six different haemoparasites were detected by LM and qPCR, including novel ***Mycoplasma haemobos.*** Analysis of thirty-eight of 117 dogs that were clinically suspected to be infected with haempoarasites confirmed, 7 (18.4%) and 31(81.6%) by LM and RT-PCR, respectively. qPCR and sequencing analysis revealed 89 (76.1%) positive samples, among which 75 (64.1%) for ***Babesia canis***, 43 (36.7%) for ***Ehrlichia canis,*** 12 (10.3%) for ***Hemoplasma canis,*** 2 (1.7%) for ***Hepatozoon canis*** and novel ***Mycoplasma haemobos*** (0.8%)***.*** Of these, single, double and triple parasite infections occurred in 49 (55.1%), 35 (39.3%) and 5 (5.6%) respectively. Overall, we outline the first report of ***Mycoplasma haemobos*** in dogs in Nigeria. We showed significant abundance and common occurrence of potentially zoonotic haemoparasitic infections in Nigerian dogs. These findings call for development of molecular diagnostic procedures for routine screening of sick companion animals, and further studies to understand the mechanisms of coinfection in altering parasite load and transmission and the relative risk of human infection when cohabitating with haemoparasite-infected dogs.

1116

KNOWLEDGE MANAGEMENT SYSTEM FOR NEGLECTED ZOONOTIC DISEASES IN PERU: A PROPOSAL FOR A ONE HEALTH APPROACH

Ricardo Castillo-Neyra[1], Cesar Naquira[2], Michael Z. Levy[1]

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]Universidad Peruana Cayetano Heredia, Lima, Peru

The One Health approach seeks synergy between human, animal and environmental health. If typically each of these fields is an island, a Knowledge Management System (KMS) can help bridge them. Universities are well positioned to build such bridges by facilitating collaboration and providing data sharing platforms. We propose an inter-institutional KMS for animal, human, and environmental health in Peru. The objectives of the National Service of Agriculture Health in Peru (SENASA) do not include to improve public health. However, in working toward its goal to increase animal productivity, SENASA is making important contributions to prevent transmission of zoonoses. Similarly, the MOH addresses zoonoses through human case management or preventive education, but no attention is paid to animal hosts. Despite overlapping interests, effective

communication between these 2 governmental agencies, to integrate work on humans and animals did not exist in Arequipa, Peru. Currently, the Zoonotic Disease Research Group in Peru of UPenn and Universidad Peruana Cayetano Heredia is bridging both agencies to share information, coordinate actions, and develop projects to leverage available data. The university role in the KMS is catalyzing exchange. Fasciola hepatica, known for its economic impact on livestock, has long been studied by SENASA. Through animal screening and awareness campaigns, it has dramatically reduced the prevalence in herds, and the impact on public health is being analyzed by our group and shared with the MOH for controlling human fascioliasis. Similarly, hydatid disease was not considered an important livestock illness in Arequipa. On medical records, we found over 150 hydatid disease patients in the last 2 years, most residing in Arequipa. These data is now being used to discover animal transmission ***foci***. Using a KMS, the data produced by SENASA's activities to evaluate animals are now being used for public health and MOH medical records are being used to identify animal hosts.

1117

HUMAN MONKEYPOX TRANSMISSION DYNAMICS THIRTY YEARS AFTER SMALLPOX ERADICATION IN THE SANKURU DISTRICT, DEMOCRATIC REPUBLIC OF CONGO

Chelsea L. McMullen[1], Prime Mulembekani[2], Nicole A. Hoff[3], Reena H. Doshi[3], Patrick Mukadi[4], Robert Shongo[2], Benoit Kebela-Illunga[5], Emile Okitolonda[6], Jean-Jacques Muyembe[2], Anne W. Rimoin[3]

[1]Duke University, Mooresville, NC, United States, [2]National Institute of Biomedical Research, Kinshasa, Democratic Republic of the Congo, [3]University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, [4]National Institute of Biomedical Research, Kinsahsa, Democratic Republic of the Congo, [5]4th Direction, Ministry of Health, Kinsahsa, Democratic Republic of the Congo, [6]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Reports from the first monkeypox (MPX) active surveillance program in the Democratic Republic of Congo (DRC) in the 1980s determined that the disease was not of epidemic potential, with R_0<1. However, during an active surveillance period from 2005-2007, researchers found a 20-fold increase during the last 30 years. The purpose of this study was to analyze the contact data from 2005-07 and compare characteristics to those of the 1980s. Results were used to assess the current R_0 of MPX, and to determine whether there has been a significant change since the first program. Contact tracing information and samples from active lesions were collected. Samples were screened by PCR and positive cases were ranked by generation and grouped into chains of transmission according to date of rash onset, contact tracing, and location. R_0 was determined using calculations provided in the 1980s study and chain size distribution was compared. Of 1407 suspected cases of MPX investigated in 2005-07, 570 provided contact information with an average of 6.4 (range, 1-21) contacts each. Among the 733 positive cases, 435 distinct chains of transmission were identified. Average chain size was 5.3 cases (range, 1-13), with the longest reaching six generations. Among confirmed cases, 293 reported contact tracing information, and the crude secondary attack rate (AR) was 0.067. Stratified into household and non-household contacts, AR was 0.070 and 0.49, respectively. R_0 was found to be between 0.419-0.570 as opposed to 0.815. Contact characteristics and types of contacts differed from those of the 1980s program. This analysis found a higher crude secondary attack rate, but a lower number of contacts on average, as well as a smaller difference in the attack rates within household and non-household members. This could be the result of a higher proportion of unvaccinated contacts, or that the virus is better able to transmit between humans with a more limited amount of contact. Further analysis of R_0 should be continued in order to evaluate the many variables potentially involved in the transmission differences.

1118

PREVALENCE OF *TOXOPLASMA GONDII* INFECTION IN VETERINARY STUDENTS AT WESTERN UNIVERSITY OF HEALTH SCIENCES AND EVALUATION OF RISK FACTORS: PRELIMINARY RESULTS

Emily J. Trumbull, Hannah Mirrashed, Jessica Coote, Cesar Ochoa, Helen Engelke, James Reynolds, Nishita Patel, Malika Kachani

Western University of Health Sciences, Pomona, CA, United States

Toxoplasmosis is a parasitic, zoonotic infection causing a significant One Health impact globally. In recent history, it was thought that ***Toxoplasma gondii*** infections were asymptomatic, but new research suggests that the outcome of these infections have been fatal for both animals and people. Over the last two decades, toxoplasmosis has been associated with neurological disorders in mice and humans. The infected individuals are at a higher risk for car accidents, suicide and schizophrenia. Currently, the prevalence of infection among the population in the United States is largely unknown. This study aims to determine the seroprevalence of ***T. gondii*** in a group of students attending the College of Veterinary Medicine at Western University of Health Sciences. Blood samples have been collected and tested for ***T. gondii*** immunoglobulin G (IgG). The participants have also completed a survey aimed to identify risk factors associated with acquiring the ***T. gondii*** infection. The preliminary results will be presented and discussed. The results of this study will direct the development of public health education and outreach efforts to reduce the transmission of ***T. gondii*** among animal patients and veterinarians. Considering that toxoplasmosis has been selected by the Center of Disease Control and Prevention as one of the neglected diseases for public health action, this project could structure future prevention measures for the general public of Southern California.

1119

CO-PREVALENCE OF AIDS AND OTHER DISEASES AND THE DEMOGRAPHIC CHARACTERISTICS OF TUBERCULOSIS PATIENTS IN A MUNICIPALITY OF SOUTHEASTERN BRAZIL

Rodolpho Telarolli Jr.[1], Beatriz D. Pereira[1], Rosangela M. Silva[2], Eduardo F. Hage[2]

[1]Faculty of Pharmaceutical Sciences, Araraquara, Brazil, [2]SESA - University of Sao Paulo, Araraquara, Brazil

In the second half of the twentieth century, the eradication of tuberculosis in the world was believed to be possible. The emergence of AIDS in the 1980s which changed the behavior of tuberculosis. In the twenty-first century, tuberculosis remains a serious public health concern in Brazil, with 75,120 cases reported in 2014. Araraquara is a medium-sized city located in the state of Sao Paulo, a region with the highest Human Development Index in Brazil. The prevalence of tuberculosis in Araraquara was 30% lower compared with the national average in Brazil in 2011 (27.0 cases and 38.4 cases per 100,000 inhabitants respectively). This can be explained in large part by the high average income and other social, economic and health factors of the city. 533 new cases of tuberculosis were recorded in Araraquara between 2002 and 2011 of which 72.6 % were male and the rest female (67.4 % were men and 32.6 % were women in Brazil in 2011). The predominant age group consists of young adults between 20 and 49 years old, contributing to 66.0 % of the total. 4% of the patients were under the age of 20 and 4.9 % were 70 years and older. AIDS was diagnosed in 20.4 % of male TB patients and 29.4 % of female TB patients in the same period, well above the national average of 10.4 % in men and 9.3 % in women. AIDS was also diagnosed in 5 children with less than 5 years of age who had TB-HIV co-prevalence. Following the trend that is present throughout Brazil of which hepatitis C is the most common, hepatitis C was diagnosed in 10.1% of men and 8.9 % of women with tuberculosis and hepatitis B in 5.9 % of men and 4.1% of women with TB in the period between 2002 and 2011. Throughout the period of study,

cure rates of almost 80 % were obtained in the municipality while the mortality rate was 12.3 %. The findings of the study present a worrying situation for the city of Araraquara and there is a need to improve the diagnostic routines and medical care of TB patients. The co-prevalence of tuberculosis and AIDS, much higher than the national average (3 times higher in women and 2 times in among men), is also very alarming and calls for further studies.

1120

THE IMPACT OF ANTI-TUBERCULOSIS TREATMENT ON THE ELABORATION OF PRO-INFLAMMATORY CYTOKINES IN HIV SERO-NEGATIVE TUBERCULOSIS PATIENTS

Chikere A. Anusiem[1], Samuel Ikenna Ghasi[1], Amarachi Ujunwa Esione[1], Angela Chigorom Anusiem[2], Paul Obiekwe Okonkwo[1]

[1]College of Medicine University of Nigeria Teaching Hospital Enugu, Enugu, Nigeria, [2]University of Nigeria Teaching Hospital Enugu, Enugu, Nigeria

Tuberculosis has continued to be a major public health challenge in Sub-Saharan Africa and some other regions of the world even though the causative bacterium was discovered more than one century ago. The emergence and spread of drug resistant strains of the bacteria, concurrent HIV/AIDS epidemics, lack of better biomarkers, and unavailability of more effective vaccines have all contributed to the persistence of the disease in the world. Pro-inflammatory cytokines are known to play significant roles in the pathogenesis of tuberculosis. In a prospective observational study we investigated the serum concentrations of three cytokines in adult men and women suffering from tuberculosis of the lungs. The research protocol was approved by the research ethics committee of the University of Nigeria Teaching Hospital Enugu. Each patient was followed up from diagnosis to completion of 6 months WHO approved treatment. Forty two patients and 18 healthy controls participated in the study after giving informed consent. They were all HIV sero-negative. Serum Interleukin-1 β, tumor necrosis factor α, and interleukin 6 were measured in serum of the patients at the time of diagnosis, after eight weeks of treatment and after 6 months of treatment using human ELISA technique (www.ebioscience.com). Data analysis was done using Graphpad prism software, and statistical significance was determined at $p = 0.05$. All three cytokines were found to be very high compared to healthy controls at the time of diagnosis. After eight weeks of treatment there were significant reductions in the serum levels of the cytokines compared to levels recorded before treatment. Subsequently, there were further reductions in the serum concentrations of the 3 cytokines with statistically significant differences between the values at 2 months and those at 6 months. The values recorded at 6 months were close to but not identical with those of healthy controls at any time. These findings could find important applications in tuberculosis drug and vaccine development. Larger studies to validate these findings are needed.

1121

SPATIAL EPIDEMIOLOGY OF TUBERCULOSIS IN KISUMU AND SIAYA COUNTIES, WESTERN KENYA

Peter Sifuna

U.S. Army Medical Research Unit-Kenya, Kisumu, Kenya

The occurrence of tuberculosis (TB) in Kenya is characterized by spatial variations across the country. Nyanza region in western Kenya has the highest TB burden with an estimated prevalence of 500-600 cases per 100,000. Effective management of TB and reduction of TB incidence rates relies on knowledge of where, when and to what degree the disease is present. Objective The objective was to determine the spatial variability of TB disease within a holoendemic region and investigate the factors associated with the observed distribution. Methods Data on TB occurrence was obtained from the combined registers of 233 TB clinics in Kisumu and Siaya Counties. Locator information in the registers was used to link TB cases to lowest formal administrative units referred to as sub-locations. The ArcView application was used to generate maps showing the spatial distribution of TB. Results Of the 5,528 patient's records in the TB registers, 5,468 (99%) were geo-coded to a geographical location. A total of 4, 537 (82%) were residents of the study area. Significant high- and low-rate spatial and space-time clusters were identified in the two counties. A significant secondary cluster was also identified in one of the densely populated areas of the study area. Discussion and conclusion Results from this study can guide targeted TB screening and control efforts with the goal of reducing TB incidence.

1122

VARIABILITY OF THE RESPIRATORY RATE MEASUREMENTS IN CHILDREN SUSPECTED WITH NON-SEVERE PNEUMONIA NORTHEAST TANZANIA.

Florida J. Muro[1], Neema Mosha[1], Regina Malugu[2], Helena Hildenwall[3], Raimos Olomi[1], Hugh Reyburn[4], Jim Todd[4]

[1]KCMUCo, Moshi, United Republic of Tanzania, [2]Teule Hospital, Muheza, Tanga, United Republic of Tanzania, [3]Karolinska Institutet, Department of Public Health Sciences, Division of Global Health, Stockholm, Sweden, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

With so little time left for completion of the Millennium Development Goals (MDG), World Health Organization (WHO) and others are giving increased attention towards respiratory rate (RR) measurement in children in order to identify and reduce pneumonia mortality. The introduction of new devices raises the need for validity assessment and this raises the need for a 'gold standard' measure of RR. There is no such standard that is internationally accepted but one option is the use of video of respiratory movement in children that can be later reviewed by experts and results compared with those obtained by primary care workers in their daily practice. We assess the use of such video recordings taken under controlled conditions and comparing results from two independent paediatricians. Using WHO recommendation of observation for 60 seconds, RR were recorded in children aged 2 - 59 months presenting with cough or difficulty breathing in a busy clinic and then repeated at 10 minute intervals over 1 hour in a quiet setting. Random effects linear regression was used to assess variability in RR measurements. A total of 167 children were studied, the mean age was 17.5 (SD±13.8) months and 97(58.1%) were males. Half of the children were awake or calm during the one hour of observation and about a quarter of children were agitated making video review difficult. The mean RR was 35.9 (SD± 9.7) breaths per minute (bpm) and 36.4 (SD± 10.1) bpm by first and second video reviewer respectively compared to 35.8 (SD± 10.7) by the research nurse. On multivariate analysis, the video reviewers recorded high RR than the research nurse (video recorder 1= 0.53, 95% CI=0.23-0.84, video recorder 2=0.85, 95%CI=0.53-1.17). Inter-observer variability in RR between the 2 video recorders and the research nurse was high (SD=3 breaths per minute) after accounting for differences among children and over time. RR is an important clinical sign in identifying children with pneumonia who require antibiotic. Video does not appear to be a reliable gold standard of RR quality checks. Alternative tools need to be identified to facilitate correct and proper assessment of pneumonia in children.

1123

PNEUMOCOCCAL VACCINE RESPONSE IN MID-CHILDHOOD IS NOT AFFECTED BY PREVIOUS PARASITE EXPOSURE *IN UTERO* OR DURING THE FIRST THIRTY-SIX MONTHS OF LIFE IN COASTAL KENYA

Monica Nayakwadi Singer[1], Charles King[2], David M. Vu[3], Claire J. Heath[3], Indu Malhotra[2], Francis Mutuku[4], Jackson Mwinde[5], Peter Mungai[5], Dunstan Mukoko[5], A. Desiree LaBeaud[3]

[1]University of California San Francisco Benioff Children's Hospital Oakland, Oakland, CA, United States, [2]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States, [3]Stanford School of Medicine, Palo Alto, CA, United States, [4]Technical University of Mombasa, Mombasa, Kenya, [5]Division of Vector Borne and Neglected Tropical Diseases, Ministry of Public Health and Sanitation, Nairobi, Kenya

Children in developing countries respond poorly to life-saving vaccines. ***Streptococcus pneumoniae*** causes vaccine-preventable invasive disease and is currently a leading cause of mortality under age five. Increasing evidence suggests that exposure to chronic parasitic infections can significantly contribute to poor vaccination response. Our goal was to measure Str. pneumoniae vaccine response in a well-characterized cohort of Kenyan children who had been exposed to parasitic infections ***in utero*** and/or in the first 36 months of life.In 2014, the cohort, now aged 4-7 years old, were tested for malaria, soil transmitted helminths, ***Entamoeba histolytica, Giardia lamblia***, and ***Schistosoma haematobium*** infection. Participants received a 10-valent pneumococcal conjugate vaccine.Post-vaccination serum was collected after 4 weeks.Our multiplex fluorescent bead assay determined pre- and post-vaccination IgG concentrations to the ten vaccine PnPs serotypes: 1, 4, 5, 6B, 7F, 9V, 14, 18C, 19F and 23F. Ranked post-vaccination anti-PnPS IgG concentrations and pre-post increments were compared using non-parametric statistics to determine the impact of subject demographic and parasite exposure factors.Maternal infection with more than one parasite at delivery was associated with a lower PnPS 19 vaccine response. Children exposed to more than two infections ***in utero*** had elevated post-vaccine IgG response to PnPS 14.Experiencing multiple parasitic infections by 30 months of age was significantly associated with elevated PnPS 1 and 6B IgG levels.No association was found between vaccine responses and subject sex or the presence of hookworm, Trichuris, Giardia, or malaria at the time of vaccination. Anti-PnPS responses were not correlated with anti-***Haemophilus influenzae*** type b (Hib) responses earlier in infancy.Although children in this cohort who had been exposed to prenatal maternal parasitic infections demonstrated impaired response to Hib vaccination as infants, there was no consistent impairment of pneumoccocal vaccine response later in life.Mid-childhood vaccine response to PnPS 19 is lower in children born to mothers with polyparasitism at delivery.

1124

STREPTOCOCCUS PNEUMONIAE CARRIAGE RATES AND SEROTYPE PREVALENCE IN COASTAL KENYA

Claire Jane Heath[1], Monica Singer[2], David M. Vu[1], Francis Mutuku[3], Charles H. King[4], Indu Malhotra[4], A. Desiree LaBeaud[1]

[1]Stanford University, Palo Alto, CA, United States, [2]University of California San Francisco Benioff Children's Hospital Oakland, Oakland, CA, United States, [3]Technical University of Mombasa, Mombasa, Kenya, [4]Case Western Reserve University, Cleveland, OH, United States

Streptococcus pneumoniae (SP) is an important cause of many vaccine preventable invasive diseases, including bacterial meningitis, pneumonia, and sepsis, and is the leading cause of mortality in children under 5 worldwide. In industrialized countries, routine SP conjugate vaccination has decreased the incidence of invasive SP disease in vaccinated infants and unvaccinated children due to herd immunity. Epidemiological data on SP colonization rates and serotype prevalence in the developing world are relatively scarce, thus the effect of SP vaccination is less clear in these regions. The 10-valent SP vaccine was introduced into the childhood vaccination schedule in Kenya in 2012. Because serotype carriage affects immunization responses to corresponding vaccine antigens, localized characterization of colonization is important now and as the vaccine is further rolled-out, to maximize its clinical effectiveness. The purpose of this study is to measure nasopharyngeal (NP) carriage of SP in unvaccinated children. In addition, we plan to evaluate the impact of the 10-valent SP vaccine on carriage rates and serotype prevalence. Beginning in January 2014, children aged 4-7 years old were enrolled in Msambweni, Kenya. NP swabs were performed, and children then received a single dose of a 10-valent SP vaccine. Repeat swabs were obtained 4 weeks post immunization. SP carriage was determined by bacterial culture and multiplex PCR for the SP capsular gene cpsA and the serotype gene wzy. 354 samples (257 pre- and 97 post-vaccine) have been tested. 38/257 (14.7%) pre-vaccine samples were positive for SP, compared to 12/97 (11.6%) of the post-vaccine samples (p=0.61). These preliminary data suggest that the overall SP carriage rate is not greatly impacted by the vaccine. However, sample collection and molecular identification is ongoing, and analysis of paired (pre- and post- vaccine) samples will be informative in the evaluation of the vaccine impact on vaccine-serotype colonization, while also monitoring for post-vaccination replacement serotypes and emergent strains.

1125

CLINICAL AND EPIDEMIOLOGICAL CHARACTERIZATION OF TUBERCULOSIS IN CENTRAL REGION OF THE STATE OF SÃO PAULO, BRAZIL

Rita C. Carvalho, Rodolpho Telarolli Jr.

Faculty of Pharmaceutical Sciences, Araraquara, Brazil

Brazil is one of the 22 countries that accounts for 80% of all TB cases in the world. So it is important to have a better understanding of the clinical and epidemiological distribution of TB in the country. It is also important to know the performance of the disease control programs in the country. Brazil is a very heterogeneous country from an economic and social point of view. We conducted this study in one of the wealthiest regions of the country, the central region of São Paulo. This region has 24 municipalities and approximately one million inhabitants. We conducted a retrospective descriptive study using the TB Web System, which is used for TB control, as our data source. The study period was from 2006 to 2012. The incidence of TB was lower in the region studied than the average incidence in São Paulo state: 19.7 and 38.0 cases / 100,000 inhabitants, respectively. The mortality rate in the region was one death / 100,000 in 2012. As for patients who were co-infected with TB / AIDS, the mortality rate was 8.4. In 2012, there was a cure rate in 81.1% of the patients, 7.0% of abandonment and 10.8% of deaths. For TB patients co-infected with AIDS, the prognosis was worse: low cure rate (55.6%), high abandonment rate (11.7%) and high mortality rate (32.7%). From a demographic point of view, males (74%), patients aged between 20 and 49 years (62.5%) and low schooling, defined as illiterate or up to 7 years of schooling (59.9%) predominated. Supervised treatment was offered to almost 80% of patients in 2012, compared to only 5.4% in 2006. Were examined 75.6% of contacts of TB cases in period 2006-2012. Pulmonary disease was predominant: 83.6%. Diagnosis of TB in the region is still carried out late: 16.9% during hospitalization and 1.2% after death. Culture for Mycobacterium tuberculosis was performed only in 52% of cases with this epidemiological indication. The results demonstrate serious deficiencies in TB control in one of the wealthiest and most developed region in Brazil. It is essential the early diagnosis of tuberculosis and AIDS, to reduce mortality from these diseases.

1126

IMPROVING ADHERENCE TO CHILDHOOD PNEUMONIA TREATMENT: THE DESIGN AND DEVELOPMENT OF PATIENT INSTRUCTIONS AND A JOB AID FOR AMOXICILLIN DISPERSIBLE TABLETS

Kelly Ebels[1], Dunia Faulx[1], **Emily Gerth-Guyette**[1], Peninah Murunga[2], Samarendra Mahapatro[3], Manoja Kumar Das[4], Amy S. Ginsburg[1]

[1]PATH, Seattle, WA, United States, [2]PATH, Nairobi, Kenya, [3]Hi-Tech Medical College, Bhubaneswar, India, [4]The INCLEN Trust International, New Delhi, India

Pneumonia is the leading cause of death from infection in children worldwide. Despite global treatment recommendations which call for children with pneumonia to receive amoxicillin dispersible tablets (DT), only one-third of children with pneumonia receive any antibiotics and many do not complete the full course of treatment. Poor adherence to antibiotics may be driven in part by low literacy. In order to improve pneumonia treatment adherence at the community level, we developed a user-friendly product presentation for caregivers and healthcare providers (HCP). This poster presentation aims to document the development process and offers a model for future health communication tools. We employed an iterative design process which included document reviews, key stakeholder interviews, engagement with a graphic designer, and pre-testing design concepts among target users in India and Kenya through focus groups and usability testing. Though educational resources for pneumonia treatment are available in some countries, their content is incomplete and inconsistent with global recommendations. Document reviews and stakeholder interviews identified the critical information to convey to caregivers and recommendations for how to best differentiate between treatment regimens. Target users in India and Kenya confirmed the need to support better treatment adherence, recommended specific modifications to design concepts, and suggested the development of a companion job aid. There was a consensus among caregivers and HCP that these tools would be helpful and improve adherence behaviors. The output of this process is a user-friendly product presentation and job aid for amoxicillin DT that will be evaluated in a health care setting in Bangladesh. The development of new pictogram instructions for medications for low-literacy populations is a critically important but time and resource intensive process that should involve engagement with target audiences.

1127

METHODS OF A DOUBLE-BLIND RANDOMIZED CONTROLLED CLINICAL TRIAL OF THREE VERSUS FIVE DAYS AMOXICILLIN DISPERSIBLE TABLETS FOR CHEST-INDRAWING PNEUMONIA AMONG CHILDREN 2-59 MONTHS OF AGE PRESENTING TO KAMUZU CENTRAL HOSPITAL IN LILONGWE, MALAWI

Gwen Ambler[1], Salim Sadruddin[2], Ajib Phiri[3], Norman Lufesi[4], Tiyese Chimuna[5], Susanne May[6], Amy Ginsburg[1]

[1]PATH, Seattle, WA, United States, [2]Save the Children, Fairfield, CT, United States, [3]College of Medicine, Lilongwe, Malawi, [4]Ministry of Health, Lilongwe, Malawi, [5]Save the Children, Lilongwe, Malawi, [6]University of Washington, Seattle, WA, United States

Pneumonia is the leading cause of mortality from infection in under-5 children. World Health Organization's (WHO) Integrated Management of Childhood Illnesses (IMCI) guidelines recommend 5 days of twice-daily oral amoxicillin for children with chest-indrawing pneumonia. Limited data suggest 3 days of therapy, the standard of care for fast-breathing pneumonia, may be sufficient for chest-indrawing pneumonia as well. A shorter regimen could simplify prescriptions, enhance treatment adherence and reduce health system costs. To generate evidence for shorter therapy, we are initiating a double-blind randomized non-inferiority trial to compare 3 vs 5 days of amoxicillin dispersible tablets (DT) for children 2-59 months old with chest-indrawing pneumonia from an outpatient clinic in an endemic malaria region of Malawi. This is the first known study of this research question. Children will be excluded if they have WHO-defined severe pneumonia, HIV-seropositivity/exposure, severe acute malnutrition, possible tuberculosis, severe anemia, severe malaria, unresolved wheeze, or a non-pneumonia illness requiring antibiotics. Children will be randomized to receive 3 days of amoxicillin DT plus 2 days of placebo or 5 days of amoxicillin DT. Upon enrollment children will be hospitalized 48 hours for observation with follow-up on days 2, 4, 6 and 14. The primary endpoint is the proportion of children failing treatment before or on day 6, defined as: WHO danger signs, hypoxia, fever, vomiting ≥3 doses, antibiotic regimen change, prolonged hospitalization/readmission or death. A total of 2,000 children will be enrolled. We assume a treatment failure rate of 10% in the control arm and an absolute 4% non-inferiority margin. In the final analysis, there is 97.2% power to rule out a 4% increase in failure rate, even if the true difference is a 1.3% increase. We will present descriptive statistics of the enrolled study population to date and reasons for exclusion. At the time of presentation, the trial will be in progress, with an anticipated end date in January 2017. This is a novel investigation that has the potential to improve childhood pneumonia treatment.

1128

RARE CASE OF MEDIASTINAL TUBERCULOSIS

Vincent Nip[1], John Horne[2], Theresa Townley[3], Vishisht Mehta[3], Renuga Vivekanandan[2]

[1]Creighton University School of Medicine, Omaha, NE, United States, [2]Creighton University School of Medicine (Division of Infectious Diseases), Omaha, NE, United States, [3]Creighton University School of Medicine (Division of Internal Medicine), Omaha, NE, United States

A 27 year old Burmese female presented with recurrent fevers for greater than 2 months. Upon immigrating to the United States 4 years ago her tuberculin skin test (TST) was negative. She had a previous admission 1 month prior for fevers, and at that time a computed tomography (CT) scan of the chest revealed a large anterior mediastinal mass and lytic/sclerotic lesion of the manubrium. A CT-guided biopsy of the mass had chronic necrotizing granulomatous inflammation. BAL and mediastinal biopsy stains for fungi and AFB were negative. An HIV test was negative. This admission she had repeat imagining which had a new moderate right pleural effusion. Pleural fluid studies including culture and stains for bacterial, fungal and AFB pathogen were negative. TB was high on the differential and she was empirically started on 4 drug therapy. An Interferon γ release assay (IGRA) was elevated at 9.16 (normal <0.34) as were ESR and CRP. During this work up her prior mediastinal biopsy culture had growth at 3.5 weeks and TB DNA probe by PCR was positive. She had significant improvement with resolution of fevers within a week of initiating TB therapy. Mediastinal TB is rare, is decreased with increasing age, is more common in high incidence areas and is uncommon in immunocompetent hosts. Tissue culture is essential and remains the diagnostic gold standard with a sensitivity >90%. While TB PCR probes can be used on culture negative specimens, they have lower sensitivity than culture. It is essential in patients with suspected active TB disease to initiate treatment while awaiting results.

1129

MOLECULAR CHARACTERIZATION OF THE SPIKE GENE OF THE MIDDLE EAST RESPIRATORY SYNDROME CORONAVIRUS ISOLATED IN EGYPT IN 2014

Ehab Atia[1], Mayar Said[1], Samir ElRefaay[2], Mohamed Genedy[2], Gabriel Defang[1], Emad Mohareb[1]

[1]U.S. Naval Medical Research Unit - 3, Cairo, Egypt, [2]Ministry of Health and Population, Cairo, Egypt

The Middle East respiratory syndrome coronavirus (MERS-CoV) was first identified in a patient in Saudi Arabia (KSA) in 2012 and has since been detected across the Middle East, Europe and the USA. Egypt reported its first case in late April, 2014 from an adult patient who had been in

contact with a previously-confirmed case of MERS-CoV in Jeddah, KSA. We sequenced the spike (S) gene of the virus to investigate genetic changes indicative of positive strain selection or altered virulence. Sequencing of the S gene was performed on nucleic acid extracted directly from a PCR-confirmed sputum sample. Six overlapping DNA fragments covering the entire S gene were generated using specific primer sets. Sanger sequencing was performed. The generated sequence (3500 nucleotides) was aligned with other MERS-CoV sequences from GenBank, and phylogenetic analysis conducted. The S gene showed 99.9% nucleotide similarity to MERS-CoV samples isolated from a health care worker who resided in KSA (GenBank accession number: KJ829365), and a camel in KSA (KJ713296). The Egyptian MERS-CoV case clustered within the Riyadh_3 group in genetic clade B, forming a distinctive lineage with other MERS-CoV cases collected in the period of April-May 2014 from individuals who visited Jeddah, and traveled to Florida, USA and Greece. The S gene of the MERS-CoV from Egypt showed seven nucleotide differences from the prototype strain, resulting in two amino acid mutations; Q1020R in the heptad repeat region of the S protein which is present in many sequences of clade B viruses and Q833R. The close similarity between the S gene of the Egyptian case and that found in the camel indicates phylogenetic relatedness. The sustained presence of the Q1020R mutation is suggestive of a positive strain selection, concordant with previous report that arginine substitution in this position provides a potential endosomal protease cleavage site which may influence the membrane fusion activity of the S protein.

1130

CLINICAL AND ECONOMIC BURDEN OF ADULT HOSPITALIZATIONS OF DRIFTED INFLUENZA A (H3N2) VIRUS 2014-2015

Dinesh K.r Sidh[1], Sripriya D. Kolakalur[2]

[1]International University of Health Sciences, St. Kitts, Saint Kitts and Nevis, [2]Summa Health System, Akron, OH, United States

Global surveillance of influenza strains help to make recommendation for Northern Hemisphere influenza vaccine composition. Morbidity and mortality is higher when influenza viruses have antigenically drifted from vaccine strain, as noticed in 2014-15 flu season. The study enumerates the clinical and economic impact of laboratory-confirmed influenza hospitalizations of adult patient subset in a community hospital with tertiary care. Patients who tested positive for influenza A in rapid flu PCR test were studied by medical chart abstraction. Clinical spectrum was characterized with ICD-9-CM codes:Influenza with pneumonia (487.0), Influenza NOS, (487.1), Influenza with gastrointestinal symptoms(487.8); Encephalopathy due to influenza (487.8), acute respiratory failure(518.81), cardiovascular symptoms, (785) rapid heart rate, hypotension, shock. Data including, age, length of stay, underlying medical conditions, total cost of inpatient stay with imaging, medications, room and board were obtained for each patient, and was tabulated weekly for November 2014 to February 2015, A total of 218 adult hospitalized patients tested positive for influenza during this period. Influenza activity peaked in third week of December 2014(week 51),majority were adults aged 65-85years. Average length of stay was 5 days. Average inpatient cost ranged from 14,000USD for uncomplicated flu cases to 66,000USD in patients with respiratory failure. Most common underlying medical condition for this patient sample was chronic pulmonary disease, followed by cardiac diseases and diabetes mellitus.23% of adults had no underlying medical conditions to place them at risk of complications. Largest subset in clinical spectrum was Influenza with upper respiratory sympotms, followed by flu cases with respiratory failure.Six patients died of influenza complications. Effectiveness of vaccine is reduced with drifted viruses, hence in cases of clinical suspicion, anti-viral agents should be instituted early even before laboratory confirmation.

1131

CORRELATION BETWEEN LOW TEMPERATURE AND ACUTE RESPIRATORY ILLNESS IN IQUITOS, PERU

Isabel Bazán[1], Crystyan Siles[1], Stalin Vilcarromero[1], Carolina Guevara[2], Carlos Alvarez-Antonio[3], Robert Hontz[2], Amy C. Morrison[4], Julia S. Ampuero[2]

[1]U.S. Naval Medical Research Unit - 6, Iquitos, Peru, [2]U.S. Naval Medical Research Unit - 6, Lima, Peru, [3]Direccion Regional de Salud, Loreto, Iquitos, Peru, [4]U.S. Naval Medical Research Unit - 6 and University of California, Davis, Iquitos, Peru

Acute respiratory illness (ARI) is a major cause of morbidity and mortality worldwide. In Peru, ARI incidence in the Loreto Region typically exceeds the national annual average incidence. In 2013, the Ministry of Health reported 139,278 cases of respiratory infection in Iquitos, from which 104,126 and 35,152 were upperand lower respiratory tract infections, respectively. It is generally believed by clinicians in Loreto that low temperatures are closely followed by increases in ARIs. To test this perception, we evaluated minimum temperature and clinical data between January and December of 2013 in Iquitos, the largest city in Loreto. Low temperatures, as defined as temperatures below 22°C, occurred in January, April, July, and August of that year. Apparent increases in ARI incidences were observed after these episodes. Data from the U.S. Naval Medical Research Unit No.6's respiratory virus surveillance programs was used to identify the etiologies of circulating viruses and the number of cases. Correlation between low temperature in one week and ARI incidence in the following week was estimated using Spearman's rank correlation coefficient (rho). Weak correlations with prior low temperatures were found for upper acute respiratory disease (rho=0.19, p=0.17), pneumonia (rho=0.14, p=0.3) or Influenza A (rho=0.3,p=0.03). Our results do not support the perception of a close temporal relationship between low temperatures and increases in ARI cases. A better understanding of the impact of additional climate variables, such as rainfall and humidity, has the potential to improve clinical perception of ARI in Iquitos.

1132

SURVEILLANCE AND CLINICAL CHARACTERIZATION OF RESPIRATORY INFECTIONS IN WESTERN OF CAMBODIAN TO IMPROVE COMPLIANCE WITH INTERNATIONAL HEALTH REPORTING REQUIREMENTS (IHR)

Panita Gosi[1], Chanthap Lon[2], Chuang Ilin[1], Nitima Chanarat[1], Piyaporn Sia-ngam[1], Buth Samel[2], Soy Pros[2], Nichapat Uthaimongkol[1], Samon Nou[2], Seng Heng[3], Sovann Ly[3], David L Saunders[1]

[1]U.S. Army Medical Component-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]U.S. Army Medical Component-Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [3]Communicable Diseases Control, Ministry of Health, Phnom Penh, Cambodia

Information on respiratory viruses in Western Cambodia is limited, yet these are a leading cause of morbidity and mortality worldwide. Co-infection of viral and bacterial respiratory infections may worsen the severity of illness and increase mortality. We established heightened clinical and laboratory surveillance measures to characterize viral and bacterial co-infections of respiratory tract from influenza-like illness (ILI) patients in Cambodia. A total of 108 nasopharyngeal swabs collected from ILI patients with respiratory symptoms from October 2014 - March 2015 were examined for the presence of influenza A and B virus, non-influenza respiratory viruses and bacterial infections. Positive influenza A virus samples were further subtyped by multiplexed real time PCR. Overall, 25% of subjects (27/108) were positive for influenza virus, with nearly all (26 of 27) of the influenza A/H3N2 subtype, and one case of pandemic A/H1N1 (0.9%). Peak influenza activity occurred in November when 17 of 44 samples collected that month were flu positive. Non-influenza

respiratory tract viruses were detected in 46 subjects with Respiratory Syncytial virus A/B (15%), Rhinovirus (8%) and Adenovirus (5%) the top 3. Bacterial infections were detected in 15 subjects: ***Streptococcus pneumoniae*** (10%), ***Staphylococcus aureus*** (3%), ***Bordetella*** (0.9%). 12% (13/ 108) had infection with more than one virus, and 10% (11/108) had bacterial coinfection. While Influenza A/H3N2 was the most common respiratory pathogen detected in ILI patients in Western Cambodia, 43% had non-influenza etiologies. Viral-bacterial co-infections were identified rarely. Field-expedient multiplexed RT-PCR allowed rapid identification of respiratory pathogen etiologies to guide public health interventions in this previously underserved and under-described area of Cambodia.

1133

DETECTION AND MOLECULAR CHARACTERIZATION OF HUMAN RHINOVIRUSES IN SEVERE ACUTE RESPIRATORY INFECTIONS IN CAIRO, EGYPT

Engy E. Habashy[1], Magdy A. Amin[2], Aymen S. Yassin[2], Ehab A. Ayoub[1], Brent L. House[3], Emad W. Mohareb[1], Maha M. Talaat[1]

[1]U.S. Naval Medical Research Unit -3, Cairo, Egypt, [2]Faculty of Pharmacy, Cairo, Egypt, [3]Naval Medical Center, San Diego, CA, United States

Human Rhinoviruses (HRVs) are small, non-enveloped, single-stranded, positive-sense RNA virions which belong to genus Enterovirus and the family Picornaviridae. HRVs are classified into three species HRV-A, -B and -C. In addition to upper respiratory tract infections, recent studies have linked HRV, particularly HRV-C, to severe lower respiratory tract illnesses including pneumonia and chronic obstructive pulmonary disease. Little is known about the circulating types of HRV and their role in respiratory illnesses in Africa and the Middle East, specifically Egypt. In this study we aim to investigate the comparative proportion of severe acute respiratory illness (SARI) cases caused by Rhinovirus and the major species/types involved. To elucidate this we used 1,185 nasopharyngeal/oropharyngeal swab samples collected from SARI patients admitted to two fever hospitals in Cairo, in 2010. Screening samples against HRV and other respiratory viral targets, including respiratory syncytial virus, human metapneumovirus, adenovirus, parainfluenza viruses 1, 2 and 3, influenza B and influenza A and subtypes, by real time polymerase chain reaction resulted in the detection of HRV in 182 (15.4%) samples. Of them, 130 were HRV sole infection and 52 were co-infection with the aforementioned viral targets. Sequencing and phylogenetic analysis of the capsid viral protiens, VP4/VP2, of HRV positive samples revealed the presence of 91 (50%) HRV-A, 20 (11%) HRV-B and 56 (30.8%) HRV- C, which included 36, 7 and 29 types, respectively. A total of 15(8.2%) samples were untypable. All samples were genotypically related with known reference strains, except two HRV-A samples which constituted a novel provisional type. This is the first study in Egypt to demonstrate the genetic diversity found within the circulating Rhinoviruses. HRV-A and HRV-C were more prevalent causes of SARI than HRV-B. Future studies are needed to assess the impact and disease burden of each type.

1134

USE OF PRIMARY HUMAN INTESTINAL EPITHELIUM CULTURES (ENTEROIDS) TO TEST ROLE OF LEPTIN SIGNALING IN REG1-MEDIATED PROTECTION FROM *ENTAMOEBA HISTOLYTICA*

Stephanie J. Melchor, Chelsea Marie, William A. Petri, Jr.

University of Virginia, Charlottesville, VA, United States

Regenerating protein 1 (Reg1) and the "satiety hormone" leptin have both been shown to be protective against infection by ***Entamoeba histolytica.*** However, a possible link between these two proteins in mediating resistance to amebiasis has not yet been investigated. We hypothesize that leptin signaling in the gut is protective by inducing Reg1 expression through the STAT3 signaling pathway. Reg1 is expressed during inflammatory conditions in human pancreatic β cells, duodenal Paneth cells, and immature columnar cells of human intestinal crypts, where it promotes cellular proliferation and survival, and is a useful biomarker for detecting gastrointestinal and systemic inflammation. In addition to protecting against ***E. histolytica*** induced killing of intestinal epithelial cells ***in vitro***, Reg1 was found to be the most highly upregulated gene in human colon biopsy samples during ***E. histolytica*** infection. Although leptin signaling is protective against amebiasis, it was found that both humans and mice containing a common polymorphism in the leptin receptor (Q223R) are more susceptible to amebic infection by ***E. histolytica***. This increased susceptibility is due in part to impaired STAT3 signaling. To test the impact leptin has on Reg1 expression, we first generated 3-D enteroids by isolating stem-cell containing duodenal and colonic crypts from both humans and wildtype mice. The crypts were isolated with EDTA and then grown in 24 well plates in Matrigel with media containing Wnt3A, noggin, R-spondin 1, and EGF (among other growth factors) to stimulate the proliferation of the intestinal stem cells. Enteroid formation was observed by light microscopy a few days later. To further test whether the leptin-mediated protection from amebiasis is due to Reg1 expression, we will create enteroids from Reg1 knockout mice, as well as enteroids from Q223 and R223 leptin receptor mice, treat with leptin, and observe Reg1 expression, cellular proliferation, and resistance to killing by ***E.histolytica.*** Successful completion of these studies will further delineate the relationship between leptin and Reg1 mediated resistance in amebic colitis.

1135

THE ROLE OF AMOEBAPORES AND AMOEBIC LYSOSOMES IN AMOEBIC TROGOCYTOSIS AND CELL KILLING

Allissia Anne Gilmartin[1], Katherine S. Ralston[2], William A. Petri, Jr.[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]University of California, Davis, Davis, CA, United States

Entamoeba histolytica is a protozoan parasite that causes amebiasis, and is an important contributor to the global problem of diarrheal disease. ***E. histolytica*** has the potent ability to kill a variety of host cell types, and tissue destruction is the hallmark of invasive ***E. histolytica*** infection, however, little is known about the mechanisms responsible for these two processes. We have recently discovered that ***E. histolytica*** kills by ingesting fragments of live host cells, which we have termed amoebic trogocytosis. Our data suggest that amoebic trogocytosis is the primary mechanism of cell killing and that amoebae must continue to ingest multiple host cell fragments before the host cell dies. Elevated amoebic lysosomal pH has been shown to decrease cytotoxicity. Pharmacological inhibitors of lysosomal acidification were used to perturb lysosomal function. The rate of trogocytosis and host cell killing, as well as the rate of acidification and turnover of ingested host material were determined using imaging flow cytometry. We found that inhibiting lysosomal acidification significantly decreases ingestion of host material and cell killing, indicating a crucial role of amoebic lysosomes in amoebic trogocytosis. In addition, we are re-examining the role of amoebapores, a family of pore-forming proteins, in cell killing. Amoebapores were long believed to act as secreted effectors. However, based on findings that amoebapores localize to lysosomes and require pH ~5.2 for pore-forming activity, we are investigating the role of amoebapores in the degradation of ingested host fragments within the amoebic lysosome. This work will contribute to a better understanding of the nature of trogocytosis as a fundamental biological process, and may change the current thinking on the role of amoebic lysosomes and amoebapores in cell killing.

1136

AMEBIASIS IN THE FIRST TWO YEARS OF LIFE: NATURAL HISTORY OF AMEBIASIS IN BANGLADESHI CHILDREN

Carol A. Gilchrist[1], Sarah E. Petri[1], Brittany N. Schneider[1], Nona Jiang[1], Koji Watanabe[1], Caroline Stewart[1], Karla P. Elliot[1], Stacey L. Burgess[1], Jennie Z. Ma[1], Masud Alum[2], Mamun Kabir[2], Rashidul Haque[2], William A. Petri[1]

[1]University of Virginia Health Science Center, Charlottesville, VA, United States, [2]International Centre for Diarrhoeal Diseases Research, Bangladesh, Dhaka, Bangladesh

Annually one million children die before their fifth birthday from diarrhea. Previous population based surveys of pediatric diarrheal disease identified the protozoan parasite ***Entamoeba histolytica***, the etiological agent of amebiasis, as one of the top causes of diarrhea in the sub-Saharan Africa and South Asia. We examined the impact of this parasite on the health of disadvantaged children in an urban slum in Dhaka Bangladesh during their second year of life. This report is from an ongoing longitudinal study where ***E. histolytica*** colonization was followed by specific qPCR and immunodiagnostic assays of diarrheal and monthly surveillance stools collected during every-other-day home visits. Development of mucosal adaptive immunity was determined by a sIgA ELISA assay and parasite burden and the expansion of ***P. copri*** (an indicator of a pro-inflammatory microbiome) were measured by qPCR. Approximately 80% of infants in the study were infected with ***E. histolytica*** by the end of the second year of life. Consistent with previous results, the development of a fecal sIgA response was correlated with some protection from infection. In contrast to the results obtained in the first year of life, parasite burden in older children was not associated with symptomatic disease but was associated with an expansion in ***P. copri*** levels. Our findings suggest that mucosal defense has an important role in the short-term protection against parasite colonization in endemic regions and that the microbiome could play a significant role in the development of amebiasis in the 1 to 2 year old age group.

1137

GIARDIA DUODENALIS: CHARACTERIZATION OF A ZOONOTIC STRAIN ISOLATED IN DOG BY PROTEOMICS AND BIOLOGICAL CRITERIA

Camila Henriques Coelho[1], Rosiane Pereira[2], Ana Carolina Silva[3], Jonas Perales[4], Alex Chaperouge[4], Frederico Crepaldi[3], Angela Serufo[3], Haendel Busatti[3], Adriana Costa[3], Ana Paula Fernandes[3]

[1]Georgetown University, Washington, DC, United States, [2]Rene Rachou Center of Research- Fiocruz-MG, Belo Horizonte, Brazil, [3]Federal University of Minas Gerais, Belo Horizonte, Brazil, [4]Fiocruz, Rio de Janeiro, Brazil

Giardiasis is a neglected disease that affects more than 200,000,000 people in the world, mainly children in developing countries.. Symptoms include abdominal pain, diarrhea, steatorrhea and malabsorption syndrome. Giardiasis is considered a zoonotic disease and transmission may occur from animals, including pets, to humans. Canine strains are far less characterized than human isolates of ***Giardia duodenalis.*** In this study, a novel a strain (BHFC1), isolated from a symptomatic dog, was characterized through growth aspects, infectivity for Swiss mice, phylogenetic and ultra-structural analysis, encystment profile, reactivity with canine and human sera, proteomic map and presence of viral genome. The results revealed that BHFC1 is more infective for Swiss mice and grows faster than the human strain Portland-1. Electron microscopy revealed that the flange of the canine strain is larger and the encystment process is slower or incomplete, at 48 hours of growth, when compared to Portland-1. Antibodies in human sera from patients with giardiasis, reacted more strongly with proteins of the canine than the human strain, suggesting a zoonotic potencial for BHCFC1 strain. The proteomic map of soluble and insoluble fractions led to the identification of 212 know and 28 hypothetical proteins of ***G. duodenalis***. Some of these proteins correlated with virulence and pathogenic mechanisms. No amplification of viral genome was detected, suggesting absence of Giardiavirus. These data provide an important source of information for future studies correlating various aspects of the biology of this parasite, such as virulence, protein interaction, metabolomics, ultrastructural characterization, among others. In addition, this well characterized ***G. duodenalis*** strain, virulent in experimental model becomes an useful tool for investigations of antigenicity, immunogenicity, drug resistance and the development of vaccines, diagnosis and effective treatment.

1138

TOLERANCE FACTORS FOR THE ACQUISITION OF *MYCOBACTERIUM ULCERANS* BY WATER BUGS IN AFRICA ARE ASSOCIATED WITH THEIR ECOLOGICAL TRAITS

Solange Meyin A Ebong

Centre Pasteur du Cameroun, Yaoundé, Cameroon

Belostomatidae and Naucoridae families of aquatic Hemiptera which are voracious predators of micro and macro aquatic organisms, may host ***Mycobacterium ulcerans*** the causative agent of Buruli ulcer and transmit them through bites to human. We tested the existence of a correlated evolution between some water bugs' ecological traits and their tolerance to acquire ***M. ulcerans*** using a comparative analysis taking into account the phylogenetic relationships between the different aquatic bugs taxa. These phylogenetic relationships were reconstructed using 171 sequences of the mitochondrial gene coding for the first subunit of cytochrome oxidase (COI). Analyses were performed at water bugs' family level using the BayesTraits program to test first correlated evolution between several ecological traits of water bugs and tolerance to ***M. ulcerans*** acquisition, and secondly to assess the likelihood values of directional and transition rates of MU acquisition with significant Hemiptera ecological traits from the previous analysis. We observed correlated evolution between some ecological traits and tolerance to ***M. ulcerans*** acquisition. Assessing of the likelihood values of directional and transition rates shows that feeding on macro-preys and living near the bottom of water column may facilitate the acquisition of ***M. ulcerans***. However, living on aquatic vegetation does not appear to directly relate to ***M. ulcerans*** acquisition by some water bugs taxa thus challenging the hypothesis of a direct transmission through biofilms developing on the aquatic vegetation. These new findings tend to confirm the possibility of a ***M. ulcerans*** acquisition by some water bugs through their trophic habits with a primary contamination happening at the bottom of the water column where these bacilli might naturally persist in aquatic ecosystems.

1139

SEROPREVALENCE OF FIVE PARASITIC PATHOGENS IN PREGNANT WOMEN FROM 10 CARIBBEAN COUNTRIES

Fengguang Guo[1], Martin S. Forde[2], Stephen R. Werre[3], Guan Zhu[1], Rosina Claudia Krecek[4]

[1]Department of Veterinary Pathobiology, College of Veterinary Medicine and Biomedical Sciences, Texas A&M University, College Station, TX, United States, [2]Department of Public Health and Preventive Medicine, School of Medicine, St. George's University, St. George's, Grenada, [3]Laboratory for Study Design and Statistical Analysis, Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA, United States, [4]Interim Assistant Dean of One Health, Office of the Dean, College of Veterinary Medicine and Biomedical Sciences, Texas A&M University, College Station, TX, United States

Parasitic infections cause considerable suffering, economic losses, and mortality in both developing and developed countries. Epidemiological studies of several important parasitic infections in the Caribbean region to date have been very limited. The objective of this study was to examine the seroprevalence of five parasitic pathogens in pregnant women residing in 10 English-speaking Caribbean countries. From 2009 to 2011, a total of 435 serum samples were collected and separately tested for the presence of IgG antibodies to ***Ascaris lumbricoides***, ***Entamoeba***

histolytica, *Giardia lamblia*, *Schistosoma mansoni,* and *Toxocara canis*. In all tested countries, the seroprevalence values were significantly different among the parasites studied (p<0.001). The most prevalent parasites were *G. lamblia* (40.5%) and *A. lumbricoides* (37.9%), followed by *T. canis* (14.5%), *E. histolytica* (6.7%) and *S. mansoni* (3.0%). *G. lamblia* and *A. lumbricoides* were prevalent in all tested countries, and were the only two parasites positively reported in Bermuda. A comparison of serology results between countries within each parasite showed that with the exception of *G. lamblia* (p=0.09), seroprevalence were significantly different among tested countries for the other four parasites (p<0.05). While overall seroprevalence for *E. histolytica* was 6.7%, 32.6% of participants from Jamaica were serum positive to this parasite. Furthermore, a significant association between *T. canis* and *A. lumbricoides* infections was discovered (Odds Ratio = 13.7, 95% Confidence Interval = 5.4 – 34.4). This study confirms that parasitic infections are occurring in prenatal women in the Caribbean and that the predominant parasites are different among tested countries. Further, this study also highlights the necessity of enhancing existing surveillance programs to evaluate the public health burden of parasitic diseases in the Caribbean.

1140

MOLECULAR CHARACTERIZATION OF *CRYPTOSPORIDIUM* AND ZOONOTIC TRANSMISSION OF CRYPTOSPORIDIOSIS IN HIV/AIDS PATIENTS IN ETHIOPIA

Haileeyesus Adamu Belay[1], Beyene Petros[1], Guoqing Zhang[2], Hailu Kassa[3], Said Amer[4], Lihua Xiao[2]

[1]Addis Ababa University, Addis Ababa, Ethiopia, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Bowling Green State University, Bowling Green, OH, United States, [4]Kafr El Sheikh University, Kafe El Sheikh, Egypt

Cryptosporidiosis is an important cause for chronic diarrhea and death in HIV/AIDS patients. Among common *Cryptosporidium* species in humans, *C. parvum* is responsible for most zoonotic infections in industrialized nations. Nevertheless, the clinical significance of *C. parvum* and role of zoonotic transmission in cryptosporidiosis epidemiology in developing countries remain unclear. In this cross-sectional study, 520 HIV/AIDS patients were examined for *Cryptosporidium* presence in stool samples using genotyping and subtyping techniques. Altogether, 140 (26.9%) patients were positive for *Cryptosporidium* spp. by PCR-RFLP analysis of the small subunit rRNA gene, belonging to *C. parvum* (92 patients), *C. hominis* (25 patients), *C. viatorum* (10 patients), *C. felis* (5 patients), *C. meleagridis* (3 patients), *C. canis* (2 patients), *C. xiaoi* (2 patients), and mixture of *C. parvum* and *C. hominis* (1 patient). Sequence analyses of the 60 kDa glycoprotein gene revealed a high genetic diversity within the 82 *C. parvum* and 19 *C. hominis* specimens subtyped, including *C. parvum* zoonotic subtype families IIa (71) and IId (5) and anthroponotic subtype families IIc (2), IIb (1), IIe (1) and If-like (2), and *C. hominis* subtype families Id (13), Ie (5), and Ib (1). Overall, *Cryptosporidium* infection was associated with the occurrence of diarrhea and vomiting. Diarrhea was attributable mostly to *C. parvum* subtype family IIa and *C. hominis*, whereas vomiting was largely attributable to *C. hominis* and rare *Cryptosporidium* species. Calf contact was identified as a significant risk factor for infection with *Cryptosporidium* spp., especially *C. parvum* subtype family IIa. Results of the study indicate that *C. parvum* is a major cause of cryptosporidiosis in HIV-positive patients and zoonotic transmission is important in cryptosporidiosis epidemiology in Ethiopia. In addition, they confirm that different *Cryptosporidium* species and subtypes are linked to different clinical manifestations.

1141

TOWARDS SOLVING THE MYSTERY OF HOW CHILDREN ACQUIRE *CRYPTOSPORIDIUM* IN AFRICAN HOUSEHOLDS

Heidi Hillesland[1], Patricia Pavlinac[1], Jaqueline Naulikha[2], Michael Arndt[1], Wesley C. Van Voorhis[1], Benson Singa[2], Judd Walson[1]

[1]University of Washington, Seattle, WA, United States, [2]Kenya Medical Research Institute, Nairobi, Kenya

Recently *Cryptosporidium* emerged as the second most frequent cause of moderate-to-severe diarrhea in children under two in sub-Saharan Africa and Asia; only slightly behind rotavirus in its frequency. *Cryptosporidium* is also highly associated with mortality in this population. Yet, despite its impact, the source of transmission of *Cryptosporidium* to these vulnerable children is unclear. Previous studies have found that zoonotic transmission is rare in Africa and contaminated water also does not appear to be a primary route of transmission in the resource-limited setting. We are currently enrolling child-caregiver pairs in Western Kenya to test the hypothesis that adults are a reservoir for *Cryptosporidium* and that transmission between caregiver and child occurs frequently. Stool samples from children with acute diarrhea and their caregivers are being tested for *Cryptosporidium* using microscopy, an enzyme-linked immune assay, and PCR. Furthermore, we are genotyping all cases of *Cryptosporidium* to test the hypothesis that more children with acute diarrhea due to *Cryptosporidium* will have a caregiver with a genetically matched isolate than expected by chance alone. Additionally, clinical and household correlates of genetically matched isolates from child and caregiver will be assessed. If we find evidence of household *Cryptosporidium* transmission, then interventions for reducing the morbidity and mortality attributable to this parasite will need to also address infections in household members.

1142

STANDARDIZATION OF SOLID-PHASE FLUORESCENT ASSAY FOR THE SIMULTANEOUS DETECTION OF SPECIFIC ANTI-*TOXOPLASMA GONDII* IGG, IGM AND IGA ANTIBODIES FOR TOXOPLASMOSIS ANTENATAL CARE SCREENING

Jaqueline P. Rodrigues, Heitor Franco Andrade Junior

Tropical Medicine Institute of São Paulo, São Paulo, Brazil

Toxoplasma gondii infections are very common, causing treatable central nervous system and eye diseases on the foetus, and pregnant woman must be screened for efficient therapy. Due to lowering toxoplasmosis prevalence in children, an expected high proportion of toxoplasmosis seronegative women would imply costly follow-up additional assays, demanding the development of new, quick and inexpensive assays. New solid-phase fluorescent assays allows direct antibody quantification in microplates as we demonstrated in a previous study the high efficiency, low cost and high throughput of single-well anti-*T. gondii* IgG and IgM detection due to improved fluorescent conjugates. In this work, we standardized a simultaneous detection of IgG, IgM and IgA specific antibodies in solid-phase fluorescent assay for toxoplasmosis antenatal care screening. Affinity-purified conjugates were prepared with different amine-reactive Alexa Fluor® fluorescent dyes and tested in single-well IgG/IgM/IgA detection. We used 34 serum samples from adult volunteers at a large public hospital with external and in house isolated and conjunct anti-*T. gondii* immunoglobulin detection. There are excellent agreement (Kappa index=100%) between isolated and conjunct detection without false-positives and false-negatives results. These initial results suggest that solid-phase fluorescent simultaneous detection of IgG, IgM and IgA could be a promising high throughput serological technique for toxoplasmosis screening. New tests will be perform to evaluate the efficiency of simultaneous fluorescent detection in several numbers of clinical serum samples and then compare with conventional screening immunoassays for validation. The development of new integrated diagnostic approaches should be directed to elimination of interferences found in the current

methods, reducing the number of both: tests and trained staff in multiple techniques, allowing rapid and efficient serological screening for safe patient treatment.

1143

REACTIVATION OF CHRONIC *TRYPANOSOMA CRUZI* INFECTION IN PATIENTS WITH HIV/AIDS

Marisa L. Fernandez[1], Ezequiel Cordova[2], Marcelo Corti[3]

[1]Instituto Nacional de Parasitología Dr M Fatala Chaben, ANLIS Dr C Malbran, Buenos Aires, Argentina, [2]Hospital C Argerich, Buenos Aires, Argentina, [3]Hospital de Infecciosas FJ Muñiz, Buenos Aires, Argentina

This study was a retrospective study based on data collected from medical records of patients hospitalized at Infectious Diseases FJ Muñiz Hospital, Buenos Aires, Argentina from 1992 to 2014. Chagas disease reactivation was defined as demonstration of trypomastigotes on cerebrospinal fluid (CSF), blood, pericardial fluid or amastigotes in tissues biopsies in patients with HIV/AIDS. Twenty three patients were included. Twenty-one (91%) patients were male. The media of age was 38 years old. Seven (30%) did not know their HIV status before hospitalization.The media of CD4+ T cell counts was 90 cell/ml (range 1-501) Twenty-one patients were tested for ***Trypanosoma cruzi*** serology: 16 (76%) were reactive, 4(19%) were non-reactive, and 1(5%) was discordant. One patient had vertical transmission as the only risk for both infections. Ten (43%) patients were intravenous drugs users (IDUs) and it was the only risk for Chagas disease in 4 of them. Chagas disease reactivation involved central nervous system (CNS) in 22 patients (18 with cerebral abscesses and 4 with diffuse meningoencephalitis).Two patients had also pericardial effusion. One patient showed fever with trypomastigotes on peripheral blood without CNS damage. The CNS compromise was confirmed by the detection of trypomastigotes in CSF in 17 patients, positive strout in 1 patient, amastigotes in brain biopsy in 1 patient and necropsy in 3 . All patients were treated with benznidazole, 3 had to change to nifurtimox due to adverse drug reactions. Four patients (17%) survived more than one year. One of them died after 8 years due to cirrhosis. The other 3 patients are alive after 8, 5 and 4 years of follow up under antiretroviral treatment compliance. Three out of these 4 received secondary prophylaxis for ***T. cruzi***. In conclusion, Chagas disease reactivation must be considered in the differential diagnosis in HIV/AIDS patients. A correct diagnosis based on epidemiological, clinical and microbiological studies is crucial for this neglected parasitic infection.

1144

PREVALENCE OF PARASITIC INFECTIONS AMONG IMMIGRANTS IN CHICAGO

Patrick Maloney, Ronald Hershow, Jesica Herrick

University of Illinois at Chicago, Chicago, IL, United States

In 2013, approximately 41.3 million persons living in the US were immigrants, many of whom migrated from countries where parasitic infections are endemic and highly prevalent. Although extensive testing for infectious diseases is typically performed on refugees, these tests are not provided to immigrant populations, many of whom share similar risk factors and exposure histories as those in the refugee population. In order to assess the prevalence of parasitic infections among the immigrant population in Chicago, we recruited asymptomatic subjects who had moved to the United States within the last five years. Subjects were asked a symptom questionnaire and provided blood and stool samples. Samples were tested for: serum IgE level, complete blood count with differential (CBCD), and ova and parasite exam, with plans to perform polymerase chain reaction (PCR) testing on stool samples for enteric parasites and serologic testing for Chagas disease, neurocysticercosis, toxocara, schistosomiasis, and strongyloides. To date, 40 subjects have been recruited. Enrolled subjects had a mean age of 31 years; 18 of the 40 subjects were female (45%, 22/40 were male, 55%). Subjects had immigrated from Central and South America (13/40, 32.5%), Asia (12/40, 30%), India (10/40, 25%), the Middle East (3/40, 7.5%), and Africa (2/40, 5%). 10/40 (25%) patients were found to have elevated IgE (GM value of those with elevated IgE: 571 IU/mL), while 4/40 (10%) had an elevated absolute eosinophil count (AEC) (GM value of those with elevated AEC: 616 cell/mcL). To-date, one subject (1/40, 2.5%) has been found to have a parasitic infection. The positive subject was a 24 year-old asymptomatic female from Brazil discovered to have ***Giardia lamblia*** cysts and trophozoites on stool O&P; this subject had an elevated IgE level (567 IU/mL), but a normal AEC (100 cell/mcL). Based on our preliminary data, we believe that parasitic infections likely represent a large and as-yet-unidentified burden of disease in the immigrant population. The planned PCR and serologic testing will add additional information about these important health problems affecting our immigrant populations.

1145

ANTI-*TOXOPLASMA GONDII* IGG DETECTION IN SALIVA FOR TOXOPLASMOSIS EPIDEMIOLOGICAL STUDIES

Barbara F. Sampaio, Heitor Franco Andrade, Luciana Regina Meireles

Institute of Tropical Medicine Sao Paulo, Sao Paulo, Brazil

Worldwide distributed zoonosis affecting about one billion people, toxoplasmosis is mostly asymptomatic, despite ocular disease and severe and lethal disease in fetuses, AIDS patients and transplant recipients. Serology is the main approach for diagnosis allowing prevalence studies but incidence determination is a difficult in most countries. Children are the target in incidence studies based on conventional serology but venipuncture for this age group is an difficult approach. An alternative source of antibodies, non-invasive saliva collection is acceptable for children and it contains small amounts of IgG from mucosal and gingival crevicular fluid. Available commercial antibody detection kits are focused in serum samples, inadequate to alternative biological material, like saliva, due to technical constrains. Here, we standardized immunoassays with high sensitivity for detection of anti-***Toxoplasma gondii*** IgG in paired saliva and serum sample from 20 adult volunteers, which allows both high sensitivity DOT-ELISA and an automated prone IgG capture assay, based on staphylococcal protein A in solid support. The sensitivity and specificity of the saliva DOT-ELISA were similar to sera ELISA. We also tested 100 saliva samples from university graduates in all assays, showing 19% (95%CI 12-28%) frequency of toxoplasmosis in this group, lower than usual prevalence 50% adult prevalence reported for our area. Protein A IgG capture saliva assay was also efficient with similar results, with perfect agreement and high kappa index. Both the DOT-ELISA and protein A capture ELISA for detection of IgG anti-***T. gondii*** in saliva are very promising as tools for Toxoplasmosis incidence studies with cheap, inexpensive and non-invasive collection; high sensitivity, high specificity, low cost and ease of operation in the routine laboratory. The determination of incidence will help health services in the prevention of toxoplasmosis transmission and on-time adequate measures; especially for antenatal care. Immunoassay with saliva IgG for toxoplasmosis is a very promising tool for use for the epidemiology of toxoplasmosis in children or other protected groups.

1146

COMPARISON OF THREE METHODS TO CONCENTRATE *CYCLOSPORA* AND *CRYPTOSPORIDIUM* FROM LARGE VOLUMES OF VEGETABLE WASH WATER

Ynes R. Ortega, Maria Torres

University of Georgia, Griffin, GA, United States

Foodborne parasites have been isolated in fresh produce worldwide including the U.S. Environmental testing to identify the presence of these parasites has been challenging during outbreak investigations. Produce is usually triple washed and sanitizers are included during these

rinses before packaging. The purpose of this study was to evaluate three methods to concentrate and detect ***Cryptosporidium parvum*** and ***Cyclospora cayetanensis*** from water used for washing and processing vegetables. ***C. cayetanensis*** and ***C. parvum*** oocysts. Tap water, chlorine and peroxyacetic acid based vegetable rinses were used. The water was prepared shredding carrots to reach turbidities of 30 and 60 NTU and shredding red cabbage at 30 NTU. Water was spiked using 10 or 50 oocysts per 10 L and analyzed using three protocols: the EPA 1623 method 2) by flocculation and 3) by filtration using hollow-fiber filter. Filtrates and sediments were tested for the presence of the parasites by nested PCR, immunofluorescence, and autoflorescence. Flocculation was highly effective at concentrating oocysts when using tap and chlorinated rinse water with both spikes (10 and 50 oocysts). The PPA water did not flocculate. Envirocheck and hollow fiber filters could concentrate oocysts, however Envirocheck filters were not easy to work with and the water filtration and processing was longer that the hollow-fiber filters. More samples could be detected in hollow-fiber filtered samples than the Envirocheck filters even at high turbidity levels and low inocula. Results suggest that hollow-fiber filters are effective at concentrating oocysts from all of the rinse waters tested in this study. This system could be implemented for surveillance studies and outbreak investigations particularly in fresh produce rinse water.

1147

DEVELOPMENT OF BOILING LOOP-MEDIATED ISOTHERMAL AMPLIFICATION FOR SENSITIVE AND RAPID DETECTION OF *TOXOPLASMA GONDII*

Mi-Sun Yoo, Young-Ha Kim, Ha-Na Jung, Hee-Soo Lee, Seung-Won Kang

Animal and Plant Quarantine Agency, Anyang, Republic of Korea

Toxoplasma gondii infections are prevalent in human and warm blooded animals. Felids, including cats, are the natural hosts for this parasite because they can excrete the oocyst into the environment. This study developed a modified loop-mediated isothermal amplification (LAMP) assay for DNA extracted using a simple boiling method. The assay targeted the B1 gene for the sensitive and rapid detection of ***T. gondii*** in experimentally infected cats. The optimal B1-LAMP conditions were a temperature of 60°C and an operating time of 30 min. The B1-LAMP assay was at least 100-fold more sensitive than conventional PCR for detecting ***T. gondii***. The specificity of the ***T. gondii*** B1-LAMP assay was illustrated by the finding that it did not detect genomic DNA from ***Neospora caninum***. The B1-LAMP assay was used to detect DNA extracted from the organs of experimentally infected cats. In addition, the assay yielded positive results when used to test ***T. gondii*** DNA extracted using a crude boiling method. In addition, a positive or negative result of the LAMP products could be clearly visualized by the naked eye using a fluorescent dye (SYBR green or GeneFinder). The advantages of this assay include simplicity, a short analysis time, and low-cost, making it suitable for field laboratory applications.

1148

COPROLOGICAL DIAGNOSIS OF *BLASTOCYSTIS* SPP. IN HUMANS AND DOGS FROM FIVE BRAZILIAN BIOMES

Eduardo S. Garcia[1], Antonio F. Malheiros[1], Lucas F. Barros[1], Stephany S. Santos[1], Dimes H. Alves[1], Larissa N. Silva[1], Debora P. Santos[1], Gabriel L. Gaarcia[1], Maria E. Silva[1], **Jeffrey J. Shaw**[2]

[1]Mato Grosso State University, Cáceres, Brazil, [2]São Paulo University, São Paulo, Brazil

Blastocystosis is a parasitic infection caused by the protozoan ***Blastocystis*** spp., and although it has been known for almost a century there are considerable gaps in our knowledge regarding its pathogenicity, transmission and distribution worldwide. This study was undertaken to evaluate the presence of ***Blastocystis*** spp. in five of the seven Brazilian biomes: Caatinga, Savannah, Pantanal, Atlantic Forest and Southern Fields in association with other intestinal parasites. Fecal samples from humans and dogs were collected in 17 municipalities of the five biomes using the spontaneous sedimentation technique for direct microscopic diagnosis. A total of 2528 samples were analyzed, 38% were positive for at least one intestinal parasite and 8.5% were positive for ***Blastocystis*** spp. There was a statistical higher correlation (P<0.005) of ***Blastocystis*** spp. with ***Entamoeba coli, Endolimax nana, Iodamoeba bustchlii***. In conclusion, this is first study in Brazil to cover so many biomes and the chi-square test indicated that the biome influences the percentage of samples positive for ***Blastocystis*** spp, as well as well as a possible zoonotic potential of this parasite in relation dog fecal samples.

1149

RNA INTERFERENCE COMPLEXES: A NOVEL METHOD TO GENE SILENCING IN *CRYPTOSPORIDIUM*

Samantha Nava, Nicolas Perry, Arthur C. White, Alejandro Castellanos-Gonzales

University of Texas Medical Branch, Galveston, TX, United States

The gut protozoan parasite, ***Cryptosporidium***, is a major cause of diarrheal disease worldwide. Diarrheal diseases have been identified as a principal cause for mortality in children under five years old. Due to the parasites' resistance to chemical and mechanical disruption, it has also been identified as a Category B pathogen by the CDC as a potential water source contaminant. The current treatment for cryptosporidiosis, Nitazoxanide, has only moderate efficacy in immunocompetent adults and children, and none in immunocompromised hosts. Development of an improved treatment is urgently needed to control mortality caused by this parasite. Unfortunately, a major impediment in studying potential drug targets is the inability to genetically manipulate ***Cryptosporidium***. RNA interference is a powerful tool that has been developed to study gene function. However, genomic studies determined that ***Cryptosporidium*** lacked enzymes necessary in order to process RNAi constructs. We have proposed a novel method of gene silencing in ***Cryptosporidium*** to identify targets for drug development. We can induce specific degradation of target RNA by transfecting ***Cryptosporidium*** oocysts with the human enzyme Argonaute 2 (hAgo2) preloaded with single-stranded RNA (ssRNA). We have demonstrated the specific slicer activity of hAgo2 in ***Cryptosporidium*** oocysts using this method with subsequent decrease in target protein expression after transfection. In addition, gene silencing using hAgo2-ssRNA has led to a reduction of infection ***in vitro***. Development of a novel gene silencing method in ***Cryptosporidium*** can lead to identification of key proteins which can have a major role in the sustainability of infection.

1150

ACTION OF ATOVAQUONE AND MONENSIN AGAINST *TOXOPLASMA* DEPEND ON THE MITOCHONDRIAL MUTS HOMOLOG, TGMSH1

Tamila Garbuz, Gustavo Arrizabalaga

Indiana University School of Medicine, Indianapolis, IN, United States

The phylum Apicomplexa includes obligate intracellular parasites of great medical importance such as ***Plasmodium falciparum***, ***Cryptosporidium parvum***, and ***Toxoplasma gondii***. Despite significant effort, there are no human vaccines for any of these parasites; thus, drug treatments are the mainstay for reducing morbidity and mortality. Nonetheless, resistance, toxicity and lack of activity against certain parasite life cycle stages severely limit the value of available drugs; consequently there is a dire need for new anti-apicomplexan therapeutics. To fulfill this need we have been exploiting the experimental malleability of ***T. gondii*** to identify novel targets for drug development. We recently showed that the lethal effect of the anti-coccidian monensin on ***T. gondii*** depends on the mitochondrial MutS homolog, TgMSH1. Mitochondrial MSH proteins maintain DNA stability while nuclear MSHs both repair mismatched DNA and directly signal cell cycle arrest and apoptosis in response

to genotoxicity. Interestingly, monensin induces cell cycle arrest and autophagic cell death in ***Toxoplasma*** in a TgMSH1 dependent manner. By monitoring sequence fidelity and copy number of the mitochondrial (mt), nuclear and plastid DNA we have established that TgMSH1 is specifically required for maintenance and repair of the mtDNA. Given that mutations in mitochondrially encoded genes are associated with resistance to atovaquone and myxothiazol we investigated whether TgMSH1 mutant strains were more likely to become resistant to these important anti-parasitic drugs. Through this effort we discovered that TgMSH1 mutant strains are intrinsically tolerant to both atovaquone and myxothiazol without the need for mutations in the actual target proteins. We are currently testing our hypothesis that due to the accumulation of mtDNA damage that occurs without the repair function of TgMSH1 Toxoplasma becomes adapted to the lack of efficient respiration, which leads to a tolerance to anti-mitochondrial drugs. Through our studies we have discovered a novel mechanism by which apicomplexan parasites can become resistant to atovaquone and related drugs.

1151

IDENTIFICATION OF *BLASTOCYSTIS* SPP. GENOTYPES IN PATIENTS AT SÃO PAULO CITY, BRAZIL

Gessica B. Melo[1], Fabiana M. Paula[1], Fernanda M. Malta[2], Celina W. Maruta[2], Paulo R. Criado[3], Vera L. Castilho[3], Elenice M. Goncalves[3], **Ronaldo C. Gryschek**[4]

[1]University of Sao Paulo Tropical Medicine Institute, Sao Paulo, Brazil, [2]University of Sao Paulo, Sao Paulo, Brazil, [3]Hospital Das Clinicas University of Sao Paulo Medical School, Sao Paulo, Brazil, [4]University of Sao Paulo Medical School, Sao Paulo, Brazil

Blastocystis spp. is an organism in the intestinal tract of humans and other animals, commonly found in stool samples. This organism involves pathogenic and zoonotic aspects unknown. Currently, this organism has been associated with intestinal diseases such as irritable bowel syndrome and clinical manifestations of cutaneous allergic hypersensitivity. This study aims to identify the genotypes of ***Blastocystis*** spp. in patients from the São Paulo, Brazil. A total of 35 stool samples from ***Blastocystis*** spp positive patients of the Section of Parasitology/Division of the Central Laboratory (HC/FMUSP) were used. After collection, stool samples were stored at -20°C for subsequent DNA extraction. Polymerase Chain Reaction assay were performed using ***Blastocystis*** specific primers targeting the small subunit rRNA gene, and sequenced. PCR positivity was of 68.6% (24/35).Three subtypes (STs) were identified: ST1 (17.6%), ST2 (11.8%) and ST3 (70.6%). Phylogenetic analysis was performed in order to identify the origin of human isolates. It was observed that all human isolates were grouped with pig isolates. This study is the first to include molecular characterization and identify the genotypes of ***Blastocystis*** in São Paulo state supporting the zoonotic potential this organism.

1152

IDENTIFICATION OF FIVE NOVEL *CRYPTOSPORIDIUM* VACCINE CANDIDATES USING REVERSE VACCINOLOGY

Olukemi O. Ifeonu[1], Raphael Simon[2], Sharon M. Tennant[2], Abhineet S. Sheoran[3], Jessica C. Kissinger[4], Giovanni Widmer[3], Myron M. Levine[2], Saul Tzipori[3], Joana C. Silva[1]

[1]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Center for Vaccine Development and Department of Medicine, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Cummings School of Veterinary Medicine and Department of Infectious Disease and Global Health, Tufts University, North Grafton, MA, United States, [4]Center for Topical and Emerging Global Diseases and Department of Genetics, University of Georgia, Athens, GA, United States

Cryptosporidiosis, caused primarily by ***Cryptosporidium parvum*** and ***C. hominis,*** is a life-threatening disease in immune-compromised individuals worldwide, and a major cause of diarrhea-induced wasting and stunted growth often leading to deaths of young children in developing countries. While vaccination remains one of the most effective methods of preventing infectious diseases, there are no commercially available vaccines against human parasites, including ***Cryptosporidium***. Biological and technical challenges preclude the use of traditional vaccinology approaches for the identification of vaccine targets against human-infecting ***Cryptosporidium***, and the existence of genomic resources for multiple species in the genus make reverse vaccinology a viable alternative. We generated a much improved genome assembly and annotation for ***C. hominis***, increasing average gene length by 500 base pairs (bp), from 1,360 bp to 1,845 bp, bringing it in line with gene length in the close relative ***C. parvum***, which averages 1,785 bp. The improved gene set provides new opportunities to procure and examine novel vaccine candidates. Using bioinformatics approaches we identified close to 400 ***C. hominis*** genes containing properties typical of antigens, such as the presence of glycosylphosphatidylinositol (GPI)-anchor motifs, multiple transmembrane (TMM) domains or targeting to the secretory pathway. We down-selected this set by focusing on potential GPI-anchored proteins lacking human homologs, with at most two TMM domains, homologs in four other ***Cryptosporidium*** species and no polymorphism between two ***C. hominis*** isolates. Further experimental considerations included a minimal number of predicted post-translation modifications and adequate molecular weight of the predicted product. A total of 5 proteins, now undergoing experimental validation, were selected with approach from among all 3,745 proteins in the updated ***C. hominis*** annotation. We provide an online resource, which catalogs all ***C. hominis*** genes and their characteristics mentioned above, including physical attributes, properties related to antigenic potential, and expression data.

1153

CENTRINS OF APICOMPLEXAN PARASITE - *BABESIA MICROTI* AND THEIR ROLE IN CELL DIVISION

Bhavna Chawla, Sanjai Kumar

Food and Drug Administration, Silver Spring, MD, United States

Intra-erythrocytic apicomplexan protozoans belonging to the genus ***Babesia*** are of great economic and health significance globally. Human babesiosis caused by ***B. microti,*** is prevalent in many parts of United States and about 1250 clinical cases are reported annually with fatality of 5-20%. However, our knowledge on the mechanism of cell division and the molecules associated with this process in ***Babesia*** parasites is very limited. We are investigating the role of centrin, a calcium-binding, cytoskeletal protein involved in cell division in eukaryotes, in ***B. microti***. In ***Plasmodium falciparum***, centrins are associated with nucleus and involved in cell division. Using database searches, we have identified three centrin genes in ***B. microti*** (BmCen) genome (piroplasmadb.org), which we called BmCen2, BmCen3 and BmCen4, based on their homology to the centrins from ***Homo sapiens***, ***P. falciparum*** and ***Toxoplasma gondii***. BmCen2, BmCen3 and BmCen4 encode for polypeptides of 164, 176 and 156 amino acids respectively. BmCen2 and BmCen4 exhibited about 60% homology at amino acid level to the PfCen2 and PfCen4 respectively, whereas BmCen3 was about 25% homologous to PfCen3. Domain search on PROSITE revealed that ***B. microti*** centrins contain the conserved calcium binding EF-hand motifs; BmCen2 and BmCen4 have four EF-hands. Interestingly, BmCen4 has only 2 EF-hands, EF-hand I and EF-hand IV. We have expressed the ***B. microti*** centrins in ***E. coli***. Their purification, biochemical characterization, stage-specific expression and their role in cell division in ***B. microti*** are being investigated. The results of these studies will be presented.

EVALUATION OF A RAPID POINT-OF-CARE TEST FOR DETECTION OF *CRYPTOSPORIDIUM*

Molly E. Fleece[1], Shaila S. Khan[2], Mamum Kabir[2], Rashidul Haque[2], William A. Petri, Jr[3]

[1]Department of Internal Medicine, University of Virginia, Charlottesville, VA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Division of Infectious Diseases and International Health, University of Virginia, Charlottesville, VA, United States

Diarrheal diseases are a major cause of morbidity and mortality in the developing world. ***Cryptosporidium*** is an enteric protozoan parasite that is a common cause of waterborne diarrheal disease. There is need for a practical point-of-care diagnostic test that is rapid, reliable and feasible for use in the field. We evaluated the performance of a new fecal antigen detection test for ***Cryptosporidium*** (***Cryptosporidium*** EZ VUE, TechLab, Inc) in a cohort of children in Bangladesh. This point-of-care test is a lateral flow dipstick that detects ***Cryptosporidium*** oocyst antigen in stool. Time from sample preparation to visual readout of test results is 10 minutes. The test was conducted on 50 diarrheal stool samples that were known to be Cryptosporidia positive by antigen detection and 50 negative diarrheal stool samples from children living in an urban slum in Dhaka. The test had a sensitivity of 100% and a specificity of 94% when compared to enzyme-linked immunosorbent assay antigen detection. We concluded that the ***Cryptosporidium*** EZ VUE dipstick test offered rapid and accurate point-of-care diagnosis of Cryptosporidiosis.

1155

HIGH PREVALENCE OF *BLASTOCYSTIS* SPP. AND COST-EFFECTIVENESS ANALYSIS OF THREE PARASITOLOGICAL TECHNIQUES FOR THE DIAGNOSIS OF *BLASTOCYSTIS* SPP. IN PERU

George Vasquez- Rios[1], Maria Gamero[1], Marco Canales[2], Adriana Pezua[1], Bryan Betancourt[1], Angelica Terashima[1], Jorge D. Machicado[3], Luis A. Marcos[4]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto de Medicina Tropical "Alexander von Humboldt", Lima, Peru, [3]University of Pittsburgh, Pittsburgh, PA, United States, [4]Forrest General Hospital, Hattiesburg, MS, United States

The role of ***Blastocystis*** spp. as a pathogen is unclear to date. The aim of the present study is to compare three stool parasitological techniques [direct microscopy examination (DMS), spontaneous sedimentation in tube technique (SSTT), and Pavlova Culture (PC)] in the detection of ***Blastocystis*** spp. in stool samples in Peru. Sensitivity was calculated by considering a positive culture for ***Blastocystis*** as the gold standard. A cost-effectiveness analysis was performed in each technique by estimating direct and indirect costs. The cost of a single sample was estimated by the sum of laboratory materials and the time consumed in each technique. A total of 142 stool samples (female:male ratio = 1.7) from people living in Lima city was included in this study. Most of participants (84.51%, n= 120) were under the age of 40 years old (median: 22). More than half of the stool samples were positive for ***Blastocystis.*** Prevalence of ***Blastocystis*** was 55.6% (n=79) by DMS, 61.27% (n= 87) by SSTT and 80.99% (n= 115) by PC. The sensitivity of DMS, SSTT and PC was 68.7%, 75.65% and 100%; respectively. Specificity was 100% in all three techniques. The total cost per a single exam was 0.68$, 0.9$ and 1.2$ for DMS, SSTT and PC, respectively. The cost per case of ***Blastocystis spp.*** detection by each test was 1.22$, 1.46$ and 1.48$ for DMS, SSTT and PC, respectively. In conclusion, the SSTT is a cost-effective technique for the diagnosis of ***Blastocystis*** spp. in low- resource settings where this organism is highly prevalent in a population.

1156

THE SECRETED CATHEPSIN B PROTEASES ARE ASSOCIATED WITH TISSUE INVASION OF THE CARCINOGENIC LIVER FLUKE, *CLONORCHIS SINENSIS*

Xiaoyun Wang[1], Wenjun Chen[1], Xinbing Yu[2]

[1]The University of Chicago, Chicago, IL, United States, [2]Zhongshan School of Medicine in Sun Yat-sen University, Guangdong, China

In freshwater fish consumption areas, human clonorchiasis remains an important foodborne zoonosis caused by ***Clonorchis sinensis*** infection. Molecular characterizations of key molecules that are involved into pathogenic processes could speed up the interventions of ***C. sinensis*** infection. In this study, we expressed four ***C. sinensis*** cathepsin B cysteine proteases (CsCB1, CsCB2, CsCB3 and CsCB4) in X-33 yeast cells for biochemical characterization. Eukaryotic expressed CsCBs could hydrolyze substrates Z-Phe-Arg-AMC and Z-Arg-Arg-AMC, and the hydrolyzation could be completely inhibited by specific inhibitors and cysteine protease specific inhibitors at 100%. However, serine protease specific inhibitor PMSF and trypsin specific inhibitor TPCK could only inhibit the activity partially. EDTA has no inhibition on the activity, indicating that yCsCBs belongs to the typical cathepsin B cysteine protease family. yCsCBs exhibited the highest activity at pH value of 5.0-5.5 and temperature of 42°C. Also, yCsCBs could degrade host BSA, HSA, IgG, hemoglobin and fibronectin. Immunohistochemical results showed that CsCBs were located at the intestine of adult worm and excretory vesicle and oral sucker for metacercaria and cercaria stage. In conclusion, we profiled secreted cathepsin B cysteine proteases family for the first time and demonstrated secreted cathepsin B proteases are associated with tissue invasion of the ***C. sinensis*** infection.

1157

CO-DISPERSAL OF THE BLOOD FLUKE *SCHISTOSOMA JAPONICUM* AND *HOMO SAPIENS* IN THE NEOLITHIC AGE

Wei Hu[1], Mingbo Yin[1], Hong-Xiang Zheng[1], Jing Su[1], Zheng Feng[2], Donald Peter McManus[3], Xiaonong Zhou[2], Li Jin[1]

[1]Fudan University, Shanghai, China, [2]National Insititute of Parasitic Diseases, China CDC, Shanghai, China, [3]QIMR Berghofer Medical Research Institute, Brisbane, Australia

The global spread of human infectious diseases is of considerable public health and biomedical interest. Little is known about the relationship between the distribution of ancient parasites and that of their human hosts. ***Schistosoma japonicum*** is one of the three major species of schistosome blood flukes causing the disease of schistosomiasis in humans. The parasite is prevalent in East and Southeast Asia, including the People's Republic of China, the Philippines and Indonesia. We studied the co-expansion of ***S. japonicum*** and its human definitive host. Phylogenetic reconstruction based on complete mitochondrial genome sequences showed that ***S. japonicum*** radiated from the middle and lower reaches of the Yangtze River to the mountainous areas of China, Japan and Southeast Asia. In addition, the parasite experienced two population expansions during the Neolithic agriculture era, coinciding with human migration and population growth. The data indicate that the advent of rice planting likely played a key role in the spread of schistosomiasis in Asia. Moreover, the presence of different subspecies of Oncomelania hupensis intermediate host snails in different localities in Asia allowed ***S. japonicum*** to survive in new rice-planting areas, and concurrently drove the intraspecies divergence of the parasite.

1158

INVERTEBRATE IMMUNITY: PHENOLOXIDASE ACTIVITY IN THE SCHISTOSOME SNAIL HOST

Winka Le Clec'h, Frédéric D. Chevalier, Timothy J. Anderson

Texas Biomedical Research Institute, San Antonio, TX, United States

To complete its complex lifecycle, ***Schistosoma mansoni*** needs an aquatic snail (***Biomphalaria*** spp.) as intermediate host and a mammalian as definitive host. The immune response of the aquatic snail to parasite infection is poorly understood. Phenoloxidase (PO) enzymes are important in wound healing and tissue pigmentation, and are also considered to be an innate immune defense mechanism against intruding microorganisms and parasites. POs are characterized by their substrate specificity and fall into three groups: tyrosinases, catecholases and laccases. Their activities can be quantified with specific substrates. PO activity has been found in the hemolymph of molluscs such as mussels or oysters, but has not been characterized in Biomphalaria snails. Using spectrophotometric assays with 3 different specific substrates (L-tyrosine (monophenol) for tyrosinase activity, L-DOPA (o-diphenol) for catecholase activity, and p-phenylenediamine (PPD) (p-diphenol) for laccase activity), we first demonstrated the laccase-like activity in hemolymph from uninfected B. glabrata and alexandrina. Then we determined the optimal temperature (45°C) and pH (8.5 which is also the pH of the snail hemolymph) for the PO enzyme and the apparent Michaelis constant (Km) and the apparent Vmax using PPD substrate. After splitting the whole hemolymph into 2 distinct fraction, hemocytes (immune cells) and plasma, we found the highest laccase-like activity in the plasma. Finally, we measured the PO activity on snails parasitized by ***S. mansoni***, and demonstrated a strong reduction of this laccase-like activity starting 7 weeks after the exposure ($p < 0.0001$), most likely because developing parasites eat the snail albumen gland and hepatopancreas. This new spectrophotometric assay with PPD substrate allows accurate measurement of PO activity in the intermediate hosts for S.mansoni.

1159

A TEGUMENT-SPECIFIC VENOM ALLERGEN-LIKE PROTEIN FROM THE CHINESE LIVER FLUKE *CLONORCHIS SINENSIS*

Tai-Soon Yong, Tae Yun Kim, Hea Sun Woo

Yonsei University College of Medicine, Seoul, Republic of Korea

The SCP/TAPS (sperm coating protein/Tpx-1/Ag5/PR-1/Sc7) proteins are multifunctional protein found in eukaryotes. Venom allergen-like (VAL) proteins, members of the SCP/TAPS protein superfamily, have been reported from several parasitic helminths. However, little is known about their biological and immunological function. In this study, a VAL protein of the Chinese liver fluke ***Clonorchis sinensis*** was cloned and characterized. A cDNA encoding 25 kDa protein was identified from EST database of ***C. sinensis***. A BLAST search revealed that the protein shares 46% sequence identity with ***Schistosoma mansoni*** VAL 13 protein, and thus, the protein was named CsVAL13. Multiple sequence alignment indicated that SCP/TAPS domain of CsVAL13 shared 39~46% sequence identity with VAL proteins from parasitic helminths. His and Tyr residues, which help to stabilize protein structure, were highly conserved across the VAL protein sequences. Phylogenetic analysis showed that SCP/TAPS domain of CsVAL13 sequence clusters together with other group 2 VAL protein sequences. In the homology-modeled structure of CsVAL13, an α-β-α sandwich structure and residues for a putative active site were highly conserved. PCR-amplified cDNA sequence of CsVAL13 was subcloned into pET32a bacterial expression plasmid vector. Recombinant CsVAL13 protein was produced bacterially and purified by Ni-NTA affinity chromatography. Immune sera were obtained from BALB/c mice immunized with the recombinant CsVAL13 protein. ELISA value of IgG1 in the immune sera against the recombinant CsVAL13 protein was six-times higher than that of IgG2a suggesting that CsVAL13 can induce Th2-polarized immune response. Immunohistochemical localization using the immune sera revealed that CsVAL13 was distributed mainly in the tegument and intrauterine eggs of adult ***C. sinensis***. These findings suggest that CsVAL13 may be involved in host-parasite interactions and immune stimulation on the surrounding host environments.

THE CHALLENGE OF IMPROVING BOILING: LESSONS LEARNED FROM A RANDOMIZED CONTROLLED TRIAL OF WATER PASTEURIZATION AND SAFE STORAGE IN PERU

Kristen Heitzinger[1], Claudio A. Rocha[2], Robert E. Quick[3], Silvia M. Montano[2], Drake H. Tilley[2], Charles N. Mock[1], Adela J. Carrasco[4], Ricardo M. Cabrera[4], Stephen E. Hawes[1]

[1]University of Washington, Seattle, WA, United States, [2]U.S. Naval Medical Research Unit - 6, Callao, Peru, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Hospital San Juan de Dios, Ica Regional Ministry of Health, Pisco, Peru

Boiling is the most common method of household water treatment in low- and middle-income countries; however, it is not always effectively practiced. We conducted a randomized controlled trial among 210 households, 93% of which used improved water sources, to assess the effectiveness of water pasteurization and safe storage interventions in reducing Escherichia coli contamination of household drinking water in a water-boiling population in rural Peru. Households were randomized to receive either a safe storage container or a safe storage container plus water pasteurization indicator or to a control group. During a 13-week follow-up period, households that received a safe storage container and water pasteurization indicator had a higher prevalence of stored drinking water contamination relative to the control group, although the difference was not statistically significant (Prevalence Ratio (PR): 1.19, 95% CI: 0.93, 1.52). Receipt of a safe storage container alone had no effect on the contamination of stored drinking water (PR: 1.03, 95% CI: 0.80, 1.32). Although use of low-cost water pasteurization indicators and locally available storage containers did not significantly increase the safety of household drinking water in this study, future research could help illuminate factors that facilitate the effective use of these interventions to improve water quality and reduce the risk of waterborne disease in populations that boil drinking water.

1161

THE QUALITY OF WATER IS STRAINED: FECAL CONTAMINATION IN RURAL BRAZIL

Lucio M. Barbosa[1], Luciano Kalabric[1], Fred Julião[2], Rodrigo Almeida[2], Sonia Teixeira[2], Sonilda Teixeira[2], Luis Afonso Cruz[2], Leia Conceição[2], Jothelma Oliveira[2], Mitermayer Reis[1], Ronald Blanton[3]

[1]Oswaldo Cruz Foundation, Salvador, Brazil, [2]Federal Institute of Bahia - Santa Ines Campus, Santa Ines, Brazil, [3]Case Western Reserve University, Cleveland, OH, United States

Wherever humans concentrate, fecal contamination of surface waters becomes a problem. We previously traced the concentration of human fecal contamination along a river dividing a village in rural Brazil. In this cross-sectional study we found that concentration increased in a downstream direction and diminished as the river left the populated area. This correlated with the prevalence of schistosomiasis. In order to follow longitudinal changes in water quality, we sampled water at 8 points over a km long stretch of the Jiquiriçá River and its tributary, the Brejões, as well water from the local treatment plant. The water is clear in most places, but heavily sedimented after heavy rains. Its temperature was within 1-2 degrees of the ambient temperature and averaged 26.2 °C across all sites. Oxygen saturation was on average good (mean 3.7 mg/d) at most sites. pH decreased as population density increased. For the Jiquiriçá, pH decreased from 6.99 upstream to 6.50 downstream of the last dwelling (mean=6.75). On the Brejões, the same trend was seen (pH 6.96 to 6.63, mean=6.75). The presence of E. coli is better associated with human feces than total coliforms. We found significant correlation between the total coliforms and E. coli (r2=0.81). Over the year, the concentration of

coliforms (337 cfu/ml) and E. coli (184 cfu/ml) was consistently highest at site 8, which corresponded to a point immediately downstream of the major population concentration on the Brejões. On the Jiquiriçá, site 4 had the highest levels of coliforms (190 cfu/mL), but site 3, where the Brejões enters the Jiquiriçá, showed the highest levels of E. coli. When river flow increased we found that levels of coliforms increase statistically (r2=0.99), however, levels of E. coli did not (r2 = 0.05). Samples from the water treatment plant had abundant coliforms at times, but rarely showed E. coli. This suggests that run-off produces the greatest risk of zoonotic contamination, but does not influence the concentration of human sources. qPCR will be used to evaluate more specific markers of human fecal contamination.

1162

REPRODUCTIVE HISTORY AMONG WOMEN EXPOSED TO INSECTICIDES THROUGH MALARIA CONTROL PROGRAMS IN CENTRAL EAST INDIA

Blair Wylie[1], Mrigendra P. Singh[2], Kojo Yeboah-Antwi[3], Neeru Singh[2], Davidson H. Hamer[3]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]National Institute of Malaria Research Field Station, Jabalpur, India, [3]Center for Global Health and Development, Boston University, Boston, MA, United States

Indoor residual spraying (IRS) is a cornerstone of malaria vector control; insecticides used for IRS such as DDT, organophosphates, and pyrethroids have been linked in animal and epidemiologic studies with reproductive toxicity. As IRS requires community wide application to more than 80% of homes to be effective, reproductive aged women will be exposed. Our objective was to determine if IRS exposure impacted reproductive outcomes among women in central east India where the government has an established IRS program. Data was available from two similarly conducted cross sectional surveys of pregnant women enrolled at delivery in the states of Jharkhand and Chhattisgarh; 1730 of 1739 subjects had information on IRS exposure (ever sprayed versus never sprayed). We used multivariable logistic regression models to evaluate the association of IRS exposure with reproductive history. A large proportion of women in the cohort (688/1730, 39%) reported having had their homes sprayed by the government. The prevalence of malaria parasitemia (peripheral or placental) was 3.2% and was not affected by history of IRS exposure (p=0.63). Women whose homes had been sprayed during IRS campaigns were more likely to report a history of a stillborn infant (aOR 1.60, 95% CI 1.05-2.44) but not a history of early pregnancy loss (aOR 0.91, 95% CI 0.65-1.30) after adjusting for covariates that differed by IRS exposure group. Our findings are limited as IRS exposure was determined by maternal recall and the timing of exposure in relation to pregnancies was not defined. Further research is warranted to clarify potential toxicity to reproductive aged women from specific insecticides so that policymakers who design IRS programs will be able to identify the safest insecticide(s) for reproductive aged women.

1163

ASSOCIATION BETWEEN PROXY MEASURES OF HANDWASHING AND PREVALENCE OF CHILD DIARRHEA IN 15 LOW-INCOME COUNTRIES: ANALYSIS OF DEMOGRAPHIC AND HEALTH SURVEYS, 2010-2012

Sharifa Nasreen[1], Jaynal Abedin[1], Pavani K. Ram[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]University at Buffalo, Buffalo, NY, United States

Children in low-income countries are at increased risk of diarrheal diseases, which are largely preventable. Handwashing (HW) with soap can significantly reduce childhood diarrhoea. We assessed whether a proxy measure of HW with soap, the presence of soap and water at a HW place, was associated with a reduced prevalence of diarrhea among children aged <5 years in low-income countries. We used comparable data from Demographic and Health Surveys (DHS) conducted in 2010-2012 in 15 low-income countries. For each country and pooled across the countries, we estimated crude and adjusted risk ratios (RRs) for 2-week prevalence of diarrhea comparing children from households having water alone, or soap and water, with children from households having no water or soap at a HW place. Compared to children from households with no water or soap at a HW place, children from households with water alone had 3-62% lower prevalence of diarrhea in 6 countries and 6-35% higher prevalence of diarrhea in 9 countries. Children from households with water and soap at a HW place had 6-49% lower prevalence of diarrhea in 9 countries and had 14-45% higher prevalence of diarrhea in 5 countries compared to children from households with no water or soap. There was no difference in diarrhea prevalence between the children in both groups in one country. In pooled analyses, there was a 10% (adjusted RR 0.90, 95% CI 0.74-1.10) lower prevalence of diarrhea among children from households with water alone and an 11% (adjusted RR 0.89, 95% CI 0.76-1.04) lower prevalence of diarrhea among children from households with water and soap compared to children from households with no water or soap. There was substantial heterogeneity among the countries. Availability of HW materials at designated places for washing hands was not significantly associated with diarrhea prevalence. Availability of soap and water may be necessary but not sufficient condition for consistent practice of HW behavior. There is a need to develop indicators of HW determinants that could be used in conjunction with observation of HW materials to better predict true HW behavior of target populations in large-scale surveys such as the DHS.

1164

OBSERVED HANDWASHING BEHAVIOR DURING INFANT FEEDING, INTERVENTION ASSESSMENT OF A LARGE RANDOMIZED CONTROLLED TRIAL (RCT) IN RURAL BANGLADESH

Kaniz Khatun E Jannat[1], Leanne E. Unicomb[1], Christine P. Stewart[2], Mahbubur Rahman[1], Fosiul A. Nizami[1], Stephen P. Luby[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Program in International and Community Nutrition, University of California Davis, Davis, CA, United States

We analyzed data from a randomized controlled trial (RCT) to assess if the provision of a supportive environment improved handwashing (HW) practices before child feeding when this key time was not actively promoted during intervention. We studied caregivers' HW practices before feeding different food items. The WASH Benefits study is an ongoing RCT in four districts in Bangladesh. Participants received messages to wash hands with soap after defecation, after cleaning a child's anus and before preparing food, but not before child feeding. Participants also received two HW stations; at the food preparation area and the latrine. We randomly selected 54 households each from the control, HW, combined water, sanitation, HW (WASH), and WASH plus nutrition (WASH, N) arms. At each household we conducted five-hour structured observations from February-July 2014, approximately 1.5 years after initiation of the intervention. During the observation, children were 6-18 months old. HW with soap before breastfeeding was very low (3%) in all three intervention arms and absent among controls. Though the proportion was low HW with soap before feeding water was more common in the HW intervention arm (9%) compared to controls (2%, RR 4.47; 95%CI 1.40, 14.35). This difference was less apparent in the combined arms (6%, RR 3.13, 95%CI 0.99, 9.94). We observed that HW with soap before feeding solid moist food, which maybe particularly conducive to bacterial growth, was more common in the HW intervention arm (26%) compared to the control arms (3%; RR 7.4; 95%CI 2.6, 21.1). This practice was also higher in the WASH (15%; RR 6.4; 95%CI 2.3, 17.8) and WASH, N arms (10%; RR 3.4; 95%CI 1.1, 10.3) compared to controls. HW with soap before feeding dry food (<1%) and fruits (<2%) was rare. Focused promotional messages for HW before child feeding were lacking but a supportive setting was associated with increased HW with soap before feeding solid moist food to children.

Hand cleanliness during complementary feeding may be prompted for habit formation by ensuring a supportive environment for HW. Increased awareness of the impact of HW with soap on child health can foster practices beyond those specific events promoted.

1165

EXPRESSION OF CYTOKINES IN RESPONSE TO *MYCOBACTERIUM AVIUM* COMPLEX IN ENTEROCYTES AND ITS ASSOCIATION WITH ENVIRONMENTAL ENTEROPATHY

Gershom Chongwe[1], Charles Michelo[1], Paul M. Kelly[2]

[1]Department of Public Health, University of Zambia, Lusaka, Zambia, [2]Blizard Institute, Barts and the London School of Medicine and Dentistry, London, United Kingdom

Environmental enteropathy is a chronic inflammatory condition associated with stunting in children, poor vaccine response as well as malabsorption. Although its aetiology is unknown, it is known to be associated with T-cell activation. Mycobacteria is known to elicit activation of cytokines including tumour necrosis factor, interleukin 6, interferon γ and matrix metalloproteinases. The role played by mycobacteria in the aetiology of enteropathy is unknown. We carried out an investigation to determine the gut cytokine response to ***Mycobacterium avium*** complex. Intestinal biopsy samples were cultured with ***M. avium*** lysate in tissue culture medium in an environment with 95% O2/5% CO2 at 37°C for 24 hrs. The supernatant was collected and we used the cytometric bead array (CBA) human Th1/Th2/Th17 cytokine kit on a Facsverse machine to estimate cytokine expression. Preliminary results from 9 patients show that ***M. avium*** complex increased the expression of interleukin 4 (p=0.01), interlukin-10 (p=0.02), and interferon gamma (p=0.01) in enterocytes compared to negative control samples. There was no difference in the expression of interleukin-2 (p=0.80), interleukin-6 (p=0.23), interleukin-17A (p=1.0) and tumour necrosis factor (p=0.63) in enterocytes compared to the negative controls. Our results have shown that ***M. avium*** induces inflammatory (interferon gamma) as well as anti-inflammatory (il-4 and il-10) cytokines in enterocytes. ***M. avium*** could play a role in environmental enteropathy

1166

SPATIO-TEMPORAL PATTERN OF HOSPITAL-ACQUIRED *ACINETOBACTER BAUMANNII* INFECTION IN TEACHING HOSPITAL IN SOUTHERN THAILAND

Sarunyou Chusri, Kachornsakdi Silpapojakul, Edward McNeil, Virasakdi Chongsuvivatwong

Prince of Songkla University, Hat yai, Songkhla, Thailand

Molecular and mathematical methods are increasingly used in microbiologic diagnostics, particularly in epidemiologic investigations. Various molecular typing methods are employed to study the molecular epidemiology of ***Acinetobacter baumannii.*** The studied population included 197 ***A. baumannii*** undergone genotypic grouping using pulse field gel electrophoresis (PFGE). Relationship between admission ward, and timing of their occurrence were examined. Randomized representative isolates from each group were further analyzed for multilocus sequence typing (MLST), which were then compared with international database. Fisher test with 2,000 replicate Monte Carlo simulations and dotplot analysis were carried out on the cross-table between PFGE group and Ward Among carbapenem-resistant ***A. baumannii*** (CRAB), multiplex PCR for the bla_{OXA-23}, bla_{OXA-40}, and bla_{OXA-58} genes were done. Ten PFGE groups were identified causing 23 clusters. The average cluster size was 6.09 ± 6.61 cases. The average duration of outbreak was 12.6 ±13 days. The average wards per cluster were 2.41 ± 1.68 wards. Certain PFGE groups tended to be common in certain wards with P value of 0.0005. Dotplot analysis showed those clusters were relatively short and replaced with other successful groups rapidly. The eight sequence typing (STs) were previously described in Thailand, Vietnam and China while 2 STs were novel. Most common gene encoding for carbapenemase is bla_{OXA-23} followed with bla_{OXA-58}. In conclusion, outbreaks of ***A. baumannii*** in this study had a strong spatio-temporal pattern. The etiologic organisms were from different new and endemic sources. Prevention of new incoming organism may be useful in addition to the attempt on prevention of transmission during the outbreak.

1167

UNDERSTANDING WATER STORAGE PRACTICES OF URBAN RESIDENTS OF AN ENDEMIC DENGUE AREA IN COLOMBIA: PERCEPTIONS, RATIONALE AND SOCIO-DEMOGRAPHIC CHARACTERISTICS

Diana R. Higuera-Mendieta, Tatiana García-Betancourt, Catalina González-Uribe, Juliana Quintero

Fundación Santa Fe de Bogotá, Bogotá, Colombia

Household water storage has received special attention in prevention strategies for controlling ***Aedes aegypti*** reproduction, but the evidence about the rationale of this human practice is limited. The objective of this study was to identify and describe water storage practices among residents of an urban area in Colombia (Girardot) and its association with reported perceptions, rationale and socio-demographic characteristics with mixed methods approach. Knowledge, attitudes and practices and entomological surveys from 1,721 household were conducted as well as 26 Semi-structured interviews among residents of Girardot and vector borne technicians. A multiple logistic analysis was performed to identify associations between water storage practice and socio-demographic characteristics, and knowledge, attitudes and practices about dengue and its vector´ immature forms, which were then triangulated with qualitative information obtained from the semi structured interviews. Water storage is a common, and cultural practice in Girardot, 82% of respondents reported this activity. This practice was not associated with socioeconomic characteristics such as years of education (OR 0.97, 95% CI 0.79-1.19), lower income (OR 0.81, 95% CI 0.48-1.36) or knowledge about the vector and it's breeding sites. There are two main reasons for storage: the scarcity concern based on a long history of shortages of water in the region and the perception of high prices in water rates, contrary to what was reported by the local water company. The use of stored water depends on the type of container used, while water stored in large cement basins is mainly used for domestic cleaning chores, water in plastic containers is used for cooking. Despite of the common believe that water storage practices are related to socioeconomic conditions, this practice relays on cultural beliefs. It is essential to understand social practices that can increase or reduce the number of breeding sites of ***Ae. aegypti***. Identification of individuals who store water and the rationale of such storage allow a better understanding of the social dynamics that lead to water accumulation.

1168

INCREASED ISOLATION FREQUENCY OF TOXIGENIC *VIBRIO CHOLERAE* O1 FROM ENVIRONMENTAL MONITORING SITES IN HAITI

Thomas A. Weppelmann

University of Florida, Gainesville, FL, United States

Since the identification of the first cholera case in 2010, the disease has spread in epidemic form throughout the island nation of Haiti; as of 2014, about 700,000 cholera cases have been reported, with over 8,000 deaths. While case numbers have declined, the more fundamental question of whether the causative bacterium, ***Vibrio cholerae*** has established an environmental reservoir in the surface waters of Haiti remains to be elucidated. In a previous study conducted between April 2012 and March 2013, we reported the isolation of toxigenic ***V. cholerae*** O1 from surface waters in the Ouest Department. After a second year of surveillance (April 2013 to March 2014) using identical methodology, we observed a more than five-fold increase in the number of water samples containing culturable ***V. cholerae*** O1 compared to the previous year (1.7% vs 8.6%),

with double the number of sites having at least one positive sample (58% vs 20%). Both seasonal water temperatures and precipitation were significantly related to the frequency of isolation. Our data suggest that toxigenic ***V. cholerae*** O1 are becoming more common in surface waters in Haiti; while the basis for this increase is uncertain, our findings raise concerns that environmental reservoirs are being established.

WATER SANITATION AND HYGIENE PRACTICES IN SOME COMMUNITIES IN BAYELSA STATE, NIGERIA

Agwu Nkwa Amadi[1], Uwadiegwu Zachaeus[2], Chinasa Orie Amadi[1], Ikechukwu Nosike Simplicius Dozie[1], Uchechukwu Madukaku Chukwuocha[1], Adanna Nneoma Chukwuocha[1], Geoffrey Chima Nwakwuo[1]

[1]Department of Public Health Technology, Federal University of Technology, Owerri, Nigeria, [2]Environmental Health Programme, College of Medicine and Health Science, Abia State University, Uturu, Nigeria

A study on water sanitation and hygiene practice was carried out in three randomly selected communities in Bayelsa State, South-South geopolitical zone of Nigeria. The study adopted a descriptive cross-sectional design, with the aid of a questionnaire, bacteriological water analysisand sanitary inspection strategies for data collection. The study showed that 57 (33%) out of 169 heads of households studied were aware of improved water supply benefits and 37 (21.9%) were aware of sanitation/hygiene benefits. Eight one percent (81%)of the households sampled did not have access to improved water supply.The meanwater supply coverage was 17.85%, while sanitation was 46.89% in the three communities. From the findings, 45% of the households used private neighborhood borehole and about 20% depended on river and pond water as the main sources of water supply. The bacteriological water analysis showed that 120 out of 160 sampleswere contaminated with ***Escherichia coli, Streptococcus faecalis*** and ***Salmonella typhi***. Based on the above findings, massive health education/promotion is required to minimize water associated infections/ diseases.

1170

PREVALENCE OF *SALMONELLA* SPP. IN RAW MILK SAMPLES FROM FARM LIVESTOCK DUAL PURPOSE IN CÓRDOBA, COLOMBIA

Linda M. Chams, Virginia Rodriguez, Alfonso Calderon Rangel

Universidad de Córdoba, Monteria, Colombia

Raw milk has not been subjected to any process of thermisation or sterilization and so is considered one of the main transmission routes of pathogens causing food borne diseases (FBD). Salmonellosis is one of the most prevalent zoonosis around the world. Despite advances in technology and educational efforts to improve the food products handling throughout the production and marketing the FBD outbreaks due to ***Salmonella*** spp. are still prevalent in particular those involving dairy foods consumption. This study was undertaken to determine the prevalence of ***Salmonella*** spp. in raw milk samples from livestock dual purpose farms from the department of Córdoba, Colombia. Milk samples obtained during maximum and minimum precipitation periods in 149 farms were collected. ***Salmonella*** spp. were determined by conventional isolation according to protocols established by INVIMA. The suspected strains underwent biochemical tests and confirmed by Polymerase Chain Reaction (PCR) determining the ***InvA*** gene. All data were analyzed using the SAS statistical package. ***Salmonella*** spp. was detected in 1,34% (2/149) and 2,01% (3/149) of the samples collected at minimum and maximum rainfall respectively, which was isolated by conventional bacteriology methods and molecularly confirmed by amplification of a 284 bp region corresponding to ***InvA*** gene. It was established that 60% (3/5) and 40% (2/5) of the isolates corresponded to samples taken at low and high precipitation respectively. In conclusion, the presence of ***Salmonella*** spp. in raw milk can become a risk to human health, so it is clear that the application of best management practices and good sanitary conditions contribute directly in reducing the ***Salmonella*** spp. milk contamination.

1171

DIAGNOSIS OF INFECTIONS CAUSED BY BACTERIA, FUNGI AND GASTROINTESTINAL PARASITES IN MEAT HANDLERS IN A SLAUGHTERHOUSE IN THE NORTH OF COLOMBIA, 2014

Linda M. Chams, Alberto Mestra, Luis Hernandez

Universidad de Córdoba, Monteria, Colombia

To determine the presence of infections caused by bacteria, fungi and gastrointestinal parasites in beef handlers in a slaughterhouse in the city of Santa Marta, Magdalena, Colombia 2014. The research corresponded to a cross-sectional descriptive study. The study sample corresponded to the whole of the 36 existing workers in the slaughterhouse. Prior socialization to company officials about the scope of the investigation and achieved the informed consent, the respective throat swab tests, direct examination with 10% KOH for hand and nail fungus and serials stool (three) were performed. Diagnosis of throat swab practiced showed the presence of gram-positive cocci in 36/36 (100%) of the samples, Gram positive in 1/36 (2.8%), Gram negative bacilli in 9/36 (25%) and fungal mycelia in 7/36 (19.4%) of them. The leukocyte reaction, possibly as a result of the presence of cocci, bacilli and fungi, showed a low leukocyte reaction in 23/36 (63.9%) samples, moderate leukocyte reaction in 12/36 (33.3%) and increased leukocyte reaction 2/36 (5.5%) of the samples. The throat swab also showed fusoespirilar association in 6/36 (16.7%) of the patients examined. The stool tests showed a higher proportion of amoeba infections, highlighting ***Endolimax nana*** infection 7/36 (19.4%), followed by ***Entamoeba histolytica*** infections 5/36 (13.9%) and ***E. coli*** 4/36 (11.1%). Protozoa of the genus ***Blastocistis hominis*** were also observed in 4/36 (11.1%) workers infected with ***Giardia lamblia*** and 1/36 (2.8%). Nematode infections were observed only for the genus ***Uncinaria*** spp., 1/36 (2.8%). The presence of yeasts was found in 4/36 (11.1%) handlers. No fungal infections diagnosis with 10% KOH in hands and nails were found. The study showed manipulators throat infections at enteric level compatible with several genera of bacteria and parasites of clinical importance, these infections would also become a source of contamination of manipulated meat, possibility given to consumers. With this study we intend to seek guidance from academic practices by health authorities to ensure the health of handlers and food security.

1172

A MOLECULAR MECHANISM OF ARTEMISININ RESISTANCE IN *PLASMODIUM FALCIPARUM* MALARIA

Alassane Mbengue[1], Souvik Bhattacharjee[1], Trupti Pandharkar[1], Haining Liu[2], Guillermina Estiu[2], Robert V. Stahelin[1], Shahir S. Rizk[1], Dieudonne L. Artemisinins are the cornerstone of anti-malarial drugs. Emergence and spread of resistance to them raises risk of wiping out recent gains achieved in reducing worldwide malaria burden and threatens future malaria

control and elimination on a global level. Genome-wide association studies (GWAS) have revealed parasite genetic loci associated with artemisinin resistance. However, there is no consensus on biochemical targets of artemisinin. Whether and how these targets interact with genes identified by GWAS, remains unknown. Here we provide biochemical and cellular evidence that artemisinins are potent inhibitors of ***Plasmodium falciparum*** phosphatidylinositol-3-kinase (PfPI3K), revealing an unexpected mechanism of action. In resistant clinical strains, increased PfPI3K was associated with the C580Y mutation in ***P. falciparum*** Kelch13 (PfKelch13), a primary marker of artemisinin resistance. Polyubiquitination of PfPI3K and its binding to PfKelch13 were reduced by the PfKelch13 mutation, which limited proteolysis of PfPI3K and thus increased levels of the kinase, as well as its lipid product phosphatidylinositol-3-phosphate (PI3P). We find PI3P levels to be predictive of artemisinin resistance in both clinical and engineered laboratory parasites as well as across non-isogenic strains. Elevated PI3P induced artemisinin resistance in absence of PfKelch13 mutations, but remained responsive to regulation by PfKelch13. Evidence is presented for PI3P-dependent signalling in which transgenic expression of an additional kinase confers resistance. Together these data present PI3P as the key mediator of artemisinin resistance and the sole PfPI3K as an important target for malaria elimination.

1173

IDENTIFYING AND CHARACTERIZING A NOVEL TRAFFICKING COMPONENT OF THE *PLASMODIUM FALCIPARUM* VIRULENCE FACTOR PFEMP1

Aaron T. Neal[1], Lisa C. Ranford-Cartwright[2], Richard T. Eastman[1], Chris I. Newbold[3], Rick M. Fairhurst[1]

[1]National Institutes of Health, Rockville, MD, United States, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of Oxford, Oxford, United Kingdom

Plasmodium falciparum erythrocyte membrane protein 1 (PfEMP1) is the main parasite virulence factor due to its central role in mediating the cytoadherence of infected red blood cells (iRBCs) to the host microvascular endothelium. Directly targeting PfEMP1 as a therapeutic strategy is greatly limited due to the protein's hypervariable nature, which gives rise to ~60 different variants. However, interfering with the trafficking of PfEMP1 to the iRBC surface is an attractive approach, as hypervariability becomes inconsequential and previous studies have demonstrated that reduced surface PfEMP1 levels significantly weaken cytoadherence, likely lessening the severity of malaria symptoms and promoting parasite clearance by the spleen. Interestingly, the ***in vitro*** culture-adapted parasite line 3D7 is inherently defective in exporting PfEMP1 to the iRBC surface. Presuming that PfEMP1 export from the parasite to the iRBC surface is controlled at the genetic level, we hypothesized that 3D7 harbors one or more genetic determinants of impaired PfEMP1 trafficking. To test this possibility, we examined the surface PfEMP1 levels of 16 progeny clones from the genetic cross between 3D7 and the 'trafficking-competent' parasite line HB3. This was assessed using Western blotting and a two-color, three-layer flow cytometry assay with plasma from malaria-immune Malian adults. Normalized to HB3, we found that 3D7 displays 75% less PfEMP1 on the iRBC surface, with progeny phenotypes ranging from 37% more to 88% less PfEMP1. QTL analysis using genome-wide SNP markers identified a near-significant locus with a LOD score of 4.96 on chromosome 12 that explains ~50% of the phenotypic variance. This locus contains a single gene, Pf3D7_1245600, encoding a putative kinesin-6 protein. The role of this gene in the trafficking of PfEMP1 was directly assessed through CRISPR-Cas9-driven parental allele-exchange transfection experiments, and indirectly assessed though ***in vitro*** microtubule manipulation studies. The results of this study strengthen our understanding of malaria pathogenesis and direct attention to a highly understudied parasite protein family.

1174

FORM AND FUNCTION OF REGULATED MRNP COMPLEXES IN *PLASMODIUM* TRANSMISSION

Elyse E. Munoz, Mark F. Kennedy, Kevin J. Hart, Mackenzie M. Shipley, **Scott E. Lindner**

Center for Malaria Research, Pennsylvania State University, University Park, PA, United States

Translational repression of specific mRNAs allows control of gene expression by ***Plasmodium*** species, which the parasite uses to prepare for transmission events between a mammalian host and a mosquito vector. Our previous studies demonstrate that Puf2, a RNA-binding translational repressor protein, plays an integral role in maintaining the infectivity of transmitted salivary gland sporozoites, in regulating RNA homeostasis, and in translationally repressing specific transcripts. In the absence of Puf2, the transcript abundances of other RNA-binding proteins are affected, including those that encode for members of the CCR4/Not and DOZI/CITH complexes, which are essential to RNA metabolism and translational repression. To this end, have studied the intersection of these critical mRNA/protein (mRNP) complexes and processes during transmission through genetic manipulation of the rodent-infectious parasite ***Plasmodium yoelii***. First, we have identified that the ALBA4 protein plays an integral role in both gametocytes and sporozoites, and its genetic disruption leads to an enhancement of the number of transmissible gametocytes from host-to-vector, but dampens the wave of sporozoites migrating from the midgut to the salivary gland. Conversely, genetic disruption of CCR4 (a general deadenylase) dampens the wave of gametocytes that can be transmitted from the host, but does not affect sporozoite development. Secondly, we have isolated the mRNP complexes associated with the ALBA family of proteins from transmissible gametocytes and asexual blood stages, and have used high mass accuracy mass spectrometry and RNA-seq to define their composition. Lastly and excitingly, we have for the first time developed the techniques required to isolate mRNP complexes from the ***Plasmodium*** sporozoite. We are extending these approaches to characterize both the ALBA and Puf2 mRNP complexes in developing sporozoites to identify commonalities in their form and function between gametocytes and sporozoites. Taken together, these efforts illuminate the differences between discrete storage granules present during both transmission events.

1175

EXPERIMENTAL CEREBRAL MALARIA INDUCES CEREBRAL VASCULAR DYSFUNCTION AND COGNITIVE IMPAIRMENT VIA ENDOTHELIN A RECEPTOR SIGNALING

Brandi D. Freeman, Yuri C. Martins, Mahalia S. Desruisseaux

Albert Einstein College of Medicine, Bronx, NY, United States

Cerebral malaria (CM) is a diffuse encephalopathy caused by ***Plasmodium falciparum*** infection, which kills and disables millions of children each year. The potent vasoactive peptide, endothelin-1 (ET-1), which is thought to be involved in CM, mediates blood brain barrier (BBB) permeability, inflammation, and vascular tone. Researchers propose that elevated levels of ET-1 during severe ***P. falciparum*** infection may contribute to cerebrovascular dysfunction ultimately impairing neurocognition. However, the underlying mechanism of ET-1 in the pathogenesis of CM is not fully understood. In the current study, we tested the hypothesis that ET-1 mediates vascular and cognitive dysfunction in the ***P. berghei*** ANKA (PbA) experimental CM (ECM) model. We previously demonstrated that ECM resulted in significant memory loss, even after successful antimalarial treatment. ***P. berghei*** NK65 (PbN) generally does not induce ECM in C57BL/6 mice and has been used as a non-CM negative control for PbA. Here, we demonstrate that exogenous administration of ET-1 induced memory deficits in PbN-infected mice triggering an ECM-like phenotype. Moreover, treatment with an endothelin type A receptor antagonist (ETARA) prevented BBB disruption, cerebral vasoconstriction, and neuroinflammation in PbA-infected mice. ETARA reduced brain endothelial

activation concomitantly diminishing brain microvasculature congestion. Interestingly, ETARA adjunctive therapy prevented neurocognitive impairments induced by PbA-infection. We propose that these effects were mediated by activation of c-Jun N terminal kinase (JNK), a downstream substrate of ET-1 signaling associated with cognitive impairment and is important in the development of ECM. Here, we demonstrate that ET-1 induced the expression of JNK phosphorylation in the brains of PbN-infected mice, while ETARA prevented increased JNK phosphorylation in PbA-infected animals. We therefore conclude that cerebrovascular disturbances and cognitive impairments in ECM are due, in part, to ET-1 signaling. Thus, targeting the ET signaling-axis may serve as a potential adjunct therapy in the treatment of patients with CM.

1176

A_2MACROGLOBULIN CAN CROSSLINK MULTIPLE *PLASMODIUM FALCIPARUM* ERYTHROCYTE MEMBRANE PROTEIN 1 (PFEMP1) MOLECULES AND MAY FACILITATE ADHESION OF PARASITIZED ERYTHROCYTES

Liz Stevenson[1], Erik Laursen[1], Graeme J. Cowan[2], Betty Bandoh[3], Lea Barfod[1], David R. Cavanagh[2], Gregers R. Andersen[4], **Lars Hviid**[1]

[1]University of Copenhagen, Copenhagen, Denmark, [2]University of Edinburgh, Edinburgh, United Kingdom, [3]University of Ghana, Accra, Ghana, [4]University of Aarhus, Aarhus, Denmark

Rosetting, the adhesion of ***Plasmodium falciparum***-infected erythrocytes to uninfected erythrocytes, involves clonal variants of the parasite protein ***P. falciparum*** erythrocyte membrane protein 1 (PfEMP1) and soluble serum factors. While rosetting is a well-known phenotypic marker of parasites associated with severe malaria, the reason for this association remains unclear, as do the molecular details of the interaction between the infected erythrocyte (IE) and the adhering erythrocytes. Here, we identify for the first time a single serum factor, the abundant serum protease inhibitor $\alpha_2$macroglobulin (α_2M), which is both required and sufficient for rosetting mediated by the PfEMP1 protein HB3VAR06 and other rosette-mediating PfEMP1 proteins. We map the α_2M binding site to the Cterminal end of HB3VAR06, and demonstrate that α_2M can bind up to four HB3VAR06 proteins, plausibly augmenting their combined avidity for host receptors. IgM has previously been identified as a rosette-facilitating soluble factor that acts in a similar way, but it cannot induce rosetting on its own. This is in contrast to α_2M and probably due to the more limited cross-linking potential of IgM. Nevertheless, we show that IgM works synergistically with α_2M and markedly lowers the concentration of α_2M required for rosetting. Finally, we demonstrate that the capacity to bind α_2M is a common phenotype among ***P. falciparum*** isolates ***in vitro*** as well as ***ex vivo***. Together, our results are evidence that ***P. falciparum*** parasites are able to expand the repertoire of host receptors available for PfEMP1-mediated IE adhesion to include receptors with low affinity for individual PfEMP1 molecules. These receptors likely include carbohydrate moieties that will lead to formation of rosettes when present on erythrocytes. The study opens opportunities for broad-ranging immunological interventions targeting the α_2M- (and IgM-) binding domains of PfEMP1, which would be independent of the host receptor specificity of the clinically important rosette-mediating PfEMP1 antigens.

1177

ETHICS AND EBOLA: RECOMMENDATIONS OF THE U.S. PRESIDENTIAL COMMISSION FOR THE STUDY OF BIOETHICAL ISSUES

Kata Chillag

Presidential Commission for the Study of Bioethical Issues, Washington, DC, United States

In February 2015, the Presidential Commission for the Study of Bioethical Issues released Ethics and Ebola: Public Health Planning and Response. The report addresses ethical issues raised by the west African Ebola virus disease (EVD) epidemic, including public health, public, media, and political reactions to U.S. EVD cases, and the actual and perceived likelihood of a U.S. epidemic. After hearing from affected communities, public health leaders, journalists, historians, sociologists, and the public, the Commission focused its deliberations and analysis in three areas: 1) U.S. participation in the global epidemic response; 2) restrictive measures such as travel bans; and 3) research ethics in public health emergencies. The Commission made seven recommendations, including one focused on ethical considerations of implementing liberty-restricting measures during a public health emergency. Public engagement and ethics preparedness can help public health officials to determine when restrictive measures are appropriate and respond to calls for unwarranted quarantine or travel restrictions. Ethical dimensions of restrictive measures include their impact on health care professionals' ability and willingness to participate in epidemic response, which, in turn, can impact the effectiveness of the public health response. Restrictive measures might be ethically implemented in circumstances where the evidence deems them helpful and their public health rationale is effectively communicated to an anxious public. Drawing on examples from EVD and other epidemics such as SARS, the Commission highlighted the importance of restrictive measures being based on scientific evidence and employed only when they will prevent harm to others and have the least possible impact on civil liberties. Moreover, the Commission underscored that decisions about the use of restrictive measures should consider both the immediate burdens they impose on affected individuals and communities (such as loss of income), as well as issues of justice and fairness, including the potential of these measures to exacerbate stigma and social and economic inequalities.

1178

THE UK'S IMPORTED FEVER SERVICE DURING THE EBOLA EPIDEMIC: A CENTRALIZED ADVICE AND DIAGNOSTIC UNIT FOR IMPORTED INFECTIONS

Alastair McGregor[1], Caoimhe Nic Fhogartaigh[1], Tri Wangrangsimakul[1], Elham Khatamzas[1], Hanif Esmail[1], Jane Osborne[1], Emma Aarons[1], Andrew Simpson[1], Amanda Semper[1], Nicholas Beeching[2], Peter Chiodini[3], Tim Brooks[1]

[1]Public Health England, Salisbury, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Hospital for Tropical Diseases, London, United Kingdom

The Rare and Imported Pathogens Laboratory (RIPL) is a specialist centre run by Public Health England for advice and diagnosis of a wide range of uncommon infections. In addition to its standard diagnostic activities (24000 samples tested pa.) it operates a telephone hotline (the imported fever service – IFS) for infection specialists seeking advice and access to tests for imported infections, including Ebola. Between April 2014 and March 2015, RIPL received 599 referrals. 316 of these were calls for diagnostics and advice for an imported fever (compared to 187 such calls the previous year), of which 130 required testing for Ebola. Another 243 (46%) were calls about travellers from West Africa specifically related to Ebola testing, of which 101 (42%) were tested. All IFS samples, as well as 83/101 of Ebola requests, were tested using molecular and serological assays for flaviviruses, alphaviruses, phleboviruses and rickettsiae, the exact choice of tests guided by the incidence of infection in each of 10 large geographical areas. In 159 travellers from non-outbreak countries, RIPL diagnoses (including those where IFS advice led to the correct test being performed) were made in 23 and included chikungunya (5), dengue (5), leptospirosis (2), rickettsiosis (3), hantavirus (2), coxiellosis, CCHF, hepatitis E, malaria genus (species determined by MRL), scrub typhus, West Nile (one each). In travellers from the outbreak area (231 individuals) RIPL diagnoses were made in 32 (14%): undiagnosed malaria (18), rickettsiosis (5), Ebola (3), dengue (3), leptospirosis, Rift Valley and Toscana virus (one each). IFS experience shows the value of a one-stop specialist diagnostic network to support clinicians in local hospitals. Malaria is overrepresented and chikungunya is absent in our travellers from West Africa. A significant number of infections, some of serious clinical or public health importance,

have been identified in cases referred to RIPL. The centralisation of specialised testing facilitates communication and quality control and a unit such as RIPL is well placed to respond to the need for testing returnees from outbreak areas who are unwell.

1179

NIGERIA'S RESPONSE TO THE EBOLA OUTBREAK: CRITICAL LESSONS FOR HEALTH SYSTEMS STRENGTHENING IN AFRICA

Oluwatosin Omole[1], Patience Ugwi[2], Ngozi Egu-Okoronkwo[1]

[1]Howard University Hospital, Washington, DC, United States, [2]University of Iowa College of Public Health, Iowa City, IA, United States

The Ebola virus spread from Liberia to Lagos, Nigeria in July 2014 and an uncontrolled Ebola outbreak would have been catastrophic in Nigeria, a country of 170 million people. Nigeria succeeded in containing Ebola through a "quick and forceful" rapid public health response. 20 people were affected and 8 died. While there has been extensive international aid to help Ebola affected countries, few of these efforts have been specifically targeted to building up their health systems. The Ebola outbreak is a huge health crisis but also a wake up call for immediate sustainable and scalable health systems strengthening. From a focused literature review, and on site visit to Nigeria this paper uses Nigerias experience as a trajectory and suggests methods for health systems strengthening by seeking answers to critical questions 1) Why was the response from African countries to Ebola slow and uncoordinated ? 2) Was Nigeria prepared or lucky? 3) What steps had Nigeria taken in the past to inadvertently prepare for Ebola and what can other countries learn? 4) What did Nigeria do differently during the crisis 5) How can African countries move from short term public health measures to long term initiatives and disaster preparedness and what are the next steps in developing a people centred health system? African countries with fragile health systems need a more robust approach in responding to health challenges including : improved health governance, research funding, quality improvement, effective health worker training and retention, and widespread public health education. Conclusions, countries must embrace strategic and pragmatic thinking as innovative solutions are sought for challenging and emerging public health problems.

1180

FORGING GLOBAL HEALTH PARTNERSHIPS THROUGH EBOLA PREPAREDNESS: US NAVAL MEDICAL RESEARCH UNIT-3 ASSISTS IN REGIONAL PUBLIC HEALTH RESPONSE, INFECTION CONTROL TRAINING AND SAMPLE MANAGEMENT IN CAIRO, EGYPT

Mustafa Abdel Aziz, Emad Mohareb, Moustafa Mansour, Stephen Lizewski, Gabriel Defang, Tamer Saeed, Hoda Mansour, **Rhonda A. Lizewski**

Naval Medical Research Unit - 3, Cairo, Egypt

The recent outbreak of Ebola Virus Disease (EVD) has prompted many nations outside of West Africa to strengthen their public health response to prepare for regional epidemics. In Egypt, US Naval Medical Research Unit No. 3 (NAMRU-3) assisted local and regional partners in EVD preparedness thereby fostering global health engagement. NAMRU-3 acquired the capability to test EBOV-Zaire strain by rtPCR and as a World Health Organization (WHO) Collaborating Center for Emerging Infectious Diseases, responded to WHO's request for training of laboratory and public health representatives in the region. Scientific seminars covering the virology of EBV, sample inactivation, handling and transport, and infection control precautions were offered through "just-in-time assessments", workshops and training for the host nation and Eastern Mediterranean Region (EMRO) partner nations. As a regional asset, NAMRU-3 also contributed 3 microbiologists to the US DoD Operation United Assistance to build lab capacity in Liberia. After the initial seminar on 2 September, the local authorities assessed their Ebola Treatment Unit (ETU). They requested assistance with assessing the ETU and their Personal Protective Equipment (PPE) protocols for infection control. The training team assessed the ETU hospital site, provided hands-on training on PPE, and infection control. Additional training was provided to the Mobile Response Team. A three-day workshop for 13 participants from Jordan, Morocco, Tunisia, Lebanon, and Egypt was held from 28-30 October. Hands-on rtPCR laboratory and PPE training followed two days of educational seminars. Pre- and post- assessment quizzes showed an increase in the participants understanding of EBV from 60% to 73%. Specifically clarification was needed to distinguish between the PPE of avian influenza and EBV and exact route of transmission. The longstanding partnership between NARMU-3, Egypt, WHO and the EMRO region will allow for more agile response and preparedness to an evolving disease epidemic. During this session we will present how these relationships serve as a model for international global public health cooperation.

1181

DOCUMENTING THE RESPONSE TO THE EBOLA EPIDEMIC IN LIBERIA THROUGH THE PERSPECTIVE OF THE LOCAL PRESS

Kwame Sakyi, **William R. Brieger**

Johns Hopkins University, Baltimore, MD, United States

Mass media plays an important role in documenting national responses to crises like Ebola. Reviewing media documentation helps a country better prepare for current and future public health challenges. Ebola articles first appeared in the Liberian press in March 2014. Our objectives were to determine the frequency of newspaper accounts and the major issues covered. We conducted content analysis of Ebola coverage in three Liberian newspapers from March through December 2014. We reviewed electronic publications of three main newspapers by searching for the term "Ebola". Data collected for each article included date of publication, and topic. Data were compiled in Microsoft Excel. After reading the first 50 articles, we inductively generated codes to capture the news content and compiled these into a codebook. The codebook was constantly refined as additional articles were read. Codes were organized into major themes. A total of 1,793 articles were published across the 3 newspapers over the 10-month period. The frequency of publications on Ebola ranged from 27 in March 2014, but increased to 95 April. Coverage dropped to only 15 in June, but began to rise sharply in August (227), reaching its peak in October (345). News reports frequency paralleled the incidence pattern of the disease. Major themes included the state of the epidemic, health care, psychosocial issues, international aid, political response, prevention, and local support. Overall political response to Ebola and the impact of Ebola on health workers received the most attention. In the early days common themes were border security and requests for aid. At the peak key themes were health worker problems and political responses. A review of the national press during a crisis like Ebola provides a valuable overview of the response of the different players ranging from health services and NGOs to international partners and government. It reflects political will and conflicts and can help a central operations team better coordinate resources and responses of partners.

1182

PRECIOUS....LIFESAVING, BUT NOT WITHOUT PROBLEMS; A MIXED-METHODS STUDY EXAMINING BARRIERS AND FACILITATORS TO INFECTION PREVENTION AND CONTROL IN HEALTH FACILITIES DURING THE EBOLA VIRUS DISEASE EPIDEMIC IN SIERRA LEONE

Lara Ho[1], **Ruwan Ratnayake**[1], Hannah Brown[2], Rashid Ansumana[3], Laura Miller[4], Matthias Borchert[5], Thomas Kratz[5], Foday Sahr[6], Shannon A. McMahon[7]

[1]International Rescue Committee, New York, NY, United States, [2]Durham University, Durham, United Kingdom, [3]Mercy Hospital Research Laboratory, Bo, Sierra Leone, [4]International Rescue Committee, Freetown, Sierra Leone, [5]Charité – Universitätsmedizin, Berlin, Germany, [6]University of Sierra Leone, Freetown, Sierra Leone, [7]Independent Consultant, Berlin, Germany

During the Ebola virus disease (EVD) epidemic in Sierra Leone, health care workers (HCW) were frequently infected due to poor infection prevention and control (IPC). IPC was initially prioritized in Ebola treatment units (ETUs) though cases continued to present to primary health facilities. By December 2014, 64% of HCW infections had occurred outside of ETUs. Following a national scale-up of IPC in primary health facilities, we investigated gaps in IPC uptake. We conducted a mixed-methods study in eight facilities in Bo and Kenema Districts. Interviews with HCWs and focus groups with community members explored attitudes and experiences with IPC. Workshops for HCWs and health authorities were conducted to examine preliminary findings and develop IPC improvement plans. Quantitative measures of knowledge, attitudes and practice, including a survey and structured observations of HCWs, were administered before and after the workshops. Community members and HCWs described a similar series of emotions relating to EVD: from incredulity and disbelief to fear and sadness. HCWs described IPC practices as "precious" and "life-saving," but personal protective equipment (PPE) as uncomfortable and inducing fear, panic and "bad scenes" among patients. Endline measures of acceptance of glove use with patients (90.2%), PPE use with family members (87.8%) and HCWs (70.7%), and self-efficacy in screening (90.2%) were high. Structured observations showed consistent gaps in practice. Gloves and PPE items were inappropriately reused between screenings and multiple HCWs were present in screening areas. Screening behaviors, including standing the correct distance [RR 1.1, 95% CI 1.0-1.2] and facing patients from the side [RR 2.5, 95% CI 1.6-3.7], improved. Although PPE is available and attitudes are favorable, critical practice gaps merit consideration. HCWs may make informed judgments about IPC by valuing highly self-protection but valuing less inter-patient transmission. They may lack a sense of urgency given that fewer patients screen positive. As EVD wanes in Sierra Leone, IPC in routine practice requires refinement and reinforcement.

1183

THE MOBILE EBOLA LABORATORY EXPERIENCE: PERSPECTIVES ON FUTURE DISEASE SURVEILLANCE AND RESPONSE IN SIERRA LEONE

Sharon E. Altmann[1], Paul D. Stamper[1], Joanne M. Horn[1], David P. Roberts[2], Gary Carter[3], Jeanette M. Coffin[4], Robert E. Hegarty[3], Joseph A. Bogan[4]

[1]MRIGlobal, Frederick, MD, United States, [2]MRIGlobal, Palm Bay, FL, United States, [3]MRIGlobal, Kansas City, MO, United States, [4]MRIGlobal, Rockville, MD, United States

As part of the global Ebola response effort in West Africa, MRIGlobal deployed a DTRA-funded mobile laboratory to the Moyamba District of Sierra Leone in late December, 2014. Operating in association with the Ebola Treatment Center (ETC) managed by Médicos del Mundo España and Solidarités International in the village of Moyamba, the Moyamba Ebola Diagnostic Center (MEDaC) processed clinical samples from the ETC and the local government-run hospital, and buccal swabs collected by burial teams throughout the district as part of corpse disposal procedures. As the global response effort increasingly focuses on the outbreak's end, questions regarding the transition of laboratory capabilities to future disease surveillance and response efforts are being raised. Based on our lessons learned on the ground in Sierra Leone, we have identified challenges that should be considered for laboratory sustainment and capacity building in-country. Discussion of the future must include impending challenges related to maintaining the laboratories themselves, such as operating costs, utilities, material availability and replacement, and staffing, as well as challenges related more directly to laboratory operations, including laboratory location, laboratory diagnostic capabilities, in-country communications, and sample logistics.

1184

REFERRAL FROM COMMUNITY HEALTH WORKERS: EVIDENCE FROM CLUSTER RANDOMIZED TRIALS OF MRDTS IN TWO AREAS OF HIGH AND LOW MALARIA TRANSMISSION IN UGANDA

Sham Lal[1], Richard Ndyomugyenyi[2], Kristian S. Hansen[1], Pascal Magnussen[1], Siân E. Clarke[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Ministry of Health, Kampala, Uganda

Integrated community case management (iCCM) is being scaled up in Sub-Saharan Africa to increase access to prompt and effective treatment. The global research agenda on iCCM has prioritised the need for evidence on the referral processes from community health workers (CHWs). We evaluated the impact of training in community case management of malaria and referral [with and without malaria rapid diagnostic tests (mRDTs)] on referral practices by CHWs and caretaker compliance to CHW's referral advice, as part of a cluster randomised trial in which villages were randomised to either mRDT or presumptive diagnosis (control) arms. CHWs in both arms were trained how to prescribe ACTs and recognise illnesses requiring referral to a health centre. Data from CHWs' treatment registers were linked to health centre records and analysed using logistic regression. Over 18 months CHWs in the high transmission area saw 18,497 children. Compared to control arm, CHWs using mRDTs referred more children (35% vs. 1% control) and referral of mRDT negative children was higher (61% vs. 3% mRDT positive). CHWs only referred 60% of children that met the eligibility criteria for referral, and were less likely to refer children at the weekend or during the rainy season. There was no difference with distance to the nearest health centre. Only 10% of all referred children complied with CHW's referral advice. Compliance with referral advice was higher amongst children who had received an mRDT test (odds ratio (OR) 8.0, 95% confidence interval (CI) 1.6-40.8); and was lower during the rainy season (OR 0.6, 95%CI 0.4-0.8); weekend (OR 0.6, 95%CI 0.4-0.8) and as distance to the health centre increased (OR 0.7, 95%CI 0.5-0.9). In conclusion, mRDT testing was associated with both increased referral making by CHWs and with increased caretaker compliance, compared to a presumptive malaria diagnosis. Independent factors that negatively affected CHW's decision to refer and caretaker's decision to comply included age, day and season of consultation and distance to the health centre. Data on referral in the 3651 children consulting CHWs in the low transmission trial will also be presented.

1185

A SYSTEMATIC REVIEW ON THE EFFECTIVENESS OF STRATEGIES TO IMPROVE HEALTH WORKER PERFORMANCE IN LOW- AND MIDDLE-INCOME COUNTRIES: PRELIMINARY RESULTS ON HEALTH OUTCOMES

Samantha Rowe[1], Alexander K. Rowe[1], David H. Peters[2], Kathleen A. Holloway[3], John Chalker[4], Dennis Ross-Degnan[5]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]World Health Organization Southeast Asia Regional Office, New Delhi, India, [4]Management Sciences for Health, Yealmpton, Devon, United Kingdom, [5]Harvard Medical School, Harvard Pilgrim Health Care Institute, Boston, MA, United States

Health workers (HWs) play essential roles in delivering health care. In low- and middle-income countries (LMICs), HW performance is often inadequate. To characterize the effectiveness of strategies to improve HW performance in LMICs, we conducted a systematic review of 15 electronic databases, 30 document inventories of international organizations, and bibliographies of 510 articles. We included studies meeting accepted criteria for methodological adequacy (e.g., trials with adequate comparison groups) of any strategy on any health topic in any language, published or not. After screening, data from relevant reports were double-abstracted and entered into a database. This analysis focuses on studies that measured health outcomes (morbidity and mortality rates). Effect sizes were calculated as percent change over time in the intervention group minus percent change over time among controls. We screened >105,000 citations, 822 reports met inclusion criteria, and 63 studies measured health outcomes as a rate (29 on morbidity only, 27 on mortality only, and 7 with both). Many intervention strategies have been tested, usually with multiple intervention components. However, most strategies were tested by only one study. The median effect size (MES) across all studies was an improvement of 10 percentage-points (%-points) (interquartile range [IQR]: 0, 40). We examined strategies tested by at least 3 comparisons between an intervention arm and control arm for better generalizability. Among 45 studies focused on facility-based HWs, the strategy with the greatest health impact was HW training + group problem solving (MES = 31 %-points across 5 comparisons, IQR: 5, 67). Among 18 studies focused predominantly on lay HWs, the strategy with the greatest health impact was patient or community education + HW training (MES = 53 %-points across 18 comparisons, IQR: 6, 64). Contextual and methodological heterogeneity made comparisons difficult. Results from this review, which will be finalized by mid-2015, should inform decision-making on how best to improve performance of both facility-based and lay HWs and health outcomes in LMICs.

1186

ENSURING HEALTHCARE DELIVERY TO NOMADS: ENUMERATION OF SETTLEMENTS AND MONITORING FOR POLIO VACCINATION CAMPAIGNS. SEPTEMBER 2012-MARCH 2015. MARU, ZAMFARA STATE- NIGERIA

Aishatu Sadiq[1], Chima Ohuabunwo[2], Patrick Nguku[1], Gabriele Poggensee[1]

[1]Nigeria Field Epidemiology and Laboratory Training Programme, Abuja, Nigeria, [2]National Stop Transmission of Polio Programme, Abuja, Nigeria

Nigeria maintains wild polio virus transmission. States in the north of the country are the main source of polio infection for other regions and neighboring countries. Nomadic communities common in the north are completely missed or partially covered during immunization plus days (IPDs) due to frequent mobility and remoteness of settlements. Most cases of wild polio virus (WPV) identified in 2012 were among nomadic children. Existing local government and ward micro planning was inadequate to identify and reach nomads. We revised ward micro plans, conducted a census of nomadic populations and subsequently monitored IPDs.Secondary data abstractions of existing ward micro plans and key informant interviews with traditional leaders were conducted. Indigenous nomadic guides and data collectors were trained in the use of GPS devices and data entry tools. Missed children, unlisted settlements and unreported acute flaccid paralysis (AFP) cases were identified.14 teams dispatched and supervised to 10 wards gathered baseline data on nomadic settlements, assessed vaccination coverage, under-five population and obtained GPS co-ordinates. Data were entered and analyzed with Epi-info software. out of 283 nomadic settlements 172(60.8%) were listed in the micro plan, 111(39.2%) unlisted settlements were identified. 63 (22%) of total settlements had never been visited by vaccination teams, 47(17%) of settlements were missed during the previous IPDs. 1 case of unreported acute flaccid paralysis (AFP) was identified. The total under-five population was 1272, 525(41.3%) were recorded in the micro plan. Among under-fives in unlisted settlements 345 (46.2%) were never vaccinated. During monitoring of subsequent IPDs 747(58.7%) under-fives in enumerated unlisted settlements were vaccinated by special teams. Ward level micro plans were adequately updated.Special nomadic teams providing added personnel are essential to ensuring effective vaccination coverage of nomadic communities.Partnership between traditional rulers, religious leaders and immunization teams established and maintained ensured success.

TARGETING ANTIMALARIAL SUBSIDIES TO CONFIRMED CASES IN THE RETAIL SECTOR - TESTING A DIAGNOSIS-DEPENDENT VOUCHER SCHEME IN WESTERN KENYA

Wendy Prudhomme O'Meara[1], Jeremiah Laktabai[2], Manoj Mohanan[1], Elizabeth Turner[1], Elisa Maffioli[1], Alyssa Platt[1], Adriane Lesser[1], Diana Menya[2]

[1]Duke University, Durham, NC, United States, [2]Moi University, Eldoret, Kenya

In an era of emerging resistance to artemisinin, diagnosis of malaria infection before treatment with ACTs is critical and has been recommended by the WHO since 2010. Significant improvements in malaria testing and ACT targeting have been reported in the formal health sector of several countries. However, a large proportion of suspected malaria patients purchase medicines over the counter in the informal retail sector. These patients generally do not have a diagnostic test and targeting of ACTs to true malaria cases is poor. We designed a randomized experiment to test the effect of community-based malaria testing coupled with a diagnosis-dependent voucher on testing and treatment decisions of participants. Individuals experiencing an acute malaria-like illness were randomized to one of four groups; 1) free malaria testing, 2) free malaria testing plus an ACT voucher if the test is positive, 3) malaria testing at a cost of 0.45 USD, 4) malaria testing for 0.45 USD plus an ACT voucher for a positive test. Participants who chose to be tested visited their local CHW for a malaria RDT. The voucher was provided to patients with a positive test in groups 2&4 and could be redeemed at a drug retailer for a discount of 0.50 USD towards a quality-assured ACT. The study was designed to measure whether a diagnosis-dependent voucher created an incentive to be tested before purchasing a drug. We will report the main effect of the conditional voucher on uptake of testing and estimate whether the effect is attenuated by charging a fee for testing. Preliminary results from the first 320 of 500 enrolled show that across all groups 60% of participants were tested for malaria. 65% of positive participants bought AL compared to only 16.5% of negative and 21% of untested participants. We will describe treatment choices for RDT-negative clients and RDT-positive clients in all four groups in order to understand whether adherence to the test results was influenced by the voucher or by the cost of the RDT. This approach could target retail sector antimalarial subsidies to individuals with confirmed infection, thus enhancing the sustainability of government and donor sponsored subsidies.

1188

IMPROVING THE EXCHANGE OF INFORMATION OF CHWS AND HEALTH WORKERS IN BENIN THROUGH MHEALTH INITIATIVES

Lola Gandaho[1], Fortune Dagnon[1], Gilbert Andriandrasana[1], Jane Fieldhouse[2], Ramine Bahrambegi[2], Pablo Aguilar[2], Joseph Carter[2]

[1]ARM3/MCDI, Cotonou, Benin, [2]Medical Care Development International, Silver Spring, MD, United States

Medical Care Development International (MCDI), through the United States Agency for International Development/PMI-funded ARM3 project, implemented an mHealth initiative utilizing Dimagi's CommCare platform to facilitate the exchange of real-time health information between community and facility-level health workers in two health zones (HZ) in northern Benin. Over 12 months in 2014, 140 community and facility health workers used Android-enabled smartphones to report data electronically (replacing traditional paper-based forms). The reporting information included referrals for malaria, diarrhea, and pneumonia cases in children <5; counter-referrals; and drug stock outs. MCDI conducted an assessment in Nov. 2014 to identify lessons learned, best practices, and assess the feasibility of scale up to other HZs. A cross-sectional study using quantitative/qualitative metrics and an LQAS sampling method was conducted from a sample of 38 CHWs, 10 health facility chiefs, and 2 statisticians and completeness was assessed through a review of data sent by CHWs to the CommCare HQ database. 92% (35/38) of CHWs felt the electronic reporting system was useful in their daily work and 98% of all users preferred electronic to paper reporting. 84% of CHWs explained the usefulness of the system as allowing for real time data exchange, improving patient referral, and enhancing monitoring of CHW activities. The monthly average of completed reports submitted was 18% (Tchaourou) and 32% (Bassila). Reporting rates peaked when users had training/retraining on the "Case Sharing" feature (53% in Tchaourou and 60% in Bassila). Low reporting rates were explained by various technical challenges, including internet outages, malfunctioning solar chargers, and interruptions in phone credit allocation (due to strikes by health workers). Findings from the pilot show that leveraging mHealth initiatives may be an effective way to improve reporting and the exchange of information between CHWs and health facility workers. However, regular supervisory visits and refresher trainings are required to enhance the CHW motivation to complete reports and technical challenges need to be considered before scale up.

1189

ADHERENCE TO ANTIMALARIALS AND ANTIBIOTICS PURCHASED AT PRIVATE SECTOR DRUG SHOPS IN EASTERN UGANDA

Phyllis Awor

Makerere University, Kampala, Uganda

Little is known about adherence to medication purchased in the private sector in low income countries. There is particularly no evidence on adherence to antibiotics purchased for children under-5-years of age from private sector drug shops in these settings. Low adherence to first line medication can lead to microbial resistance, higher expenditure on second or third line drugs and increased morbidity. This study was undertaken to determine the level of adherence to anti-malaria drugs (Artemisinin Combination Therapy – ACTs) and antibiotics (amoxicillin) purchased for children less than 5 years of age from drug shops in Eastern Uganda. Twenty drug shop were randomly selected from all registered drug shop (N=44) in one district in Eastern Uganda. Sample size was estimated for cross sectional studies based on 95% CI, 5% error margin and 10% non-response. The outcome was adherence to drugs bought at the drug shop, measured using both pill count and caregiver reports on day 4 for ACTs and day 6 for Amoxicillin. Patients were classified as non-adherent if they have any leftover tablet(s) in the blister pack. All drugs sold were pre-packaged, age-specific, single dose, and sold in blister packets with pictures demonstrating how and when the medication should be taken. The study was conducted between in May and June 2012. A total of 499 children were recruited into the study. Adherence to ACTs was assessed in 259 children and adherence to Amoxicillin was assessed in 240 children. 85% of the children still had the blister packet that was dispensed with the medication and showed this to the data collectors. Adherence to both ACTs and amoxicillin was similarly low, 54% and 53% respectively. The main reasons for non-adherence were improvement in symptoms of the child (38%) and caretaker forgetfulness (35%). Predictors of non-adherence will be presented. In conclusion, we found low adherence to ACTs and amoxicillin purchased at drug shops for children under-5 years of age. Community awareness on importance of completing doses by children is recommended. Further, drug sellers dispensing drug should emphasize completion of doses to caretakers of children.

1190

HEALTH SYSTEM BARRIERS TO THE UPTAKE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY IN MALI

Namratha Rao, Meredith Klein, Emily Hurley, Steven A. Harvey

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Auxiliary midwives and community health volunteers provide most antenatal care (ANC) to women in rural Mali. The country recommends at least three doses of sulfadoxine-pyrimethamine (SP) during pregnancy as intermittent preventive treatment of malaria (IPTp). Nevertheless, only 20% of pregnant women receive at least two doses of SP. This study aimed to identify health system barriers to adequate IPTp uptake among pregnant women in the Sikasso and Koulikoro regions of Mali. We conducted in-depth interviews and focus groups with pregnant women, members of the community health associations, community health workers and community health volunteers. We also conducted key informant interviews and structured observations of antenatal care (ANC) visits at health clinics. Our results show four major facility-level barriers to SP uptake: i) inadequate community health worker training, ii) stock-outs of SP iii) poor counselling by health workers and iv) failure to administer SP as directly observed therapy (DOT). The management cited poor training of health care workers as a principal barrier. Stock outs are reportedly not a major issue, but when they occur, women are referred to private pharmacies which charge for SP. Cost is a major deterrent to SP acquisition. The use and distribution of SP was compared with that of the long-lasting insecticidal nets (LLINs) in the same study population. There is a lower demand for and less knowledge about SP use compared to that of LLINs. Pregnant women have incorrect or low knowledge about SP, pointing to inadequate counseling by healthcare workers. Health workers also allow women to take SP home rather than adhering to DOT guidelines. Our preliminary analysis suggest that interventions targeting training of health care workers on SP and improved counselling practices will improve IPTp uptake. We realize that an increase in the proportion of women attending two or more ANC visits is imperative to increase IPTp uptake. Further analysis of how these facility-level barriers inform the broader health system in Mali is needed.

1191

THE MALPIGHIAN TUBULE TRANSCRIPTOME OF THE ASIAN TIGER MOSQUITO, *AEDES ALBOPICTUS*: NEW INSIGHTS INTO BLOOD MEAL PROCESSING BY MOSQUITO 'KIDNEYS'

Peter M. Piermarini, Bryan J. Cassone, Carlos J. Esquivel

The Ohio State University, Wooster, OH, United States

The renal (Malpighian) tubules of mosquitoes play critical roles in salt and water balance. For example, in adult females, which ingest the equivalent of their body mass in blood when feeding on vertebrates, , the Malpighian tubules mediate a pronounced diuresis that begins while still on the host and lasts for 1-2 h after feeding to excrete the excess salt and water of the

ingested blood. However, the physiological roles of the Malpighian tubules during the chronic processing of blood meals (3-24 h after ingestion)_ when the ingested blood cells are digested and metabolized_are not well known. Here we attempt to fill this gap of knowledge by using RNA-Seq to characterize the transcriptome of Malpighian tubules in adult female Asian tiger mosquitoes (***Aedes albopictus***) under non-blood fed and blood fed (3-24 h after ingestion) conditions. The Asian tiger mosquito is one of the most invasive mosquito species in the world and a vector of important arboviruses, such dengue and chikungunya fevers. We found that the transcriptome of Malpighian tubules in non-blood fed mosquitoes is enriched with transcripts encoding proteins associated with 1) the active transport of ions and water, and 2) redox/detoxification mechanisms. After blood feeding, we find a shift in the transcriptome, where 1) transcripts encoding proteins associated with redox and detoxification mechanisms are up-regulated, such as glutathione S-transferases (GSTs), thioredoxin, xanthine dehydrogenase, and ABC transporters; and 2) transcripts encoding proteins associated with the active transport of ions and water are down-regulated, such as subunits of the V-type H^+-ATPase, aquaporins, and ion channels/transporters. Assays to measure urine excretory capacity in mosquitoes, GST activity in Malpighian tubules, and uric acid content in Malpighian tubules confirm that the changes in transcript expression after a blood meal manifest as functional changes in the mosquito and Malpighian tubules. Our results indicate that the Malpighian tubules play a previously unrecognized role in the chronic processing of blood meals by mosquitoes.

GENOMIC ISLANDS, REPRODUCTIVE ISOLATION AND ASYMMETRIC INTROGRESSION BETWEEN *ANOPHELES COLUZZII* AND *AN. GAMBIAE*

Abdoulaye Niang[1], Simon P. Sawadogo[1], Patric Stéphane Epopa[1], Hamidou Maiga[1], Lassana Konaté[2], Roch K. Dabiré[1], Abdoulaye Diabaté[1], Frederic Tripet[3]

[1]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [2]Laboratoire d'Ecologie Vectorielle et Parasitaire, Département de Biologie Animale de l'Université Cheikh Anta Diop, Dakar, Senegal, [3]Keele University, Keele Staffordshire, United Kingdom

Within the ***Anopheles gambiae*** complex, the sibling species ***An. coluzzii*** and ***An. gambiae*** s.s. are major vectors of malaria thought to be undergoing a process of sympatric speciation with gene flow. In the absence of intrinsic post-zygotic isolation between the two cryptic taxa, speciation is thought possible through the association of assortative mating and ecological adaptation genes with genomic regions protected from recombination. These regions of genetic divergence are located within the pericentric regions of chromosomes and known as speciation islands. Spatial swarm segregation has been shown to play a major part in assortative mating in sympatric populations of the two species. Given its role in the process of speciation, the genetic determinants of spatial segregation are expected to be associated with one or several of the known islands of speciation described in the pericentric regions of the X, 2L and 3L chromosomes. In order to demonstrate the association between spatial swarm segregation and speciation islands, we sampled 2063 male and 266 female ***An. coluzzii*** and ***An. gambiae*** individuals from swarms in an area of western Burkina Faso where hybridization is known to occur. Individuals were genotyped at 16 SNPs located within the X, 2L, 3L and assigned to either species based on a majority rule. Despite evidence from extensive introgression between the two sibling species, the overall majority of swarms where still found to be monospecific. Whether non-hybrid, first generation, or backcrossed individuals male and females were associate with ***An. coluzzii*** or ***An. gambiae*** swarms was strictly determined by their genotype at the X chromosome island of speciation. The association between swarm type and the 3L chromosome island was significantly weaker than that with the X island. The association with the 2L island was broken down by the recent adaptive introgression of pesticide resistance loci located within this genomic region. These findings are important for our understanding of the ecological processes and genomic structures associated with the process of sympatric speciation in this important vector species complex.

1193

APPLICATIONS FROM A FAIRE-SEQ OPEN CHROMATIN PROFILING STUDY IN *AEDES AEGYPTI*

Molly Duman Scheel[1], Joseph Sarro[2], Susanta K. Behura[2], Ping Li[1], Keshava Mysore[1], David W. Severson[2], Scott J. Emrich[2]

[1]Indiana University School of Medicine, South Bend, IN, United States, [2]University of Notre Dame, Notre Dame, IN, United States

Despite substantial progress in mosquito genomic research, few cis-regulatory elements (CREs), DNA sequences that control gene expression, have been identified in vector mosquitoes. The resulting deficiency, a significant gap in the basic knowledge of mosquito genetics, has resulted in a lack of drivers to manipulate gene expression in selected tissues at specific times. Such tools, which have revolutionized research in genetic model organisms, would benefit all avenues of mosquito research. FAIRE-seq, formaldehyde-assisted isolation of regulatory elements paired with DNA sequencing, is emerging as a powerful new high-throughput tool for global CRE discovery. During the FAIRE process, chromatin is cross-linked with formaldehyde, sheared, and then phenol-chloroform extracted, allowing for preferential recovery of open chromatin DNA fragments, an evolutionarily conserved indicator of regulatory activity. We recently performed a FAIRE-seq study in the dengue vector mosquito ***Aedes aegypti***. These efforts resulted in identification of thousands of CREs throughout the ***A. aegypti*** genome. We will present results from a high throughput screen in transgenic insects that examines the ability of these elements to promote tissue-specific gene expression ***in vivo***. In addition to validating the FAIRE-seq data set, the screen was designed to select for elements that will drive gene expression in tissues of vector importance in multiple vector insect species. The FAIRE-seq data set has facilitated our analysis of gene regulatory networks in the developing mosquito nervous system. Genome-wide CRE identification has also allowed us to explore how DNA polymorphisms in regulatory regions have contributed to the changes in gene expression observed in dengue susceptible and refractory strains. This investigation, which is generating a toolkit of gene drivers for mosquito research, facilitating the study of mosquito gene regulatory networks, and promoting an understanding of how enhancer evolution contributes to pathogen susceptibility, will promote the use of FAIRE-seq in additional vector mosquito species.

1194

COMPLEX AND EVOLVING INSECTICIDE RESISTANCE SPANS SPECIES BARRIERS IN *ANOPHELES COLUZZII*

Bradley J. Main

University of California Davis, Davis, CA, United States

In 2006, the insecticide resistance allele (kdr) introgressed from ***Anopheles gambiae*** s.s. into ***A. coluzzii*** in parts of West Africa, coincident with the start of an insecticide treated bed net campaign. Here, we demonstrate that no other major genomic regions were introgressed, but we describe a selective sweep on putative cis-regulatory variation in the P450 insecticide resistance candidate gene CYP9K1. The modern ***A. coluzzii*** with kdr and a nearly fixed haplotype at CYP9K1 (cyp-I) is highly resistant to permethrin compared to ***A. gambiae*** (KD50=54min(N=86) vs 21min(N=55)) and has increased in relative frequency in the population from ~65% prior to 2006 to 88% in 2014 (N=179). Interestingly, preliminary bioassay results suggest that cyp-I is not more resistant than another ***A. coluzzii*** haplotype (cyp-II) in the absence of kdr (KD50=32min(N=40) vs 38min(N=7), respectively), potentially indicative of an allele-specific interaction between kdr and cyp-I. To functionally validate putative regulatory mutations associated with the highly selected cyp-I haplotype in ***A. coluzzii*** we have estimated allele-specific expression in F1 hybrids between ***A. coluzzii*** and ***A. gambaie***

(cyp-lll) individuals in the context of insecticide exposure. We have also explored the role of cis-regulatory variation in species divergence between A. gambaie and ***A. coluzzii***.

1195

BUBBLY GENOMES OF POLYMORPHIC VECTOR SPECIES: ASSEMBLY QUALITY AND PRESERVED VARIATION

R. Rebecca Love[1], Neil I. Weisenfeld[2], David B. Jaffe[2], Nora J. Besansky[1], Daniel E. Neafsey[2]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, United States

The existence of a reference genome assembly for a vector species facilitates analysis of the physiology, behavior, and population genomics of that species, all of which are critical to vector control efforts. However, creating a reference is often a technically challenging process requiring costly inputs; the high levels of polymorphism found in many insect vectors can complicate assembly even more. New assembly algorithms offer a chance for relatively simple and low-cost genome assembly, but have not been stringently evaluated in highly polymorphic insect vectors. Using 250 bp paired-end reads sequenced from a single library of the major malaria vector ***Anopheles arabiensis***, we show that DISCOVAR ***de novo*** can generate an assembly with contig N50 of 20,645, exceeding the contiguity of recently released assemblies for some closely related vectors. This DISCOVAR assembly of ***An. arabiensis*** contains nearly all the sequence present in an assembly for the same species made from multiple libraries of three insert sizes. The new assembly also recovers a set of universal benchmarking genes with completeness approaching that of the existing assembly, and with better completeness than an existing transcriptome assembly, which represents one of the most common low-cost alternatives to whole genome assembly. Additionally, DISCOVAR ***de novo*** preserves polymorphism information often lost during the assembly process. Using this information, we find that more than a third of the genome comprises polymorphic haplotypes in our sample, despite inbreeding by isofemale founding to reduce heterozygosity. We categorize the observed variants, and approximate their physical location based on alignment to the PEST reference genome for ***An. gambiae***, a major malaria vector closely related to ***An. arabiensis.*** We also analyze haplotype information present in the output. We discuss the potential functional consequences of these genomic variants, both for their direct relevance to a major malaria vector and as a demonstration of the kinds of information that could be gleaned for other vector species.

1196

WEST AFRICAN *AEDES AEGYPTI FORMOSUS* COLLECTIONS SHOW DIFFERENTIATION AT SEX CHROMOSOMES

Corey L. Campbell[1], Laura B. Dickson[2], Saul Lozano-Fuentes[1], Punita Juneja[3], Francis M. Jiggins[4], William C. Black, IV[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Colorado State University, Institut Pasteur – Centre National de la Recherche, France, [3]Department of Genetics, University of Cambridge, Cambridge, United Kingdom, [4]University of Cambridge, Cambridge, United Kingdom

Sex in the yellow fever mosquito, ***Aedes aegypti***, is known to be controlled by an autosomal sex determination locus (SDL) on chromosome 1. Attempts to construct F_1 intercross families between West African and New World ***Ae. aegypti*** parents produced post-zygotic reproductive isolation patterns. Additional crosses indicated patterns consistent with Haldane's rule wherein families arising from male hybrids had significantly lower egg to pupal survival as compared to offspring of female hybrids. Because Haldane's rule applies to species with heterogametic sex chromosomes, we further examined the linkage of sex and ***white-eye*** which are known to be 14 cM apart on chromosome 1. Ninety-four families from four West African collections and 11 families from a Mexican collection were tested. ***White-eye*** and sex co-segregated at 14 cM in Mexico families but segregated independently of sex in 16-60% of West Africa families. Genetic diversity on the three autosomes was compared using high throughput sequencing (HTS) of exon-enriched libraries from pooled males or females from a rural Thailand collection and a sylvatic collection from southeastern Senegal (PK10). Genetic differences (F_{ST}) between marker frequencies in males and females were uniform across all chromosomes in the Thailand collection but were significantly different among sexes in PK10, with the largest differences occurring on chromosome 1; these differences were uniformly distributed across chromosome 1. These observations are consistent with the presence of two subspecies of ***Ae. aegypti*** in West Africa; one with and the other without heterogametic sex chromosomes.

1197

ANOPHELES GAMBIAE PREFOLDIN AS A *PLASMODIUM* AGONIST INTERACTING WITH LRRD7

Seokyoung Kang, Simone L. Sandiford, Yuemei Dong, Andrew Pike, Nathan J. Dennison, George Dimopoulos

Johns Hopkins University, Baltimore, MD, United States

In the malaria vector ***Anopheles***, the IMD pathway is a major player in regulating the mosquito's innate immune defense against ***Plasmodium falciparum***. IMD pathway exerts its anti ***P. falciparum*** response through effector molecules. Previously, we and others have identified LRRD7 (also known as APL2 or LRIM17) is involved in the defense against both human and rodent ***Plasmodium*** parasites. In order to elucidate the mechanisms of anti-malaria function of LRRD7, we used yeast two-hybrid system to fish out the putative interaction partners of LRRD7 and identified prefoldin subunit 6. Subsequently, RNAi-mediated gene silencing assays showed that depletion of prefoldin resulted in a significant decrease in the number of oocysts per midgut, suggesting prefoldin as a ***Plasmodium*** agonist that can interact with LRRD7. The role of prefoldin as a ***Plasmodium*** agonist suggested that it could serve as a target for transmission blocking antibodies. We fed mosquitoes on ***P. falciparum*** gametocyte cultures containing different concentrations of the purified prefoldin antibody, and determined infection intensity. These experiments showed a dosage-dependent transmission-blocking activity, suggesting prefoldin as a putative blocking target to inhibit ***Plasmodium***. Prefoldin, a heterohexameric chaperone, is associated with other molecules to promote proper protein folding. Here we describe the characterization of prefoldin and its potential function as a ***Plasmodium*** agonist that interact with, and presumably inhibit, ***Plasmodium*** antagonists such as LRRD7, or Tep1 in the anti-***Plasmodium*** protein complex. We also discuss ***Plasmodium*** transmission-blocking strategies in mosquitoes using small molecules that inhibit prefoldin.

1198

HIGH RATES OF ENTERIC FEVER DIAGNOSIS AND LOW BURDEN OF CULTURE-CONFIRMED DISEASE IN RURAL NEPAL

Jason R. Andrews[1], Krista Vaidya[2], Surendra K. Madhup[2], Biraj Karmacharya[2], Bibush Amatya[2], Shawn Wen[3], Shiva R. Adhikari[4], Elizabeth Hohmann[5], Amy B. Smith[6], Rajendra Koju[2], Edward T. Ryan[5], Isaac I. Bogoch[7]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Dhulikhel Hospital, Dhulikhel, Nepal, [3]Massachusetts Institute of Technology, Cambridge, MA, United States, [4]Tribhuvan University, Kathmandu, Nepal, [5]Massachusetts General Hospital, Boston, MA, United States, [6]Massachusetts Institute of Technology, Boston, MA, United States, [7]University Health Network, Toronto, ON, Canada

Kathmandu has been described as the "enteric fever capital of the world", but there are few data on the burden of enteric fever in rural areas of Nepal. We reviewed data on reported enteric fever cases from the Health Management Information System from 1995-2014. We performed a prospective study at four facilities (3 rural, 1 peri-urban), recruiting patients >1 year of age presenting for care who reported fever for >3 days. We

administered a structured questionnaire and obtained blood for culture. Annual enteric fever cases reported in the public sector increased from 85,137 cases in 1995-1996 to 499,761 cases in 2013-2014 (587% increase), when 2.0% of the country's population was diagnosed with enteric fever in the formal sector alone, and enteric fever was the most common diagnosis cited for hospitalization. Total outpatient visits rose significantly during this period, but enteric fever cases rose 40% more. From July 2013-March, 2015, we enrolled 1,776 patients with acute febrile illnesses; enteric fever was the most common clinical diagnosis at all sites. Overall, 1.9% (34) of participants had typhoidal ***Salmonella*** recovered from blood (rural: 0.4%; peri-urban: 2.4%). All but one of the ***Salmonella*** isolates had intermediate susceptibility or resistance to Ciprofloxacin. Enteric fever is commonly diagnosed in rural Nepal, with annual diagnosis rates that exceed incidence rates reported from high burden, urban settings. By contrast, the prevalence of culture-confirmed typhoid among febrile patients at rural sites was <1%. Even assuming a low sensitivity of blood cultures of 40%, our results suggest that the vast majority of individuals in rural Nepal who are clinically diagnosed and treated for enteric fever do not actually have that illness. Additional analyses of collected samples is on-going. Geographically representative laboratory surveillance for typhoid and other acute febrile illness are needed to inform antibiotic use in rural areas.

TYPHOID FEVER IN YOUNG CHILDREN IN BANGLADESH: CLINICAL FINDINGS, ANTIBIOTIC SUSCEPTIBILITY PATTERN AND IMMUNE RESPONSES

Farhana Khanam[1], Abu Sayeed[1], Feroza Kaneez Choudhury[1], Edward T. Ryan[2], Firdausi Qadri[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, MA, United States

Typhoid fever caused by Salmonella enterica serotype Typhi (S. Typhi) is a potentially life-threatening systemic disease. High prevalence rates of typhoid fever have been reported in resource-limited regions of the world, with children under 5 years of age bearing a large burden. However, immune responses and clinical findings in children are not well defined. We describe clinical and immunological characteristics of young children with typhoid fever and antimicrobial susceptibility patterns. Previously we characterized antibody-in-lymphocyte secretion responses (TPTest) during acute typhoid fever in adults and also measured the membrane preparation (MP) IgA responses in young children at day of enrolment, and then 7-10 days and 21-28 days later. We also assessed plasma IgA, IgG and IgM responses, and T cell proliferation responses to MP antigen. We compared the responses in young children (1-5 years) with those seen in older children (6-17 years), adults (18-59 years), and age-matched healthy controls. We found that, the patients in all age cohorts had significantly higher MP-IgA responses in lymphocyte secretion at clinical presentation compared to age-matched controls, and the values fell in all groups by late convalescent stage. Similarly, plasma IgA responses in patients were elevated at presentation compared to controls, with acute and convalescent IgA and IgG responses being highest in adults. T cell proliferative responses were increased in all age cohorts by late convalescence. In all age cohorts clinical characteristics were similar, although younger children were more likely to present with loss of appetite, less likely to complain of headache compared to older cohorts, and adults were more likely to have ingested antibiotics. Multi-drug resistant strains were present in approximately 15% of each age cohort, and 97% strains had resistance to nalidixic acid. This study demonstrates that S. Typhi bacteremia is associated with comparable clinical courses, immunologic responses in various age cohorts, including in young children, and that TPTest can be used as marker of recent typhoid fever, even in young children.

1200

COMPARISON OF THE PERFORMANCE OF THE TPTEST, TYPHIDOT AND TUBEX IMMUNODIAGNOSTIC ASSAYS IN DETECTING PATIENTS WITH ENTERIC FEVER IN BANGLADESH, INCLUDING LATENT CLASS MODELING

Kamrul Islam[1], Emran Hossen[1], Md Abu Sayeed[1], Jason Andrews[2], Farhana Khanam[1], Edward T. Ryan[3], Firdausi Qadri[1]

[1]Centre for Vaccine Sciences, International Centre For Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Division of Infectious Diseases and Geographic Medicine, Stanford University School of Medicine, Stanford, CA, United States, [3]Division of Infectious Diseases, Massachusetts General Hospital, Department of Medicine, Harvard Medical School, Boston, MA, United States

Enteric fever caused by Salmonella enterica serotype Typhi (S. Typhi) and serotype Paratyphi are important public health problems in Bangladesh. Previously, we developed and evaluated a diagnostic method for typhoid and paratyphoid fever (TPTest) and found highly sensitive and specific. In this study, we compare the TPTest with Tubex and Typhidot in our setting. For analysis, we categorized 92 patients into four groups: S. Typhi bactermic patients (n=28); patients with fourfold change in Widal test from day 0 to convalescent period (n=7); patients with Widal titer ≥1:320 (n=13); patients suspected enteric fever, but with negative blood culture and Widal titer (n=44). We also tested healthy controls (n=20) and other febrile illness patients (n=15) (kala-azar and tuberculosis). Out of 28 S. Typhi bacteremic patients, 28 (100%), 21 (75%) and 18 (64%) patients were positive by TPTest, Tubex and Typhidot respectively. For the four-fold change of Widal titre, the TPTest, tubex and typhidot were positive in 7 (100%), 6 (86%), 5 (71%) respectively. For patients with Widal ≥1:320, the TPTest, Tubex and Typhidot were positive for 9 (69%), 5 (38%), 3 (23%). The TPTest method was negative for all healthy controls whereas Tubex and Typhidot were positive for 3 (15%) and 5 (25%) respectively. For other febrile illnesses, TPTest, tubex and typhidot were negative for 14 (93.3%), 14 (93.3%), and 13 (86.7%) respectively. Among 44 patients who were negative by blood culture and Widal test, but clinically diagnosed as enteric fever, 24, 09 and 15 were positive by TPTest, Tubex and Typhidot respectively. In latent class model in which sensitivity and specificity of all diagnostics were estimated simultaneously, the sensitivity of TPTest was estimated at 96.0% (95% CI: 87.1%-99.8%), Tubex was 60.2% (95% CI: 49.3%-71.2%), and Typhidot was 59.6% (95% CI: 50.1%-69.3%). Specificity was estimated at 96.6% (90.7%-99.2%) for TPTest, 89.9% (79.6%-96.8%) for Tubex, and 80.0% (67.7%-89.7%) for Typhidot. These results suggest that the TPTest is highly sensitive and specific in diagnosis of enteric fever in endemic regions like Bangladesh compared to tubex and typhidot assays.

1201

A NOVEL HUMAN MODEL OF SALMONELLA ENTERICA SEROVAR PARATYPHI A CHALLENGE IN HEALTHY ADULT VOLUNTEERS

Brian J. Angus[1], Hazel Dobinson[2], Helena Thomaides-Brears[2], Claire Jones[2], Danielle Campbell[2], Merryn Voysey[3], Simon Kerridge[2], Laura B. Martin[4], Odile Leroy[5], Flavia Dalessio[5], Andrew J. Pollard[2]

[1]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [2]Oxford Vaccine Group, Department of Paediatrics, University of Oxford and the NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom, [3]Primary Care Clinical Trials Unit, Nuffield Department of Primary Care Health Sciences; Oxford Vaccine Group, Department of Paediatrics, University of Oxford and the NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom, [4]Novartis Vaccines Institute for Global Health, Siena, Italy, [5]European Vaccine Initiative, Heidelberg, Germany

A new human paratyphoid challenge model provides an opportunity to gain insight into the immunobiology of this little studied cause of enteric

fever . A dose (de-)escalation oral challenge study with S. Paratyphi A (NVGH308 strain) was conducted in 40 healthy adult volunteers. Following ingestion of bicarbonate buffer solution to neutralise gastric acid, participants ingested either 103 (n=20) or 800 (n=20) CFU of S. Paratyphi A. Successful infection was defined by positive blood culture and/or fever ≥ 38°C for at least 12 hours. Antimicrobial treatment was commenced on diagnosis or 14 days after challenge. The 103 CFU oral challenge dose was associated with a higher attack rate (60% vs. 40%), shorter incubation period (median 6 vs. 8 days), longer duration of bacteraemia (mean, 4 vs. 3 days; range, 1-7 vs 1-6 days) and higher fever rate amongst those developing enteric fever (7/12 vs. 2/8). Fever correlated with symptoms (mean, 32 solicited symptoms per participant with fever ≥38°C vs. 8 in those who were bacteraemic without fever), with headache and general malaise most commonly reported. Preliminary serological data after challenge with the 103 CFU dose confirms that those participants who developed paratyphoid have raised IgM, IgA and IgG antibody responses against LPS by day 28 after challenge. An attack rate between 60% and 75% rate in an antigen-naïve cohort is attained at a dose of 103 CFU of S. Paratyphi A, providing a model for study of novel paratyphoid vaccines.

1202

A MAGNETO-DNA NANOPARTICLE SYSTEM FOR THE RAPID DIAGNOSIS OF ENTERIC FEVER

Richelle C. Charles[1], Kisoo Park[1], Hyun J. Chung[1], Farhana Khanam[1], Hakho Lee[1], Rasheduzzaman Rashu[2], Stephen B. Calderwood[1], Firdausi Qadri[2], Ralph Weisleder[1], Edward T. Ryan[1]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

There is currently no optimal assay for diagnosing patients with acute typhoid or paratyphoid fever. Amplification techniques that target bacterial genomic nucleic acids have been limited due to the low bacterial burden present in peripheral blood. Alternative approaches for typhoid diagnostic assays are needed. We have previously described the gene expression profile of Salmonella enterica serovars Typhi and Paratyphi A in the blood of infected humans in Bangladesh. Using this information, we designed primer pairs for S. Typhi and S. Paratyphi A genes expressed at high levels in the blood of infected humans. We selected genes that were specific for S. Typhi (staG) and S. Paratyphi A (hsdR and SPA2472), and we designed primer pairs for conserved genes specific to Salmonella spp. (sopB and sipC). To evaluate this approach, we first produced cDNA from mid-log ***in vitro*** cultures of S. Typhi, S. Paratyphi A, S. Typhimurium, and E. coli. Using asymmetric amplification, we detected target products for all 3 Salmonella serovars, but no amplification product was observed from E. coli samples. We detected amplified target cDNA using novel magneto-DNA probes and a miniaturized nuclear magnetic resonance device. The detection limit of this assay was 0.01-1.0 CFU/ml. For proof of principle, we extracted total RNA from a 500 mcl blood sample from 3 patients bacteremic with S. Typhi in Bangladesh, and we were able to detect amplified target cDNA in 3 out of 3 samples using the hand-held nuclear magnetic resonance device. Our results suggest that a magneto-DNA nanoparticle system may be a promising platform for the rapid and culture-free diagnosis of enteric fever and non-typhoidal Salmonella bacteremia.

1203

DIARRHEA ASSOCIATED WITH *SHIGELLA* IN CHILDREN UNDER FIVE YEARS AND SUSCEPTIBILITY TO ANTIMICROBIALS IN RURAL WESTERN KENYA, 2008-2012: THE GLOBAL ENTERIC MULTICENTER STUDY (GEMS)

Richard Omore[1], Ciara E. O'Reilly[2], John Williamson[3], Nygren L. Benjamin[2], Fenny Moke[1], John B. Ochieng[1], Jane Juma[1], Joseph Oundo[3], Barry Fields[3], Joel M. Montgomery[3], Michele B. Parsons[2], Tamer H. Farag[4], Karen L. Kotloff[4], James P. Nataro[5], Myron M. Levine[4], Kayla F. Laserson[3], Pekka J. Nuorti[6], Eric D. Mintz[2], Robert F. Breiman[7]

[1]Kenya Medical Research Institute-Centre for Global Health Research, Kisumu, Kenya, [2]Division of Foodborne, Waterborne and Environmental Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Global Disease Detection Division, Kenya Office of the Centers for Disease Control and Prevention, Nairobi, Kenya, [4]University of Maryland, School of Medicine, Center for Vaccine Development, Baltimore, MD, United States, [5]Department of Pediatrics, University of Virginia School of Medicine, Charlottesville, VA, United States, [6]University of Tampere School of Health Sciences, Tampere, Finland, [7]Global Health Institute, Emory University, Atlanta, GA, United States

We examined clinical features, risk factors and antimicrobial susceptibility of ***Shigella*** among children with moderate-to-severe diarrhea (MSD) in rural western Kenya using prospective, hospital-based surveillance. MSD case was defined as a child aged 0-59 months, passing ≥3 loose stools in the previous 24 hrs. with ≥1 of the following: sunken eyes, skin tenting, dysentery, IV rehydration, or hospitalization within 7 days of diarrhea onset. Bacterial pathogens identified in stool were tested against commonly used antibiotics by Kirby-Bauer disk diffusion. Characteristics of ***Shigella***- infected vs. non-infected MSD cases were compared using unconditional logistic regression. From January 2008-September 2012, 130 (7.3%) of 1,778 specimens collected from MSD cases tested positive for ***Shigella***, including 80 ***S. flexneri*** (61.5%), 24 S. sonnei (18.5%), 20 S.dysenteriae (15.4%), and 6 S. boydii (4.6%). The median age of ***Shigella***- infected vs. non-infected patients was 19.5 (IQR: 10.0-34.0) versus 12.0 (IQR: 7.0-23.0) months (P <0.0001). Compared to non-infected patients, those with ***Shigella*** were more likely to be 24-59 months old (40.8% vs. 24.6%, %) (odds ratio [OR] 2.45; 95% confidence interval [CI] 1.61-3.74]) and experience blood in stool (39.5% vs. 8.8%, ([OR 6.77, 95% CI 4.58-10.02]); they were less likely to vomit ≥ 3 times/24hrs (31.5% vs. 49.6%; OR 0.47, 95% CI 0.32-0.69). Isolates were susceptible to in decreasing order: ceftriaxone (99.2%), gentamicin (98.4%), ciprofloxacin (98.4%), chloramphenicol (56.9%) 51.2%, amoxicillin-clavulanic acid (51.2%), ampicillin (37.4%) and tetracycline (14.6%). In conclusion, ***Shigella*** was most prevalent among the older range of under-five children with MSD, and was significantly associated with bloody diarrhea; ***S. flexneri*** was the most prevalent species. Although ***Shigella*** isolates were largely susceptible to ciprofloxacin and ceftriaxone, reduced susceptibility to many of the inexpensive and commonly used antimicrobials in this setting limits therapeutic options, increasing the economic burden and risk of treatment failure for shigellosis.

1204

DEVELOPMENT OF A LIVE ATTENUATED ORAL VACCINE AGAINST SHIGELLOSIS AND TYPHOID FEVER

Yun Wu[1], B. Kim Lee Sim[1], Sumana Chakravarty[2], Minglin Li[1], Tint Tint Wai[1], Dennis J. Kopecko[1], Stephen L. Hoffman[2]

[1]Protein Potential LLC, Rockville, MD, United States, [2]Sanaria Inc, Rockville, MD, United States

There are more than 125 million cases of shigellosis globally; with an estimated ~450,000 cases in United States every year. 72% of the US cases are caused by ***Shigella sonnei***, and antibiotic-resistant ***S. sonnei***

is on the rise. Our goal is to address several significant vaccine challenges simultaneously: 1) The lack of a licensed vaccine for prevention of morbidity and mortality due to shigellosis; 2) The need for a multivalent vaccine that will simultaneously protect against multiple disease agents, and 3) The need for an easy-to-administer, child-friendly, safe, oral vaccine vector platform for administration of multiple foreign immunogens that generates long term efficacy following a rapid immunization regimen and can be distributed without the need for refrigeration. We have exploited the extensive safety record of the live, oral, attenuated ***Salmonella*** Typhi vaccine (Ty21a) by utilizing it as a vector to develop a safe, stable, easily administered combination oral vaccine that will simultaneously protect against shigellosis and typhoid fever. As a first step, we have recombineered the ***S. sonnei*** (Ss) form 1 O antigen gene cluster into the Ty21a chromosome to create Ty21a-Ss, which stably expresses ***S. sonnei*** O antigen for up to 100 generations. A fully characterized seedbank was used to immunize mice either intraperitoneally or through mucosal route. Mice immunized with Ty21a-Ss produced high levels of serum IgG antibodies against both ***S. sonnei*** (53G) and ***S.*** Typhi. In contrast, mice immunized with Ty21a only produced comparable antibodies against S. Typhi but not ***S. sonnei***. The titers against ***S. sonnei*** are higher than that from a previously published ***S. sonnei*** LPS-based vaccine that protected guinea pigs from ***S. sonnei*** infection. We are currently assessing the protective efficacy of Ty21a-Ss by a mucosal challenge with lethal ***S. sonnei*** infection. Our work provides the foundation for construction of a multivalent anti-shigellosis vaccine that will protect against more than 85% of shigellosis worldwide and against typhoid fever.

1205

RAPID REORGANIZATION OF THE PARASITE PLASMA MEMBRANE INDUCED BY NEW CLASSES OF ANTIMALARIAL DRUGS THAT DISRUPT NA+ HOMEOSTASIS

Sudipta Das[1], Suyash Bhatnagar[1], Joanne M. Morrisey[1], Isabelle Coppens[2], Akhil B Vaidya[1]

[1]Drexel University, Philadelphia, PA, United States, [2]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

An international collaborative effort has identified pyrazoleamide (PA) class of compounds with highly potent activity against malaria parasites, leading to the designation of PA21A092 as a preclinical antimalarial candidate. Our investigations suggest the PA compounds and another recently developed antimalarial, spiroindolone (KAE609), target a common vulnerable pathway. These compounds rapidly and potently disrupted Na+ homeostasis in ***Plasmodium falciparum***. We are investigating consequences of Na+ homeostasis disruptions by these compounds using a variety of approaches. Live cell imaging revealed significant increase in intraerythrocytic parasite volume within a 2 h exposure to PA and other compounds. Furthermore, exposures to several compounds with distinct chemical structures (but all with the ability to disrupt Na+ homeostasis) result in rapid parasite plasma membrane reorganization as indicated by the acquisition of saponin-sensitivity assessed as leakage of cytosolic proteins following mild saponin treatment. Experiments involving methyl-beta-cyclodextrin mediated cholesterol extraction of freed parasites suggest that the treatment with PA compounds results in rapid cholesterol incorporation into the (usually cholesterol-poor) plasma membrane of the trophozoite stages. Electron microscopy also suggests that these compounds cause a rapid reorganization of the parasite plasma membrane. These and other observations suggest that this series of compounds are prematurely initiating a cascade of events generally associated with the egress of parasites at the last phase of schizogony. We hypotheize that such changes contribute to a rapid clearance of infected RBCs from the circulation ***in vivo***

1206

THE PHENYLALANYL-TRNA SYNTHETASE IS A DRUGGABLE TARGET IN *PLASMODIUM FALCIPARUM*

Tomoyo Sakata-Kato[1], Nobutaka Kato[2], Eamon Comer[2], **Amanda K. Lukens**[2], Victoria C. Corey[3], Elizabeth A. Winzeler[3], Christina A. Scherer[2], Stuart L. Schreiber[2], Dyann F. Wirth[1]

[1]Harvard T. H. Chan School of Public Health, Boston, MA, United States, [2]The Broad Institute, Cambridge, MA, United States, [3]University of California San Diego School of Medicine, La Jolla, CA, United States

Sustained availability of efficacious drugs is essential for worldwide efforts to eradicate malaria. The emergence and spread of drug resistance to current antimalarial therapies remains a pressing concern with reports of artemisinin-based treatment failures escalating the need for novel antimalarial chemotherapies. Thus the discovery of novel druggable targets and pathways including those that are critical for multiple life stages is a major challenge for the development of next-generation therapeutics. Using an integrated chemogenomic approach combining screening efforts of a Diversity Oriented Synthesis (DOS) library, drug-resistance selection, and whole genome sequencing, we have identified the ***Plasmodium falciparum*** cytoplasmic phenylalanine-tRNA synthetase (***Pf***cPheRS) as the target of a novel antimalarial candidate, BRD3444. The DOS library aims to cover chemical space extending beyond the common confinements set by "drug-like" parameters, which is characteristic for traditional pharmaceutical libraries and limits the diversity of represented compounds. The additional structural complexity exploited by the DOS library allows us to probe novel pathways and targets in the parasite, as exemplified by BRD3444. Aminoacyl-tRNA synthetases (aaRSs) are validated targets in several microorganisms and have more recently been proposed as attractive targets for chemotherapeutic intervention in malaria. Our work identifies PheRS as a druggable target in ***Plasmodium*** and provides a path forward to next-generation antimalarials.

1207

A DOSE RANGING CLINICAL TRIAL TO EVALUATE THE PHARMACOKINETICS AND PHARMACODYNAMICS OF THE COMBINATION OF DSM265 AND OZ439 IN A *PLASMODIUM FALCIPARUM* INDUCED BLOOD STAGE MALARIA SYSTEM

James S. McCarthy[1], Paul M. Griffin[1], Silvana Sekuloski[1], Suzanne M. Elliott[2], Louise Marquart[1], Kerenaftali Klein[1], Stephan Chalon[3], Nathalie Gobeau[3], Jörg Möhrle[3]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Q-Pharm Pty Ltd, Brisbane, Australia, [3]Medicines for Malaria Venture, Geneva, Switzerland

WHO recommends that ***Plasmodium falciparum*** malaria be treated using a combination of two drugs with complementary pharmacokinetic and pharmacodynamics properties as well as targeting different biochemical pathways in the parasite to optimise cure and prevent resistance. In the past, drug and dose selection of the combination therapy has been empirical and, in general, formal dose finding was not conducted. As a consequence, therapies were not necessarily optimized, thereby risking suboptimal clinical efficacy, selection of resistance, unexpected toxicities, promotion of gametocytemia, and un-necessary cost of goods. For the development of novel antimalarial combination therapies, new approaches for dose finding and selection of partners are therefore required. Recently, the Induced Blood Stage Malaria (IBSM) human challenge model has been validated using approved antimalarials, and used to characterise new chemical entities (NCE) as single agents. We have investigated for the first time the combination of two NCE, OZ439 and DSM265 in the IBSM model. The study was designed as adaptive approach, using sequential cohorts each of 8 healthy subjects. Participants in the first cohort were treated with OZ439 and DSM265, administered as single oral doses of 200 mg and 100 mg respectively. No significant pharmacokinetic interactions or adverse effects were observed. In contrast to the outcome of a previous

study where OZ439 was used in IBSM in an identical dose, clearance of parasitemia was observed. However, 4/8 subjects experienced recrudescent parasitemia between 11 and 21 days after treatment. The mean Minimal Inhibitory Concentrations at this dose level were 0.3 ng/ml and 573 ng/ml for OZ439 and DSM265 respectively. The study is still ongoing, with data from subsequent cohorts to be presented. However, these preliminary results show that the OZ439 / DSM265 combination shows promise for future development, and suggest that the IBSM model is suitable for documenting the pharmacokinetics and pharmacodynamics of the combination of antimalarials under development.

1208

A PHASE 2, RANDOMIZED, CONTROLLED, DOSE-ADAPTIVE TRIAL OF PRIMAQUINE IN COMBINATION WITH DIHYDROARTEMISININ-PIPERAQUINE TO REDUCE TRANSMISSION OF *PLASMODIUM FALCIPARUM* MALARIA IN MALI

Alassane Dicko[1], Joelle Brown[2], Halimatou Diawara[1], Harouna Soumare[1], Almahamoudou Mahamar[1], Ibrahim Baber[1], Koualy Sanogo[1], Fanta Koita[1], Ingrid Chen[2], Eugenie Poirot[2], Helmi Pett[3], Francois Nosten[4], Teun Bousema[5], Roly Gosling[2]

[1]Malaria Research and Training Center, Bamako, Mali, [2]University of California San Francisco, San Francisco, CA, United States, [3]Helsinki University, Helsinki, Finland, [4]Shoklo Malaria Research Unit, Bangkok, Thailand, [5]Radboud University Nijmegen, Nijmegen, Netherlands

Despite considerable progress in malaria control, tools that specifically prevent malaria transmission are needed to achieve malaria elimination in the majority of African settings. Primaquine (PQ), when added to artemisinin combination therapy, may radically prevent malaria transmission to mosquitoes. High doses of PQ (0.75 mg/kg) have been associated with hemolysis. We determined the safety and efficacy of single-low dose (SLD) PQ. Between September 2013-December 2015, we conducted a phase 2, randomized, double-blind, controlled, dose-adaptive study of SLD PQ among 81 G6PD non-deficient males in Mali infected with uncomplicated ***Plasmodium falciparum*** malaria. Microscopy positive gametocyte carriers were treated with dihydroartemisinin-piperaquine (DP) and allocated 0.5, 0.25, 0.125, 0.0625 and 0 mg/kg primaquine. The primary outcome was percent change in mosquito infectivity at Day 2 following primaquine treatment. Mosquito infectivity was assessed through membrane-feeding assays at enrolment and days 2 and 7 following treatment; gametocyte carriage was quantified by Pfs25 mRNA quantitative reverse transcriptase PCR (qRT-PCR). Safety endpoints included the average within-person change in hemoglobin concentration and adverse events (AE) during follow-up. We found large and statistically significant reductions in mosquito infectivity following treatment with PQ doses ranging from 0.25 mg/kg to 0.5 mg/kg primaquine, compared to controls. Participants taking 0.25 mg/kg PQ experienced a 93% reduction in infectivity at Day 2 (vs. 11% reduction in controls, $P<0.01$) and a 93% reduction in infectivity at Day 7 (vs. 45% reduction in controls, $P=0.01$). Compared to DP, qRT-PCR gametocyte carriage was significantly reduced in all PQ arms and lowest in the 0.5mg/kg PQ arm. We did not find meaningful or statistically significant drops in hemoglobin in any group during follow-up. AE occurrence was not associated with PQ treatment group ($P=0.34$). SLD PQ, given in conjunction with DP, appears to be safe and efficacious for the prevention of malaria transmission in G6PD non-deficient populations.

1209

DRUG-DRUG INTERACTION STUDY OF TAFENOQUINE AND THE ACTS DIHYDROARTEMISININ-PIPERAQUINE (DHA-PQP) AND ARTEMETHER-LUMEFANTRINE (AL)

Justin A. Green[1], Khadeeja Mohamed[1], Navin Goyal[2], Allen Wolstenholm[2], Maxine Taylor[3], Renata Buckley[1], Sion Jones[1], Azra Husseini[4], Alex Papangelou[4], Ivan Kostov[4], Gavin C. Koh[1], Stephan Duparc[5]

[1]GlaxoSmithKline, Uxbridge, United Kingdom, [2]GlaxoSmithKline, Collegeville, PA, United States, [3]GlaxoSmithKline, Ware, United Kingdom, [4]Parexel, Baltimore, MD, United States, [5]Medicines for Malaria Venture, Geneva, Switzerland

Tafenoquine (TQ) is an 8-aminoquinoline (8-AQ) in development as a single dose treatment for the radical cure of ***Plasmodium vivax*** malaria. Tafenoquine is being co-administered with chloroquine to kill the blood stages of ***P. vivax*** during phase 3 registrational studies. However, artemisinin combination therapies (ACTs) may also be used in combination with 8-AQs to achieve radical cure. Recognizing the recommendation in some national treatment guidelines to use ACTs as first line treatment for ***P. vivax*** malaria, a better understanding of potential drug-drug interactions (DDI) is required. We have therefore undertaken a DDI study (200951, NCT02184637) of TQ co-dosed with dihydroartemisinin-piperaquine (DHA-PQP) or artemether-lumefantrine (AL). This 5-cohort, randomized, open-label, parallel-group study recruited a total of 120 glucose-6-phosphate dehydrogenase (G6PD) phenotypically non-deficient healthy volunteers equally into each cohort. The co-primary objectives of this study were to characterize both the effects of a 300mg single dose of TQ on the pharmacokinetics (PK; using changes in AUC(0-t), AUC(0-∞), and Cmax as endpoints) of each of the two ACTs and their major metabolites when co-administered according to their prescribed dose as well as the effects of the ACTs on the PK of TQ. Key secondary objectives included documenting frequency of adverse events, changes in haemoglobin (in particular related to genetic G6PD deficiency status) and characterizing QTcF changes by analysing maximum change from baseline in all cohorts and for subjects who receive DHA-PQP, a measure of the change from baseline versus 4-hours post-third dose. Headline PK and safety data from this study will be presented and implications for co-administration of ACTs and TQ will be discussed.

Intermittent preventive treatment with sulfadoxine pyrimethamine (SP) remains one of the primary interventions for the prevention of malaria in HIV-uninfected pregnant women in Africa. However with the spread of antifolate resistance, new interventions for the prevention of malaria in pregnancy are urgently needed. We are conducting a double blinded randomized controlled trial comparing 3 dose SP vs. 3 dose dihydroartemisinin (DP) vs. monthly DP in HIV-uninfected pregnant women living in Tororo district, Uganda, a high malaria transmission setting. Between June-October 2014, 300 women were enrolled at 12-20 weeks of gestation based on ultrasound dating, given a long lasting insecticide treated net, and randomized to therapy. Participants are being followed up in a dedicated study clinic for all their medical care and encouraged to

deliver at the hospital adjacent to the study clinic. The primary outcome is risk of placental malaria by histopathology. Secondary outcomes included other measures of malaria during pregnancy and delivery, adverse events and birth outcomes. As of 28th February 2015, 195 women had delivered and 9 women were prematurely withdrawn before delivery. Malaria incidence during pregnancy was 1.88 and 0.45 episodes per person year before and after starting study drugs, respectively. Of the 195 deliveries, 3 (1.5%) were spontaneous abortions 2 (1.0%) were stillbirths, 4 (2.1%) had congenital anomalies, 22 (11.2%) were preterm deliveries, and 31 (16.3%) were low birth weight. The risk of placental malaria was 40.7% by histopathology and 3.7% by placental blood smear. During follow-up, a total of 27 grade 3 or 4 adverse events occurred, of which 15 were due to anemia. It is anticipated that all women will have delivered by May 2015 and that the final un-blinded results of the trial will be presented at the meeting.

IMPACT OF THE NUTRITIONAL STATUS ON ARTEMETHER-LUMEFANTRINE EFFICACY IN UNCOMPLICATED FALCIPARUM MALARIA IN CHILDREN IN MALI

Cheick P. Sangare[1], Aminata Fofana[2], Aboubacrine Haidara[1], Kadidiatou Haidara[2], Hamidou Niangaly[1], Mamadou Tekete[1], Nadine Coulibaly[3], Jean Bosco Ouedraogo[3], Ogobara K. Doumbo[1], Abdoulaye Djimde[1]

[1]Malaria Research and Training Center, Bamako, Mali, [2]Laboratoire National de la Sante, Bamako, Bamako, Mali, [3]Institut de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso

The aim of this study was to evaluate the impact of nutritional status on the Artemether-Lumefantrine (AL) efficacy in children under 5 years on 42 days. From July 2014 to December 2014 during a prospective longitudinal study in children with uncomplicated malaria aged 6 to 59 months, we measured the efficacy of AL on falciparum malaria in Faladje in Mali. Anthropometric measures (malnourished, z-score < -2 SD, and non-malnourished, z-score:-1 and -2 SD) and body mass index (BMI) based on NIH WHO Guidelines for girls and boys were used and AL efficacy was compared between the various nutritional statuses. Deuterium was used as a tracer to estimate body composition using three saliva samples collected pre-dose (H0 before treatment), post-dose1 (at 3 hours) and post-dose 2 (at 4 hours). The percentage of body fat was determined using a Fourier transform infrared spectrophotometer (FTIR). Cases of severe malnutrition were not included in this study. 151 children were included with a rate of lost to follow-up of 1%. Without molecular correction we found that rates of early treatment failures were 0%, late clinical failures were 18.% and late parasitological failures were 36.1% and raw adequate clinical and parasitological response were 45.8%. Anthropometric measures showed 11% (n=17) of emaciation, 18% (n=27) of underweight and 14% (n=21) of chronic malnutrition. AL efficacy by 42 days was comparable in malnourished and non-malnourished children. Salives analysis on 104 subjects revealed that 16.35% (n = 17) were malnourished against 83.65% (n = 87) for non malnourished. According to body composition, the efficacy of A L by 42 days of follow-up was comparable in the two groups. Molecular correction of treatment efficacy is underway. Conclusion : Without molecular correction, the AL efficacy was not impacted by mild-malnutrition status.

1212

HAITI 2012 NATIONAL COMMUNITY SURVEY: MALARIA PREVALENCE IS LOW WITH A NOTABLE PROPORTION OF ASYMPTOMATIC CASES

Kimberly E. Mace[1], Eric Rogier[1], Samuel E. Jean[2], Ito Journel[3], Alexandre Existe[3], Michelle Chang[1], John W. Barnwell[1], Venkatachalam Udhayakumar[1], Jean Frantz Lemoine[4]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Population Services International/OHMaSS, Port au Prince, Haiti, [3]Laboratoire National de Santé Publique/Ministère de la Santé Publique et de la Population, Port au Prince, Haiti, [4]Programme National de Contrôle de la Malaria/Ministère de la Santé Publique et de la Population, Port au Prince, Haiti

Haiti intends to eliminate malaria by 2020 and its low level of transmission is most recently evidenced from a community survey conducted in 2011 which showed that the national parasitemia prevalence was <1%, even by sensitive polymerase chain reaction (PCR). In December 2012, during the expected high transmission season, the survey was repeated after implementation of new treatment guidelines and a bed net campaign earlier that year. This survey employed a cross-sectional, two-stage cluster survey design, where enumeration areas (EAs) were selected with a probability proportional to size and 20 households (HHs) within EAs were systematically selected. Questionnaires were conducted and HH members of all ages were tested for malaria by rapid diagnostic tests (RDTs), expert microscopy, PCR, and serology (presented separately). Sixty-two EAs were sampled and 7,607 persons surveyed. Some participants did not consent to provide specimens for all procedures. RDTs were performed for 6,365 persons, and 84 (1.3%) were positive. A total of 5,001 blood slides were read by a reference lab, and 3 (0.06%) were positive. Dried blood spots (DBS) were provided by 5,511 persons; photo-induced electron transfer (PET)-PCR found 17 (0.3%) positive for ***Plasmodium*** genus. Nested PCR confirmed 14 ***Plasmodium falciparum (Pf)***, two ***P. malariae*** (***Pm***), and one mixed ***Pf*** and ***Pm*** infections. PCR confirmed two of three positive microscopy results and one RDT, although 32 positive RDTs could not be tested by PCR. The median age of those with a positive test was 13.5 years; range <1 to 71 years. For those with any positive test, fever was reported in the prior two weeks for four of 100 persons. In low transmission settings, discordance among tests is likely. These results confirm the low-transmission setting for Haiti and demonstrate that almost all parasitemia was asymptomatic. Additionally, inclusion of more sensitive serological methods and applying a sub-national, sampling strategy will be essential for characterizing transmission hotspots.

1213

CHARACTERIZING TYPES OF HUMAN MOBILITY TO INFORM DIFFERENTIAL AND TARGETED MALARIA ELIMINATION STRATEGIES IN NORTHEAST CAMBODIA

Koen Peeters Grietens[1], Charlotte Gryseels[1], Susan Dierickx[1], Sambunny Uk[2], Rene Gerrets[3], Sarah Hoibak[4], Joan Muela Ribera[5], Susanna Hausmann-Muela[5], Sochantha Tho[2], Lies Durnez[1], Vincent Sluydts[1], Umberto d'Alessandro[6], Marc Coosemans[1], Annette Erhart[1]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [3]Amsterdam Institute of Social Science Research, Amsterdam, Netherlands, [4]The Global Fund, Geneva, Switzerland, [5]PASS International, Tessenderlo, Belgium, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom

Population mobility has been identified as a major challenge for malaria elimination in the Greater Mekong Subregion. Given the large sociocultural differences between various types of mobile populations, the aim of this study was to characterize different types of mobility in relation to malaria vulnerability. The study was conducted in Ratanakiri Province, Cambodia.

A parallel mixed-methods study design was used, combining qualitative ethnographic research (n=410 interviews, participant observation) and quantitative surveys. Different surveys were used to quantify malaria vulnerability among different types of mobile populations and in relation to malaria control measures (n=824 Indigenous Population Survey; n=704 Khmer Migrant Population Survey; n=4996 Indigenous Malariometric Survey). Different structural types of human mobility were found with differential risk and vulnerability towards malaria. Among the indigenous population, although access to malaria testing and treatment through village malaria workers and LLIN coverage was high, control strategies fail to take into account farmers' residence system, entailing overnights and prolonged stays at forest farms/fields (61% during rainy season), increasing their malaria risk (OR 1.66, 95% CI 1.21-2.28, p=0.002). Additionally, various types of irregular mobility were identified including cross-border mobility, hunting and logging. Khmer migrants are active on rubber plantations and mines (82%), representing a fundamentally different social group that was not reached by LLIN-distribution campaigns (67%) since most were not registered (79%) and (95%) unaware of the village malaria worker system due to poor social integration. Furthermore, most purchased non-treated bed nets (75%), the majority of which (55%) were damaged. In conclusion, different mobility patterns co-exist and are associated with differential malaria risk. This study demonstrates the need for differential malaria control strategies among groups that are, nevertheless, usually jointly categorized as "mobile populations".

RE-ORIENTING TOWARDS ELIMINATION IN MATABELELAND SOUTH, ZIMBABWE: PERFORMANCE OF AN ENHANCED DIGITIZED CASE-BASED SURVEILLANCE SYSTEM

Conart Mpofu[1], Jason Owen[2], Munashe Madinga[3], Yonatan Gossaye[4], Charlotte Dolenz[5], Arnaud Le Menach[5], Deepa Pindolia[5], Kudzai Makomva[6], Abaden Svisva[7], Joseph Mberikunashe[8]

[1]Matabeleland South Provincial Medical Directorate, Bulawayo, Zimbabwe, [2]Clinton Health Access Initiative, Harare, Zimbabwe, [3]Clinton Health Access Initiative, Bulawayo, Zimbabwe, [4]Clinton Health Access Initiative, Addis Ababa, Ethiopia, [5]Clinton Health Access Initiative, Boston, MA, United States, [6]Elimination 8, Windhoek, Namibia, [7]Population Services International, Harare, Zimbabwe, [8]Zimbabwe National Malaria Control Programme, Harare, Zimbabwe

Matabeleland south province in Zimbabwe plans to reach malaria elimination by 2017. Currently, cases are reported in two surveillance systems: a routine passive system where data are aggregated monthly, and an individual case-based system. To support elimination efforts, the individual case-based system was re-oriented from a paper-based to digitized system in September 2014. The transition involved questionnaire and documentation revision, and district and health facility level capacity assessments. The new system provides real-time case data, enabling identification and targeting of high risk areas and populations, and generating evidence for policy change. Data was extracted from the paper-based system database at baseline (January to July 2013), the current digitized system database (September to December 2014), and routine surveillance database for both time periods. Proportion of cases reported, proportion of cases classified as local or imported, and proportion of cases investigated were estimated and compared over time. At baseline, discrepancies were found between case numbers reported in the paper-based reporting system (276) and the routine passive system (910). With the new digitized system, 295 confirmed malaria cases were reported compared to 390 confirmed cases from the routine surveillance system, revealing a 48% reduction in discrepancy. At baseline, the case investigation rate was low (28%), travel history was recorded for 5% of cases, but none were classified. Significant improvements were noted using the new digitized system: 54% of cases were investigated, and 59% of cases were classified. Improved performance can be attributed to simplification of data entry with a reduction from 300 to 30 fields in data collection forms and availability of real-time case data (one month maximum delay). The new, digitized case-based surveillance system has shown significant improvements in epidemiological and efficiency indicators, and results have already been used to improve targeting and efficiency of interventions.

1215

THE GAMETOCYTOCIDAL EFFICACY OF PRIMAQUINE IN MALARIA ASYMPTOMATIC *PLASMODIUM FALCIPARUM* CARRIERS IN THE GAMBIA: RESULTS OF A RANDOMIZED CONTROLLED TRIAL

Joseph Okebe[1], Muna Affara[1], Gian Luca DiTanna[2], Frank Sanya-Isijola[1], Edgard Dabira[1], Alice C. Eziefula[2], Abdoulaye Gaye[1], Davis Nwakanma[1], Teun Bousema[2], Jean-Pierre Van geertruyden[3], Chris Drakeley[2], Umberto D'Alessandro[1]

[1]Medical Research Council Unit, Banjul, Gambia, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Institute of Tropical Medicine, Antwerp, Belgium

Primaquine is recommended for treatment campaigns against ***Plasmodium falciparum*** gametocytes in (pre-) elimination settings. Although the recommended dose is believed to be safe, there is weak evidence on its efficacy. Studies are needed on the efficacy of primaquine, particularly in asymptomatic parasite carriers as they can maintain transmission. Asymptomatic, malaria infected, G6PD-normal individuals determined through community screening were randomised to receive either dihydroartemisinin-piperaquine (DHAPQ) alone (control arm) or with a single dose of primaquine (PQ) at three different dosages, i.e. 0.75mg/kg, 0.40mg/kg and 0.20mg/kg. The primary endpoint was the prevalence of ***Plasmodium falciparum*** gametocyte on Day 7 of a 42-day follow-up determined by quantitative nucleic acid sequence based amplification assay. A total of 667 participants were enrolled in the trial. Preliminary analysis shows significant reduction in Day-7 gametocyte prevalence between the control and the 0.75mg/kg PQ and the 0.40mg/kg arms. Adverse events were few with 8 (2.4%) reports of anaemia (Hb <8.0g/dl) which resolved on iron supplements. DHAPQ plus PQ; 0.75mg/kg and 0.40mg/kg PQ seem to be able to reduce gametocyte carriage at Day-7. The safety profile of primaquine was overall good.

1216

TOWARDS MALARIA ELIMINATION IN ZANZIBAR: DEVELOPMENT OF EARLY EPIDEMIC DETECTION THRESHOLDS IN AN INCREASINGLY LOW TRANSMISSION SETTING

Abdulwahid H. Almafazy[1], Abdullah S. Ali[1], Stephen K. Kaptoge[2], Narjis G. Thawer[3], Fabrizio Molteni[4], Issa A. Garimo[5], Humphrey R. Mkali[5], Mahdi M. Ramsan[3], Shabbir Lalji[3], Lynn A. Paxton[6], Jeremiah M. Ngondi[3]

[1]Zanzibar Malaria Elimination Program, Zanzibar, United Republic of Tanzania, [2]Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom, [3]RTI International, Dar es Salaam, United Republic of Tanzania, [4]Swiss Tropical and Public Health Institute, Dar es Salaam, United Republic of Tanzania, [5]RTI International, Dar es Salaam, Tanzania, Zanzibar, United Republic of Tanzania, [6]President's Malaria Initiative/Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania

The Malaria Early Epidemic Detection System (MEEDS) was implemented in Zanzibar in 2008 to monitor malaria incidence. We analysed MEEDS data from 2008 to 2014 to assess trends in malaria in Zanzibar, and to develop thresholds for monitoring at district and heath facility levels. We conducted mixed effects negative binomial regression modelling at district and health facility levels using weekly malaria cases as the primary dependent variable. Specification of the predictor variables involved 5 key features: fixed effects for districts; flexible smooth characterisation of seasonal variations by inclusion of restricted cubic spline transformations of epidemiologic week number; interaction of district dummy variables

and the week spline terms; yearly random effects to model deviations from typical mean; and random effects for health facilities. Alert and alarm thresholds were respectively defined as the 95th and 99th percentile of a Poisson distribution with corresponding smoothed mean function. We compared our results to the cumulative sum and the 75th percentile methods, with allowance for different lengths of the baseline reference period. Across the 10 districts of Zanzibar, the number of health facilities participating in the MEEDS surveillance programme increased from 137 facilities in 2008 to 160 in 2014. Our thresholds conformed with apparent seasonal variations, and in contrast to thresholds based on conventional methods, were less susceptible to erratic variations when underlying data were sparse. The thresholds identified all known historical excesses of malaria cases in some districts for some particular years, and the frequency of alerts and alarms raised per year were acceptably few when considering only threshold breaches lasting for at least two consecutive weeks. Zanzibar has made tremendous progress in achieving millennium development goal #6, reducing malaria incidence by 70% in children and about 50% in adults over a 7-year period. These thresholds should facilitate greater efficiency in continued monitoring and delivery of interventions, eventually progressing to malaria elimination in Zanzibar.

1217

POTENTIAL IMPACT OF RAPID DIAGNOSTIC TEST DIAGNOSTIC ERROR ON INCREASED MALARIA TRANSMISSION OF EMERGING UNTREATABLE MALARIA

Maciej F. Boni[1], Andrew A. Lover[2], Thang D. Ngo[3], Thang X. Nguyen[3], Awalludin Sutamihardja[2], Duong T. Tran[3], Nicholas Martin[4], **Colin Ohrt**[2]

[1]Nuffield Department of Medicine, University of Oxford, Oxford, UK and Oxford University Clinical Research Unit, Wellcome Trust Major Overseas Programme, Ho Chi Minh City, Vietnam, Ho Chi Minh, Vietnam, [2]University of California, San Francisco, Hanoi, Vietnam, [3]National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, [4]Naval Medical Research Center-Asia, Singapore, Singapore

Emerging untreatable malaria in the Greater Mekong Subregion could result in a public health disaster when it reaches Africa. Malaria diagnostic tests are recommended by the World Health Organization to obtain a specific malaria diagnosis before; however, all diagnostic test have errors associated with use. We examined diagnostic quality in Vietnam, where microscopy is the standard of care and RDTs are recommended only where or when microscopy is not available. In remote areas of Vietnam, RDTs are now being distributed where presumptive treatment was previously used. While microscopy appears to be of a very high quality, both diagnostic tests will have errors resulting in patients with undiagnosed, and hence, untreated malaria. This has the potential for malaria will mortality, as well as persistent parasitemia, and gametocytemia leading to on-going malaria transmission. In two provinces in central Vietnam, a project was established to capture diagnostics data to allow assessment diagnostics error in the real-world setting. Mathematical modeling tools will be employed to investigate the benefit of malaria microscopy and RDTs, as well as estimate the potential danger of false negative diagnostic results in an elimination setting. This evaluation began in January 2015 and will complete in August 2015. In the two provinces, 2.14% of 654 negative where reread by expert microscopists as positive (3 ***Plasmodium falciparum***, 10 ***P. vivax***, 1 both species). The sensitivity of front-line microscopists (commune-based) was 85.6% with a species accuracy of 68.5%. Real world RDT assessment is pending. While the manufacturer's package insert reports xx, for both species, some field studies (in South America) suggest 92.0% for Pv and 88.1% for Pf. In Vietnam, approximately XX cases were diagnosed with malaria microscopy and XX with RDT in 2014 ((confirm)). With this number of cases and the documented performance of microscopy and RDTs, we initially estimate XX ***P. falciparum*** and YY ***P. vivax*** cases are going initially untreated. These results will be used to model the potential impact of these diagnostic error within a malaria elimination program.

1218

CHANGES IN MALARIA PARASITE POPULATION GENETICS WITH APPLICATION OF MASS DRUG ADMINISTRATION IN ZAMBIA

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]University of California San Francisco, San Francisco, CA, United States, [3]PATH-MACEPA, Lusaka, Zambia, [4]Institute for Medical Research and Training, University Teaching Hospital, Lusaka, Zambia, [5]National Malaria Control Centre, Zambia Ministry of Health, Lusaka, Zambia, [6]PATH-MACEPA, Seattle, WA, United States, [7]PATH-Malaria Control and Elimination Partnership in Africa (MACEPA), National Malaria Control Centre, Lusaka, Zambia, [8]Center for Applied Malaria Research and Evaluation Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

We have detected dramatic changes in parasite population genetic signals over time in Senegal under conditions of major intervention application. These signals indicate both decline in transmission and rebound of transmission using epidemiological modeling frameworks. Based on these data, we hypothesize changes in parasite population structure in Zambia under conditions where Mass Drug Administration (MDA) has been applied in the Southern Province. These predicted signals include decreases in complexity of infection (COI) and increases in the proportion of monogenomic infections (PMI) as well the increase in relatedness among parasites as detected using a molecular barcode approach. We applied genotyping approaches to samples obtained from a nested cohort within a larger community randomized trial testing use of MDA with dihydroartemisinin piperaquine (DHAp) to reduce malaria burden. The trial contains three arms: 1) community-wide MDA; 2) focal MDA (fMDA), where everyone in a household receives treatment if anyone in that household tests positive by malaria rapid diagnostic test (RDT); and 3) control, where current standard malaria control practice is carried out without mass treatment campaigns. The study was stratified by malaria transmission above and below 10% prevalence, and after one round of intervention parasite prevalence decreased from 8.3% to 4.6% at a time when transmission normally rises dramatically. Genotyping data from the first 6 months of this infection incidence cohort study will be presented to ask if genetic signals track with clinical or epidemiological indicators anticipated to decline under MDA; and if these differ between the two populations with high or low transmission intensity. Specifically we will share data showing whether COI or PMI changed, and whether there was evidence of increasing clonality or relatedness among parasites as interventions were deployed; whether these indicators track with clinical or epidemiological indicators; the relatedness between parasites within household clusters; and, any changes in drug resistance markers as a consequence of MDA application in these settings.

1219

PHASE 1 STUDY OF DIFFERENT FORMULATIONS OF A TETRAVALENT DENGUE PURIFIED INACTIVATED VACCINE (DPIV): SAFETY AND IMMUNOGENICITY DATA IN HEALTHY ADULTS FROM PUERTO RICO THROUGH MONTH 13

Clemente Diaz[1], Luis J. Martinez[2], Kenneth H. Eckels[2], Leyi Lin[2], Maribel Campos[1], Richard G. Jarman[2], Rafael De La Barrera[2], Edith Lepine[3], Alix Collard[3], Bruce L. Innis[4], Irma Febo[1], Stephen J. Thomas[2], Alexander C. Schmidt[3]

[1]University of Puerto Rico School of Medicine, San Juan, Puerto Rico, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]GlaxoSmithKline Vaccines, Rixensart, Belgium, [4]GlaxoSmithKline Vaccines, King of Prussia, PA, United States

The safety and immunogenicity of 2 doses of an investigational tetravalent DPIV were studied in Puerto Rico. We report results up to study month (M) 13. In this ongoing Phase 1, observer-blind study (NCT01702857), 100 healthy adults were randomized 1:1:1:1:1 to receive saline placebo or 1 of 4 DPIV formulations (1µg per dengue virus [DENV] type adjuvanted with aluminum hydroxide [Alum], $AS01_E$ or $AS03_B$, or 4µg per DENV type adjuvanted with Alum) at Days (D) 0 and D28. Subjects were followed up for serious adverse events (SAEs), potential immune-mediated diseases (pIMDs) and medically-attended AEs (MAEs) up to M13. Hematological and biochemical laboratory parameters were assessed up to M13. Neutralizing antibody titers were determined by microneutralization assay (MN50). Two subjects in the 4µg+Alum group reported 4 SAEs, and 2 in the placebo group reported 5 SAEs; all were considered unrelated to vaccination. Worsening of a pre-existing pIMD (rheumatoid arthritis) was reported for 1 subject in the 1µg+$AS03_B$ group and 1 case of auto-immune thyroiditis in the placebo group. Fifty-two MAEs were reported, without notable differences across groups. Three subjects had grade 3 anemia (2 in the 4µg+Alum group at M7 and M10, and 1 in the 1µg+$AS03_B$ group at M7, M10, and M13). Iron deficiency was considered as the most likely etiology. The M13 per-protocol immunogenicity cohort included 83 participants (78 seropositive for ≥1 DENV type). M13 geometric mean titers (GMTs) against DENV-1, -2, -3, -4 were 1122, 793, 447, 1142, respectively, in the 1µg+Alum group; 2291, 1272, 1092, 3133 in the 4µg+Alum group; 1309, 1566, 1139, 1751 in the 1µg+$AS01_E$ group; 2051, 1847, 1389, 3267 in the 1µg+$AS03_B$ group; 983, 603, 348, 1441 in the placebo group. M13/D0 GMT ratios were highest in the 1µg+$AS03_B$ group and ranged from 3.2 to 3.7 for the 4 DENV types (1.5 to 2.1 in the 4µg+Alum group; 0.9 to 1.3 in the placebo group). D56/M13 GMT ratios ranged from 1.2 to 1.7 in the 1µg+$AS03_B$ group (1.0 to 1.7 in the 4µg+Alum group; 0.7 to 1.1 in the placebo group). All DPIV formulations were well tolerated and no safety signals were identified up to M13; MN50 GMTs remained high up to M13.

1220

A SINGLE DOSE OF TV003 ELICITS PROTECTIVE EFFICACY AGAINST CHALLENGE WITH A HETEROTYPIC DENGUE VIRUS TYPE 2

Anna P. Durbin[1], Beth D. Kirkpatrick[2], Cecilia Tibery[1], Paltama Grier[1], Kristen K. Pierce[2], Catherine J. Larsson[2], Linda Farley[1], Anna Janiak[1], Janece Lovchik[1], Marya P. Carmolli[2], Ben McElvaney[2], Eli Sendra[2], Cassandra Ventrone[2], Sean Diehl[2], Stephen S. Whitehead[3]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]University of Vermont College of Medicine, Burlington, VT, United States, [3]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Dengue is the most important arboviral infection in the world. Several candidate dengue vaccines are in clinical trial; however, variable efficacy of the lead candidate CYD due to DENV serotype and dengue-immune status at vaccination have made it difficult for vaccine manufacturers to determine which candidates should be evaluated in efficacy trials in endemic areas where vaccine failure or partial immunity could predispose subjects to more severe disease upon subsequent DENV infection. A dengue human infection model (DHIM) would be useful in down-selecting candidate vaccines prior to testing in endemic areas as well as identifying putative correlates of protection. We have developed a DHIM to evaluate the protective efficacy of the live attenuated tetravalent dengue vaccine TV003 developed by the NIAID. In Phase I clinical trials, a single dose of TV003 induced neutralizing antibody to DENV-1, DENV-2, DENV3, and DENV-4 in 92%, 76%, 97%, and 100% of vaccinees, respectively. It induced a tetravalent response in 74% of vaccinated subjects and a trivalent or better response in 98%. Because the frequency of seroconversion to DENV-2 was lowest, we sought to evaluate protection against a heterotypic strain of DENV-2. We vaccinated 24 flavivirus-naïve subjects with a single dose of TV003; an additional 24 subjects received a placebo. Six months later all recipients received 1,000 PFU of rDEN2Δ30, an under-attenuated DENV-2 strain. TV003 elicited 100% protection against viremia, rash, and neutropenia induced by rDEN2Δ30. In contrast, 100% of placebo recipients who received rDEN2Δ30 at challenge were viremic (mean peak titer = 2.3 $\log_{10}$ PFU/mL, mean duration of viremia = 6.1 days); 80% developed rash (38% graded as moderate); and 20% developed neutropenia (75% graded as moderate). Only 6 vaccinees had > 4-fold increase in $PRNT_{50}$ to DENV-2 following challenge, indicating that TV003 induced sterilizing immunity in 71% of vaccinees. Therefore, a single dose of TV003 induces strong protective efficacy against challenge to at least 6 months and should be further evaluated in dengue-endemic areas.

1221

SAFETY EVALUATION AND IMMUNOGENICITY OF A SINGLE-DOSE LIVE-ATTENUATED TETRAVALENT DENGUE VACCINE IN DENGUE ENDEMIC POPULATIONS

Stephen S. Whitehead[1], Anna P. Durbin[2], Donald P. Francis[3], Alexander Precioso[4], Ricardo Palacios[4], Beatriz Thome[4], Esper G. Kallas[5], Lucia M. Campos[5], Veerachia Watanaveeradej[6], Louis R. Macareo[7], Sriluck Simasathien[6], Chonticha Klungthong[7], Butsaya Thaisomboonsuk[7]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Global Solutions for Infectious Diseases, San Francisco, CA, United States, [4]Butantan Institute, Sao Paulo, Brazil, [5]University of Sao Paulo, Sao Paulo, Brazil, [6]Phramongkutklao Hospital, Bangkok, Thailand, [7]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Dengue virus (DENV) continues to be the most important arbovirus worldwide with millions of cases of dengue fever and severe dengue occurring annually. Because a secondary DENV infection with a serotype different from that which caused the primary infection is a significant risk factor for severe disease, a safe and effective DENV vaccine must induce a long-lived, protective immune response to all four DENV serotypes. The goal of the NIAID intramural DENV vaccine program remains focused on the development of a single-dose, live-attenuated tetravalent dengue vaccine that is minimally reactogenic, highly immunogenic in both dengue virus primed and naïve recipients, and is cost-effective and safe for the community. Fifteen years of research has produced an optimal tetravalent mixture of viruses with a suitable level of infectivity and balance and has yielded clinical results in naïve adult subjects that support its continued development and progress into Phase 2/3 evaluation. Adult cohort studies in Brazil and Thailand were undertaken to evaluate the properties of the vaccine among populations with previous exposure to some DENV serotypes due to the endemic nature of the virus in these areas. To date, the favorable safety profile of the vaccine remains unchanged compared to that observed in DENV-naïve adult subjects. The vaccine has been evaluated in progressively younger subjects in Bangkok, including adolescents (13 - 17 years old), children (5 - 12 years old), and eventually in younger children (1 - 4 years old). A Phase 2 study under the direction of the Butantan Institute in Sao Paulo has been conducted and supports

the further evaluation of the vaccine in its first Phase 3 efficacy trial. Summary data from these two international studies will be presented and discussed.

1222

SAFETY AND IMMUNOGENICITY OF A TETRAVALENT RECOMBINANT SUBUNIT VACCINE FOR DENGUE: RESULTS OF A PHASE I CLINICAL TRIAL

Susan B. Manoff, Michele L. Sausser, Amy F. Russell, Brynne Tannenbaum, Tyler Finn, Jason Martin, David Radley, Donna Hyatt, Christine Roberts, Andrew J. Bett, Luwy Musey, Beth-Ann G. Coller

Merck and Company, North Wales, PA, United States

A recombinant subunit vaccine is being developed to prevent dengue. The vaccine candidate comprises truncated dengue envelope proteins (DEN-80E) from all 4 serotypes produced in Drosophila S2 cells. Nine active vaccine formulations were assessed in a randomized, placebo-controlled, Phase I trial in healthy, flavivirus-naïve adults in Australia. Three dosage levels of the tetravalent DEN-80E antigens were evaluated in a dose-escalation design. The 9 vaccine formulations either included ISCOMATRIX™ adjuvant (2 different dosage levels), aluminum-hydroxide adjuvant, or were unadjuvanted, and were compared to phosphate-buffered saline placebo. Volunteers received 3 injections of the assigned product on a 0, 1, 2 month schedule, and were followed for safety through 1 year after the last injection. Antibody levels were assessed at 6 time points: enrollment, 1 month after each dose, and 6 and 12 months Postdose 3 (PD3). The primary immunogenicity endpoint was the seroconversion rate (SCR) of virus-neutralizing antibody, measured by a qualified Focus Reduction Neutralization Test with 50% neutralization cutoff. The protocol-specified criterion for a positive immune response, applied to each formulation, was that at 28 days PD3, at least 3 serotypes will have a seroconversion rate of ≥75%. The trial has been completed. Of the 98 randomized participants, 90 received all 3 injections. All 9 active vaccine formulations were generally well tolerated; the safety profiles varied by the adjuvant component, but not by dose level of antigen or adjuvant. All 6 formulations with ISCOMATRIX™ adjuvant met the criterion for a positive immune response; per-protocol serotype-specific SCRs at 28 days PD3 ranged from 85.7% to 100%. Among the 3 formulations that were either aluminum-adjuvanted or unadjuvanted, 2 showed evidence of immunogenicity but did not meet the pre-specified criterion; per-protocol serotype-specific SCRs at 28 days PD3 ranged from 14.3% to 62.5%. These data suggest that a tetravalent DEN-80E vaccine may be generally well tolerated and immunogenic in flavivirus-naïve individuals. Complete unblinded study results will be presented.

1223

RECENT SCIENTIFIC AND CLINICAL ADVANCES IN SANOFI PASTEUR'S DENGUE VACCINE PROGRAM

Nicholas Jackson[1], Bruno Guy[1], Janice Moser[2], Karen Fanouillere[1], Matthew Bonaparte[2], Corinne Dunod[1], Remi Forrat[1], Anh Wartel-Tram[3], Diane Van der Vliet[1], Laurent Coudeville[1], Fernando Noriega[1], Melanie Saville[1]

[1]Sanofi Pasteur, Lyon, France, [2]Sanofi Pasteur, Swiftwater, PA, United States, [3]Sanofi Pasteur, Singapore, Singapore

In 2014, results from the first phase 3 efficacy studies of a dengue vaccine, across ten endemic countries in more than 30,000 children and adolescents in Asia (CYD14, aged 2-14) and in Latin America and the Caribbean (CYD15, aged 9-16) were reported, and the clinical safety database now includes over 28,000 subjects who have received at least one dose of vaccine. The pre-protocol primary endpoints were successfully achieved in both trials, showing a reduction in overall disease by 56.5% (CYD14) and 60.8% (CYD15) against virologically-confirmed symptomatic disease, regardless of severity, against any serotype, as reported previously. In the active phase of surveillance (from first vaccination through to 25 months), a favourable safety profile was observed consistent with prior trials and additional results demonstrated efficacy against hospitalized and severe disease, serotype-specific efficacy and the importance of the dengue baseline status and age on subsequent efficacy. Pertinent meta-analysis for point estimates of serotype-specific efficacy during the active phase, regardless of severity, show the consistence of efficacy against individual serotypes; the hierarchy was >70% for serotype 3 and 4, 50.2% for serotype 1 and 39.6% for serotype 2. Long-term surveillance of hospitalized dengue cases in both trials continues with a high level of sustained subject participation and available data will be presented. Post-phase 3 investigations are addressing ***post-hoc*** analyses based on the unprecedented level of accrued cases and related clinical data, including the sequencing of viruses and the application of new immunological assays. Mathematical modelling demonstrates the ability of the dengue vaccine to significantly reduce the burden of disease in endemic regions. In totality, a vaccination strategy targeting high disease burden age ranges and combines routine vaccination with several catch-up cohorts at introduction, would substantially reduce the burden of dengue disease in endemic regions.

1224

PERSISTENCE OF NEUTRALIZING ANTIBODIES ONE YEAR AFTER TWO DOSES OF A CANDIDATE RECOMBINANT TETRAVALENT DENGUE VACCINE IN SUBJECTS AGED FROM 1.5 TO 45 YEARS

Derek Wallace, DEN-203 Study Group

Takeda Vaccines Pte Ltd, Singapore, Singapore

Takeda's live attenuated tetravalent dengue vaccine candidate (TDV) contains a molecularly characterized dengue serotype 2 virus (TDV-2) and three recombinant viruses expressing the pre-membrane (prM) and envelope (E) structural genes for serotypes 1, 3, and 4 in the TDV-2 genetic backbone. In a previously reported phase II placebo-controlled, multi-center, age-descending trial (NCT 01511250) we assessed the safety, reactogenicity and immunogenicity of two doses of TDV or placebo, 90 days apart, in subjects living in dengue endemic areas (Puerto Rico, Colombia, Singapore or Thailand). Subjects in four age-cohorts: 21-45 year-old adults (n = 38), 12-20 year-old adolescents (n = 36), and 6-11 (n = 38) and 1.5-5 year-old (n = 36) children, were randomized 2:1 to receive TDV or placebo. Vaccination was well tolerated with no safety signals in any age group. When neutralizing antibodies against each of the four serotypes were measured after one dose at Day 28, 94.4-96.7% of vaccinees were seropositive to DENV-1, DENV-2 or DENV-3, while responses to DENV-4 were between 59.1% and 85.7% according to age group. A second dose at Day 90 increased responses to DENV-4 to 87.5% of vaccinees, but had little impact on other serotypes. By Day 120, 98% of vaccinees were seropositive to multiple serotypes compared with 4% of placebo recipients. When assessed at Days 180 and 360 there was little or no waning of antibodies in those vaccinees initially seropositive at baseline. Subjects who were seronegative at baseline did display some waning of antibodies, but all vaccine-groups remained seropositive compared with placebo recipients. These patterns of antibody response were similar across the four age groups. One dose of the candidate TDV vaccine elicited immune responses against the four DENV serotypes in initially seropositive and seronegative subjects, from 1.5 to 45 years of age, with little impact of a second dose, and persistence of neutralizing activity through 360 days irrespective of age or initial immune status.

1225

A NOVEL PROTEIN SCAFFOLD-BASED RECOMBINANT DENGUE 2 CANDIDATE VACCINE INDUCES ROBUST NEUTRALIZATION AND CONFERS PROTECTION AGAINST DENGUE INFECTION IN NON-HUMAN PRIMATES

William Messer[1], Sean P. McBurney[2], Justine E. Sunshine[1], Nancy L. Haigwood[2]

[1]Oregon Health & Science University, Portland, OR, United States, [2]Oregon Health & Sciences University and Oregon National Primate Research Center, Portland, OR, United States

Dengue virus (DENV) is the most prevalent arthropod-borne virus worldwide causing approximately 200 million infections each year, and currently there is no licensed vaccine. Here we describe construction and characterization of a novel protein-scaffold based DENV-2 vaccine candidate. The acyltransferase component (E2) of the pyruvate dehydrogenase complex of Geobacillus stearothermophilus self-assembles into a 60-mer core with icosahedral symmetry and a 24 nm diameter. E2 can be modified to express E2 fused with exogenous proteins that subsequently self-assemble into 60-mer virus like particles (VLPs). For this candidate vaccine, DENV-2 envelope protein domain III (EDIII)-E2 recombinant proteins were generated in E.coli and purified by gel filtration. EDIII specific mAb were used to confirm correct presentation of the DENV-2 EDIII antigen. Six DENV-naïve rhesus macaques (RMs) were vaccinated with intramuscular delivery of EDIII-E2 VLPs and a DNA plasmid encoding DENV-2 EDIII at wk 0, 4, and 12, achieving 50% neutralization titers (FRNT50) ranging from 1:3,000 to 1:100,000 by 14 wks post vaccination. The vaccinated RMs and 3 naïve controls were subsequently challenged with DENV-2, with complete protection (6/6) against detectable DENV-2 viremia by infectious virus assays and partial protection (3/6) by PCR. Interestingly, days of PCR detected viremia was negatively correlated with pre-infection FRNT titers (r=-0.88, p=0.01), suggesting a threshold neutralizing titer was necessary to fully control detectable viremia. These preliminary studies demonstrate proof of principle for protein scaffold based dengue vaccines and lay the groundwork for developing formulations of EDIII-E2 fusion proteins of each serotype that could self-assemble into tetravalent VLPs.

1226

EFFECTS OF THE EBOLA VIRUS EPIDEMIC ON NTD INTERVENTIONS IN LOFA COUNTY, LIBERIA AND PLANS FOR RESUMPTION OF MASS DRUG ADMINISTRATION

Joshua Bogus[1], Lincoln Gankpala[2], Kerstin Fischer[1], Alison Krentel[3], Gary J. Weil[1], Peter U. Fischer[1], Fatorma K. Bolay[2]

[1]Washington University School of Medicine, St. Louis, MO, United States, [2]Liberian Institute for Biomedical Research, Charlesville, Liberia, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

We initiated a study in 2012 to compare the impact of annual and semiannual mass drug administration (MDA) for the control and elimination of neglected tropical diseases (NTDs, lymphatic filariasis, onchocerciasis, soil-transmitted helminths, schistosomiasis) in Foya and Kolahun Districts in Lofa County, NW Liberia. MDA compliance rates by village ranged from 70-83% in 2013. Emergence of Ebola virus disease (EVD) in Lofa interrupted a follow-up parasitological survey in April 2014. By February 2015, 705 EVD cases (332 confirmed) and 433 deaths were recorded in the county. Although EVD cases were highly clustered in a small number of villages, MDA was suspended in the county and across the country for more than 1 year. This study was conducted to assess the willingness of our study communities to resume MDA for NTDs and to regain trust required for high compliance. Anecdotal reports indicated that people were suspicious of international health workers and researchers because of the EVD outbreak, and some thought that these outsiders were responsible for the epidemic. We conducted questionnaire survey in March 2015 of 140 community leaders in 32 villages (3 to 7 participants per village). Despite a continued fear of EVD, participants reported high levels of enthusiasm for MDA and a willingness to participate in parasitological surveys. Participants reported 92% compliance with MDA in 2013, and a similar percentage said they were willing to take the medications now. Community leaders consistently said that it was important to widely publicize the plan to resume MDA prior to drug delivery and to make it clear that the medicines were the same ones that they had received earlier to control worm infections. In this way, resumption of MDA provided by the MOH may be reassuring to some as evidence that the country's health system is capable of resuming general health services and moving past the Ebola crisis. Social mobilization will start soon, and the next round of MDA will be distributed in in May 2015. This study has provided new information on the indirect impact of events such as the EVD outbreak on NTD programs and on factors to consider prior to restarting MDA.

1227

EVALUATING TREATMENT COVERAGE FOR MASS DRUG ADMINISTRATION: A MULTI-COUNTRY COMPARISON OF THREE SURVEY METHODS

Windtaré R. Bougma[1], Harriet Lwanga[2], Square Mkwanda[3], Edridah M. Tukahebwa[4], Michael Deming[5], **Katherine Gass**[6]

[1]Programme National de Lutte contre les maladies tropicales négligées, Ministère de la Santé, Ouagadougou, Burkina Faso, [2]RTI Envision Program, Kampala, Uganda, [3]Lymphatic Filariasis Elimination Programme, Ministry of Health, Lilongwe, Malawi, [4]Vector Control Division, Ministry of Health, Kampala, Uganda, [5]Parasitic Diseases Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]Task Force for Global Health, Decatur, GA, United States

Coverage surveys are an important tool for evaluating the performance of mass drug administration (MDA) for neglected tropical diseases (NTDs). Unfortunately they are seldom implemented by national programs, which may be attributed, in part, to a lack of standardized guidelines for conducting coverage surveys across the NTDs. When coverage surveys are conducted a commonly used approach is the Expanded Program on Immunization's 30-cluster survey (EPI), widely known for its practicality but criticized for falling short of probability sampling. We compared the feasibility of the EPI sampling design to two alternative sampling designs for measuring MDA coverage in Burkina Faso, Uganda and Malawi. The first of these alternatives, Lot Quality Assurance Sampling (LQAS), divided a district into five programmatically relevant supervisory areas (SAs) from which 19 persons were selected and the SA coverage was classified as good/poor. SA results were weighted and combined at the district level to estimate overall coverage with a precision of ± 10%. The second method, Probability Sampling with Segmentation (PSS), used segmentation within each selected cluster to simplify and expedite the selection of individuals while maintaining probability sampling. The EPI and PSS sample sizes were calculated for a precision of ± 5%, considered more useful for MDA evaluation. In Burkina Faso and Malawi, each method was conducted in a separate district; in Uganda, all three were used in the same district. When averaged across the three countries, LQAS took the least days to complete (16), followed by EPI (18) and PSS (20). Cost was closely tied to duration, with LQAS being the least expensive and PSS the most; however, all three methods were under $5,000 to implement per district. When asked about ease of use, survey teams generally scored the three methods similarly. Since PSS required only a relatively small increase in time and cost and was the only method of the three that generated unbiased coverage estimates with the desired precision, we conclude that it may be the best tool for conducting coverage evaluations to improve the performance of NTD programs.

1228

COMMUNITY DRUG DISTRIBUTOR PERFORMANCE IN THE CONTROL OF NEGLECTED TROPICAL DISEASES: ARE WE ASKING TOO MUCH?

Fiona M. Fleming[1], Fred Matovu[2], Joanne P. Webster[3], Narcis B. Kabatereine[1], Edridah M. Tukahebwa[4], Kristian S. Hansen[5]

[1]Schistosomiasis Control Initiative, Imperial College London, London, United Kingdom, [2]Faculty of Economics and Management, Makerere University, Kampala, Uganda, [3]Pathology and Pathogen Biology, Royal Veterinary College, London, United Kingdom, [4]Vector Control Division, Ministry of Health, Kampala, Uganda, [5]Department of Global Health and Development, London School of Hygiene & Tropical Medicine, London, United Kingdom

Trusted literate, or semi-literate, community drug distributors (CDDs) are the primary implementers in integrated preventive chemotherapy (IPCT) programmes for Neglected Tropical Disease (NTD) control. The CDDs are responsible for safely distributing drugs and for galvanising communities to repeatedly, often over many years, receive annual treatment, create and update treatment registers, monitor for side-effects and compile treatment coverage reports. These individuals are 'volunteers' for the programmes and receive, no, or minimal, remuneration for their annual work commitment. A mixed methods approach, which included pictorial diaries to prospectively record CDD use of time, structured interviews and focus group discussions, triangulated data on how 58 CDDs allocated their time towards their routine family activities and to NTD control activities in Uganda. The opportunity costs of CDD time were estimated using salary values; performance assessed by determining the relationship between time and programme coverage; and CDD motivation for participating in the programme was explored. Key findings showed approximately 2.5 working weeks (range, 0.6 to 11.4 working weeks) were spent on NTD control activities per year. The amount of time on NTD control activities significantly increased with each additional drug delivery that was required within an IPCT campaign. CDD time spent on NTD control activities had an impact of time available for subsistence and income generating engagements. As CDDs took more time to complete NTD control activities their treatment performance decreased. Motivation for the programme was low and CDDs felt undervalued.CDDs contribute a considerable amount of opportunity cost to the overall economic cost of the NTDCP in Uganda due to the commitment of their time. Nevertheless, programme coverage of at least 75%, as required by World Health Organization, is not being achieved and vulnerable individuals may not have access to treatment. The presenter will make recommendations for improvements in programme implementation and alternative support systems for the CDDs in order to utilise resources effectively and efficiently.

1229

PARTNERING FOR SUCCESS: INTEGRATED TRANSMISSION ASSESSMENT SURVEYS FOR LYMPHATIC FILARIASIS, SOIL-TRANSMITTED HELMINTHS AND MALARIA IN HAITI

Alaine K. Knipes[1], Jean Frantz Lemoine[2], Franck Monestime[3], Carl Fayette[3], Abdel Direny[3], Luccene Desir[4], Valery Madsen Beau de Rochars[5], Thomas Streit[4], Kristen Renneker[6], Brian Chu[6], Amanda Barry[1], Venkatachalam Udhayakumar[1], John Barnwell[1], Eric Rogier[1], Michelle Chang[1], Kimberly Mace[1], Kimberly Won[1], Patrick Lammie[7]

[1]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Programmes Nationaux de Malaria et de Filariose Lymphatique, Ministère de la Santé Publique et de la Population, Port au Prince, Haiti, [3]IMA World Health, Washington, DC, United States, [4]University of Notre Dame/Hôpital St. Croix, Léogane, Haiti, [5]University of Florida/The Carter Center, Atlanta, GA, United States, [6]Neglected Tropical Diseases Support Center, Task Force for Global Health, Atlanta, GA, United States, [7]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Neglected Tropical Diseases Support Center, Task Force for Global Health, Atlanta, GA, United States

The island of Hispaniola is the only remaining Caribbean island that is endemic for malaria and lymphatic filariasis (LF), with Haiti bearing the greater burden of both diseases. Haiti's National Program for the Elimination of LF (NPELF) reached full national coverage with mass drug administration (MDA) for LF in 2012. Several areas have reduced antigenemia prevalences to <2%, and in 2014 NPELF began conducting transmission assessment surveys (TAS) to determine eligibility to stop LF MDA. Haiti plans to conduct 48 TAS by the end of 2017. National malaria prevalence is low (0.4% in 2011), and with 16,872 confirmed cases reported in 2014, elimination of this disease is also considered feasible. Elimination goals for both diseases revealed opportunities to explore potential programmatic synergies, particularly as both programs must establish surveillance methods to identify potential remaining ***foci*** of transmission. In 2014, the World Health Organization (WHO) was finalizing guidelines for using LF TAS as a platform for soil transmitted helminth (STH) assessments, prompting NPELF to develop its own integrated protocol that also included malaria ('TAS-STH-malaria'). Haiti's TAS-STH-malaria survey addressed the need to determine if LF transmission had been interrupted, while also responding to WHO's call for integration of programs with common features of control and elimination strategies. In November 2014, a TAS-STH-malaria survey was piloted in Nippes department, Haiti. Teams enrolled 1632 children in 45 schools. Children were tested for LF, malaria, and STH. In all, three (0.2%) of 1632 children were positive for LF (immunochromatographic card test), zero (0%) of 1632 were positive for malaria (rapid diagnostic test), and 47 (17%) of 284 were positive for STH (Kato Katz). Blood spots are currently being analyzed for antibody responses to LF (Wb123, Bm14, and Bm33) and malaria (LSA-1, MSP-1-19, MSP-1-42(D), MSP-1-42(F), AMA-1, NS MSP-1-19) antigens using a multiplex platform. This approach demonstrated feasibility of an integrated TAS-STH-malaria survey, which is presently being implementing in four additional evaluation units.

1230

EVALUATING NEGLECTED TROPICAL DISEASE DATA REPORTING SYSTEMS: RESULTS FROM 6 DATA QUALITY ASSESSMENTS

Katie Zoerhoff[1], Pamela Mbabazi[2]

[1]RTI International, Washington, DC, United States, [2]World Health Organization, Geneva, Switzerland

With the WHO target date of 2020 for NTD elimination fast approaching, it is essential that national program managers understand their program performance so that they can take any necessary corrective actions in a timely manner. However, in order to use evidence for decision-making

appropriately, data must be available, complete, timely, and accurate. Data Quality Assessments (DQAs) are an effective tool to measure the quality of NTD data and the data management system, in order to identify areas that need improvement and develop actions to strengthen the reporting system. Six countries in Africa and Asia implemented DQAs in 2013-14 to evaluate the quality of their NTD data and reporting system. Available data were recounted and compared to reported values to assess data accuracy, and focused assessments were conducted with key stakeholders at every level of the reporting system in each country, totaling 165 sites. We found the following: overall, 77% of reports were available for recounting, 65% being complete with all the indicators assessed; data were submitted on time in only 12% of instances; approximately 50% of reported data were verified through recounting, with overreporting occurring in almost 1/3 of instances. Nearly all (91%) respondents indicated that data flow was through the national system, and 71.7% reported that there were designated staff responsible for reviewing quality of data received. However, many respondents noted that the data collection tools (e.g., treatment registers) did not have sufficient precision to measure indicators accurately. These findings suggest that the quality of data and reporting systems need to be strengthened for national program managers to make optimally informed decisions. As a result of these DQA exercises, countries have revised their data collection tools to better capture data, including sex- and age-disaggregated results, and strengthened training to include a larger focus on data management. Further effort and innovative approaches are needed to improve timeliness of data submission. Follow-up DQAs should be conducted as part of overall program evaluation activities.

1231

ARE WE REACHING WOMEN AND MEN EQUALLY WITH MASS DRUG ADMINISTRATION FOR NEGLECTED TROPICAL DISEASES? DATA FROM TWELVE COUNTRIES

Daniel Cohn, Kalpana Bhandari, Margaret Baker

RTI International, Washington, DC, United States

Preventive chemotherapy (PC) is a key strategy for control and elimination of a group of Neglected Tropical Diseases (NTDs): Lymphatic filariasis, onchocerciasis, schistosomiasis, soil-transmitted helminthes and trachoma. With over 800 million persons treated globally in 2012, it is essential to understand whether there is evidence of gender equity in the availability and utilization of the benefits of PC programs. Datasets created by national NTD programs supported by United States Agency for International Development recorded persons treated betweenOctober 2012 and September 2013. Records included nearly 200 million treatments, delivered to around 90 million people in 12 countries from 3 world regions. Gender-disaggregated data were available in all 12 countries for at least 1 NTD and for all targeted districts and diseases in 7 countries. Treatment ('epidemiologic') coverage was determined by dividing total (or sex-disaggregated) persons treated by the at-risk population, with gender-specific proportions of the at-risk population estimated from values of the most recent national census. Analysis showed that treatment coverage among females was overall similar to that of males, averaging 60.4% for females and 59.5% for males. This apparent gender equity held true when analyzed both by disease and by world region, though differences could sometimes be seen in countries with mass drug administration that targeted schistosomiasis or trachoma. No evidence of lower utilization of PC services by women was found. This suggests that the strategies used to take NTD treatment to communities, many living beyond the reach of routine health services, is providing good access to health for women. On the other hand, if women not eligible for treatment (for certain PC-NTD drugs, this may include women who are pregnant and/or in the first trimester of pregnancy, or lactating in the first week after birth) were to be removed from the denominator, treatment coverage would be consistently lower for men - a finding that warrants further exploration.

1232

GOING PAPERLESS? A MULTI-COUNTRY EXPERIENCE ON THE USE OF SMART PHONES IN THE CONTROL OF NEGLECTED TROPICAL DISEASES

Yolisa J. Nalule, Michael French, Jane Whitton, Guiseppina Ortu, Sarah Knowles

Schistosomiasis Control Initiative, Imperial College London, London, United Kingdom

Up-to-date disease distribution maps coupled with routine disease monitoring and evaluation data are crucial to design, plan and guide neglected tropical disease control programs (NTD). Data collection using mobile phones has increasingly been suggested as a favourable alternative to the paper based system. Country wide integrated NTD mapping in Rwanda, Burundi and Ethiopia and NTD treatment coverage survey validation in Uganda, Zanzibar and Malawi was conducted using the Task Force for Global Health's LINKS and EpiCollectPlus SMART phone data collection systems respectively. The tools allowed for simultaneous data collection and entry, quick uploading to a central database and real time data visualisation, analysis and storage. No extra data entry staff were needed and any errors in the uploaded data were promptly spotted and corrected. The progress of the teams, and the project itself, could be easily be monitored using the time stamps captured at each upload. However, requiring internet connectivity to upload data was a considerable limitation in the rural areas. Additionally sample processing necessitated the full time use of gloves making physical use of mobile phone difficult. Entries requiring open ended answers could not be incorporated using LINKS and significantly slowed down data entry using EpiCollectPlus due to slow typing speeds. The LINKS tool could only be modified in Atlanta, removing the flexibility of fixing any errors even when caught early during the field survey. The server also being stored in Atlanta, raises important questions over ownership of data/sovereignty of the programme. These challenges, in addition to the inevitable loss or damage of phones, resulted in the continued use of paper forms on site as backups, possibly introducing errors. Training time was prolonged as training on the use of a SMART phone was needed first before training on using the tool itself. In our experience, SMART phones were useful for household coverage surveys which have a limited number of questions however they are not yet robust and/or versatile enough to do away with the need to collect information on paper forms.

1233

COMPARABILITY BETWEEN INSECTICIDE RESISTANCE BIOASSAYS FOR MOSQUITO VECTORS: TIME TO REVIEW CURRENT METHODOLOGY?

Henry F. Owusu[1], Danica Jancaryova[1], David Malone[2], Pie Müller[1]

[1]University of Basel/Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]IVCC, Liverpool, United Kingdom

Insecticides play an integral role in the control of mosquito-borne diseases. With resistance to insecticides on the rise, surveillance of the target population for optimal choice of insecticides is a necessity. The Centers for Disease Control and Prevention (CDC) bottle assay and the World Health Organization (WHO) susceptibility test are the most frequently used methods in insecticide resistance monitoring. However, the two bioassays differ in terms of insecticide delivery and how resistance is measured. To evaluate how equivalent data from the two assays are, we compared them side-by-side. We did a literature search from 1998 to December 2014 to identify publications that performed both assays on the same mosquito population. We then tested the two bioassays on laboratory strains of ***Aedes aegypti***, ***Anopheles stephensi***, ***An. gambiae*** and ***An. arabiensis*** with different resistance levels against permethrin, λ-cyhalothrin, DDT, bendiocarb and malathion. We also measured the relationship between time-to-knockdown and 24 hours mortality. Both published data and results from the present laboratory experiments showed heterogeneity

in the comparability of the two bioassays. Following their standard procedures the two assays showed poor agreement in detecting resistance at the WHO cut-off of 90% (Cohen's $\kappa = 0.06$). There was better agreement when 24 hour mortality was recorded in the CDC bottle assay and compared with that of the WHO susceptibility test (Cohen's $\kappa = 0.5148$). Although statistically significant, time-to-knockdown was a weak predictor of 24 hour mortality (OR = 0.97, $p < 0.001$). In conclusion, though the two assays can detect insecticide resistance, they may not be used interchangeably. While the diagnostic dose in the WHO susceptibility test does not allow for detecting shifts at low or extreme resistance levels, time-to-knockdown measured in the CDC bottle assay is a poor predictor of 24 hours mortality. Therefore, dose-response assays could provide the most flexibility. New standardized bioassays are needed that produce consistent dose-response measurements with a minimal number of mosquitoes.

1234

ENVIRONMENTALLY FRIENDLY USE TOOL TO CONTROL MOSQUITO POPULATIONS WITHOUT RISK OF INSECTICIDE RESISTANCE: THE LEHMANN'S FUNNEL ENTRY TRAP

Abdoulaye Diabate[1], Roger Sanou[1], Lea Pare/Toe[1], Roch K. Dabire[1], Frederic Tripet[2], Enrico Prenna[3], Annette Habluetzel[3], Jim Lavery[4]

[1]IRSS/Centre Muraz, Bobo-Dioulasso, Burkina Faso, [2]Keele University, Keele, United Kingdom, [3]University of Camerino, Camerino, Italy, [4]University of Toronto, Toronto, ON, Canada

Malaria vector control needs ground-breaking approaches to complement existing tools and accelerate our global efforts toward the disease elimination. For decades malaria vector control in Africa has relied on IRS and LLINs, both of which operate within houses. The emergence and spread of insecticide resistance and changes in vector biting behaviour have seriously challenged these conventional tools/strategy and there is an urgent call for innovation. Malaria vectors present several vulnerable points during their life cycle that can be exploited to tackle them, but they have seldom been investigated. Here we exploit the inherent feeding behaviour of malaria vectors inside houses to design an environmentally friendly use trap to cut down the high reproductive rate of mosquitoes. The Lehmann's trap needs no insecticide and it combines the function of killing and blocking entry into houses. Preliminary studies conducted in two ecological settings in Burkina Faso has indicated that the trap could reduce mosquito density by up to 80% in houses and has the potential to swift population structure by cumulatively killing old females that are epidemiologically dangerous. Here we focus on improving the trap design for improved performance and end user acceptability and standardized product specifications to enable broad manufacturing. There is a global consensus that new intervention tools are needed to cross the last miles in malaria elimination and the Lehmann's trap can contribute to fill this gap. It showed an excellent promise in suppressing mosquito densities even in area of high insecticide resistance. It requires no chemicals, is self-operational and it stands from its simplicity.

1235

ENTOMOLOGICAL SURVEILLANCE SYSTEM IN ZANZIBAR: CONTRIBUTIONS TO MALARIA ELIMINATION EFFORTS ON THE ISLANDS

Juma Hassan Mcha[1], Bakar O. Khatib[1], Khamis A. Haji[1], Abdullah S. Ali[1], Mahdi M. Ramsan[2], Stephen M. Magesa[2], Jeremiah M. Ngondi[2], Silas Majembere[3]

[1]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [2]RTI International, Dar es Salaam, United Republic of Tanzania, [3]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania

Malaria vector surveillance is important for planning and implementation of evidence-based vector control interventions. In Zanzibar transition from malaria control to elimination stage has been complicated by the changing ecology and behaviour of local mosquito populations. Studies conducted by the Zanzibar malaria elimination program (ZAMEP) in 22 sentinel surveillance sites, (10 in Pemba and 12 in Unguja) from 2007 to 2014 show that malaria transmission is probably mediated by ***Anopheles arabiensis***. This vector feeds more on the bovine 72% rather than on human (8%) in Pemba. The behavioral patterns of different species (***An. fanestus***, ***An. arabiensis*** and ***An. gambiae***) has maintained ongoing malaria transmission in hotspot sites in Unguja Island. Historically, malaria transmission has been dominated by vector species that primarily feed and rest indoors, where they can be efficiently targeted with long lasting insecticidal nets (LLINs) and indoor residual spraying (IRS). Following universal coverage of vector control through LLINs and IRS, majority of bites are now out-doors (91% and 55% in Pemba and Unguja, respectively). There is growing evidence across the islands that the widespread use of LLINs and IRS is driving vector species composition toward those with more flexible behaviour such as ***An. arabiensis***. This could not only prevent the achievement of elimination, but also undermine the continued effectiveness of interventions. Therefore LLINs and IRS will need to be supplemented by other vector control interventions to reduce mosquito-human contact. In addition, enhanced entomological surveillance will be important to target appropriate vector control interventions. Monitoring vectors to identify ***foci*** of transmission during the elimination phase can be challenging as estimate of most factors of vectorial capacity become extremely difficult due to the very small number of infected vectors, as a result of control interventions. Nonetheless, at least monitoring of larval and adult vector densities is important and should be an integral part of all elimination efforts.

THE USE OF ENDECTOCIDES IN CATTLE TO CONTROL OUTDOOR RESIDUAL MALARIA TRANSMISSION IN WESTERN KENYA

Saul Lozano-Fuentes[1], Rebekah Kading[1], Daniel Hartman[1], Edward Okoth[2], Naftaly Githaka[2], Vish Nene[2], Richard Poche[1]

[1]Genesis Laboratories, Wellington, CO, United States, [2]International Livestock Research Institute, Nairobi, Kenya

The opportunistic blood feeding behavior of malaria vector species such as ***Anopheles arabiensis*** Patton complicates vector control by conventional methods such as indoor residual spraying and insecticide treated nets. The objective of this research was to evaluate the efficacy of the insecticidal active ingredients eprinomectin and fipronil, at reducing malaria vector abundance when applied to cattle (***Bos indicus***) in a small scale field study. Pilot studies were carried out in the Samia District of western Kenya during 2014-2015. Treatment and control areas were allocated by a randomized block design comprised of 50 homes per area. Prior to cattle treatments, baseline mosquito collections were performed by pyrethrum spray catch or backpack aspiration. For the eprinomectin trial, cattle in the treatment area were administered topical applications of eprinomectin at 0.5 mg/kg once per week for two consecutive weeks. For the fipronil trial, cattle were dosed once orally with fipronil at 0.5 mg/kg body weight. Post-treatment mosquito collections were performed weekly for two weeks following the eprinomectin treatments, and for four weeks following the fipronil treatment. Mosquitoes were identified morphologically, and screened for molecular species identification, sporozoite presence, and blood host by PCR-based methods. For the eprinomectin trial, the indoor resting density of ***An. arabiensis*** was significantly lower (95% probability) in the treatment area compared to the control area one week post-treatment, representing a significant reduction in the indoor resting population of this species by 32%. Two weeks post-treatment with eprinomectin, the number of mosquitoes per hut was not significantly different between the treatment and control areas. Additional entomological parameters will be presented, as well as the results of the fipronil field trial. Endectocidal treatment of cattle has the potential to significantly impact residual, outdoor malaria transmission driven by ***An. arabiensis*** and is an important tool to supplement existing vector control interventions which target more anthropophilic species.

1237

DEPLOYMENT OF OPTIMAL-DOSE, VOLATILE PYRETHROIDS FOR THE PREVENTION OF BITING AND DISEASE TRANSMISSION BY INSECTS

Gregor J. Devine[1], Scott A. Ritchie[2], Gissella M. Vasquez[3], Jonathan Darbro[1], Lisa M. Rigby[1], Craig A. Stoops[3]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]James Cook University, Cairns, Australia, [3]U.S. Naval Medical Research Unit - 6, Lima, Peru

Existing vector control tools are compromised by coverage, cost, insecticide resistance and human compliance. Outdoor biting insects are particularly hard to target. Fast, flexible, safe methods of insecticide delivery, offering dramatic decreases in biting, across a range of environments, are highly desirable. An under-exploited group of volatile pyrethroids offers considerable potential in this regard. Passive formulations of odourless, polyfluorinated compounds, applied at optimal doses, can stop mosquitoes biting and may therefore have profound effects on disease transmission. We demonstrate the potential of metofluthrin, transfluthrin and heptafluthrin to deliver dramatic protection from bites via a mixture of lethal and confusant effects on knock down, mortality, host-seeking and probing. In real-world, well-ventilated rooms, >40% of ***Aedes aegypti*** mosquitoes were knocked down and > 80% of bites were prevented 3 metres from a passive device that used neither heat nor power and that remained effective for >20 days (10% metofluthrin w/w). In salt marsh habitats, 3m3 tents baited with humans and containing the same device contained just 5% of the mosquitoes (Aedes vigilax) that were collected from unprotected baited tents. None of those remaining mosquitoes attempted to bite. In the same salt marshes, simple candle formulations of another volatile, heptafluthrin (5% w/w), reduced light-trap and human landing catches by >93% in close proximity (1.5m) downwind of the candles. Importantly, these compounds may be largely unaffected by conventional pyrethroid-resistant mechanisms. Strongly permethrin and lambdacyhalothrin resistant ***Aedes aegypti*** were as behaviourally affected as fully susceptible insects in the presence of sublethal metofluthrin doses. Neither have we observed any evidence of true repellency (orientation away from the volatile point source) from the formulations that we tested (3-10% w/w). This suggests that treatment of one area by these compounds does not simply redistribute vectors to unprotected zones.

1238

SUB-LETHAL EFFECTS OF INSECTICIDES: CONSEQUENCES FOR MALARIA VECTOR CONTROL

Mafalda Viana[1], Jason Mathiopoulos[1], Angela Hughes[2], Hilary Ranson[2], Heather Ferguson[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]University of Liverpool, Liverpool, United Kingdom

Insecticides have been the most effective and widespread control strategy for vector-borne diseases. Increasing levels of insecticide resistance in malaria vectors across Africa and Asia have potential to threaten the effectiveness of this control strategy. These fears stem from observed declines in the proportion of mosquitoes killed on immediate contact with treated surfaces. However, the epidemiological consequences of this resistance may be lower than expected if mosquitoes that survive direct contact with insecticides suffer a reduction in longer-term fitness (sub-lethal effects). Sub-lethal effects could manifest either as reduced long-term survival, and/or reproduction through changes to their egg production or larval development. Here we investigate the potential epidemiological impact of sub-lethal effects of insecticides as expected to arise from long lasting insecticide treated bednets. Using data from laboratory experiments in which the survival of African malaria vectors that survived initial contact with insecticide was measured, we extend traditional survival and transmission models to include age structure and investigate immediate and age-specific long lasting effects of the interventions. Our aim is to illustrate if and by what extent current estimates of the detrimental impacts of insecticide resistance on malaria vector control may be overestimated by the existence of sub-lethal effects.

1239

DO HOLES IN LONG LASTING INSECTICIDAL NETS COMPROMISE THEIR EFFICACY AGAINST PYRETHROID RESISTANT *ANOPHELES GAMBIAE* AND *CULEX QUINQUEFASCIATUS*? RESULTS FROM A RELEASE-RECAPTURE STUDY IN EXPERIMENTAL HUTS

Olivier J. Briet[1], Sanjiarizaha Randriamaherijaona[2], Sébastien Boyer[2], Aziz Bouraima[3], Raphael N'Guessan[4], Christophe Rogier[2], Vincent Corbel[5]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [3]Centre de Recherches Entomologiques de Cotonou, Cotonou, Benin, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]Institut de Recherche pour le Développement, Montpellier, France

Experimental hut and observational studies in Benin show that pyrethroid resistance reduces the insecticidal effect and personal protection of long lasting insecticidal nets (LLINs) especially when they become torn. The World Health Organization has proposed a threshold for when nets are "too torn" at 1,000 cm2. This study examines whether there is a threshold above which LLINs don't reduce malaria transmission by resistant mosquitoes. Intact and artificially holed LLINs and untreated nets were tested by releasing mosquitoes from a susceptible ***Anopheles gambiae*** colony, a local pyrethroid-resistant ***An. gambiae*** population and a local resistant ***Culex quinquefasciatus*** population in closed experimental huts in Benin. The efficacy of LLINs and untreated nets was evaluated in terms of protection against blood feeding, insecticidal effect and potential effect on malaria transmission. Personal protection by both LLINs and untreated nets decreased exponentially with increasing holed surface area, without evidence for a specific threshold beyond which LLINs could be considered as ineffective. The insecticidal effect of LLINs was lower in resistant mosquitoes than in susceptible mosquitoes, but holed surface area had little or no impact on the insecticidal effect of LLINs. LLINs with 22,500 cm2 holed surface area and target insecticide content provided a personal protection of 0.60 (95% CI: 0.44-0.73) and a low insecticidal effect of 0.20 (95% CI: 0.12-0.30) against resistant ***An. gambiae***. Nevertheless, mathematical models suggested that if 80% of the population uses such nets, they could still prevent 94% (95% CI: 89-97%) of transmission by pyrethroid-resistant ***An. gambiae***. Even though personal protection by LLINs against feeding mosquitoes is strongly reduced by holes, the insecticidal effect of LLINs is independent of the holed surface area but strongly dependent on insecticide resistance. Badly torn nets that still contain insecticide have potential to reduce malaria transmission. The relationship between LLIN integrity and efficacy needs to be understood in order to guide LLIN distribution policy.

1240

GENETIC MODIFICATION OF PARASITE ANTIGEN RESCUES HOST DENDRITIC CELL ACTIVATION

Jessica S. Duprez[1], Marjorie Besançon[2], Judith E. Allen[2], David W. Taylor[1], Simon A. Babayan[3]

[1]Division of Pathway Medicine, School of Biomedical Studies, University of Edinburgh, Edinburgh, United Kingdom, [2]Institute of Immunology, Infection, and Immunity, University of Edinburgh, Edinburgh, United Kingdom, [3]Institute of Biodiversity, Animal Health and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom

Filarial nematodes establish chronic infections by suppressing the host's immune system. Successful DNA vaccination using the ***Litomosoides sigmodontis*** model demonstrated that immunisation targeting suppressive molecules such as the abundant larval transcript-1 (Ls-ALT) and

the cysteine protease inhibitor-2 (Ls-CPI), can increase immune responses during subsequent infection and consistently reduce the production of microfilariae two months post first exposure to the parasite. However, because protective effects of these vaccines are only detected during late stages of the infection, it remains unclear how these vaccines push the immune system into a more protective phenotype before exposure to the parasites. Since dendritic cells (DC) play a key role in initiating adaptive immune responses, and as homologues of Ls-CPI have previously been shown to interfere directly with antigen presentation and DC activation, we decided to examine the effects of vaccines containing either Ls-CPI or the modified, functionally impaired, Ls-CPIm on DC activation ***in vitro*** and ***in vivo***. Surface activation marker CD86 expression was increased on DC from Ls-CPIm- but not in Ls-CPI-immunised mice. The functional significance of these effects was then assessed by allowing bone-marrow derived DC (BMDC) to prime T cells ***in vitro***: prior to the addition of T cells, BMDC loaded with Ls-CPIm produced more IL-12 and IL-6, and less IL-10, than BMDC loaded with Ls-CPI. Co-culture with naive T cells showed increased CD86 and MHC-II expression on BMDC, and increased IL-12 and IL-6 production with Ls-CPIm as compared to Ls-CPI. We are now investigating if the increased DC activation also corresponds to an increase in T cell activation, and whether it has an effect on Th2 polarization. So far we demonstrate the importance of DC activation before the onset of infection and provide an insight on how anti-filarial vaccines can achieve protection.

1241

CHRONIC *LITOMOSOIDES SIGMODONTIS* INFECTION IMPROVES BACTERIAL SEPSIS OUTCOME VIA TLR2 DEPENDENT MACROPHAGE MODULATION

Fabian Gondorf[1], Afiat Berbudi[1], Benedikt C. Buerfent[1], Jesuthas Ajendra[1], Dominique Blömker[2], Sabine Specht[1], David Schmidt[1], Anna-Lena Neumann[1], Laura E. Layland[1], Achim Hoerauf[1], **Marc P. Hübner**[1]

[1]University Hospital of Bonn, Bonn, Germany, [2]University Hospital of Essen, Essen, Germany

Immunomodulation by the filarial nematode ***Litomosoides sigmodontis*** (L.s.) has been demonstrated to improve various inflammatory disorders including autoimmune diseases and allergy. In the current study we investigated whether chronic L.s. infection reduces E. coli-induced acute, systemic inflammatory immune responses as they occur during sepsis. Chronic L.s.-infected BALB/c mice had a milder E. coli-induced hypothermia, diminished systemic pro-inflammatory cytokine concentrations and improved bacterial clearance compared to E. coli-only challenged controls and led to an increased sepsis survival. Analysis of peritoneal macrophages from E. coli-challenged L.s.-infected mice further revealed a reduced macrophage activation and apoptosis as well as an improved phagocytosis. Peritoneal macrophages were essential for the improved sepsis outcome, as L.s.-mediated protection was lost in clodronate liposome treated mice. Wolbachia endosymbionts of L.s. express lipoproteins that activate mononuclear cells via TLR2. ***In vitro*** priming of macrophages with L.s. extract reduced macrophage activation in a TLR2 and Wolbachia dependent manner and PCR array analysis further showed that negative regulators of TLR/NFkB signaling were upregulated in macrophages of E. coli-challenged, L.s.-infected mice. Transfer of ***in vivo*** and vitro modulated macrophages improved sepsis outcome in a TLR2 and Wolbachia-dependent manner and L.s. infection of TLR2 deficient mice did not improve macrophage phagocytosis and E. coli challenge resulted in an increased bacterial load, exacerbated systemic inflammation and sepsis caused death. Taken together this study suggests that macrophage modulation by L.s. infection has a dual beneficial effect on bacterial sepsis, reducing systemic inflammatory immune responses and improving bacterial clearance.

1242

MATERNAL PARASITIC INFECTIONS DURING PREGNANCY AND SPECIFIC ANTI-PARASITE CYTOKINE RESPONSES IN CORD BLOOD ARE ASSOCIATED WITH IMPAIRED VACCINE EFFICACY IN KENYAN INFANTS

Indu Malhotra[1], Peter Mungai[1], Maxim McKibben[1], Laura J. Sutherland[1], Eric Muchiri[2], Nathsan Morris[1], Charles H. King[1], Christopher L. King[1], A. Desiree LaBeaud[3]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Division of Vector Borne Diseases, Nairobi, Kenya, [3]Stanford University, Stanford, CA, United States

We have shown that antenatal malaria and helminth infections impair the IgG antibody response to Haemophilus influenzae (Hib) and diphtheria toxoid (DT) among infants. We have also shown that soluble products of these chronic parasitic infections can cross the placenta and induce a spectrum of immune responses in the fetus, which persist into early childhood and may impair early childhood response to vaccines. To examine this possibility we investigated whether prenatal exposure to helminth and malaria infections and subsequent T cell response in cord blood lymphocytes (CBL) affect the infant immune response to Hib and DT. 450 Kenyan mother/infant pairs were enrolled in the study and tested for lymphatic filariasis (LF), urogenital schistosomiasis and malaria. The newborns were followed every 6 months from birth to 3 years of age and plasma was tested for PRP-specific (induced by Hib) and DT-specific IgG at each time point. IFN-Υ, IL5, IL13, IL10, IL6 and TNF-α recall responses were evaluated in CBL to blood stage malaria antigens (***Plasmodium falciparum***), ***Schistosoma*** antigen (SWAP), and filarial antigen (BMA). Overall, 79% of the mothers were infected with LF, urogenital schistosomiasis and/or malaria. There was a spectrum of immune responses in cord blood lymphocytes that included pro-inflammatory responses characterized by predominantly IL-6 and TNFa production, a Th2-type phenotype (predominantly IL5 and/or IL13) or regulatory responses (IL10). Using a generalized estimating equation analysis, parasite antigen-induced pro-inflammatory responses were associated with markedly reduced DT-specific IgG levels (p=0.02 to 0.0003), and regulatory responses were associated with reduced DT-specific IgG, p=0.0007. By contrast, parasite-specific Th2-type responses were associated with enhanced DT-specific IgG (0.02 to 0.0007) and PRP-specific IgG (p=0.027 to 0.046). Thus, the type of fetal immune response acquired to parasite antigens ***in utero*** may persist into early infancy and modulate IgG levels to childhood vaccines.

1243

MASS DRUG ADMINISTRATION WITH PRAZIQUANTEL BOOSTS ANTI-SCHISTOSOME PROTECTIVE ANTIBODY RESPONSES IN SCHOOL CHILDREN FROM WESTERN KENYA

Eric M. Ndombi[1], Diana Riner[2], Bernard Abudho[3], Nupur Kittur[2], Horace Ochanda[1], Yeuk-Mui Lee[4], Colin M. M. Fitzsimmons[5], David W. Dunne[5], William E. Secor[4], Diana M. Karanja[6], Daniel G. Colley[2]

[1]University of Nairobi, Nairobi, Kenya, [2]University of Georgia, Athens, GA, United States, [3]Maseno University, Kisumu, Kenya, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]University of Cambridge, Cambridge, United Kingdom, [6]Kenya Medical Research Institute, Kisumu, Kenya

Most countries where schistosomiasis is prevalent have intensified efforts to control the disease through annual mass drug administration (MDA) using praziquantel. The main target of MDA programs are school-age children as recommended by the World Health Organization (WHO). However, the effect of annual MDA on schistosome-specific immune responses in this age group has not been investigated. About thirty children per class (total of 314, age range 6-18) were recruited from 4 primary and secondary schools in Rarieda, Siaya County, western Kenya.

Venous blood was collected, and plasmas were prepared. Thereafter, MDA was carried out in the four schools. One year later, follow-up samples were collected from 98 children (ages 7 to 13) who had received treatment. Total IgG, IgG4 and IgE antibody responses to schistosome crude egg (SEA) and adult (SWAP) antigens as well as the recombinant ***Schistosoma mansoni*** Tegument-Allergen-Like (SmTAL) proteins, SmTAL-1, SmTAL-2, and SmTAL-5 were assayed by ELISA. Treatment increased the number of responders to SEA and mean anti-SEA IgE levels while decreasing mean anti-SWAP and anti-SEA IgG4. Moreover, there was a more robust IgE response to TAL-1 (a surrogate for resistance) in older children at baseline and a general increase in the percentage of children with IgE responses to TAL-1 after treatment. Additionally, following MDA there was a striking decrease in mean anti-SmTAL 5 IgE, which is expressed in cercariae and worms but not eggs. However, there was a significant boost in mean IgG4 levels against anti-SmTAL 2 (an egg-specific antigen), in all age groups after treatment. The most notable finding from this study is that MDA boosts IgE responses and tends to increase the number of responders in younger age-groups. IgE is associated with resistance to reinfection in schistosomiasis; thus, our data suggest that MDA, in addition to treating current infections, may help protect children from subsequent infection.

1244

IMMUNE RESPONSE OF INNATE LYMPHOID CELLS IN HUMAN FILARIAL INFECTIONS

Sandra Bonne-Annee, Thomas B. Nutman

National Institutes of Health, Bethesda, MD, United States

The CD4+ T cell response in acute filarial infection is characterized by an expansion of IL-4-producing (Th2-associated) cells that gradually contracts with longstanding infection. The factors involved in initiating this Th2 expansion are still not completely understood, but certainly involve innate lymphoid cells (ILCs). Previously, we have shown that a subset of human ILCs that express CD117 (cKit) were expanded during relatively acute filarial infections. With better definition of human lineage negative (Lin-) ILCs consisting of 3 distinct subsets: ILC1s (Lin-CD45+CD127+cKit-NKp44-), ILC2s (Lin-CD45+CD127+CRTH2+) and ILC3s (Lin-CD45+CD127+cKit+NKp44-/+), we have established standardized protocols using multiparameter flow cytometry and analyzed the frequency and composition of ILCs in human whole blood (n=45) and human skin (n=6) from healthy donors. Under homeostatic conditions, human blood is dominated by ILC1 (Geometric Mean (GM) 59%) whereas the remainder is split almost equally between ILC2 (GM=22%) and ILC3s (GM=19%). In contrast, human skin has a quite different ILC composition with more than 29% ILC2s, 26% ILC3s and 13%ILC1s; the remaining 32% of the ILCs in the skin were "unclassifiable" in that they were Lin-CD45+CD127+ but CRTH2-NKp44-ckit-. When these more clearly defined definitions of ILC populations were examined in relatively acutely infected patients with filarial infections (microfilariae [mf] positive) and uninfected controls we found that the filarial-infected individuals had a marked (up to 5-fold) increased frequency of ILCs compared to uninfected individuals. Surprisingly, the composition of expanded ILC subsets in filarial infected individuals were largely ILC3s (63%) with ILC1s (22%), ILC2s (9%) and "unclassifiable" (6%) making up the rest. Studies are currently underway to determine if ***ex vivo*** exposure to live mf (found in the blood) or L3 parasites (that transit through the skin) directly (or indirectly) drive CD4+ T cell subset differentiation through parasite-induced ILC activation.

1245

A NEWLY IDENTIFIED ROLE FOR IL-22 IN BLADDER IMMUNITY

Jared Honeycutt[1], **Michael H. Hsieh**[2]

[1]Stanford University, Stanford, CA, United States, [2]Biomedical Research Institute, Rockville, MD, United States

In contrast to mechanisms demonstrated in the gut and lung, it is currently unclear how inflammatory pathways in the urinary tract contribute to host protection and pathology during parasitic or bacterial infection. Recent reports indicate that interleukin-22 (IL-22) is a key cytokine supporting epithelial immunity while its improper regulation may contribute to pathologies such as fibrosis and cancer. We hypothesized that IL-22 may have a role in bladder immunity during ***Schistosoma haematobium*** and E.coli infections. IL-22-null (KO) and wild type (wt) female mice underwent bladder wall injection with S. ***haematobium*** eggs or transurethral infection with type 1 piliated uropathogenic E. coli UTI89. Levels of IL-22 and its soluble binding protein, IL-22BP, were increased in the bladder after exposure to S. ***haematobium*** eggs. Genes typically induced by IL-22 were expressed at higher levels after S. ***haematobium*** egg injection. IL-22 receptor α1 expression was detectable in the urothelium by immunofluorescence and qPCR. Injection of S. ***haematobium*** eggs into IL-22-KO vs wt mice resulted in differential expression of genes related to glutathione transferase activity, transferase activity, and epithelial cell development. Numerous genes for the uroplakins and Wnt/Hedgehog pathways were downregulated in egg-injected, IL-22-KO mice relative to their wt counterparts. These changes suggest that, as in the gut, IL22 is important for replenishing the bladder epithelial lining during infection-related injury. IL-22-KO and wild-type littermate mice were transurethrally infected with UTI89, which uses the adhesin FimH to adhere to mature urothelial cells. IL-22-KO mice had lower bacterial counts in their urine, bladder, and kidneys. Giving stabilized IL-22 cytokine (IL-22-Fc) to UTI89-infected mice led to higher kidney bacterial counts and increased morbidity. Our data suggest that IL-22 is indeed important in urinary tract immunity and may interfere with clearance of bacteria from the urinary tract, potentially through its role in maintenance of mature urothelium.

1246

PAN-AMERICAN MIGRATION PROMOTES THE SPREAD OF PATHOGENIC *TRYPANOSOMA CRUZI* HYBRID STRAINS

Louisa A. Messenger[1], Juan-David Ramirez[2], Martin S. Llewellyn[1], Felipe Guhl[3], Michael A. Miles[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Universidad del Rosario, Bogota, Colombia, [3]Universidad de Los Andes, Bogota, Colombia

The principal reproduction strategy of ***Trypanosoma cruzi***, the aetiological agent of Chagas disease, is the subject of an intense, decades-old debate. Despite the existence of two recent natural hybrid lineages (TcV and TcVI), which are sympatric with severe disease in southern endemic areas, a pervasive view is that recombination has been 'restrained' at an evolutionary scale and is of little epidemiological relevance to contemporary parasite populations. With improved sampling strategies, the geographical distribution of TcV and TcVI appears to be expanding. High resolution nuclear and mitochondrial genotyping of potential hybrid isolates from domestic vectors and human infections in Colombia was undertaken, in comparison to representative strains from across South America, to resolve their putative status as novel recombinants. All suspected Colombian hybrids were highly heterozygous, minimally diverse and possessed intact parental alleles at each loci. Compared to local Colombian isolates, hybrids were distinct from, but more closely related to, those identified in southern reference TcVI strains. Based on independent inheritance patterns of microsatellite loci, our data support the hypothesis that two recombination events led to the formation of TcV and TcVI. However, more private alleles among Colombian hybrids and the sharing of mitochondrial haplotypes between southern TcV isolates and a Colombian TcVI strain, suggests the evolution of these recombinant lineages may be more complicated than previously assumed. The origin of these Colombian hybrids is unclear; they are unlikely to be predecessors of southern TcVI strains, but were also not clear descendants, and may instead represent a sibling group, which diverged and anthroponotically dispersed northwards, following a single hybridization event between heterozygous southern TcII and TcIII isolates. We discuss the important implications the geographical range expansion of TcVI has for emergent

human Chagas disease in Colombia, considering the successful, epidemic establishment of this low-diversity genotype among domestic transmission cycles in the South.

1247

GENOTYPING OF *TRYPANOSOMA CRUZI* DNA IN BLOOD SAMPLES FROM AUTOCHTHONOUS CHAGAS DISEASE PATIENTS FROM SOUTHEASTERN AND CENTRAL TEXAS

Claudia P. Herrera[1], **Melissa N. Garcia**[2], Rodion Gorchakov[2], Sarah Murphy[2], Pierre Buekens[3], Kristy O. Murray[2]

[1]Tulane University, School of Public Health and Tropical Medicine, Department of Tropical Medicine, Vector-Borne Infectious Disease Research Center, New Orleans, LA, United States, [2]Baylor College of Medicine, Houston, TX, United States, [3]Tulane University, School of Public Health and Tropical Medicine, New Orleans, LA, United States

The parasitic protozoa ***Trypanosoma cruzi***, the causative agent of Chagas disease, represents a major public health problem in Latin America. Although the United States was initially defined as non-endemic for Chagas disease due to the rarity of human cases, ***T. cruzi*** has now been amply demonstrated as enzootic in different regions of the Southern United States. Recently our group described the first newly identified geographic clustering of locally-acquired human infections in the Southern US. This study focused on the molecular identification and genotyping of ***T. cruzi*** in human blood samples collected from autochthonous Chagas disease patients in Southeastern and Central Texas. ***T. cruzi*** infection was determined by standard PCR using primers specific for the minicircle variable region of the kinetoplastid DNA with the primers 121-122 and the highly repetitive genomic satellite DNA with the primers TcZF-R. Genotyping of discrete typing units (DTUs) was performed by amplification of mini-exon using a set of three primers, reported by different authors, to evaluate the sensitivity in the DTUs detection. We found a higher than expected percentage of blood samples positive by PCR for ***T. cruzi*** using two different DNA markers. The kDNA marker was more sensitive than the satDNA marker. Of the PCR positive samples, we were able to genotype approximately half. Single infection with TcI DTU and mixed infection with TcI and non-TcI DTUs were detected in a minority of the samples. Single infection with the non-TcI DTU was detected in the majority of the samples. Sequencing is currently underway to classify the non-TcI DTUs. Cardiac findings were measured by electrocardiogram (ECG), and classified using current clinical guidelines for Chagas cardiac related ECG abnormalities. Cardiac morbidity was prevalent and associated with both TcI and non-TcI DTU types. The novel results of this study provide a unique insight into the distribution of locally circulating DTUs for enhanced diagnosis of Chagas disease in the Southern US. Additionally, our findings provide supporting evidence that the circulating DTUs are competent causes of cardiac morbidity.

1248

ESTIMATING THE BURDEN OF CHAGAS DISEASE IN THE UNITED STATES

Jen Manne-Goehler[1], Chukwuemeka Umeh[2], Veronika J. Wirtz[2]

[1]Beth Israel Deaconess Medical Center, Boston, MA, United States, [2]Boston University School of Public Health, Boston, MA, United States

With changing human migration patterns, the burden of Chagas disease in the United States has increased. The most recent prevalence estimate for Chagas disease in the US was created in 2009. The objective of this study is to provide an update of the current national case estimate for Chagas disease in the US and, for the first time, to estimate the number of cases at the state level and analyze the epidemiologic data on cases diagnosed and treated from 2007-2013. State-level estimates of Chagas disease cases were computed using State-Level Foreign-Born Hispanic Population Estimates by single Country of Origin group from the 2012 American Community Survey for a five-year period (2008-2012) and country prevalence estimates from the World Health Organization. Geographic Information Systems was used to compare the distribution of estimated cases in each state to the number of infections identified in the donated blood supply from 2007-2013 per data from the AABB (formerly American Association of Blood Banks) and treatment releases of benznidazole and nifurtimox over the same period per data from the US Centers for Disease Control and Prevention. The results of this analysis show an updated national estimate of 243,048 cases of ***T. cruzi*** infection in the United States. The state level results show four states with over 10,000 cases and an additional two states with over 5,000 cases. Moreover, since 2007, the AABB has confirmed 1,908 cases of ***T. cruzi*** infection in the donated blood supply and the CDC has released treatment for 422 infected patients over this same period. In conclusion, this study demonstrates a decreased but still substantial burden of Chagas disease in the US at the national level and offers the first state level prevalence estimates for Chagas disease. We show a geographically focal burden and one that is largely but not completely congruent with confirmed cases in the US blood supply. Finally, this study not only lends important new insight into the distribution of this disease in the US but also suggests the need for greater study and resources to support both screening and treatment.

1249

BUILDING AN INVENTORY OF THE HEALTH FACILITY INFRASTRUCTURE IN COUNTRIES WITH ENDEMIC SLEEPING SICKNESS FOR TARGETING DIAGNOSTIC RESOURCES

Paul R. Bessell[1], Sylvain Biéler[2], Joseph M. Ndung'u[2]

[1]Epi Interventions Ltd., Edinburgh, United Kingdom, [2]FIND, Geneva, Switzerland

Human African Trypanosomiasis (HAT) is a highly debilitating vector born disease that is endemic in a number of Sub-Saharan African countries. It is important to identify cases early in infection when clinical signs can be mild but the highly toxic and onerous treatment makes it vital to obtain the correct diagnosis. Being forced to travel long distances can form a barrier to reporting and diagnosis, whilst poorly targeted resources can result in an infrastructure that is difficult to maintain and support. Therefore, in order to correctly target HAT diagnostics, it is necessary to have up to date information on the location and capacity of diagnostic facilities. To collect these data, we worked with HAT control programmes in 8 African nations to compile databases of health infrastructure in their HAT ***foci***. Data collected include the location, equipment and staffing resources and history of diagnosing HAT cases. Facilities in ***foci*** in Uganda, Tanzania, Nigeria and Guinea have been mapped entirely, whilst in South Sudan, Chad and the DRC, the ***foci*** with the greatest prevalence have been characterised. In total, detailed data has been collected on 4803 facilities. The data have been used to inform HAT elimination programs in all countries except Tanzania through the delivery of enhanced diagnostics in an integrated hierarchical structure in the passive surveillance systems. As part of these programs, 1310 facilities have been equipped with new rapid diagnostic tests, 53 with new fluorescence microscopes and 13 large facilities with loop mediated isothermal amplification of DNA (LAMP) incubators. This required the selection of appropriate facilities for improvement of diagnostics to ensure full coverage of the population at risk and on-going monitoring of diagnostic activities at the facilities. By improving HAT screening infrastructure in all levels of health systems, new cases have been identified through passive surveillance in participating countries. Crucial to this surveillance model is the detailed characterisation of health facilities. These data are owned by the countries and can be used for general management of healthcare provision.

FEASIBILITY OF ELIMINATING VISCERAL LEISHMANIASIS FROM THE INDIAN SUBCONTINENT

Epke A. le Rutte[1], Luc E. Coffeng[1], Daniel M. Bontje[1], Epco C. Hasker[2], Rinke C. Hoekstra[1], Roel Bakker[1], Marleen Boelaert[2], Sake J. de Vlas[1]

[1]Erasmus MC, Rotterdam, Netherlands, [2]Institute of Tropical Medicine, Antwerp, Belgium

The neglected tropical disease visceral leishmaniasis (VL), transmitted by sand flies, is set for elimination as a public health problem on the Indian subcontinent (ISC) by 2017 (incidence of symptomatic cases <1/10,000 at (sub)district level). ISC-countries are committed to reaching this ambitious target and have set different intervention strategies, mainly focusing on early detection and treatment of symptomatic VL cases as well as vector control. We developed a mathematical model to investigate whether elimination may be achieved with current strategies, and what additional interventions might be required. Based on an existing model we created a deterministic compartmental model as well as a stochastic individual-based (IBM) variant. The IBM includes individual heterogeneities regarding exposure to the sand fly and health seeking behavior. Also, it allows for estimating elimination probabilities under the selected strategies. The model was fitted to the KALANET dataset from the highly endemic Bihar region (India) and was tuned to predict different transmission scenarios (degree of endemicity, and equilibrium or outbreak situation). Our model predictions suggest that the target incidence of <1/10,000 can be achieved with the selected strategies for districts that currently experience endemicity levels at or below 10/10,000. Settings with higher baseline endemicities require additional efforts such as increased screening. Further, our simulations suggest that patients with post kala-azar dermal leishmaniasis, which occurs months to years after symptomatic VL, may serve as a reservoir of infection when nearing the elimination target. Our findings are robust against alternative assumptions about duration of immunity and infectiousness of different disease states (e.g. asymptomatic infection). We conclude that elimination of VL on the ISC is feasible for most regions with current strategies, but the duration of control and monitoring and evaluation of transmission will be pivotal to prevent recrudescence of infection.

DYNAMICS OF AMERICAN TEGUMENTARY LEISHMANIASIS IN A HIGHLY ENDEMIC REGION FOR *LEISHMANIA (VIANNIA) BRAZILIENSIS* INFECTION IN NORTHEAST BRAZIL

Juliana Silva[1], Adriano Queiroz[1], Izabella Moura[1], Rosana Souza[1], Luiz Henrique Guimarães[1], Paulo R. Machado[1], Marcus Lessa[1], Mary E. Wilson[2], **Albert Schriefer**[1]

[1]Hospital Universitário Prof. Edgard Santos, Salvador, Brazil, [2]University of Iowa, Iowa City, IA, United States

Intimate knowledge of the geographic distribution of leishmaniasis and how it propagates within ***foci*** of active transmission may guide new approaches to disease control measures. We explored incidence and geographic location data of three clinical types of American tegumentary leishmaniasis (ATL) cases, diagnosed in three different time periods, contained within a two decades time span. These patients lived in a focal region of northeast Brazil that is highly endemic for ***Leishmania (Viannia) braziliensis***. The study revealed that cutaneous (CL), mucosal (ML) and disseminated leishmaniasis (DL) actively spread within the affected region, but in different patterns. Whereas CL and DL seemed to propagate in clusters, ML was characterized by sporadic appearance of cases. The incidence of ML also fluctuated over time at a rate that was distinct from those of CL and DL. These findings might be used to improve the efficacy of control measures, for example exploring the combination of early detection of sentinel patients with focused active surveillance for surrounding cases of disease.

1252

NATURAL INFECTION AND THE DYNAMICS TRANSMISSION OF *LEISHMANIA (VIANNIA) BRAZILIENSIS* IN WILD AND SYNANTHROPIC RODENTS INVOLVED IN THE ZOONOTIC CYCLE OF CUTANEOUS LEISHMANIASIS IN ENDEMIC AREA OF ATLANTIC RAIN FOREST IN NORTHEAST BRAZIL

José F. Marinho-Junior[1], Juliana F. Lima[1], Luana P. Brito[1], Ana W. Carvalho[1], Francisco G. Carvalho[1], Milena P. Cavalcanti[1], Jeffrey J. Shaw[2], Orin Courtenay[3], **Sinval P. Brandão Filho**[1]

[1]Centro de Pesquisas Aggeu Magalhães, Fundação Oswaldo Cruz, Recife, Pernambuco State, Brazil, [2]Universidade de São Paulo, São Paulo, São Paulo State, Brazil, [3]University of Warwick, Coventry, United Kingdom

In northeast Brazil the predominant ***Leishmania*** species causing American cutaneous leishmaniasis (ACL) is ***L.*** (***Viannia***) ***braziliensis***. One of the principle difficulties in understanding the eco-epidemiology of ACL associated with ***L.*** (***V.***) ***braziliensis*** is identifying the relative importance of its reservoir hosts and sand fly vectors. The Amaraji municipality is located in the Zona da Mata biome of Pernambuco state, and is an important ACL focus. The objective of this study was the detection of natural infections of ***Leishmania*** (***Viannia***) spp in wild and synanthropic animals responsible for in maintaining zoonotic cycle in this region. Wild and synanthropic mammals were captured in Amaraji between May 2012 and July 2014 Captured animals were anesthetized, marked with microchip and skin samples (right ear) and blood were collected. They were then returned to their capture site. DNA was extracted and purified from all the tissue samples, and the ***Leishmania*** parasite load was determined by real-time PCR. A total of 637 animals were collected that belonged to 11 different species. 602 specimens were taken from 327 males and 275 females each being marked with a microchip. The predominant species were ***Nectomys squamipes*** (244/637) and ***Rattus rattus*** (148/637), corresponding to respectively 38.3% and 23.2%. Based on DNA blood and tissue analysis 106 (16.6%) animals were positive, the average parasite load being 3528fg/uL (9,26-50060 fg/µL). We observed that the highest infection rates as well as highest parasite loads occurred between the months of October and November 2012 (55 positive animals - 8266fg/uL); June 2013 (33 positive animals - 1503fg/ µL) and January 2014 (25 positive animals - 505fg/ µL). In conclusion, the results suggest that the potential for transmission was greatest during these periods and that accordingly the risk of human infections is greater. On going studies are in progress to correlate this data with sand fly xenodiagnosis infectivity assays to support the hypothesis that the intensity of wild and synanthropic rodent ***Leishmania*** infections modulates zoonotic ACL.

1253

DENGUE VIRUS NON-STRUCTURAL PROTEIN 1 INDUCES ACTIVATION OF HEPARANASE/CATHEPSIN-L AND DEGRADATION OF THE ENDOTHELIAL GLYCOCALYX, LEADING TO ENDOTHELIAL PERMEABILITY

Henry Puerta Guardo, Dustin Glasner, Eva Harris

Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States

Dengue is the most prevalent arboviral disease in humans and a major public health problem worldwide. Systemic plasma leakage leading to shock is a critical determinant of dengue severity. Increased vascular permeability without morphological damage to the capillary endothelium in severe dengue suggests the shock syndrome may be due to endothelial dysfunction. In the endothelium, dynamic structures, including intercellular junctional proteins and the endothelial glycocalyx (EG), a network of membrane-bound proteoglycans and glycoproteins, control the barrier function critical for vascular homeostasis. However, the mechanism of vascular dysfunction in dengue is still unclear. We previously described the role of soluble NS1 in inducing endothelial permeability by measuring trans-endothelial electrical resistance (TEER) in human pulmonary

microvascular endothelial cells (HPMEC) grown on a transwell permeable membrane system. Here, we demonstrate that DENV NS1-induced endothelial permeability is initially triggered by the increased expression/activation of heparanase, an endo-β-d-glucuronidase that degrades heparan sulfate (HS) in the extracellular matrix of HPMEC, resulting in altered distribution of EG components such as sialic acid, syndecan-1 and perlecan. This effect is specific to DENV NS1 and is not observed with NS1 from the related flavivirus West Nile Virus. Specific inhibitors of heparanase and its activator, cathepsin-L, prevent NS1-mediated endothelial permeability associated with altered distribution of HPMEC EG components. Further, conditioned supernatant from NS1-treated HPMEC monolayers increases endothelial permeability when transferred to naïve HPMEC, even in the presence of anti-NS1 monoclonal antibodies. Finally, recombinant syndecan decreases TEER in a dose-dependent manner. Our findings propose a new mechanism of NS1 directly triggering endothelial vascular dysfunction through the early enzymatic activation and cleavage of HS proteoglycans by heparanase that leads to disassembly of the extracellular matrix, contributing to increased plasma leakage that occurs in severe dengue.

1254

FLUID MANAGEMENT OF DENGUE FEVER PATIENTS - EVIDENCE FROM AN OBSERVATIONAL MULTICENTER PROSPECTIVE STUDY IN FOUR SOUTHEAST-ASIAN AND THREE LATIN AMERICAN COUNTRIES

Thomas Jaenisch[1], Kerstin Rosenberger[1], Neal Alexander[2], Thomas Junghanss[1], Bridget Wills[3]

[1]Section Clinical Tropical Medicine, Department for Infectious Diseases, Heidelberg University Hospital, Heidelberg, Germany, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Effective case management of patients with severe dengue relies on frequent monitoring and judicious IV fluid therapy. However, in patients with vascular leakage early use of IV fluids may aggravate fluid accumulation and result in respiratory distress. Using data from a major multi-centre observational study, we describe the clinical status of confirmed dengue patients at first severe event, and analyse the subsequent development of complications. Trained physicians followed suspected dengue cases prospectively at seven hospitals across Asia and Latin America, using a single comprehensive report form that included daily clinical assessment for fluid accumulation. A CXR/USS assessment was also performed around defervescence. Applying univariable and multivariable Cox regression, we evaluated risk factors for the development of shock with and without fluid accumulation, as well as for respiratory distress. Among 1734 confirmed dengue patients, the majority (88%) never experienced DSS. Fluid accumulation was identified in 45% of cases without shock and in almost twice that proportion with shock: 176/210 (84%) cases. Respiratory distress was diagnosed in 78 patients, including 44 cases with shock. In the univariable model, referral from another facility and IV fluid use before enrolment were protective for shock without fluid accumulation, but increased the risk for shock with fluid accumulation. In the multivariable model, the risk for respiratory distress with fluid accumulation increased significantly as the infused volume increased (AHR 1.15 [95% CI 1.08-1.23)] per 10 ml/kg over the preceding 24h period; p<0.001), irrespective of age group, respiratory rate, or presence of serosal effusions or shock in the preceding 24h. Age below 15 years, increased respiratory rate, and presence of ascites in the preceding 24h were independent risk factors for respiratory distress with fluid accumulation. Fluid accumulation, either assessed clinically or potentially quantified by radiological methods, could be a useful intermediate severity endpoint for therapeutic intervention trials and/or pathogenesis studies.

1255

INHIBITION OF MAMMALIAN HOST GLUCOSIDASE ENZYMES USING THE IMINOSUGAR UV-4B DOES NOT SELECT FOR RESISTANT INFLUENZA AND DENGUE VIRUSES

Kelly L. Warfield[1], Emily Plummer[2], Suman Das[3], Aruna Sampath[1], Rebecca Halpin[3], Timothy Stockwell[3], Bjoern Peters[2], Sujan Shresta[2], Urban Ramstedt[1], Michael V. Callahan[1]

[1]Unither Virology LLC, Silver Spring, MD, United States, [2]La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States, [3]J. Craig Venter Institute, Rockville, MD, United States

Unither's iminosugar platform targets host αglucosidases I and II, enzymes that contribute to glycosylation and folding of proteins in the endoplasmic reticulum. Blockade of host αglucosidases impairs glycosylation resulting in improperly folded viral envelope glycoproteins and impaired functionality, stability, orientation and immune stealth. Glucosidase inhibition results both in reduced virus numbers and production of defective viruses that are replication incompetent. The iminosugar UV-4B has ***in vitro*** activity against a diverse set of glycosylated, enveloped RNA and DNA viruses including dengue, influenza, Ebola, and vaccinia and promotes survival in lethal dengue and influenza mouse models. An important benefit of host-targeted antivirals is reduced selection for resistant viruses. Antiviral drugs directed against genetic sequences or viral encoded proteins quickly select for resistant viruses within a few replication cycles especially in the case of RNA viruses that have high mutation rates and exist as quasi-species. Targeting a host enzyme does not expose the virus to direct selective pressure, but rather denies the virus a critical substrate for which there is no biochemical or viral gene-encoded alternative and minimizes selection of resistance. Absence of viral resistance to glucosidase inhibitors was confirmed against multiple mutation-prone viruses. Dengue viruses exposed to UV-4B ***in vitro*** did not generate resistant variants after 38 serial passages. In addition, no change in efficacy was detected in dengue or influenza after the five serial passages performed in mice treated with UV-4B. Deep sequencing was performed to examine the appearance of resistance-conferring mutations in the drug passaged dengue and influenza viruses. The absence of viral escape mutants elicited from sustained exposure to UV-4B over multiple passages ***in vivo***, provides additional evidence that there is a high genetic barrier to the generation and selection of escape mutants exposed to host-targeted iminosugar antivirals.

1256

EFFECT OF IMINOSUGARS ON DENGUE VIRUS STRUCTURAL PROTEINS

Mansoora Khaliq[1], Aruna Sampath[1], Andrew Miller[2], Joyce Jose[2], Zhenguo Chen[2], Devika Sirohi[3], Urban Ramstedt[1], Matthew Duchars[1], Richard J. Kuhn[3]

[1]Unither Virology, Silver Spring, MD, United States, [2]Markey Center for Structural Biology, Department of Biological Sciences, Purdue University, West Lafayette, IN, United States, [3]Markey Center for Structural Biology, Department of Biological Sciences and Bindley Bioscience Center, Purdue University, West Lafayette, IN, United States

Dengue virus (DENV) is among the most rapidly emerging human pathogens and can cause severe illness and death. Currently, no effective therapeutics are available. Unither Virology (UV) has identified multiple iminosugar analogs, UV-1, UV-4B, and UV-12 that show ***in vitro*** activity against DENV serotype 2. We recently demonstrated the efficacy of UV-4B (Perry et al. 2013) ***in vivo*** against a lethal DENV challenge in mice even when administered 24-48 hours post-infection (PI). Iminosugars inhibit resident ER α-glucosidases involved in processing of N-glycans on nascent glycoproteins found on DENV envelope (E) protein. Inhibition prevents proper folding of E, affecting critical steps in the viral life cycle. Targeting a host protein, decreases the likelihood of developing viral resistance. We investigated the effects of iminosugar analogs (UV-1, UV-12) on modifications of E and their effect on virus entry and maturation.

Comparisons of viral counts in the supernatant of cells treated with UV-1 or UV-12 (100 µM) collected every 24 hours PI reveal the number of virus particles released (RNA molecules/ml) remains the same over time compared to untreated cells. However, the number of infectious virus particles released (PFU/ml) is decreased compared to untreated cells suggesting treatment with UV-1 and UV-12 affects infectivity. Cryo-EM reconstruction of particles prepared in the presence of UV-1 failed to converge on a reference structure of native DENV-2 particle. Additionally, quantification of purified virus particle types (smooth, mosaic, spiky, and bumpy) indicates structural heterogeneity between particles within subpopulations. Preliminary mass spectrometry analysis of purified particle maturation (cleavage efficiency (M/(prM+M)) showed a decrease in percent maturation of treated virus relative to untreated virus. Live imaging of single virus particles revealed that particles treated with UV-1 and UV-12 were delayed in attachment/adsorption. Our results indicate that UV-1 and UV-12 affect proper E protein folding, preventing maturation and infectivity of the virus.

EXPLORING THE ROLE OF DNA SENSORS DURING DENGUE VIRUS INFECTION

Sebastian Aguirre, Maria T. Sanchez-Aparicio, Priya Luthra, Anthony Fredericks, Dabeiba Bernal-Rubio, Adolfo Garcia-Sastre, Lubertus Mulder, Ana Fernandez-Sesma

Department of Microbiology, Icahn School of Medicine at Mount Sinai, New York City, NY, United States

Dengue virus (DENV) is an enveloped (+) strand RNA virus transmitted by mosquitos, which infect near to 390 million humans per year. Upon infection, DENV can replicate in immune cells like macrophages and dendritic cells (DCs). DCs are professional immune cells that contain complex networks of sensing macromolecules that can quickly detect and signal the control of invading intracellular pathogens through the activation of the IFN system and the subsequent establishment of the antiviral state. We have described in our laboratory that DENV can counteract the induction of type I IFNs by cleaving the adaptor STING in human cells. In this work we explored the partner molecules that collaborate with STING in detection of DENV replication. Using a qRT-PCR approach, we observed activation of genes involved in DNA sensing, independently of the IFN production in primary human MDDCs. Preliminary results suggest that the novel DNA sensor cGAS is involved in the detection of DENV infection by recognizing illicit cytoplasmic DNA generated during the replication. Using ***in vitro*** and ***ex vivo*** models we perform a systematic study to characterize the PAMP sources that can be stimulating the cGAS/STING/IRF3 pathway during DENV infection. Also, by pull down experiments of cGAS in DENV infected cells, we analyzed the nature of the DNA molecules that were bound to it. Finally we propose a new mechanism of DENV detection by the cellular DNA sensing machinery.

1258

DENGUE VIRUS INFECTIONS OF HUMAN TONSIL HISTOCULTURES AND PRIMARY CELLS REVEAL SEROTYPE-SPECIFIC PROFILES

Rebecca E. Hamlin, Dabeiba Bernal-Rubio, Michael Donovan, Ana Fernandez-Sesma

Icahn School of Medicine at Mount Sinai, New York, NY, United States

Dengue virus (DENV) is the most prevalent mosquito-borne virus causing disease in humans, with an estimated 390 million infections per year worldwide. There are currently no licensed vaccines or specific therapeutics, and the death rate for severe dengue without proper supportive care can be over 20%. Of the four circulating DENV serotypes, DENV-2 infection has been correlated with increased disease severity while DENV-4 infections have been associated with a milder clinical presentation. In this study, we have investigated the infection kinetics and immune responses of DENV-2 versus DENV-4 during primary infections of human monocyte-derived dendritic cells (DCs) and in a newly developed, human tonsil histoculture (HC) model system. We hypothesize that DENV-4 will be attenuated compared to DENV-2 and that these relevant human models will yield new insights into immune responses against these viruses, which will help elucidate DENV immunopathogenesis in patients. In preliminary studies in human DCs, DENV-4 shows faster replication kinetics that peak at 24 hours post infection but drastically diminish by 72 hours post infection, while DENV2 exhibits slower but longer lasting replication kinetics. Similarly, DENV-4 replication dramatically decreases after 72 hours post infection compared to DENV-2 in tonsil HCs. Furthermore, while our laboratory has previously demonstrated that DENV-2 abrogates type I interferon (IFN) production in human primary DCs, our current data shows that DENV-4 infection induces both type I IFN and the IFN-stimulated gene IP-10 in both DCs and tonsil HCs. Moreover, DENV-4 infection of tonsil HCs induces higher levels of IFN-γ, TNF-α, IL-10, and RANTES during a 12-day time course compared to DENV-2 infection. This suggests that DENV-4 may be more immunogenic than DENV-2 in humans and can be more efficiently inhibited by antiviral responses, which could correlate with its diminished replication capacity in our human systems.

1259

EFFICACY OF RUPATADINE IN ACUTE DENGUE INFECTION

Ananda Wijewickrama[1], Samitha Fernando[2], Praveen Madushanka[2], Damayanthi Idampitiya[1], Chandanie Wanigatunga[2], Harsha Dissanayake[2], Shamini Prathapan[2], Chandima Jeewandara[2], Laksiri Gomes[2], Graham Ogg[3], **Gathsaurie Neelika Malavige**[2]

[1]Infectious Diseases Hospital, Colombo, Sri Lanka, [2]University of Sri Jayawardenapura, Nugegoda, Sri Lanka, [3]University of Oxford, Oxford, United Kingdom

Vascular leak is the hall mark of severe dengue infection. Our previous studies showed that platelet activating factor (PAF) was a potent mediator of vascular leak. Therefore, we proceeded to investigate the efficacy of rupatadine which is a PAF receptor blocker in patients with acute dengue infection. We are conducting a phase II, open labeled, randomized control trial to determine the efficacy of rupatadine in preventing or reducing vascular leak in patients with acute dengue and also to determine its efficacy in reducing complications.The study was designed to be conducted in three arms, which were 80 patients for ruptadine 10mg, 80 patients for rupatadine 40mg and 80 patients for the placebo arm. The tablets were given orally once a day to the participants. Apart from receiving the drug, all patients were managed according to the 2011 World Health Organization guidelines. The patients were examined at least twice a day and the haematocrit and platelet counts were measured at least twice a day to detect any complications and fluid leakage. Daily ultra sound scans were done in all patients from the time they were admitted to hospital to determine the presence and the quantity of fluid leakage. Our primary end point was a reduction in fluid leakage in the rupatadine treated group. The secondary end points were reduction in the incidence of liver failure; reduction in the development of shock; reduction in the need for blood transfusion or colloids; or the duration of illness. The efficacy and safety findings of this clinical trial will be presented at the conference.

1260

A FOUR-YEAR PROSPECTIVE STUDY OF THE IMPACT OF RED BLOOD CELL VARIANTS ON CHILDHOOD FALCIPARUM MALARIA IN SOUTHERN MALI

Krause[1], Ababacar Diouf[1], Samuel E. Moretz[1], Gregory S. Tullo[1], Kazutoyo Miura[1], Wenjuan Gu[3], Michael P. Fay[1], **Steve M. Taylor**[4], Carole A. Long[1], Mahamadou Diakite[2], Rick M. Fairhurst[1]

[1]National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [2]Malaria Research and Training Centre, Bamako, Mali, [3]Leidos Biomedical Research, Rockville, MD, United States, [4]Duke University Medical Center, Durham, NC, United States

Red blood cell (RBC) variants protect African children from severe ***Plasmodium falciparum*** malaria. Their individual and interactive impacts on mild disease and parasite density, and their modification by age-dependent immunity, are poorly understood. We conducted a 4-year, prospective cohort study of children aged 6 months-17 years in Mali in 2008-2011. RBC variants were hemoglobins S (HbS) and C (HbC), α-thalassemia, ABO blood groups, and glucose-6-phosphate dehydrogenase (G6PD) deficiency encoded by the X-linked A- allele. The primary outcome was malaria incidence, which was modeled as incidence rate ratios (IRRs) with quasi-Poisson regression; the secondary outcome was ***P. falciparum*** density, which was analyzed with Generalized Estimating Equations. We diagnosed 4,091 malaria episodes in 1,543 children over 2,656 child-years of follow-up. RBC variants were common, with prevalences of: HbAS 14%, HbAC 7%, α-thalassemia 28%, type O blood group 40%, and G6PD deficiency 9% in boys and 20% in girls. The overall malaria incidence was 1.54 episodes per child-years of follow-up, and ranged from 2.78 at age 3 years to 0.4 at age 17 years. Malaria incidence was reduced 34% in HbAS compared with HbAA children (adjusted IRR [aIRR] 0.66; 95% CI 0.59-0.75) and 49% in G6PD A-/A- compared with A+/A+ girls (aIRR 0.51; 95% CI 0.29-0.90), but was increased 15% in HbAC compared with HbAA children (aIRR 1.15; 95% CI 1.01-1.32). Parasite density was reduced in HbAS (median 10,550 parasites/μL) compared with HbAA children (15,150 parasites/μL; p=0.0004). Age significantly modified the effects of HbAS on both malaria risk (p=0.022) and parasite densities (p<0.0001); both outcomes were reduced more substantially in the youngest children. There was no statistically-significant interaction between HbAS or HbAC and α-thalassemia for either malaria risk or parasite density. Individual and interactive impacts of HbAS, HbAC, and G6PD A-/A- on malaria risk and parasite density define clinical and cellular correlates of protection. Further identification of the molecular mechanisms of these protective effects may uncover novel targets for intervention.

1261

EVALUATION OF THE NATURAL HISTORY OF ASYMPTOMATIC *PLASMODIUM FALCIPARUM* PARASITEMIA IN A HIGHLY ENDEMIC AREA OF UGANDA

John Rek[1], Shereen Katrak[2], Agaba Katureebe[1], Bryan Greenhouse[2], Moses R. Kamya[3], Emmanuel Arinaitwe[1], Sarah Staedke[4], Grant Dorsey[2], Prasanna Jagannathan[2]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]Department of Medicine, University of California San Francisco, San Francisco, CA, United States, [3]Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Understanding the epidemiology of asymptomatic ***Plasmodium falciparum*** infection in the era of bednets (ITNs) and artemisinin-based combination therapy (ACT) remains an important goal. We enrolled a dynamic cohort of children 0.5-10 years of age (n=333) from 100 randomly selected houses from an area in Eastern Uganda, where transmission is holoendemic with 2 seasonal peaks and an aEIR of 310 infective bites PPY. Participants were provided an ITN at enrollment and received all care, including passive surveillance for malaria and active surveillance for parasitemia by microscopy every 3 months between Aug 2011-Sep 2014. Associations between the probability of asymptomatic parasitemia during active surveillance and risk factors of interest were made using generalized estimating equations, and associations between risk factors and the cumulative risk of developing malaria following asymptomatic infection were estimated using a cox proportional hazards model adjusted for repeated measures. The overall prevalence of parasitemia at routine surveillance was 24%, and 82% of these episodes were asymptomatic. Compared to children < 3 years of age, the odds of being asymptomatic if parasitemic were significantly higher in children 3-7 (aOR=1.97, P=0.008) and 7-10 years of age (aOR=3.09, P<0.001). Increasing parasite densities were associated with significantly lower odds of being asymptomatic (aOR 0.28 per log10 increase in parasite density, P<0.001), with no significant associations with calendar year or season. Following asymptomatic infection, children 3-7 years and 7-10 years of age were significantly less likely to develop malaria within 30 days compared with children < 3 years (aHR 0.38 and 0.21, P<0.001, respectively). Both the high season (aHR 1.31, P=0.04) and calendar year (aHR 1.42 yr 3 compared to yr 1, P=0.047) were associated with an increased hazard of developing malaria following asymptomatic parasitemia, although parasite densities had no association. A better understanding of the epidemiology of asymptomatic parasitemia will inform efforts for malaria control in high transmission settings.

1262

DETERMINANTS OF HETEROGENEITY IN MALARIA TRANSMISSION IN PAPUA NEW GUINEA

Leanne J. Robinson[1], Johanna H. Kattenberg[2], Cristian Koepfli[3], Natalie E. Hofmann[4], Rahel Wampfler[4], Maria Ome-Kaius[2], Benson Kiniboro[2], Matthew Phillip[2], Daisy Mantila[2], Benishar Kombut[2], Shadrach Jally[2], Elisheba Malau[3], Jessica Brewster[3], Peter Siba[2], Daniel Tisch[5], Inoni Betuela[2], James Kazura[5], Ingrid Felger[4], Ivo Mueller[6]

[1]PNG Institute of Medical Research; Walter & Eliza Hall Institute of Medical Research, Madang, Papua New Guinea, [2]PNG Institute of Medical Research, Madang, Papua New Guinea, [3]Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [4]Swiss Tropical and Public Health Institute, Basel, Switzerland, [5]Case Western Reserve University, Cleveland, OH, United States, [6]Walter & Eliza Hall Institute of Medical Research; Barcelona Institute for Global Health, Parkville, Australia

A renewed emphasis on malaria control in Papua New Guinea has resulted in a significant overall reduction in the prevalence and incidence of malaria. However the reduction observed at the national/provincial level masks substantial heterogeneity of transmission at the local district and village level. To investigate this, repeated community cross-sectional surveys and longitudinal child cohorts were undertaken in two hyper-/holoendemic areas of PNG, combining sensitive molecular diagnosis of infections (multiplicity of infection (MOI), molecular force of blood-stage infection ($_{mol}$FOB) and gametocyte-specific RT-qPCR), with demographic and household GPS data. ***Plasmodium falciparum*/*P. vivax*** prevalence (PCR) decreased from 71.6% (2005) to 10.9% (2013) in cross-sectional community surveys. Cluster analysis for high rates of infection identified 4 spatial clusters for infections of any species, 6 ***P. falciparum*** and 7 ***P. vivax*** clusters. Risk factors for households to be in a cluster were a lower proportion of the household reporting LLIN use for all infections, distance to health centre for ***P. vivax*** infections and altitude for infections with any species. Many hotspots identified in 2013 were areas of the highest prevalence in 2005. In a 2009 cohort of 5-10 year old children, the prevalence of ***P. falciparum*** was 24%, making ***P. vivax*** the most common species (48% by PCR). Prevalence at enrolment and $_{mol}$FOB varied significantly between neighbouring villages for both species with up to 40-fold differences in $_{mol}$FOB (***p***<0.001). More recently, the prevalence of

malaria infections at enrolment in longitudinal cohorts of 1-5 and 5-10 year old children was 24% and 37% respectively. The vast majority of these infections are asymptomatic and ongoing analysis of demographic, molecular and spatial data will provide an in-depth perspective on malaria transmission at the village and household level. Understanding the extent of local heterogeneity in malaria transmission and the driving factors is critical to be able to identify and implement targeted control strategies to ensure the ongoing success of malaria control in PNG and make progress towards elimination.

INFECTION DYNAMICS OF NATURAL *PLASMODIUM* INFECTIONS IN PAPUA NEW GUINEAN CHILDREN

Natalie E. Hofmann[1], Rahel Wampfler[1], Mariabeth Silkey[1], Leanne J. Robinson[2], Ivo Mueller[3], Thomas Smith[1], Ingrid Felger[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [3]Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

Measuring key parameters of malaria infection dynamics such as acquisition and clearance rates of individual parasite clones is challenging in semi-immune individuals because of multi-clone infections, frequent super-infections and generally low parasite densities. Investigating the persistence of individual clones in longitudinal studies is complicated by imperfect detectability causing apparent loss and reappearance. Little data exists on the dynamics of natural malaria infections particularly in non-African settings where ***Plasmodium*** species co-exist. We combined high-resolution genotyping with mathematical modelling to assess detectability, acquisition and clearance rates in a longitudinal study in Papua New Guinean (PNG) children aged 5-10 years from an area with ***P. vivax*** as predominating species. Mean detectability of ***P. falciparum*** clones was 57% and age-independent while ***P. vivax*** detectability decreased from 48% in the youngest to 18% in the oldest children corresponding to age patterns in parasite density. Adjusting for imperfect detectability increased clone acquisition rates by 25% for ***P. falciparum*** and 16% for ***P. vivax***. Acquisition rates were 3.5-fold higher for ***P. vivax*** than ***P. falciparum*** and correlated well with prevalence by village for both species (R2 = 0.83 and 0.97), while no association with age was observed. Naturally cleared infections with ***P. falciparum*** persisted longer than with ***P. vivax*** (77 and 48 days). An increase in infection duration with age was observed for ***P. vivax***, reaching 154 days in the oldest children, but not for ***P. falciparum***. Unlike ***P. vivax***, ***P. falciparum*** infection duration was moderately correlated with endemicity (R2 = 0.54) with maximum of 114 days in a highly endemic village. In endemic settings, age serves as a proxy of exposure and thus of natural immunity. Our data support the hypothesis that acquired immunity, present against ***P. vivax*** but not ***P. falciparum*** in PNG children of this age, controls infection mainly by limiting parasite densities thus allowing infections to persist at low level for extended periods in semi-immune individuals and potentially contributing to transmission.

1264

PLACENTAL MALARIA EXPOSURE AND SEVERE MALARIAL ANEMIA IN AFRICAN CHILDREN

Elizabeth B. Brickley[1], Angela M. Wood[2], Jonathan D. Kurtis[3], Edward Kabyemela[4], Alassane Dicko[5], Michal Fried[6], Patrick E. Duffy[6]

[1]National Institute of Allergy and Infectious Diseases and University of Cambridge, Rockville, MD, United States, [2]University of Cambridge, Cambridge, United Kingdom, [3]Brown University Medical School, Providence, RI, United States, [4]Muheza Designated District Hospital, Muheza, United Republic of Tanzania, [5]University of Bamako, Bamako, Mali, [6]National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

Previous studies suggest offspring of mothers with placental malaria (PM) may be at higher risk of clinical malaria infection and reduced hemoglobin in early childhood. However, in a region with high drug resistance, intermittent preventative treatment in pregnancy with sulfadoxine-pyrimethamine (IPTp-SP) has been associated with increased risk of severe malaria. Using multi-center, birth cohort data from 880 participants in the MOMS Project Study in Tanzania, 2002-2006, and 1502 participants in the MRTC-Laboratory of Malaria Immunology and Vaccinology Immuno-Epi Observational Study in Mali, 2010-2015, the authors investigated the relations of PM and IPTp-SP with severe malarial anemia (SMA), defined as a positive bloodsmear for ***Plasmodium falciparum*** and hemoglobin (Hb) <5g/dL, in children under four years. Children exposed to PM were at increased risk of incident SMA (adjusted hazard ratio (AHR) = 2.17, 95% confidence interval (CI): 1.16, 4.08), an effect which was stronger in children of younger mothers (***P*** for interaction with mother's age = 0.002), and also experienced malaria infections with elevated parasite density (***P*** = 0.019) and reduced levels of interferon-γ (***P*** = 0.044) and erythropoietin (***P*** = 0.011) relative to their unexposed peers. Further investigation revealed that the relation with PM was specific to malaria-related anemia events: Whereas there was no evidence of an association with non-malarial severe anemia (Hb<7g/dL) risk (AHR = 0.85, 95% CI: 0.61, 1.20), PM was positively associated with malarial severe anemia (Hb<7g/dL) risk (AHR = 1.68, 95% CI: 1.24, 2.26). Furthermore, in Mali where drug resistance remains low, maternal IPTp-SP had an inverse, dose-response association with SMA (AHR per dose = 0.59, 95% CI: 0.30, 1.14). In conclusion, these findings support the hypothesis that prenatal exposure to PM can alter the pathogenicity of subsequent pediatric malarial infections and suggest the prevention of malaria in pregnancy may have substantive ancillary benefits for children's health.

1265

THE EFFECT OF MALARIA DURING PREGNANCY ON INFANT SUSCEPTIBILITY TO MALARIA

Sarah Boudova[1], Titus Divala[2], Randy Mungwira[2], Patricia Mawindo[2], Tamiwe Tomoka[3], Terrie E. Taylor[2], Miriam K. Laufer[1]

[1]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Blantyre Malaria Project, Blantyre, Malawi, [3]University of Malawi, Blantyre, Malawi

Malaria during pregnancy threatens the health of mothers and newborns and may have long-lasting consequences on infant health. Observational studies suggest that placental malaria is associated with increased risk of malaria in the infant. However, previous studies are limited by the inability to control for shared exposures and to detect episodes of malaria that occurred prior to delivery. We hypothesize that placental malaria will be associated with elevated risk of malaria during infancy and that maternal peripheral malaria in the absence of placental infection will be protective as compared to no maternal malaria. We conducted a randomized clinical trial of three chemo-prevention strategies resulting in three distinct malaria exposure groups during pregnancy: placental malaria; peripheral malaria without placental infection; and no malaria during pregnancy. We are following the infants through active and passive molecular surveillance

for malaria; 412 infants have been followed for a median duration of 197 days after birth. Of these, 308 infants were born to mothers with no evidence of malaria during pregnancy, 55 to mothers with placental malaria and 49 to mothers with only peripheral infection. Malaria infection was detected in 10.5%, 14.3% and 16.7% of those born to mothers with no malaria, placental malaria and peripheral malaria during the first nine months of life, respectively. The cumulative incidence of malaria per person year was highest among infants born to mothers with placental malaria, 0.29 compared to 0.15 and 0.12 per person year of follow up among infants born to mother with no malaria and peripheral malaria respectively. These differences were not statistically significant (p=0.2). Follow up is underway to collect more data from the infants as they get older and experience more malaria episodes. Results of this study will inform the design and implementation of innovative and highly effective prenatal interventions to protect the health of pregnant women, newborns and infants from malaria.

1266

MORE THAN FOUR ANTENATAL MALARIA SCREENS REDUCES THE EFFECTS OF MALARIA ON ADVERSE PREGNANCY OUTCOMES

Kerryn A. Moore[1], Jacher Wiladphaingern[2], Thein Cho[2], Oh Moo[2], Moo Koh Paw[2], Lily Keereecharoen[2], Freya J. Fowkes[3], Julie A. Simpson[1], Nicholas J. White[4], François Nosten[2], Rose McGready[2]

[1]University of Melbourne, Melbourne, Australia, [2]Shoklo Malaria Research Unit, Mae Sot, Thailand, [3]Burnet Institute, Melbourne, Australia, [4]Mahidol University, Bangkok, Thailand

125 million pregnancies are at risk of malaria each year, and malaria in pregnancy causes preterm birth and intrauterine growth restriction (IUGR). Preterm birth and small for gestational age (SGA), a proxy for IUGR, increase the risk of neonatal death 15-fold. Women are often infected multiple times, but the effect of the number and gestational age at the time of ***Plasmodium*** spp. infections on adverse pregnancy outcomes, especially in first trimester, has not been fully elucidated. We analysed prospective data on 43,664 pregnancies screened frequently for malaria by microscopy at antenatal visits on the Thai-Myanmar border between 1986 and 2014. Cox regression with time-varying exposures was used to estimate the effect of the number and gestational age of malaria episodes on preterm birth and SGA, including an interaction with the number of malaria screens. 35,717 pregnancies had no malaria and 7,947 pregnancies had between one and eleven episodes. 8% of newborns were preterm, and 10% were SGA. In those who had four malaria screens or less, the hazard of preterm birth and SGA increased with each malaria episode by 1.34 fold (95% confidence interval (CI): 1.13, 1.61) and 1.66 fold (95% CI: 1.09, 2.52), respectively. Compared to no malaria, both second- and third-trimester episodes were equally harmful, increasing the hazard of preterm birth by 2.11 fold (95% CI: 1.59, 2.80) and SGA by 2.92 fold (95% CI: 1.28, 6.66), while first-trimester episodes had minimal effect on either preterm birth (HR: 1.24; 95% CI: 0.89, 1.74) or SGA (HR: 0.66; 95% CI: 0.29, 1.48). Notably, malaria was either not associated or weakly associated with preterm birth and SGA in women who had more than four screens, regardless of the number or gestational age of episodes. These patterns, albeit weaker, held true when analyses were restricted to ***P. vivax*** infections only. Screening and treatment can help to counter the cumulative adverse effects of both ***vivax*** and falciparum malaria throughout pregnancy. However, the WHO recommends four antenatal visits, whereas our data suggest that the optimum number of antenatal malaria screens for preventing adverse outcomes is likely greater than four.

1267

EMERGENCY EVALUATION OF CONVALESCENT PLASMA FOR EBOLA VIRUS DISEASE (EVD) IN GUINEA

Johan van Griensven on Behalf of the Ebola_Tx Consortium

Institute of Tropical Medicine, Antwerp, Belgium

Evaluation of convalescent plasma (CP) for the treatment of Ebola Virus Disease (EVD) has been prioritized by the WHO in the current epidemic. The Ebola_Tx trial is designed to assess the feasibility, safety and efficacy of CP against EVD in Conakry, Guinea. Pathogen-reduced CP is administered as two units (200-250ml each) given consecutively on the same day, from two different donors. Survival 14 days after intervention is the primary outcome measure. The survival of patients treated with CP + supportive care will be compared to that of patients receiving supportive care alone, in an open-label, non-randomised comparative study. A 20% lower case fatality rate in patients treated with CP will be considered proof of clinical efficacy. All consecutive eligible and consenting patients of any age (including pregnant women) with confirmed EVD will be enrolled; exclusion criteria are limited to contra-indications for CP or patients very close to death. Available ABO compatible plasma is given, within 48 hours after diagnosis, and patients with no compatible plasma available will be enrolled as concurrent controls. The control group will be complemented with historical controls if needed. A minimum of 130 patients will be treated with CP. Secondary outcomes include 1) 30 day all-cause mortality; 2) transfusion-related serious adverse reactions; 3) change in viral load and association with titres of neutralising antibodies in the donor plasma; 4) safety risks in health workers administering CP; 5) risk factors for mortality. The first plasma collection started on February 9, 2015 and the first CP administration was done February 19. As of April 7, a total of 94 donors have presented for plasma donation, of which 81 have donated at least once. Qualified plasma (no transfusion transmissible infections detected) was obtained for 69. A total of 83 patients have been enrolled, of which 81 received CP. Of these, 9 additionally received favipiravir via another trial, leaving 72 patients for inclusion in primary analysis. The main analysis will be done after 130 CP-treated patients have reached day 14 (planned early June). This is the largest trial ever conducted of a convalescent blood product against EVD. If found to be effective, this intervention can then be scaled-up.

1268

LARGEST DOCUMENTED CLUSTER OF EBOLA VIRUS DISEASE AMONG HEALTH WORKERS

Mikiko Senga[1], Kimberly Pringle[2], David Brett-Major[1], Robert Fowler[3], Issa French[4], Mohamed Vandi[4], Andrew Ramsay[1], Josephine Sellu[4], Christian Pratt[4], Josephine Sidu[4], Nahoko Shindo[1], Daniel G. Bausch[1]

[1]World Health Organization, Geneva, Switzerland, [2]Centers for Disease Prevention and Control, Atlanta, GA, United States, [3]University of Toronto, Toronto, ON, Canada, [4]Kenema Government Hospital, Kenema, Sierra Leone

The 2014-15 Ebola virus outbreak in West Africa is the largest in history. Health workers (HWs) are among those at highest risk of infection because of exposure during patient care. As of April 1, 2015, 861 HW infections and 495 deaths have been reported in Guinea, Liberia, and Sierra Leone. An unusually high number of Ebola virus infections and deaths were noted among HWs in the Kenema District of Sierra Leone. To explore the nature of virus exposures in this high-risk population, we conducted a descriptive analysis using combined data sources, including the national Viral Hemorrhagic Fever database, contact tracing records, hospital staff rosters, Ebola Treatment Unit (ETU) rosters, and burial logs. A HW was defined as anyone who worked in a healthcare facility or engaged in healing practices. All suspected and confirmed HW cases were included in the analysis. A total of 94 Ebola cases in HWs were identified, of which 63 died (case fatality ratio: 67%). The most common self-reported symptoms at the time of presentation included fever (67/78, 86%), vomiting (29/76,

38%), and diarrhea (29/76, 38%). Sixty-six (70%) HWs worked at Kenema Government Hospital (KGH) and 19 (20%) in other health facilities (no data were available for the remaining 9). Less than half (32, 48%) of HWs at KGH were assigned to the ETU and only 30 (32%) reported having contact with a known Ebola case, including sick family members (43%), colleagues (30%), patients (10%), and friends (10%). It was widely suspected that many HWs also saw patients privately after normal working hours, often without full personal protective equipment. In conclusion, most Ebola-infected HWs had numerous risk factors for exposure both in ETUs, other areas of the hospital, and in the community. Specific infecting events were rarely identifiable. Infection prevention and control measures to protect HWs must address a wide array of risk factors both in formal and informal care settings as well as in the community.

MINIMALLY INVASIVE AUTOPSY: AN ACCURATE TOOL FOR CAUSE OF DEATH DETERMINATION IN DEVELOPING COUNTRIES

Paola Castillo[1], Esperança Ussene[2], Dercio Jordao[2], Lucilia Lovane[2], Miguel J. Martinez[3], Carla Carrilho[2], Mamudo R. Ismail[2], Cesaltina Lorenzoni[2], Jordi Vila[3], Clara Menéndez[1], Quique Bassat[1], Jaume Ordi[4]

[1]ISGlobal, Barcelona, Spain, [2]Maputo Central Hospital, Maputo, Mozambique, [3]Hospital Clinic, Barcelona, Spain, [4]Hospital Clinic/ISGlobal, Barcelona, Spain

There is a need for accurate estimates of cause of death (CoD) in low income regions. Verbal autopsies and clinical records have shown to be inaccurate. Complete diagnostic autopsies (CDA), the gold standard for CoD determination are challenging due to poor acceptability and limited facilities and human resources. Minimally invasive autopsy (MIA), a simplified procedure involving body fluid and organ-directed sampling followed by pathology and microbiology analyses could become an alternative to CDA. However, there is very limited information on its performance. We aimed to analyze the concordance between MIA and CDA. A standardized procedure for the MIA was tested in a series of 50 autopsies from adults performed at the Maputo Central Hospital, in Mozambique. The MIA was performed by a single pathologist and was followed by a CDA done by a different pathologist. The histological examination of the MIA was done blindly, without any knowledge of the clinical data or the results of the CDA. The microbiological evaluation of the MIA included culture of organs and body fluids as well as routine analyses for HIV, HBV, malaria and tuberculosis, plus specific analyses guided by the histological results. The final CoD obtained in the MIA was compared with the results obtained in the gold standard CDA. Final CoD, as determined in the CDA, were infectious diseases in 30/50 (60%), malignant tumors in 10 (20%) and other causes in 10 patients (20%). A complete agreement between the MIA and the CDA results was observed in 44/50 procedures (88%). The MIA identified 29/30 (97%) of the infectious diseases and in 27 of them the specific etiologic agent was identified in the microbiological analyses. 8/10 malignant tumors and 7/10 other causes were also correctly identified by the MIA. In conclusion, a simple MIA procedure identifies the specific CoD in a high proportion of cases and shows a very high concordance with the results of CDA, the gold standard for CoD attribution.

1270

GENETIC RISK FACTORS ASSOCIATED WITH DENGUE SEVERITY: A CASE-CONTROL STUDY

Junxiong Vincent Pang[1], Eileen Png[2], Chiea Chuen Khor[2], Tun-Linn Thein[1], David C Lye[1], Yee-Sin Leo[1], Martin L. Hibberd[2]

[1]Tan Tock Seng Hospital, Singapore, Singapore, [2]Genome Institute of Singapore, Singapore, Singapore

Dengue disease results in a wide spectrum of disease manifestations ranging from subclinical infection to severe and fatal disease. Severe dengue is characterized by an increase in vascular permeability that leads to life-threatening hypovolemic shock (dengue shock syndrome-DSS). Furthermore, there is an increasing trend of hospitalized dengue adult patients with warning signs over the last decades. Genetics risk factors that may have predisposed individuals to the differential dengue severity are still lacking as most studies are limited by the candidate gene approach and relatively small sample size. From our previous genome-wide association analysis (GWAS) involving about 6000 subjects, we have identified single-nucleotide polymorphisms (SNPs) in the gene MICB, which is a heavily glycosated ligands for the NKG2D type II receptor that activates the cytolytic response of natural killer cells. Using targeted-next generation sequencing, we further explored the potential causal variant of dengue severity. We identified a nonsynonymous substitution due a rare SNP (minor allele frequency=0.01) that converts an arginine amino acid to a stop codon, that was postulated to generate a truncated MICB ligand for activation of cytolytic response of immune cells. This SNP was validated in an independent cohort with 4000 DSS cases and 6000 controls with per-allele risk effect of 1.82 (P-value=0.00026). In addition, GWAS was also performed using 600 blood samples collected from hospitalised adult patients with signifcant dengue severity and 600 non-hospitalised mild patients to identify SNPs that may have predisposed these individuals. We identified SNPs from TPO (per-allele OR=1.54;P-value<0.000001) gene and noncoding regions near SNX16 gene (per-allele OR=0.65;P-value<0.000001). In conclusion, these studies have identified potential genetic risk factors in a genome-wide approach as baseline risk, which may be useful in an early triage tool for implementation of dengue prevention initiatives such as the future dengue vaccine to a more targeted population.

1271

REGULATORY T CELL RESPONSES IN ENDEMIC BURKITT LYMPHOMA PATIENTS ARE ASSOCIATED WITH POOR OUTCOME

Emily Parsons[1], David H. Mulama[2], John Michael Ong'echa[2], John Vulule[2], Juliana A. Otieno[3], Jonathan D. Kurtis[4], Christian Münz[5], V. Ann Stewart[1], Ann M. Moormann[6]

[1]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Jaramogi Oginga Odinga Teaching and Referral Hospital, Kisumu, Kenya, [4]Lifespan Department of Pathology, Rhode Island Hospital and The Miriam Hospital, Providence, RI, United States, [5]Department of Viral Immunobiology, Institute of Experimental Immunology, University of Zürich, Zürich, Switzerland, [6]University of Massachusetts Medical School, Worcester, MA, United States

Endemic Burkitt lymphoma (eBL) is a B cell lymphoma uniquely associated with both Epstein-Barr virus (EBV) and malaria, and accounts for the majority of pediatric cancers in sub-Saharan Africa. Unlike other EBV+ tumors for which novel T cell modulating therapies are being developed, T cell contribution to eBL disease progression and survival has not been characterized. Previous studies suggest that tumor development is associated with a loss of EBV-specific pro-inflammatory responses, and a role for regulatory T (Treg) cells has been shown in other EBV-associated cancers. We hypothesized that T cells from eBL patients have higher Treg cell frequencies and higher EBV-specific regulatory responses that decrease with successful disease resolution. By flow cytometry, we examined peripheral blood mononuclear cells collected in a longitudinal eBL cohort study and found that at the time of diagnosis, patients who died had significantly higher frequencies and absolute cell counts of CD25+Foxp3+ Treg cells, with higher counts of CD45RA+Foxp3lo naïve and CD45RA-Foxp3hi effector Treg subsets. Examination of longitudinal time points showed that Treg frequencies remain low in event-free survivors, while patients who relapsed had peaks of elevated Treg frequencies. CD4+ T cells in non-survivors secreted higher levels IL-10 in response to both EBV and malaria antigens. Both CD4+ and CD8+ T cells in eBL patients exhibit a more exhausted phenotype with higher levels of PD-1, and patients who died were deficient in CD8+ IFN-γ responses to EBV antigen. These

data suggest that poor outcomes in eBL patients are associated with a predominantly immunoregulatory environment. Treg frequencies are a potential biomarker of disease progression, and suppression of Treg activity is a potential therapeutic target to improve eBL survival.

1272

HIGH THROUGHPUT MULTIPLEX DNA EXTRACTION PCR IN THE EVALUATION OF PATIENTS WITH INFECTIOUS DIARRHEA

Bradley A. Connor[1], Susan Lucak[1], Maryna Rogova[2], Olga Whyte[2]

[1]Weill Cornell Medical College, New York, NY, United States, [2]New York Center for Travel and Tropical Medicine, New York, NY, United States

In the majority of cases of infectious diarrhea no specific microbial pathogen is identified. Culture independent diagnostic techniques including high throughput multiplex DNA extraction PCR should increase our diagnostic capabilities with increased sensitivity and by allowing the simultaneous detection of a variety of enteric pathogens including bacteria, protozoans and viruses. Such a multiplex approach is well-suited to the syndromic nature of infectious diarrhea. We describe the use of one such multiplex platform, the BioFire FilmArray GI panel which tests for 22 enteric pathogens. Stool specimens were collected in Cary Blair transport media from patients who presented to our clinic with either travelers' diarrhea, community acquired diarrhea or from specimens obtained in patients undergoing colonoscopy for screening or for evaluation of non-diarrheal gastrointestinal complaints. 394 patient specimens were collected from May 14, 2014 to March 5, 2015. Of these, 104 specimens were from patients who had recently traveled, 214 were from patients with community-acquired diarrhea and 76 were obtained from patients during colonoscopy. A total of 134 specimens (34%) were positive for enteric pathogens. Of these 42 specimens (31%) were positive for multiple pathogens. 47 (45%) travel patients tested positive for enteric pathogens. Pathogens most often identified in this group were EPEC (17), EAEC (16), Giardia (6) and Sapovirus (6). 71 (33%) patients with community acquired diarrhea tested positive for enteric pathogens. Most common in this group were EPEC (33), EAEC (20), and C. difficile. 16 (21%) specimens obtained from patients during colonoscopy were positive for enteric pathogens. Most common in this group were C. difficile (9), EPEC (9), and EAEC (5). Our results confirm an increased detection rate in patients with diarrhea compared with conventional methods such as bacterial culture and microscopy. Multiplex testing appears to be associated with a higher rate of mixed infections. In addition asymptomatic carriage of enteric pathogens appears to occur in patients undergoing colonoscopy for non-diarrheal indications.

1273

FIELD EVALUATION OF PORTABLE MICROSCOPES FOR THE DIAGNOSIS OF SCHISTOSOMIASIS, INTESTINAL PROTOZOA, AND MALARIA IN RURAL CÔTE D'IVOIRE

Jean T. Coulibaly[1], Mamadou Ouattara[1], Michael V. D'Ambrosio[2], Daniel A. Fletcher[2], Jennifer Keiser[3], Jürg Utzinger[3], Jason R. Andrews[4], **Isaac I. Bogoch**[5]

[1]Université Félix Houphouët-Boigny, Abidjan, Côte D'Ivoire, [2]University of California Berkeley, Berkeley, CA, United States, [3]University of Basel, Basel, Switzerland, [4]Stanford University, Palo Alto, CA, United States, [5]Toronto General Hospital, Toronto, ON, Canada

Basic microscopy services are lacking in many resource-constrained settings where the greatest need exists. Portable and mobile phone-based microscopes are being developed to provide quality diagnostic support and may be valuable tools in resource-constrained settings. Virtually all studies evaluating this new technology are in ideal laboratory environments or with expert microscopists, and more work is required to validate these devices in real-world settings. We evaluated laboratory technicians' performance of two novel microscope devices - the Newton Nm1 Portable Field Microscope and the reversed-lens CellScope for the diagnosis of schistosomiasis, intestinal protozoa and malaria infections in a community-based screening program in rural Côte d'Ivoire. One Kato-Katz prepared stool samples from 228 individuals was first evaluated by conventional light microscopy (gold standard) and subsequently by experimental microscopes. For ***Schistosoma mansoni*** and S. ***haematobium*** diagnoses, laboratory technicians using the Newton Nm1 microscope demonstrated sensitivities of 91.7% and 81.1% respectively, and specificities of 99.5% and 97.1% respectively. The sensitivity and specificity for S. ***mansoni*** and S. ***haematobium*** diagnosis using the reversed-lens CellScope was 50.0% and 35.6% respectfully, and 99.5% and 100% respectively. 121 separate slides were examined by both conventional microscopy and the Newton Nm1 microscope for intestinal protozoa infections. The Newton Nm1 microscope demonstrated a sensitivity of 80.2% for Entamoeba histolytica/dispar and Giardia intestinalis diagnoses, and specificity was 100% for both pathogens. Finally, 223 malaria thin smears were examined by both conventional microscopy and the Newton Nm1 microscopy. The Nm1 microscope demonstrated a sensitivity of 80.2% and a specificity of 100% for the diagnosis of ***Plasmodium falciparum***, and quantitative agreement of parasitemia was excellent (Pearson's r: 0.997). Portable and mobile phone microscopy have the potential to deliver quality diagnostics in resource-constrained settings and facilitate clinical and public health initiatives.

1274

A PHASE 1 TRIAL TO ASSESS THE SAFETY, ATTENUATION AND IMMUNOGENICITY OF GENETICALLY-ATTENUATED P52-/ P36-/SAP1- *PLASMODIUM FALCIPARUM* PARASITES VIA THE BITES OF INFECTED *ANOPHELES STEPHENSI* MOSQUITOES

James G. Kublin[1], Sean C. Murphy[2], Sebastian Mikolajczak[3], Lisa Shelton[3], Tracie VonGoedert[3], Brandon Sack[3], Stefan Kappe[3]

[1]Fred Hutch, Seattle, WA, United States, [2]University of Washington, Seattle, WA, United States, [3]Seattle BioMed, Seattle, WA, United States

Attenuated ***Plasmodium*** sporozoite vaccines achieve unprecedented levels of protection against infectious challenge. Both irradiated sporozoites and genetically-attenuated parasites (GAPs) are under consideration for product development. In contrast to genetic heterogeneity observed with irradiated sporozoites, GAPs undergo definitive gene deletion with permanent genetically-defined attenuation and may provide a more rational approach for inducing consistently protective immune responses. Multiple rodent GAPs have been produced, and the cumulative data show that the GAP approach can confer sterile protective immunity. A double gene deletion ***P. falciparum*** GAP lacking ***p52*** and ***p36*** (GAP2KO, Pf ***p52***$^{-}$/***p36***$^{-}$) was generated. A Phase 1 clinical trial of GAP2KO was conducted and at the high 200-bite dose, one of six subjects developed a breakthrough blood-stage infection, indicating conspicuous but incomplete attenuation. To ensure further attenuation, a third deletion was made to the critical liver stage gene encoding Sporozoite Asparagine-rich Protein 1 (GAP3KO, p52^{-}/p36^{-}/sap1^{-}). We conducted a single arm, open-label, phase 1 experimental medicine study designed to evaluate the safety and tolerability of GAP3KO. The study was designed to confirm attenuation of GAP3KO using peripheral blood smears and to evaluate cellular and humoral immune responses. A total of 10 healthy, malaria-naïve adult subjects were enrolled and received GAP3KO via the bites of 150-200 GAP3KO-infected A. stephensi mosquitoes. To confirm attenuation, subjects were evaluated for safety, reactogenicity, and signs and symptoms of malaria infection for 28 days, including monitoring in a hotel setting on Days 8-18 post-GAP3KO administration. All 10 subjects that received GAP3KO did so without incident and completed the 28 day study period. Local and systemic solicited adverse events reported as primary endpoints were classified as Grade 1 (mild) and 2 (moderate). All subjects remained negative for patent parasitemia as demonstrated by evaluation of peripheral blood smears. GAP3KO elicited significant immune responses and will proceed in development.

1275

EFFICACY AND SAFETY OF A PHASE 1 TRIAL WITH CHALLENGE TO ASSESS THE SAFETY AND BIOMARKERS OF PROTECTION IN MALARIA-NAÏVE ADULTS OF IMMUNIZATION VIA MOSQUITO BITE WITH RADIATION-ATTENUATED *PLASMODIUM FALCIPARUM* SPOROZOITES (IMRAS)

Bradley Hickey[1], Sharina Reyes[1], Joanne Lumsden[1], Jo Glenna Banania[1], Charlotte Fedders[1], Alicia Simmons[1], Anatalio Reyes[1], Carlos Vasquez[1], Yolanda Alcorta[1], Alexandra Singer[1], Cindy Tamminga[1], Nimfa Teneza-Mora[1], Silas Davidson[2], Megan Dowler[2], Lindsey Garver[2], Harini Ganeshan[1], Jun Huang[1], Maria Belmonte[1], Arnel Belmonte[1], Esteban Abot[1], Thomas Richie[1], Martha Sedegah[1], Eileen Villasante[1], Judith Epstein[1]

[1]Naval Medical Research Center, Silver Spring, MD, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States

The "IMRAS" (immunization via mosquito bite with radiation-attenuated sporozoites) study is a comprehensive, systems biology-based effort to identify and validate biomarkers of protection with ***Pf***RAS immunization, comparing sterilely protected to non-protected study subjects. The primary objective of the clinical trial is to achieve approximately 50% sterile protection. Twenty-four malaria-naïve adults will receive five doses of approximately 200 infectious bites (200-400 bites total) from ***Pf***RAS-infected mosquitoes (true-immunization) and 8 additional subjects will receive the same from irradiated, uninfected mosquitoes (mock-immunization). Three weeks after the fifth immunization, all immunized subjects (true-immunized and mock-immunized) plus non-immunized infectivity controls will undergo controlled human malaria infection (CHMI). To increase sample size and enable flexibility toward the protection goal, the study was designed with two cohorts and an adjustable dosing schedule for Cohort 2 in the event protection in Cohort 2 was <40% or >60%. During 2014, 95 subjects were screened; 28 were enrolled and assigned to study groups in Cohort 1. Seventeen subjects received at least one true (n = 13) or mock (n = 4) immunization, and six subjects were retained as infectivity controls. Fourteen subjects received the complete series of five true (n = 11) or mock (n = 3) immunizations. The immunizations were generally well tolerated although two subjects (one true-immunized and one mock-immunized) developed large, local reactions with significant proximal extension that became generalized, but confined to the skin. In both cases the reaction resolved uneventfully over one or two days without sequelae, however both subjects were withdrawn from participation. Six of the 11 (55%) true-immunized subjects were sterilely protected, thus achieving the goal of approximately 50% protection. All mock-immunized and infectivity controls were non-protected. Enrollment and immunization of Cohort 2 will mirror that of Cohort 1 and efficacy data is expected late 2015.

Plasmodium falciparum malaria continues to be a leading cause of global morbidity and mortality. Although the RTS,S/AS01 malaria vaccine has been submitted to the European Medicines Agency for regulatory review, efforts continue to improve its efficacy and durability. In one of the first ***P. falciparum*** controlled human malaria infection (CHMI) trials evaluating early formulations of RTS,S, six of seven subjects vaccinated with RTS,S/AS02$_A$ were protected against sporozoite challenge. After systemic reactogenicity was observed following the second dose, and given the limited experience with this adjuvant formulation at the time, the third dose was reduced to one-fifth of the standard dose and administered 6 months after the previous dose (0, 1, and 7 months). Despite the high level of protection, this delayed fractional dose (DFD) regimen has never been repeated in subsequent studies. It is biologically plausible that a DFD regimen may have clinically important qualitative and quantitative impacts on vaccine immunogenicity and consequently on vaccine efficacy. Considering this, we conducted a phase 2a study (NCT01857869) of RTS,S/AS01$_B$ with CHMI to re-investigate the DFD regimen in a larger trial of healthy malaria-naïve adult volunteers. The study enrolled 34 volunteers in the DFD group (received standard doses of RTS,S/AS01$_B$ at 0 and 1 months and 1/5th standard dose at 7 months) and 17 in the active control group (received standard doses RTS,S/AS01$_B$ at 0,1, and 2 months). ***P. falciparum***-infected mosquito CHMI, including infectivity controls, was performed 21 days after the third vaccine dose. Re-challenge was also conducted 7 months after the third vaccine dose, with or without a fractional booster dose in a subset of volunteers. Trial safety, reactogenicity, immunogenicity, and efficacy after CHMI will be reported.

1277

SAFETY, IMMUNOGENICITY AND EFFICACY OF THE COMBINATION MALARIA VACCINE REGIMEN OF RTS,S/AS01B CONCOMITANTLY ADMINISTERED WITH CHAD-MVA VIRAL VECTORS EXPRESSING ME-TRAP

Tommy Rampling[1], Georgina Bowyer[1], Danny Wright[1], Navin Venkatraman[1], Ruth Payne[1], Saranya Sridhar[1], Nick Edwards[1], Ian Poulton[1], Egeruan B. Imoukhuede[1], Johan Vekemans[2], Robert Sinden[1], Rachel Roberts[1], Richard Weltzin[3], Danielle Morelle[2], Bebi Yassin-Rajkumar[3], Ashley J. Birkett[3], Karen L. Ivinson[3], Christian F. The global healthcare burden of ***Plasmodium falciparum*** malaria remains high. Both RTS,S/AS01 and a prime-boost regimen using viral vectors ChAd63 and MVA expressing the ME-TRAP antigen have shown partial efficacy. In an attempt to increase vaccine efficacy an initial trial was conducted in 2013/2014 in which RTS,S/AS01$_B$ and the viral vectors were administered in a staggered fashion, and subsequently evaluated for protection by controlled human malaria infection (CHMI). A high level of protective efficacy was seen in both the RTS,S/AS01$_B$ plus viral vectors group, and RTS,S/AS01$_B$ alone groups (82.4% [95% CI 64%-100%] and 75% [95% CI 54%-96%] respectively). To further investigate this initial finding, we designed this phase I/IIa, open-label, CHMI study (NCT no. NCT02252640) to assess the safety, immunogenicity and efficacy of concomitant administration of viral vectors with RTS,S/AS01$_B$. Furthermore, to evaluate the finding of high efficacy (86% [95% CI 12%-98%]) in a CHMI trial conducted in 1997, where subjects had received 2 standard doses of RTS,S/AS02$_A$ and a reduced (1/5th standard dose) third dose, RTS,S/AS01$_B$ was administered in this current trial as a standard dose regimen or in a regimen where the third dose was reduced to 1/5th of the standard dose. We enrolled healthy malaria naïve adults into 1 of 4 groups using a factorial design. All groups received 3 doses of RTS,S/AS01$_B$. Groups 1 and 3 received 3 standard doses of RTS,S/AS01$_B$ at weeks 0, 4 and 8, whilst groups 2 and 4 received 2 standard doses at weeks 0 and 4 and a fractional (1/5th) dose at week 8. In addition, groups 3 and 4 received concomitant vaccinations at the same site with ChAd63 ME-TRAP at week 0, and MVA ME-TRAP at weeks 4 and 8. Efficacy was assessed by CHMI delivered by mosquito bites approximately 3 weeks after the last dose. Safety, immunogenicity of the vaccine regimen, and efficacy results from the CHMI will be presented.

1278

PHASE 1 TRIAL WITH CONTROLLED HUMAN MALARIA INFECTION: AN OPEN LABEL DOSE-ESCALATION SAFETY, REACTOGENICITY, IMMUNOGENICITY, AND EFFICACY STUDY OF THE CANDIDATE VACCINE *PLASMODIUM FALCIPARUM* MALARIA PROTEIN (FMP012), AN *E. COLI*-EXPRESSED CELL-TRAVERSAL PROTEIN FOR OOKINETES AND SPOROZOITES (*PF*CELTOS), ADMINISTERED INTRAMUSCULARLY WITH THE ADJUVANT SYSTEM AS01$_B$ IN HEALTHY, MALARIA-NAÏVE ADULTS

A highly efficacious malaria vaccine against ***Plasmodium falciparum*** is a key element in the effort to prevent infection and eradicate malaria. The pre-erythrocytic antigen named cell-traversal protein for ookinetes and sporozoites (CelTOS) appears to be critical in order for the sporozoite to traverse host cells in vertebrates and successfully initiate an infection. CelTOS is highly conserved among ***Plasmodia***, suggesting an important functional role. Falciparum malaria protein 12 (FMP012) is a recombinant subunit protein based on CelTOS from the 3D7 clone of ***P. falciparum*** expressed in and purified from ***E. coli*** using a unique synthetic "codon harmonized" gene construct resulting in optimal folding and expression. In an earlier clinical trial at Walter Reed Army Institute of Research, FMP012 in combination with an alternate adjuvant was well tolerated but did not induce sterile immunity. One subject had a significant delay in the pre-patent period and had both the highest antibody titer and highest IFN-γ ELISpot response to FMP012 on the day of challenge compared to the other subjects (NCT01540474). To further assess potential efficacy, we performed a phase 1 vaccine safety and immunogenicity study of FMP012 formulated with the Adjuvant System AS01$_B$ followed by controlled human malaria infection (CHMI) challenge (NCT02174978). The study incorporated dose-escalation of the antigen in combination with a fixed adjuvant dose. A total of 30 volunteers were divided into 2 dosage groups (15 subjects per group), each receiving 4 intramuscular injections at 0, 1, 2, and 6 months. A ***P. falciparum***-infected mosquito CHMI was performed in 6 infectivity control volunteers and both vaccine groups 21 days following the fourth vaccination. The safety, reactogenicity, immunogenicity, and efficacy results of the FMP012/AS01$_B$ vaccine are reported.

1279

A TRANSMISSION BLOCKING VACCINE AGAINST *PLASMODIUM FALCIPARUM*, PFS25H-EPA/ALHYDROGEL®: RESULTS FROM THE FIELD

Sara A. Healy[1], Issaka Sagara[2], Mahamadoun H. Assadou[2], Merepen A. Guindo[2], Mamady Kone[2], Ibrahima Baber[2], Erin Gabriel[3], Kourane Sissoko[2], Intimbeye Tembine[2], Djibril Traore[2], M'Bouye Doucoure[2], Sintry Sanogo[2], Amadou Konate[2], Kelly Rausch[1], David L. [1]National Institutes of Health, Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [2]Malaria Research and Training Center, Mali-NIAID ICER, USTTB, Bamako, Mali, [3]National Institutes of Health, Biostatical Research Branch, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

Transmission blocking vaccines (TBV) are a critical strategy for malaria elimination and eradication in Sub-Saharan Africa. A double blind, randomized, controlled Phase 1 clinical trial was completed to assess the safety and immunogenicity of Pfs25H-EPA/Alhydrogel® in malaria exposed Malian adults. One hundred and twenty healthy adult volunteers aged 18-45 years old living in the village of Bancoumana, Mali were enrolled into the study. Among the 120 participants, 20 (low dose of 16µg Pfs25H-EPA/Alhydrogel® or control) received 2 doses (Days 0 and 56) and 100 (high dose of 47µg Pfs25H-EPA/Alhydrogel® or control) received 4 doses (Days 0, 56, 112, and 480). The clinical study was recently unblinded in March 2015. Overall, Pfs25H-EPA/Alhydrogel® TBV has been well tolerated and produced significant antibody responses in a malaria exposed adult population. Unblinded results of safety, immunogenicity, and functional transmission blocking activity (measured by standard membrane feeds, direct skin feeds, and experimental hut studies) will be presented.

ASSESSING EFFICACY OF THE PFSPZ VACCINE BY CONTROLLED HUMAN MALARIA INFECTION IN BAGAMOYO TANZANIA

Seif Shekalaghe

Ifakara Health Institute, BRTC, Bagamoyo, United Republic of Tanzania

Assessing efficacy of the PfSPZ Vaccine by controlled human malaria infection in Bagamoyo Tanzania Seif Shekalaghe, Said Jongo, Elena Moreno, Omar Lweno, Ali Hamad, Kamaka Kassim, Omar Juma, Conrad Gwandu, William Kato, Caroline Mavere, Ramla Rashid, Jackson Mollel, Maximillian Mpina, Anneth Tumbo, Catherine Mkindi, Selina Joseph, Mohammed Mgeni, Claudia Daubenberger, Peter Billingsley, Thomas L Richie, Marcel Tanner, Salim Abdullah, Stephen L Hoffman African scientists are now spearheading phase 1 or proof-of-concept studies that have a controlled protection component. Recently, Sanaria Inc., has developed aseptic, purified, cryopreserved infectious ***Plasmodium falciparum*** (Pf) sporozoites (SPZ) (PfSPZ Challenge), suitable for parenteral injection and shippable to any location able to conduct GCP studies. PfSPZ Challenge has now been tested in the US, Europe, Africa. 3200 infectious PfSPZ administered by direct venous inoculation (DVI) reproduces the near 100% infection rate and 11-12 day pre-patent period of the traditional five-mosquito bite CHMI. For the first, we used PfSPZ Challenge to test the efficacy of a candidate malaria vaccine against CHMI administered by DVI. PfSPZ Vaccine are non-replicating due to radiation attenuation. PfSPZ Vaccine has shown 100% efficacy in a study at The Vaccine Research Center, National Institute of Allergy and Infectious Diseases, in the group received the highest (135,000 PfSPZ by DVI at wks 0, 4, 8, 12 and 20). Ifakara Health Institute at Bagamoyo has compared the same regimen, but delivered twice (270,000 PfSPZ) at each of the five time points, in adults. Vaccine was assessed for protection against CHMI delivered by DVI at 3 and 24 weeks after the fifth dose. We will present safety, tolerability and efficacy data for this unique study that is opening an exciting pathway for malaria vaccine testing and development in Africa and the world.

THE SOIL INHABITING *METARHIZIUM* FUNGI AND THEIR VIRULENCE AGAINST MALARIA MOSQUITOES *ANOPHELES GAMBIAE* S.L. IN BURKINA FASO

Etienne Bilgo[1], Brian Richard Lovett[2], Raymond J. Leger[2], Marcelo J. Lorena[3], Roch K. Dabiré[1], Antoine Sanon[4], Abdoulaye Diabaté[1]

[1]IRSS/Centre Muraz, Bobo Dioulasso, Burkina Faso, [2]Department of Entomology, College Park, MD, United States, [3]John Hopkins Malaria Research Institute, Baltimore, MD, United States, [4]Laboratoire d'Entomologie Fondamentale et Appliquée, UFR/SVT, Université de Ouagadougou, Ouagadougou, Burkina Faso

Fungi can infect mosquitoes through direct contact with the cuticle, so lend themselves to strategies currently used for delivery of chemical insecticides. In addition, they are environmentally friendly alternatives to pesticides. Much attention has focused on the ascomycetes ***Metarhizium spp***. and ***Beauveria spp***. These species are soil-inhabiting, insect-pathogenic fungi and are associated with the rhizosphere. However, not much is known about the distribution of these fungi in the rhizosphere and their potential virulence against adult malaria mosquitoes in the field in Burkina Faso. Here, we monthly explored a preferred habitat of these fungi during the dry and wet season from 2014-2015 in five different sites. Fungi were isolated and cultured in a sterile environment. Potato Dextrose Agar (PDA), a common medium for isolating fungi, and PDA + CTAB+ Chloramphenicol, a selective medium were used for isolation. ***Aspergillus spp***., ***Trichoderma spp***. and ***Metarhizium spp***. were the main genera isolated from all the sites and throughout the year. ***Metarhizium spp***. represented between 34 and 75% of isolated samples according to the sites and the season. Eleven different ***Metarhizium spp***. isolates from the rhizosphere at the concentration 10^8 conidia/mL were used for bioassays to infect adult mosquitoes ***Anopheles gambiae*** s.l. Overall, the corrected mortality percentage by the Abbott's formula was between 79% and 100% after 2 weeks infection. In addition, the LT50 of these isolates globally varied from 6 to 10 days. To follow up, the stress tolerance experiments to determine the fitness and PCR analysis for species identification will be carried out on the virulent species. These results are extremely encouraging for using locally isolated ***Metarhizium*** isolates in biological and transgenic biocontrol methods against malaria.

1282

ACTIVITY OF THE PYRROLE INSECTICIDE CHLORFENAPYR ON LLIN IN MOSQUITO BIOASSAY AND SEMI FIELD TRIALS: IMPLICATIONS FOR FUTURE INSECTICIDE TESTING

Mark W. Rowland, Richard Oxborough, Raphael N'Guessan

London School of Hygiene & Tropical Medicine, London, United Kingdom

The rapid selection of pyrethroid resistance in Africa is a serious threat to malaria vector control. Chlorfenapyr is a pyrrole insecticide which shows no cross resistance to conventional insecticide classes and is effective on mosquito nets in semi field conditions. Unlike neurotoxic insecticides, chlorfenapyr owes its toxicity to disruption of metabolic pathways in mitochondria. A series of experiments explored whether standard World Health Organization guidelines for evaluation of long-lasting insecticidal nets are adequate for evaluation of non-neurotoxic insecticides. The efficacy of WHO recommended test methods were compared for pyrethroids and chlorfenapyr. Mosquito behaviour and response to chlorfenapyr ITN in bioassays conducted at night was compared to day and across a range of temperatures representative of highland and lowland transmission. Standard bioassay tests on chlorfenapyr produced extremely low levels of mortality which was not at all predictive of the levels of mortality achieved under field conditions. The endogenous circadian activity rhythm of anophelines results in inactivity by day and

raised metabolism and flight activity by night. A model which explains improved toxicity of chlorfenapyr ITN when tested at night, and during the day at higher ambient temperature, is that activation of chlorfenapyr and disruption of respiratory pathways is enhanced when the insect is more metabolically and behaviourally active. Testing according to accepted guidelines is not suitable for certain types of non-neurotoxic insecticide which, though highly effective in field trials, would be overlooked at the screening stage of evaluation through bioassay. WHO testing methods must be tailored to the characteristics and mode of action of each insecticide class. The WHO tunnel test or experimental hut trial on night active anophelines is only reliable bioassay for identifying the toxicity of novel insecticides on nets.

1283

IVERMECTIN INHIBITS THE DEVELOPMENT OF *PLASMODIUM VIVAX* IN *ANOPHELES DIRUS*

Kevin C. Kobylinski[1], Ratawan Ubalee[1], Alongkot Ponlawat[1], Wes McCardle[1], Brian Foy[2], Daniel Szumlas[3], Jason Richardson[4]

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Colorado State University, Fort Collins, CO, United States, [3]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]Armed Forces Pest Management Board, Silver Spring, MD, United States

Novel vector control interventions are urgently needed to assist malaria drug resistance containment and elimination efforts in the Greater Mekong Subregion (GMS). In West Africa, ivermectin MDAs have been shown to significantly reduce the survivorship of ***Anopheles gambiae*** up to six days and the proportion of ***Plasmodium falciparum***-infectious ***An. gambiae*** up to fifteen days post MDA in Senegal, Liberia, and Burkina Faso. Previous laboratory work demonstrated that ivermectin inhibits the development of ***P. falciparum*** in ***An. gambiae*** (***ie***. sporontocidal). Ivermectin is lethal to numerous important GMS malaria vectors including: ***An. dirus***, ***An. minimus***, ***An. campestris***, and ***An. sawadwongporni***. Here we present that ivermectin is sporontocidal to ***P. vivax*** in ***An. dirus*** when ivermectin is co-ingested with gametocytes at the lethal concentration that kills 25 and 5 percent of mosquitoes (***ie***. LC_{25} and LC_5). Briefly, gametocytemic blood was drawn from ***P. vivax***-infected persons reporting to malaria clinics in Thailand, the blood was mixed with dilutions of ivermectin, and then fed to ***An. dirus*** in membrane feeders with and without ivermectin. Oocyst prevalence was reduced at the ivermectin LC_{25} by 34% ($\chi^2 = 22.75$, $P < 0.0001$) and LC_5 by 29% ($\chi^2 = 16.9$, $P < 0.0001$). In ***An. dirus*** that were ***P. vivax***-infected, oocyst intensity was reduced at the ivermectin LC_{25} by 42% ($P = 0.0096$) and LC_5 by 48% ($P = 0.0123$). Interestingly, ***An. dirus*** that ingested ***P. vivax*** were substantially more susceptible to the ivermectin LC_{25} compared to control blood meals with ivermectin LC_{25} with a 48% reduction in survivorship to day 7 ($\chi^2 = 64.83$, $P < 0.0001$). The combined mosquito-lethal and sporontocidal effects of ivermectin suggest that ivermectin MDAs to humans could be a powerful new tool to aid elimination efforts in the GMS. Future directions include repeating these trials with ***P. falciparum*** using malaria-naïve serum from ivermectin-treated individuals, and a clinical trial to assess the safety, tolerability, pharmacokinetic interaction, and mosquito lethal efficacy of ivermectin with artemisinin combination therapies, and primaquine.

1284

THE CYTOCHROME P450 CYP6Z1 GENE AND THE N485I ACE-1 MUTATION CONFER CARBAMATE RESISTANCE IN THE MAJOR AFRICAN MALARIA VECTOR *ANOPHELES FUNESTUS*

Sulaiman S. Ibrahim, Miranda Ndula, Jacob M. Riveron, Helen Irving, **Charles S. Wondji**

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Despite increasing reports of resistance to carbamate insecticides in the major African malaria vector ***Anopheles funestus***, its molecular basis remains uncharacterized preventing the design of suitable resistance management strategies. Here, we dissected the molecular basis of bendiocarb resistance showing that carbamate resistance is driven by both metabolic and target-site resistance and designed a diagnostic tool to detect and track this resistance. Using a microarray-based genome-wide transcription profilling and qRT-PCR, we detected candidate carbamate resistance genes in Malawian ***An. funestus***. The cytochrome P450 genes CYP6P9a, CYP6P9b and CYP6Z1 were the most up-regulated in both bendiocarb and pyrethroid resistant mosquitoes suggesting possible cross-resistance. Using In silico modelling/docking and both ***in vivo*** transgenic expression in Drosophila and ***in vitro*** recombinant enzyme metabolism assays, we demonstrated that specific CYP6Z1 confers cross-resistance to both insecticide classes whereas CYP6P9a and CYP6P9b are only pyrethroid metabolisers. Polymorphism analysis further confirmed that CYP6P9a and CYP6P9b were only associated with pyrethroid resistance. Investigation of the target resistance through the cloning of the full 2208 bp of the acetylcholinesterase 1 gene did not detect the common G119S but 4 other mutations. A Taqman genotyping of the N485I mutation revealed that it significantly correlates with bendiocarb resistance (Odds ratio 7.3; P<0.0001). Furthermore, detection of multiple haplotypes in single mosquitoes after cloning suggests the duplication of the Ace-1 gene in ***An. funestus*** and further supported by the absence of any homozygote (RR) resistant mosquitoes in the field. Genotyping of the N485I mutation in 10 countries reveals that it is only located in Southern Africa (Malawi, Mozambique and Zambia) with frequency of 10-15% suggesting a recent occurrence of this mutation. These findings will help monitor the spread and evolution of carbamate resistance and improve the design of effective resistance management strategies to control this major malaria vector.

1285

ENDECTOCIDE-TREATED BIRD FEED FOR THE CONTROL OF WEST NILE VIRUS TRANSMISSION

Chilinh Nguyen, Meg Gray, Tim Burton, Wojtek Kuklinski, Brian Foy

Colorado State University, Fort Collins, CO, United States

Currently there are limited options for controlling West Nile virus (WNV) transmission, including the use of larvicides and adulticides to target the mosquito vector. However, these applications are poorly-targeted, restricted to wealthy semi-urban and urban areas that are able to fund the efforts, and face opposition due to toxicity concerns. This study evaluated the use of endectocide-treated bird feed to control WNV transmission by targeting the primary vector in Colorado, ***Culex tarsalis***, through its blood feeding behavior. Ivermectin (IVM) susceptibility in ***C. tarsalis*** was measured through IVM-spiked bloodmeals with membrane feeders, and the LC_{50} was determined to be 49.94 ng/ml ([39.71-59.93], n = 988). Chickens were then fed IVM-treated feed to examine its safety and palatability, and mosquitoes were blood fed directly on the chickens to assess ***in vivo*** effects. Finally, IVM pharmokinetics were analyzed using vein blood from chickens as well the ***C. tarsalis*** that bloodfed on the chickens. A mixture of 200 mg IVM/kg of bird feed was determined to be a palatable and safe dose that chickens would consume while also being effective in killing ***C. tarsalis*** in bioassays with 95% mortality in IVM fed mosquitoes compared to 100% survival in unmedicated controls. Pharmacokinetic data from the ***in vivo*** tests produced conflicting results compared to ***in vitro*** blood feeds but IVM was detected in chicken blood at concentrations that may be expected to affect ***C. tarsalis***. Dosing, safety, and bioassays were also conducted in doves, where 200 mg/kg was safe and palatable, while killing 88% of IVM-fed mosquitoes compared to 15% control mortality. Additional studies are currently determining the effect of IVM on mortality in WNV-infected mosquitoes, as well as if sub-lethal doses of ivermectin reduces WNV replication and transmission. Preliminary data showed that ***C. tarsalis*** mortality is significantly increased when given a blood meal including 73.66 ng/ml of IVM and $5x10^5$ PFU/ml WNV as compared to a blood meal containing only IVM. Our study indicates that the use of IVM-treated bird feed could be a novel strategy for control of WNV transmission.

1286

SUCCESSFUL APPLICATION OF A SEQUENCE-BASED GENOMEWIDE ASSOCIATION STUDY (GWAS) TO IDENTIFY THE GENETIC BASIS OF PYRETHROID RESISTANCE IN *ANOPHELES ARABIENSIS*

David Weetman[1], Christopher S. Clarkson[1], Christopher M. Jones[2], Johnson Matowo[3], Bilali Kabula[4], Daniel E. Neafsey[5], Martin J. Donnelly[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Rothamstead Research, Harpenden, United Kingdom, [3]Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, [4]National Institute for Medical Research, Muheza, United Republic of Tanzania, [5]Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, United States

The genomic resources available for major vectors within the ***Anopheles gambiae*** complex create opportunities to apply genomewide association (GWAS) approaches to medically-important phenotypes such as insecticide resistance. However, in nature the genomes and population genetics of mosquitoes present extreme challenges for GWAS, at least using standard designs from human studies. We developed a novel hybrid-GWAS design founded on advances in ***Anopheles gambiae*** genome sequencing. Focussing on recent and spreading pyrethroid resistance in the increasingly-important vector ***An. arabiensis***, we sequenced and compared multiple pools of partially or fully resistant and susceptible females from wild populations in northern Tanzania and Zanzibar. Following application of a stringent analysis pipeline we identify very strong, replicated, association signals around gene clusters with known involvement in metabolic resistance. Our results suggest that with pragmatic experimental design, GWAS in ***Anopheles*** is both a feasible and powerful option to identify the genetic basis of medically-relevant phenotypes and discover diagnostic markers.

1287

STUDY OF CUTICULAR RESISTANCE IN *ANOPHELES GAMBIAE*, FROM PHENOTYPE TO PROTEIN FUNCTION

Yahouedo Gildas

Institut de Recherche pour le Developpement-MIVEGEC, Montpellier, France

Cuticular resistance reduce the penetration of insecticide through a change in the cuticle composition (lipids and proteins). This resistance mechanism has often been described in insects of agricultural interest but less characterized in mosquitoes. Cuticle thickness was associated with Pyrethroids (Py) resistance in ***Anopheles funestus***. The aim of this study is to determine if there is a resistance to Py through cuticular proteins in ***An. gambiae*** and to characterize their involvement in the process. To do this, we selected a resistant strain without kdr mutation to avoid interaction between resistance mechanisms. The resistant strain selection of ***An. gambiae*** without kdr allele was performed through successive cross-breeding between a wild resistant strain and the susceptible reference strain. Insecticide pressure has been applied on this strain on adult stage. Biochemical and susceptibility tests were performed for resistance monitoring level. Candidate cuticle and metabolic genes were been taken on resistant An transcriptomic data of previous studies. RT-qPCR will be performed on these candidate genes and the expressions compared between resistant and susceptible. The overexpressed genes in resistant will be confirmed by RNAi. To measure the penetration of insecticides through cuticle, we will proceed a topical application of Py. The insecticide and his metabolite within mosquitoes will be determined by GC-MS/MS or GC-ESD. The resistant mosquitoes group will be compared to the susceptible one. Microscopic study will be conducted on the ultrastructure of the resistant cuticle versus susceptible as well as proteins involved by proteomic approach. The resistant strain has been selected and the pressure selection based on insecticide is in progress. Biochemical tests already showed an overexpression of non-specific esterase alpha, beta and Glutathione S-Transferase. Currently the strain selected with deltamethrin recorded 60.93% of mortality after 30 minutes of exposure and that selected with permethrin, 84% of mortality after 40 minutes of exposure. The study is in progress and interesting results are expected in next months.

1288

GENETIC MODIFICATION OF THE DIARRHEAL PATHOGEN *CRYPTOSPORIDIUM PARVUM*

Boris Striepen

University of Georgia, Athens, GA, United States

Cryptosporidium is the second most important pathogen after rotavirus to cause moderate to severe diarrhea in children below two years of age. ***Cryptosporidium*** is also an opportunistic pathogen for immunocompromised individuals such as HIV/AIDS patients and organ transplant recipients. Currently, there are no fully effective drugs or vaccines to treat or prevent cryptosporidiosis. The main roadblock in the development of drugs and vaccines is the overall poor tractability of ***Cryptosporidium*** due to lack of continuous culture system, poor animal models and lack of genetic tools. We report here a powerful approach to genetically modify this pathogen. We demonstrate the transfection of ***Cryptosporidium parvum*** sporozoites in tissue culture and optimization of regulatory sequences and electroporation conditions to drive expression of a luciferase reporter gene. We developed a mouse model for ***C. parvum*** infection to inject electroporated sporozoites directly into the small intestine of IFN-γ knockout mice. We used the CRISPR-Cas9 system to knockout the parasite's thymidine kinase (tk) gene and replace it with a cassette expressing the luciferase reporter fused to a neomycin resistance gene that conferred paromomycin resistance ***in vivo***. Quantitative 18S ribosomal RNA PCR and luminescence measurements were used to monitor the course of parasite infection in mice and development of paromomycin-resistant transgenic parasites. We tested the stable transgenic parasites for the loss of the tk gene, and evaluated the use of transgenic oocysts for performing drug assays. Our ability to genetically engineer ***C. parvum*** will help to answer key questions related to parasite biology and accelerate the development of novel therapeutics for disease intervention.

MOLECULAR DIAGNOSTICS FOR GASTROINTESTINAL PARASITES AND IMPACT ON INTESTINAL MICROBIOTA IN RURAL ARGENTINIAN CHILDREN

Rojelio Mejia[1], Rubén Cimino[2], Ashish Damania[1], Rebecca Jeun[1], Patricia Bryan[1], Paola Vargas[2], Marisa Juarez[2], Pamela Cajal[2], Julio Nasser[2], Alejandro Krolewiecki[2], Maria E. Bottazzi[1], Peter Hotez[1], Barton Slatko[3]

[1]National School of Tropical Medicine, Baylor College of Medicine, Houston, TX, United States, [2]Universidad Nacional de Salta, Salta, Argentina, [3]New England BioLabs, Inc., Ipswich, MA, United States

Worldwide, there are over 2 billion people infected with gastrointestinal (GI) parasites. Depending on the species, these parasites can disrupt intestinal bacterial flora affecting nutritional status. We implemented a multi-parallel quantitative real-time PCR (qPCR) and have begun NextGen sequencing analysis for microbiota and 8 common GI parasites including the helminths, ***Ascaris lumbricoides (Al), Ancylostoma duodenale (Ad), Necator americanus (Na), Strongyloides stercoralis (Ss), Trichuris trichiura (Tt)*** and protozoa, ***Cryptosporidium parvum (Cp), Entamoeba histolytica (Eh)*** and ***Giardia lamblia (Gl).*** Stool samples were collected from 116 asymptomatic children (under 10 years old) from rural Argentina. qPCR and next generation sequencing was performed on microbiota enriched stool sample DNA using shotgun sequencing. Among samples, qPCR identified the helminths ***Al*** (54.3%) and 37.4% for two hookworm species (***Na*** and ***Ad***). For ***Ss*** and ***Tt***, 63.6% and

0.8% were positive, respectively. For the protozoa, ***Gl*** (65.5%), ***Eh*** (1.7%), and ***Cp*** (0%). qPCR was also able to detect polyparasitism of 2 or more parasites in 70.6% of patients. For ***Gl*** samples, microbiome analysis data shows decrease in microbiota biodiversity in the parasite infected group compared to those non-infected, with a shift away from ***Firmicutes*** toward increased ***Bacteroidetes***, with the degree of shift related to intensity of infection (qPCR data). The abundant bacteria within the ***Bacteroidetes*** were due to increased ***Prevotella,*** compared to the non-infected group with increased ***Ruminococcus*** ($p < 0.05$***)***. Clustering between the groups was examined using PCoA ordination and Shannon alpha diversity (parasite group 1.65; non-infected group 2.7, $p = 0.033$). This first use of multi-parallel qPCR and NextGen microbiota sequencing in Argentina, shows an association of GI parasite infections and decreased microbiome biodiversity in asymptomatic children. The results will enable refinement of treatment options on a public health scale, leading to better health outcomes in endemic settings.

ELUCIDATING MECHANISMS OF DIARRHEA AND ENTEROPATHY DURING MALNUTRITION AND CRYPTOSPORIDIOSIS

Luther Bartelt[1], David Bolick[1], Glynis Kolling[1], Edna Zaenker[1], John Moore[1], Jerrold Turner[2], Cirle Warren[1], Richard Guerrant[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]University of Chicago, Chicago, IL, United States

Cryptosporidium is a major cause of moderate to severe diarrhea, persistent diarrhea, and stunting in children living in resource-limited countries. Malnutrition increases risk of cryptosporidiosis, and experimental models demonstrate compounded deleterious effects of infection during nutrient deficient states. The pathogenesis of diarrhea due to ***Cryptosporidium***, however, is incompletely understood. Using a murine model of protein malnutrition (PEM), we interrogated epithelial barrier disruption ***in vivo***. We identified that PEM leads to up-regulation of claudin-1 but reduced expression of claudin-2. The combination of PEM with ***C. parvum*** enhanced disease concurrent with increased numbers of claudin-2 antibody stained cytoplasmic vesicles and led to a generalized reduction in occludin expression in the ileum, but zonula occludins (ZO)-1 was not significantly affected. IL-13, a known inducer of claudin-2 was elevated in protein malnourished mice following primary ***C. parvum*** infection, but mice re-challenged after ***C. parvum*** priming neither lost weight nor demonstrated elevated IL-13 (113.30 vs 0 pg/ml; $P<0.05$). In comparison, infection with the non-invasive protozoan G. lamblia, led to no appreciable change in claudin-2 expression, but marginal increases in ZO-1 and claudin-15. A progressive increase in lamina propria lymphocytes occurred through 21 days after ***C. parvum*** challenge, concurrent with stunted growth relative to uninfected controls. These studies demonstrate differential and pathogen-specific influences on tight-junction protein expression at the epithelial barrier during conditions of malnutrition, and in the case of ***Cryptosporidium***, raises the potential for a mechanism of diarrhea involving a unique and specific disruption in the epithelial barrier that may be in part driven by the host immune response.

IL-25 MEDIATED PROTECTION FROM AMOEBIC COLITIS

Zannatun Noor, Stacey Burgess, Carrie Cowardin, Erica L. Buonomo, Caitlin Naylor, William A. Petri, Jr.

University of Virginia, Charlottesville, VA, United States

Entamoeba histolytica is an enteric parasite that causes diarrhea. ***E. histolytica*** adheres to host cells by Gal/GalNAc lectin and disrupts the mucosal barrier, penetrates underlying tissue and destroys cells. Host responses at the site of infection are critical for resistance, thus the mucosal response against ***E. histolytica*** infection is a significant contributor to the immune response. Intestinal epithelial cells (IECs) serve as effectors of the mucosal immune system and produce inflammatory mediators including IL-1β during amebiasis. IL-1β is known to suppress the production of IL-25 and is increased during ***E .histolytica*** infection, which is also produced by IECs. We have observed that IL-25 expression is suppressed in a time course of ***E. histolytica*** infection in CBA mice. We hypothesize that during ***E. histolytica*** infection IL-25 has a protective role and to test this hypothesis we intraperitonealy administrated rIL-25 in CBA mice. We have found that rIL-25 treated mice had a significantly lower infection rate through culture, lower antigen load by ELISA and also lower numbers of ***E. histolytica*** through QPCR. Histologically there was significantly less epithelial disruption in rIL-25 treated mice. Therefore we have concluded IL-25 plays a protective role during amebiasis. We have found that Reg3gamma (Reg3g) is increased with rIL-25 administration during ***E. histolytica*** infection. Therefore we hypothesized Reg3g could play a role in IL-25 mediated protection by maintaining the epithelial barrier and ***E. histolytica*** killing. To test the importance of Reg3g, we will block Reg3g activity in rIL-25 treated mice. We have also found that IL-25 can induce the Th2 cytokine IL-13 at the acute stage of infection. IL-13 is known to induce paneth cell degranulation to release antimicrobial peptides. To confirm the role of IL-13 in IL-25 mediated protection through Reg3g, we will block IL-13 in IL-25 treated mice and hypothesize that there will be decreased level of Reg3g to make mice susceptible. This work will inform our knowledge on the role of IL-25 in the mucosal defense against amebic infection, ultimately improving treatment and vaccine strategies.

A 5-AMINOPYRAZOLE-4-CARBOXAMIDE *CRYPTOSPORIDIUM* THERAPEUTIC ALLEVIATES DIARRHEA IN THE CALF-CHALLENGE MODEL

Wesley C. Van Voorhis[1], Deborah A. Schaefer[2], Zhongsheng Zhang[1], Alejandro Castellanos-Gonzalez[3], Kasey L. Rivas[1], Lynn K. Barrett[1], A. Clinton White[3], Kayode K. Ojo[1], Erkang Fan[1], Michael W. Riggs[2]

[1]University of Washington, Seattle, WA, United States, [2]University of Arizona, Tucson, AZ, United States, [3]University of Texas Medical Branch, Galveston, Galveston, TX, United States

New therapies to treat ***Cryptosporidium*** infection are urgently needed to address severe and life-threatening diarrhea in <2 yo children in the developing world. It was previously shown that targeting calcium-dependent protein kinase 1 (CDPK1) of ***Cryptosporidium parvum*** (Cp) with pyrazolo-pyrimidine bumped-kinase inhibitors leads to reduction of parasite host cell invasion ***in vitro*** and a reduction of infection in the immunosuppressed mouse model of Cp (JID 2013;208:1342). We have now tested a 5-aminopyrazole-4-carboxamide (AC) bumped-kinase inhibitor (1517), that also inhibits CpCDPK1 (IC50 = 1nM) and blocks Cp invasion and proliferation ***in vitro*** (EC50 = 50nM). We tested the therapeutic efficacy of 1517 in the newborn-calf-Cp challenge model. Calves were challenged with Cp and subsequently treated with 1517 (10mg/kg given orally every 12 hrs for 5 days) or vehicle-alone (control) starting on day 2 after challenge. Calves began to have diarrhea on day 2 after challenge. Compared with control calves, calves treated with 1517 had a significantly improved clinical score, less days of diarrhea, and reduced fecal volume. Oocyst excretion levels are currently being evaluated and will be reported at the meeting. These data demonstrate that bumped kinase inhibitors improve clinical outcomes in calf-Cp infection, even after diarrhea is established. This suggests that these promising therapeutics could help children in the developing world with ***Cryptosporidium*** diarrhea.

1293

DEFINING THE EGRESS SIGNALING NETWORK IN THE APICOMPLEXAN *TOXOPLASMA GONDII*

Raj Gaji[1], Derrick Johnson[1], Lisa Checkley[2], Michael Ferdig[2], Andy Hudmon[1], **Gustavo Arrizabalaga**[1]

[1]University of Indiana School of Medicine, Indianapolis, IN, United States, [2]University of Notre Dame, Notre Dame, IN, United States

Egress from the host cell is a crucial and highly regulated step in the biology of obligate intracellular parasites such as ***Plasmodium falciparum*** and ***Toxoplasma gondii***. We recently established that the Toxoplasma calcium dependent protein kinase 3 (TgCDPK3) is required for efficient egress. Interestingly, we showed that the closest homolog from ***P. falciparum***, PfCDPK1, complements the lack of TgCDPK3 in Toxoplasma and we have used this transgenic parasite strain to identify novel anti-malarials. To elucidate the mechanisms by which TgCDPK3 regulates Toxoplasma egress we have successfully implemented the proximity-based protein interaction trap BioID to identify potential substrates. For this purpose we fused TgCDPK3 to a mutant version of the biotin ligase, BirA*, which in the presence of biotin modifies any nearby or interacting protein. When parasites expressing TgCDPK3-BirA* are grown in the presence of biotin, 18 unique proteins appear to be biotinylated based on Western analysis. Through mass spectroscopic analysis we have determine the identity of these proteins, which include Myosin-A, a critical component of the parasite motor system. Interestingly, Myosin-A was among the 156 proteins shown to be less phosphorylated in Tgcdpk3 mutant strains in a phosphoproteome study. We subjected Myosin-A to a non-biased peptide array analysis using purified recombinant TgCDPK3 and found that TgCDPK3 can specifically phosphorylate S21, and S743 of Myosin-A ***in vitro***. When we complemented Myosin-A null mutants with Myosin-A in which either S21 or S743 is mutated to non-phosphorylable alanine, parasites showed an egress defect suggesting that phosphorylation of S21 and S743 of Myosin-A is important for egress ***in vivo***. Importantly, TgCDPK3 mutant parasites expressing Myosin-A in which serines 21 and 743 were changed to aspartic acid exhibited normal levels of iiegress indicating that phosphomimetic mutations in the motor protein overcome the lack of the TgCDPK3 kinase function. Thus, our studies establish that phosphorylation of Myosin-A by TgCDPK3 is responsible for initiation of motility and parasite egress from host-cell.

1294

IDENTIFICATION OF PARASITE-INDUCED HOST CELL TRANSFORMATION FACTORS BASED ON THE RE-ANNOTATION OF THE *THEILERIA PARVA* GENOME AND ON COMPARATIVE GENOMICS

Kyle Tretina[1], Hanzel T. Gotia[1], Joshua Orvis[1], Olukemi O. Abolude[1], Priti Kumari[1], Vishvaneth M. Nene[2], Richard Bishop[3], Claudia Daubenberger[3], Joana C. Silva[1]

[1]University of Maryland, Baltimore, Baltimore, MD, United States, [2]International Livestock Research Institute, Nairobi, Kenya, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland

The discovery of mechanisms of virulence is critical for rational vaccine and chemotherapeutic innovation targeting apicomplexan parasites. The parasite ***Theileria parva*** has a unique mode of virulence among apicomplexans: it transforms host lymphocytes by inducing a variety of cancer-like phenotypes, including uncontrolled cellular proliferation. While comparative genomics can be leveraged to generate novel hypotheses of these mechanisms, it is highly dependent on the accurate gene structure annotation of the genome. Using the first RNA-seq dataset for the ***T. parva***, we re-annotated the parasite genome, improving the annotation of 48% of all protein-coding genes. Then, in order to identify potential virulence factors associated with host cell transformation, we used comparative genomics to identify genes, peptide domains, short linear motifs, or subcellular localizations specific to ***T. parva*** and ***T. annulata***, the latter also a host-transforming parasite, but absent in other apicomplexans including non-transforming ***Theileria*** species. We used the improved ***T. parva*** annotation as well as 55,520 publicly available protein sequences from complete proteomes of 12 apicomplexans, to generate jaccard-filtered clusters of orthologous genes. We identified hundreds of specific ***Theileria***-encoded factors potentially involved in host-cell transformation, which we are categorizing by gene ID, motif, domain, and description. In one such case, this search revealed 15 pairs of ***T. parva-T. annulata*** genes with a motif for binding host retinoblastoma protein (RB). RB is a tumor suppressor in mammalian cells and the target of some adenovirus proteins that induce host proliferation. Under homeostatic conditions, RB binds E2F transcription factors in the cytosol. Adenovirus protein E1A then uses two motifs to bind the RB pocket domain and compete off the E2F transcription factors, inducing host proliferation. In order to determine if the ***T. parva*** proteins with these motifs induce host proliferation in the same way, we are currently performing surface plasmon resonance experiments to test the binding of ***T. parva*** short peptides to the RB pocket domain.

1295

ULTRASTRUCTURAL AND BIOLOGICAL CORRELATES OF ATTENUATION IN INTRAHEPATIC *PLASMODIUM FALCIPARUM* PARASITES INDUCED BY GAMMA-IRRADIATION

Miranda S. Oakley[1], Hong Zheng[1], Vivek Anantharaman[2], Phuong Thao Pham[1], Babita Mahajan[1], Nirbhay Kumar[3], Davison Sangweme[3], Abhay Tripathi[3], Godfree Mlambo[3], L. Aravind[2], Sanjai Kumar[1]

[1]Food and Drug Administration, Silver Spring, MD, United States, [2]National Institutes of Health, Bethesda, MD, United States, [3]Johns Hopkins School of Public Health, Baltimore, MD, United States

Radiation-attenuated malaria sporozoites, while capable of invading and growing inside hepatic cells, produce non-infectious merozoites that fail to cause blood stage infection. Interestingly, radiation-attenuated sporozoites are highly effective in inducing sterilizing immunity in experimental challenge studies including in humans. In spite of their vaccine value, the structural and antigenic changes in developing liver stage parasites following infection with radiation-attenuated sporozoites are poorly understood. We performed immunofluorescence and electron microscopy and genome-wide transcriptional profiling of untreated verses radiation-treated intrahepatic parasites on days 3 and 6 post-invasion of human HepG2 hepatic cells by ***Plasmodium falciparum*** sporozoites of the 3D7 strain to study the structural alterations and identify parasite gene targets of growth attenuation and enhanced immune protection induced by radiation. While the structural changes were subtle and difficult to decipher, we found that 180 parasite genes had significantly altered transcriptional expression in response to radiation on day 3 post-cultivation in hepatic cells. We observed a marked upregulation of 37 genes coding for proteins expressed on the cell surface or exported into the host cell; at least 4 membrane associated transporters were found to be upregulated upon radiation. We think that this radiation induced expression of surface and exported proteins might be a contributing factor to sterilizing immunity by increasing the number of parasite antigens available as processed epitopes on the hepatocyte surface or as released antigens from apoptosis of infected hepatocytes. At least 10 proteins related to protein misfolding and stress-related protein processing responses and 3 members of the FAST domain family that may be involved in RNA processing are induced. The molecules identified under this study may be novel targets for the generation of genetically attenuated sporozoite candidate vaccines and biomarkers of attenuation of radiation-attenuated malaria sporozoites.

1296

A NOVEL SECRETED PROTEIN FROM *PLASMODIUM FALCIPARUM* OOKINETES MEDIATES TRANSMISSION TO MOSQUITOES

Jennifer S. Armistead[1], Matthew T. O'Neill[1], Sash Lopaticki[1], Charlie Jennison[1], Shahid M. Khan[2], Chris J. Janse[2], Maria M. Mota[3], Justin A. Boddey[1]

[1]Infection and Immunity Division, The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [2]Leiden Malaria Research Group, Department of Parasitology, Leiden University Medical Center, Leiden, Netherlands, [3]Unidade de Malária, Instituto de Medicina Molecular, Universidade de Lisboa, Lisboa, Portugal

Interventions that interrupt the transmission of malaria will be critical in the renewed efforts to eliminate and eradicate this deadly disease. Transmission-blocking interventions (TBIs) that target sexual, sporogonic, or mosquito stages and inhibit ***Plasmodium*** parasite development within the vector will be essential in achieving this goal. Identifying novel proteins that are involved in the mosquito-parasite interactions that facilitate parasite transmission, and are conserved across ***Plasmodium*** species, may potentially provide new TBI targets. Here, we report on a conserved, hypothetical protein, designated PFE0360c, that is crucial for ***P. falciparum*** transmission. Other than a signal sequence and putative PEXEL, the 107 kDa protein was not predicted to contain any other known domains, but its expression was shown to be upregulated in both sporozoites and ookinetes. Genetic deletion of PFE0360c in ***P. falciparum*** NF54 and its ***P. berghei*** orthologue, PBANKA_110690, revealed a severe midgut invasion defect in ***Anopheles stephensi***, with significant reduction in the number of oocysts, and subsequently sporozoites, per mosquito as compared to wild type controls. This reduction in transmission was not found to result from a defect in ookinete development or motility, suggesting a role in invasion or traversal of mosquito midgut epithelial cells. Infection of C57BL/6 mice with ***P. berghei*** PBANKA_110690 deficient sporozoites revealed no defect in liver stage development, time to blood stage infection, or parasitemia as compared to controls. Although the PEXEL motif of PFE0360c was cleaved by plasmepsin V ***in vitro***, attempts to confirm its export have been unsuccessful. These findings provide new insight into our understanding of parasite-mosquito interactions and indicate a novel target for investigation of future transmission-blocking interventions.

1297

MOLECULAR DISSECTION OF *PLASMODIUM* SPOROZOITES AND KUPFFER CELL INTERACTIONS USING A PHAGE DISPLAY LIBRARY

Sung-Jae Cha[1], Kiwon Park[2], Min-Sik Kim[1], Prakash Srinivasan[3], Christian Schindler[4], Nico V. Rooijen[5], Monique Stins[1], Marcelo Jacobs-Lorena[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States, [3]National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [4]Columbia University, New York, NY, United States, [5]VUMC, Amsterdam, Netherlands

Malaria infection stars when an infected mosquito releases ***Plasmodium*** sporozoites into the skin of a person. Next, sporozoites enter a blood vessel and circulate through the whole body. To generate a productive infection, sporozoites must exit the circulation in the liver to subsequently infect hepatocytes. A large body of evidence suggests that sporozoites leave the circulation in the liver by preferentially traversing Kupffer cells, a macrophage-like component of the liver blood vessel (sinusoid) lining. The molecular basis for this preferential Kupffer cell traversal is unknown. By use of a phage display library we identified a peptide - P39 - which strongly binds to Kupffer cells and by doing so, inhibits sporozoite entry. We hypothesize that P39 competitively binds to a Kupffer cell receptor that is required for sporozoite entry. In agreement with this hypothesis, an anti-P39 antibody recognizes a sporozoite surface protein(s) and inhibits sporozoite mouse liver invasion. Moreover, we found that P39 binds to CD68, a Kupffer cell surface protein and putative sporozoite invasion receptor. CD68 knockout mice showed 70 % reduced sporozoite liver burden compared to wild type mice. Molecular dissection of the ***Plasmodium*** sporozoite-Kupffer cell interactions may provide insights for the development of novel malaria control strategies.

1298

A *PLASMODIUM* RHOPTRY PROTEIN IS INVOLVED IN SPOROZOITE INVASION OF HEPATOCYTES

Tomoko Ishino[1], Yuka Sugino[1], Mamoru Nozaki[1], Mayumi Tachibana[1], Takafumi Tsuboi[2], Motomi Torii[1]

[1]Ehime University, Toon, Japan, [2]Ehime University, Matsuyama, Japan

It has been demonstrated that some of ***Plasmodium*** rhoptry proteins are released to the tight junction and involved in merozoite invasion of erythrocytes. We recently proposed that at least 9 known rhoptry proteins are also expressed in spozozoites, salivary gland and hepatocyte invasive forms. To elucidate the functions of rhoptry proteins in sporozoites, we have developed the sporozoite stage specific gene silencing system and demonstrated that RON2 is important for sporozoite invasion of the salivary gland. Here, we intended to elucidate the comprehensive functions of all possible sporozoite rhoptry proteins, and found that one protein (RON) plays important roles in sporozoite transmission to mammalian hosts. Unlike RON2-cKD sporozoites, RON repressed sporozoites (RON-cKD) can invade the salivary gland normally. On the other hand, intravenous injection of RON-cKD sporozoites into mice showed a >100-fold reduction in the infectivity ***in vivo***, compared to control sporozoites. Efficiency of the liver infection of sporozoites was measured by real time PCR using the perfused livers 24h after sporozoite inoculation. It was demonstrated that RON-cKD liver stage parasite amount was approximately 500 times lower than control parasites, indicating that RON is required for the early step for parasite infection of mammalian hosts. Furthermore, ***in vitro*** infection system using hepatoma cell line, HepG2, revealed that that the invasion ability of RON-cKD sporozoites was reduced to 25% of control. These results demonstrate that RON is involved in sporozoite invasion of hepatocytes.

1299

INHIBITION OF RETICULOCYTE MATURATION TO INCREASE *PLASMODIUM* PROLIFERATION *IN VITRO*

Katy Shaw Saliba[1], Fiona Raso[1], Carlo Brugnara[2], Manoj T. Duraisingh[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Boston Children's Hospital, Boston, MA, United States

Human malaria is caused by five different species of ***Plasmodium*** parasites. Research has largely focused on ***P. falciparum*** because a robust ***in vitro*** culture system is available. However, ***P. vivax*** is more geographically widespread, causes a relapsing disease and transmission stages develop prior to clinical symptoms; making disease control extremely challenging. One of the major obstacles to the development of an ***in vitro*** culture is the restriction of ***P. vivax*** to reticulocytes. Reticulocytes rapidly mature to erythrocytes ***in vitro***. Consequently, a persistent replenishment of reticulocytes is essential for sustained parasite propagation, which effectively dilutes the culture and masks appreciable growth. We hypothesize that inhibition of reticulocyte maturation would increase the number of viable cells for invasion and would enhance ***Plasmodium*** proliferation overall. Reticulocyte maturation involves hallmark cellular processes: (i) membrane remodeling (including loss of specific surface receptors) and (ii) autophagy of organelles. We targeted these processes with a panel of small molecules. We were able to inhibit reticulocyte maturation as evidenced by decreased surface remodeling and decreased mitophagy. We determied IC_{50} and IC_{90} values of the small molecules for the reticulocyte, ***P. falciparum*** in normocytes, ***P.***

falcipcarum in reticulocytes and *P. knowlesi* H in Rhesus normocytes to determine the top candidates. The top candidates had low IC_{90}s in the reticulocyte and relatively high IC_{50}s in the parasite, i.e. a low concentration is needed to inhibit reticulocyte maturation without harming the parasite. Significantly, the top candidates were shown to enhance the adaptation of the macquae parasite, ***P. knowlesi,*** to growth in human reticulocytes. The top candidates are currently being tested on clinical isolates of ***P. vivax*** to determine their promise in the development of a sustained and robust ***in vitro*** culture.

1300

ECONOMIC COSTS AND BENEFITS OF MORBIDITY MANAGEMENT AND DISABILITY PREVENTION FOR LYMPHATIC FILARIASIS

Eileen Stillwaggon[1], Larry Sawers[2], Jonathan Rout[3], David Addiss[4], LeAnne Fox[5]

[1]Gettysburg College, Gettysburg, PA, United States, [2]American University, Washington, DC, United States, [3]Church's Auxiliary for Social Action, Bhubaneswar, India, [4]Children Without Worms, Decatur, GA, United States, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States

Lymphatic filariasis (LF) is endemic in 73 countries, with 120 million people infected of whom 40 million suffer serious disability (15 million with lymphedema, 25 million with hydrocele). Repeated acute attacks of fever and disabling pain (adenolymphangitis or ADL) aggravate lymphedema and prevent work for 4-7 days per attack. The Global Programme to Eliminate Lymphatic Filariasis (GPELF) has two goals: interrupting LF transmission by 2020 and caring for people already infected through morbidity management and disability prevention (MMDP). By 2014, 60 countries had ongoing mass drug administration, but only 27 had begun MMDP, in part due to its perceived high cost and low return. Simple, low-cost interventions at the community level, including instruction in limb washing and provision of soap, topical antibiotics, and antifungals can reduce ADL and slow progression of lymphedema. MMDP programs attenuate disability and productivity loss. Research to date suggests societal cost of untreated LF far exceeds cost of MMDP. In India, patients enrolled in community-based care (CBC) MMDP averaged 29 fewer lost work days per year than prior to enrolment. We estimate costs and benefits of MMDP over the lifetime of the population affected and at risk in Odisha State. Actual program costs are based on CBC delivered to 21,497 people in 2008. In the Odisha CBC-MMDP program, present value of start-up costs plus annual maintenance costs, estimated to grow 5% p.a. (discounted at 3%), is US$97 per person for the 25-year program. We calculate the potential benefit of MMDP by comparing direct and indirect costs of two scenarios, with and without MMDP. Without MMDP, per-patient cost of untreated morbidity due to acute attacks and chronic lymphedema, including lost earnings and out-of-pocket medical costs over 50 years, is US$1748. With MMDP, the lifetime per-person cost is US$828, or US$920 less. The benefit of savings in direct costs and productivity loss of $920 per person compares favorably with a lifetime program cost of $97 per person (benefit-cost ratio of 9.5) and provides an economic rationale in addition to the ethical mandate for MMDP, the second pillar of GPELF.

1301

COMBINING NUTRITIONAL SUPPLEMENTATION WITH SEASONAL MALARIA CHEMOPREVENTION IN NIGERIA DECREASES THE ODDS OF CONFIRMED CLINICAL MALARIA: FINDINGS FROM A CASE-CONTROL STUDY

Arnaud Le Menach[1], Abigail Ward[1], Andrea Guillot[1], Sharon K. Greene[2], Justin C. Graves[1], Kathleen Maloney[1], Omowunmi F. Omoniwa[1], Leslie Emegbuonye[1], Charles Opondo[3], Marko Kerac[3], Antoinette Bhattacharya[1], Karen Milch Hariharan[1], Lyudmila Gorokhovich[1], Owens Wiwa[1], Justin M. Cohen[1]

[1]Clinton Health Access Initiative, Boston, MA, United States, [2]Independent Consultant, New York, NY, United States, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

In 2012, the World Health Organization recommended seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine and amodiaquine (SP-AQ) to prevent malaria in children in the Sahel region. As malnourished children are twice as likely to die from malaria, the delivery of SP-AQ was combined with Lipid-based Nutrient Supplements (LNS) for children aged 6-24 months in Kano state in northern Nigeria during the 2014 malaria season. The commodities were delivered door-to-door to approximately 4,000 children each month from August to November. We conducted an unmatched case-control study to assess the impact of combining SP-AQ and LNS on uncomplicated and severe malaria. All children aged 6-24 months consulting for fever in one of the 13 primary health care facilities in the pilot study area between August 28 and December 1, 2014 were recruited. A case was defined as any child with a fever ≥37.5 C within the past 48 hours and a positive malaria rapid diagnostic test. Controls had fever but a negative malaria test. Information was collected on demographics (age, gender, residence), disease history, bednet use, and intervention coverage. The relationship between exposure to SP-AQ and LNS and confirmed malaria was estimated using multivariable logistic regression, adjusting for demographics, facility, month of consultation, and bednet use. A total of 96 cases and 285 controls were recruited. Cases had on average half the odds of controls of having taken SP-AQ in the last 30 days, but the result was not statistically significant (OR= 0.47; 95% CI: 0.18-1.23, p=0.13). Cases had one-fifth the odds of having taken both SP-AQ and LNS (OR=0.17; 95% CI: 0.05-0.51, p=0.002). Receiving both SP-AQ and LNS was associated with significantly lower odds of confirmed malaria compared to receiving SP-AQ alone (p=0.02). Adding LNS to the delivery of SP-AQ during an SMC campaign was associated with decreased odds of malaria in children visiting health facilities. The absence of statistical significance of SP-AQ alone may be due to the small sample size. Larger studies are needed to confirm these findings and estimate the cost-effectiveness in this and other settings.

1302

INEQUALITIES IN CHILD SURVIVAL IN A RURAL AREA OF SENEGAL WHERE MALARIA HAS DECLINED

Elhadji Konco Ba[1], Badara Cissé[2], Clare Flach[3], Jean Louis Ndiaye[2], Jules F. Gomis[2], Ernest Faye[2], Cheikh S. Sokhna[1], Oumar Gaye[2], Paul J. Milligan[3]

[1]Institut de Recherche Pour le Developpement, Dakar, Senegal, [2]Université Cheikh Anta Diop de Dakar, Dakar, Senegal, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

A sharp decline in under-5 mortality rates has been observed in Senegal, as in some other parts of Africa, over the last 10 years, associated most obviously with a reduction in malaria transmission that occurred in the same time period. Since 2008 we have maintained demographic surveillance in 725 villages in central Senegal with a population of about 600,000 people. We have analyzed variations in under-5 mortality in order to understand the reasons for the recent decline, and the extent of inequalities and the factors associated with them. Malaria incidence was

determined by collecting data from all health facilities and from villages with community case management for malaria, details of all malaria cases confirmed by Rapid Diagnostic Test. Household occupancy, births and deaths were recorded in household visits every ten months. In addition, in 123 villages, village reporters were used to cross-check completeness of reporting of deaths, and in these villages verbal autopsies were performed on all deaths in children. Data for 95,000 children under 5 years of age have been included. Random effects Poisson regression was used to assess area, household and individual risk factors for child mortality. The leading causes of death were diarrhoea (26.6%), perinatal infection (22.2%) and malaria (10.8%). Children living more than 5km from a health facility had a 2-fold (95%CI 1.6, 2.5) higher risk of mortality than those living nearer to health facilities. Mortality rates were associated with the level of malaria transmission, an increase in the malaria incidence rate in children of 1 per 1000 per year was associated with a mortality rate ratio of 1.04 (95%CI 1.02, 1.05). Children born to mothers under 16 years of age had a 1.6-fold increased risk of mortality (95%CI 1.1, 2.3) compared to children of older mothers. Senegal is close to achieving its MDG4 target, but national average figures conceal substantial inequalities. Higher rates of mortality are associated with areas of persisting malaria transmission, poverty, and poorer access to health care. Strategies targeting these communities are required to improve child survival and reduce inequalities.

1303

EVALUATION OF THE NATIONAL CASE-BASED MEASLES SURVEILLANCE SYSTEM IN SOUTH AFRICA; JANUARY 2009 TO DECEMBER 2013

Eva D. Mathatha, Muzi Hlanzi, Jack M. Manamela, Melinda Suchard

National Institute for Communicable Diseases, Johannesburg, South Africa

Measles still remains the leading cause of death among children under five years worldwide. In South Africa the case-based measles surveillance was initiated in 1998 in line with the recommendation from World Health Organization (WHO) to monitor progress towards measles elimination. Blood specimens are collected from suspected measles cases in all health facilities. This study described the epidemiology of measles in South Africa from 2009-2013 and evaluated specific performance indicators for measles surveillance recommended by WHO.A retrospective descriptive analysis was conducted on secondary measles surveillance data collected from 2009-2013 in all age groups. The blood samples were tested at the measles serology laboratory at the NICD. The percentage for each of the indicators was calculated and compared with the WHO minimum standard values for measles surveillance. In 2009-2011, there were 18,000 confirmed measles cases reported, which included cases identified during the measles outbreak from June 2009 to July 2010 in all nine provinces. The number of cases decreased to 335 between 2011-2013. The age groups most affected were those >14years, while the least affected were those between the ages of 2-4 years. Out of the seven performance indicators evaluated, five met WHO specified targets, including all districts reporting at least one measles case per year (WHO target ≥ 80% of the districts) and blood specimens collected in more than 80%of the suspected measles cases (WHO target of ≥ 80%).Two laboratory indicators did not meet the WHO targets; between 2009 and 2013, 32%, 28%, 46%, 49% and 52% of blood specimens respectively reached the laboratory within three days of being sent (WHO target ≥ 80%) and between 2009 to 2013,14%,15%,65%, 68% and 66% of blood samples respectively were tested within seven days (WHO target≥ 80%). The case-based measles surveillance met most of WHO-specified performance indicators. Addressing timeliness of specimen delivery to the laboratory, timeliness of laboratory testing and subsequent feedback of the results to the health facility will ensure proper management of cases and rapid response to outbreaks.

1304

ECONOMIC ANALYSIS OF GENETICALLY MODIFIED MOSQUITO STRATEGIES TO CONTROL DENGUE

Eduardo A. Undurraga, Yara A. Halasa, **Donald S. Shepard**

Brandeis University, Waltham, MA, United States

Vector control is currently the only prevention strategy to reduce dengue virus (DENV) transmission. Traditional vector control methods have not halted the spread of ***Aedes aegypti***, the main dengue vector, and of dengue outbreaks. Despite millions of dollars spent annually in vector control, there are few effectiveness or economic evaluations to inform policy decisions. High costs and seemingly low effectiveness have encouraged the search for new vector control technologies. While still under development, genetically modified (GM) mosquitoes are a potentially promising approach to control dengue. GM mosquitoes have been developed with the goal of producing mosquito offspring that die at an early developmental stage. We develop a framework and present a preliminary application to assess the economic impact of this technology. Combining data from various dengue-endemic countries, we generated a mathematical model of costs and benefits and calibrated it with available evidence. We assumed a mosquito suppression phase of 1 year followed by a maintenance phase of 4 years, with annual costs per capita of $25-$75 and $10-$20, respectively. Combining the highest cost and most favorable effectiveness in dengue control (50% suppression and 100% maintenance), we obtained a benefit/cost ratio of 1.1 in an area with high DENV transmission, ongoing intensive vector programs, and high income. Under these same assumptions, if the technology were applied in areas with dengue incidence, vector control programs, and income similar to Brazil, the cost-effectiveness of the program would range from $30,000 to $163,000 per disability adjusted life year (DALY). In a lower incidence area like Mexico, the cost-effectiveness would range from $180,000 to $457,000 per DALY. Without major cost reductions, GM vector control is unlikely to be cost-effective. The most salient need for more data is clarifying the relation between vector population and DENV transmission. If effective, new and improved technologies of vector control could save billions of dollars annually in averted medical costs, productivity losses, and premature deaths from dengue.

1305

ASSESSING THE IMPACT OF HOUSEHOLD AIR POLLUTION ON HEALTH: FEASIBILITY OF AMBULATORY BLOOD PRESSURE MONITORING AND REPEAT-ASSESSMENT "HOME" BLOOD PRESSURE MONITORING IN A RURAL GHANAIAN SETTING

Ashlinn Quinn[1], Kenneth Ae-Ngibise[2], Blair Wylie[3], Ellen Boamah[2], Joseph Schwartz[1], Mohammed Mujtaba[2], Daichi Shimbo[1], Yeetey Enuameh[2], Marwah Abdalla[1], Seth Owusu-Agyei[2], Patrick Kinney[1], Darby Jack[1], Kwaku Poku Asante[2]

[1]Columbia University, New York, NY, United States, [2]Kintampo Health Research Centre, Ghana Health Service, Brong Ahafo Region, Kintampo, Ghana, [3]Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States

Over half the global disease burden of Household Air Pollution (HAP) from biomass burning is attributable to cardiovascular disease (CVD), yet few studies have examined HAP in relation to CVD risk factors and the feasibility of collecting out-of-clinic blood pressure (BP) assessments, especially in rural settings. In a pilot study, we assessed the feasibility of collecting 24-hr Ambulatory Blood Pressure (ABP) and home-based blood pressure assessments to evaluate BP before and after delivery of a cleaner cookstove intervention to a subset of participants in Kintampo, Ghana as part of the Ghana Randomized Air Pollution and Health Study (GRAPHS). Two BP methods were tested. In the ABP group, 24-hour ABP monitoring was conducted with SpaceLabs 90207 monitors (Snoqualmie, WA). BP was recorded every 20 minutes (daytime) and 30 minutes (nighttime). In

the Home BP group, trained field workers measured BP twice daily for 5 consecutive days using Omron (Lake Forest, IL) digital automatic BP monitors. Enrollment: 44 women (27 in the ABP group; 17 in the Home BP group). 53 BP recordings out of an expected 54 were completed in the ABP group; and 33 out of 34 in the Home BP group. According to the validity criteria of the International Database of Ambulatory Blood Pressure in relation to Cardiovascular Outcome (IDACO) project, 89% of the completed ABP sessions were valid. Within valid ABP sessions, the mean [SD] number of BP readings was 51.7 [11.8] (daytime: 30.1 [9.4]; nighttime: 20.9 [4.1]). Within completed Home BP sessions, 99% of targeted measurements were obtained, with a mean [SD] number of readings per 5-day session of 9.9 [0.3] (mornings: 4.9 [0.2]; evenings: 4.9 [0.2]). Mean [SD] BP levels were as follows. ABP group: SBP 107 [6.4]; DBP 62.6 [4.8]. Home BP group: SBP 100 [8.6], DBP 65.5 [5.5]. These results indicate that both 24-hour ABP monitoring and repeat-assessment "Home" BP monitoring are well-tolerated and feasible methods of BP assessment in this predominately rural West African setting. Results with regard to the hypothesis that switching to a cleaner cookstove is associated with a reduction in post-intervention BP will be available in 3-4 months.

1306

A DOUBLE BURDEN OF CHILD MALNUTRITION IN COMMUNITIES WITH DIFFERENTIAL ACCESS TO ROADS: ANALYSIS IN RURAL ECUADOR, 2004-2013

Velma Lopez[1], Carey Dombecki[1], James Trostle[2], Alexandra Jaramillo[3], William Cevallos[3], Jason Goldstick[4], Joseph Eisenberg[1]

[1]University of Michigan, Ann Arbor, MI, United States, [2]Trinity College, Hartford, CT, United States, [3]Universidad San Francisco de Quito, Quito, Ecuador, [4]Oakland University, Rochester, MI, United States

Nutritional trends towards both over and under nutrition are occurring globally throughout low and middle-income countries. Access to roads can influence both protective and risk factors associated with nutrition by affecting a number of social and biological processes. In northern coastal Ecuador the construction of a new road created a gradient of remoteness among villages, providing a unique opportunity to examine the impact of roads on the double burden of over and under nutrition. Within the study, anthropometric and hemoglobin measurements were collected on 2,369 children < 5 years in Esmeraldas, Ecuador from 2004-2013 across 24 villages with differing road access. Logistic general estimating equations assessed the relationship between village remoteness and prevalence of stunting, wasting, underweight, overweight, obesity, and anemia, accounting for longitudinal dependencies. Race was tested as a modifier of the remoteness-malnutrition relationship. Overall prevalence of stunting was 13%, underweight 6%, wasting 5.7%, overweight 5.6%, obesity 1.9%, and anemia 55%. Stunting, while still high, decreased as obesity increased over time and other nutritional outcomes remained stable. Remoteness relative to a road was found to be significantly associated with stunting (OR=0.46, 95% CI=[0.31, 0.68]) and anemia (OR = 0.53, 95% CI=[0.41, 0.68]). Over time, greater remoteness becomes less associated with lower stunting (OR=0.36, 95% CI=[0.20, 0.66] early versus OR=0.57, 95% CI=[0.35, 0.94] late). Indigenous Chachi children were found to have a higher prevalence of all malnutrition outcomes compared to Afro-Ecuadorian and Mestizo children. These results suggest an emerging double burden of child malnutrition in the study site, which is likely is the result of how changes in remoteness influence food availability and consumption. Within rural areas, heterogeneous nutritional outcomes are observed; however, as road development continues, this heterogeneity diminishes. This suggests that the influence of roads on health outcomes, such as nutrition, unfold over multiple time scales.

1307

GENOME ANALYSES REVEAL INSIGHTS INTO THE UNIQUE PARASITIC LIFESTYLE OF THE LYME DISEASE TICK, *IXODES SCAPULARIS*

Catherine A. Hill, The Ixodes scapularis Genome Consortium

Purdue University, West Lafayette, IN, United States

Ticks (subphylum Chelicerata: subclass Acari; suborder Ixodida) are notorious ectoparasites and the most important arthropods affecting human and animal health globally. We describe the 2.1 Gbp nuclear genome of the tick, ***Ixodes scapularis*** (Say), the vector of the pathogens that cause Lyme disease, granulocytic anaplasmosis, and babesiosis. The genome sequence, the first for a medically important chelicerate, offers insights into the molecular processes that underpin the remarkable parasitic life-style of the tick and its success as a vector. The large genome reflects extensive accumulation of repetitive DNA, including multiple families of low complexity tandem repeats, new lineages of retro-transposons, and gene architecture patterns resembling ancient eukaryotes rather than pancrustaceans. Annotation revealed 20,486 protein-coding genes and expansions of gene families associated with tick-host interactions. Genome analyses informed on parasitic processes unique to ticks, including host "questing", prolonged feeding, blood meal concentration, novel methods of hemoglobin digestion, heme detoxification, reproduction and prolonged survival off-host. Proteins associated with transmission of anaplasmosis, an emerging disease, and the encephalitis causing Langat virus, were identified. Analyses of ~ 34,000 SNP markers identified from individual ***I. scapularis*** using the Restriction-site Associated DNA sequencing (RADseq) approach support a single species classification for the tick across North America and revealed a North-South population structure correlated to life-history traits and Lyme disease transmission. Foundational studies of genome organization and population genomics, coupled with the development of genomics resources, will advance research to determine the genetic basis of tick phenotypes. Efforts are also underway to discover novel chemistries that selectively disrupt molecular targets identified from the genome and deliver new, selective interventions for the control of ticks and tick-borne diseases.

1308

DEVELOPMENT AND IMPLEMENTATION OF ODORANT BAITED TRAPS TO MONITOR AND CONTROL *TRIATOMA DIMIDIATA* IN TOLEDO, BELIZE

Gwyneth Sullivan[1], Eric Noakes[1], Naomi Penney[1], Roy Polonio[2], John Grieco[1], Zain Syed[1]

[1]University of Notre Dame, South Bend, IN, United States, [2]University of Belize, Punta Gorda, Belize

Triatoma dimidiata (Hemiptera: Reduviidae:) is one of the three most epidemiologically significant vectors for Chagas' disease in the Americas. Although Chagas' disease has been eliminated in many regions from the domestic habitats, there are emerging threats of re-infestation by sylvatic species. ***T. dimidiata*** inhabits domestic, peri-domestic, and sylvatic niches, thus posing a serious threat to the continued interruption in Chagas transmission. This study aimed to develop a novel odor baited trap (OBT) employing odors derived from hosts and natural habitats to monitor ***T. dimidiata*** populations in Toledo, Belize. Odorants were isolated using electrophysiological methods linked to gas chromatography and identified by mass spectrometry. The identified chemostimuli were tested under different regimes to determine their behavioral effects. The odorants or blends that induced attraction were incorporated into OBTs that were tested in the field. Captures from the OBTs were compared against manual searches in the Toledo district of Belize. Verbal questionnaires were utilized to determine end user acceptability of trap design as well as identify gaps in knowledge regarding vectors and Chagas transmission. Our efforts are

aimed at providing recommendations to the Ministry of Health (MOH) regarding the utility of OBTs and development of educational material targeted towards Triatomine surveillance and vector control.

1309

RHODNIUS PROLIXUS SURVIVAL WHEN INFECTED WITH *TRYPANOSOMA CRUZI* AND *T. RANGELI*: THE EFFECT OF INFECTIVE DOSE AND CO-INFECTION

Jennifer Kate Peterson[1], Andrew P. Dobson[1], Andrea L. Graham[1], Omar Triana Chávez[2]

[1]Princeton University, Princeton, NJ, United States, [2]Universidad de Antioquia, Medellín, Colombia

All parasite-host interactions are not created equal; they begin under an array of possible conditions. This is especially true for interactions between Chagas disease agent ***Trypanosoma cruzi*** and its triatomine bug vectors. ***T. cruzi*** infects 100s of mammal species, all of which present different parasitemias and disease courses, resulting in the triatomine bug vectors receiving highly variable infective doses from the different host species they feed upon. Additionally, in many areas ***T. cruzi*** circulates with a sister parasite species called ***T. rangeli***. ***T. rangeli*** is of interest, as it presents the opposite pathogenicity as ***T. cruzi***, being pathogenic to triatomine bugs, but apathogenic to its mammal hosts. Thus, all ***T. cruzi*** infections of its vector begin not only with varying infectious doses but also various co-infection statuses. However, does this variation matter for Chagas disease transmission? We investigated this question in the triatomine bug species ***Rhodnius prolixus*** when infected with ***T. cruzi*** and ***T. rangeli***, both in single and co-infections. We measured the effect of ***T. rangeli*** infective dose, ***T. cruzi-T. rangeli*** co-infection order (***T. cruzi*** first vs. ***T. rangeli*** first), and co-infection timing (simultaneous vs. staggered) on insect survival in the 100 days post-infection. We observed that insects almost always had higher survival when co-infected at lower ***T. rangeli*** doses, regardless of infection order or timing, suggesting that ***T. cruzi***-T. rangeli co-infection is beneficial to the insects at low ***T. rangeli*** doses. At high ***T. rangeli*** doses, we found that co-infected insects had decreased survival, unless they were infected with ***T. cruzi*** first, suggesting that infective dose, order and timing interact in their effect on ***R. prolixus*** survival. Our results indicate that vector-borne ***T. cruzi*** transmission dynamics may be influenced by the parasite load and parasite species composition of the blood meal taken up by the vector, and these factors may be important to consider when assessing local ***T. cruzi*** transmission and designing vector control strategies.

1310

RAPID AND NON-DESTRUCTIVE NEAR-INFRARED SPECTROSCOPY CAN PREDICT THE AGE AND *WOLBACHIA* INFECTION IN *AEDES AEGYPTI* MOSQUITOES

Maggy Sikulu[1], Peter Masabho[2], Michael Henry[2], Nikita Lysenko[3], Robert Wirtz[4], Floyd Dowell[5], Greg Devine[1]

[1]QIMR Berghofer Medical Research Institute, Herston, Australia, [2]Ifakara Health Institute, Ifakara, United Republic of Tanzania, [3]Swiss Tropical Institute, Basel, Switzerland, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]United States Department of Agriculture, Manhattan, KS, United States

Regular monitoring of infection and survival rates of the Wolbachia based vector control strategy is a prerequisite for its sustainability. Currently, molecular techniques such as polymerase chain reaction (PCR) are employed to detect Wolbachia infections in mosquitoes whereas the use of transcriptional profiles is used to monitor their survival. However, these techniques are not amenable to a large scale intervention. We have investigated the potential of using a non-destructive and instantaneous near-infrared spectroscopy (NIRS) as a high throughput technique for detecting the age and the presence or absence of two strains of Wolbachia infection in male and female laboratory reared ***Aedes aegypti*** mosquitoes. Calibrations were developed using spectra collected from heads and thoraces of laboratory reared mosquitoes using partial least squares (PLS) regression and were used to predict the age and infection of samples that were excluded from the calibration model. A highly significant correlation was found between the true and predicted ages of mosquitoes. The correlation coefficients for ***Ae. aegypti*** females and ***Ae. aegypti*** males were R2=0.83 and 0.78 respectively (P< 0.001 in both instances). The age of female and male ***Ae. aegypti*** could be identified as < or ≥ 8 d old with an accuracy of 91% and 76%, respectively. The mean predicted age was generally within ±3 d of the actual age. NIRS differentiated females and males infected with wMelPop from uninfected samples with an accuracy of 97% and 93%, respectively and females and males infected with wMel from uninfected samples with accuracies of 93% and 88%, respectively. Moreover, NIRS differentiated females infected with wMelPop from wMel infected females with 98% accuracy. This non-destructive technique is at least 35 times faster and over 10 times cheaper than conventional age prediction and polymerase chain reaction techniques. While robust calibrations using mosquitoes reared from different geographical regions are required to validate NIRS as an age/infection prediction tool for wild caught ***Ae. aegypti***, our results strongly indicate the potential of the NIRS for this purpose.

1311

IDENTIFYING OVIPOSITION ATTRACTANTS FROM THE LARVAL REARING MEDIUM OF *PHLEBOTOMUS PAPATASI*, THE VECTOR OF OLD-WORLD ZOONOTIC CUTANEOUS LEISHMANIASIS

Bahjat Fadi Marayati[1], Charles Apperson[2], Coby Schal[2], Loganathan Ponnusamy[2], Madhavi Kakumanu[2], Gideon Wasserberg[1]

[1]University of North Carolina at Greensboro, Greensboro, NC, United States, [2]North Carolina State University, Raleigh, NC, United States

Phlebotomine sandflies are the vectors of the protozoan parasites of the genus ***Leishmania***. The control of sand flies is currently limited to personal protection and residual spraying. An attract-and-kill approach has been shown to be effective in a variety of other vector by which an attractive blend is used to attract the insect to a lethal trap. Targeting control efforts on gravid females could affect disease transmission by reducing the abundance of blood-fed females and by suppressing the vector's population growth rate. The study presented here describes results from a multidisciplinary project in which we applied a systematic integrated approach to elucidate the cues that drive the oviposition behavior of the sand fly ***Phlebotomus papatasi***. Since sand fly larvae feed on decomposing organic material of predominantly fecal origin, we hypothesized that gravid female sand flies would be attracted to volatile olfactory cues indicating the presence of such material. We have used a multiple-choice oviposition bioassay in which gravid ***P. papatasi*** females were presented with five candidate source materials from their larval rearing habitat on filter paper disks placed on a layer of plaster at the bottom of oviposition cups. To evaluate whether the total oviposition response measured in the oviposition cup bioassays also indicates attraction, we have conducted Olfactometer bioassays using a 3-chamber linear Olfactometer in which we tested all five candidate materials. Our results from the behavioral bioassays and the Olfactometer experiments suggest that the total oviposition response and highest attractance occurred when the treatment was frass from the 2nd-3rd instar larval medium. We have cultured the 2nd-3rd instar larval material and isolated its constituent bacterial community. Bacterial isolates were tested individually and in mixture in olfactometer bioassays for behavioral evaluation. Several candidate bacterial strains have demonstrated high attractance at specific concentrations, which indicates potential applications in constructing the optimal attractive bait.

1312

MOSQUITO HEARING: OPENING THE DOOR TO A NEW MOSQUITO SENSORY MODALITY

Laura C. Harrington, Gil Menda, Ronald R. Hoy

Cornell University, Ithaca, NY, United States

For over a century, vector biologists have focused on sensory ecology of mosquito sensation as they relate to host finding such as olfaction and heat seeking, which confirms the primacy of these modalities. However acoustic sensation has been largely ignored. Recent work by our lab and others has demonstrated the important role of acoustics in the pre-copulatory mating interaction. Here we present new neurophysiological and behavior findings on the acoustic sensitivity of male mosquitoes that demonstrate their ability to hear sounds in the far auditory field at lower intensity and over greater distances than ever imagined. Collectively, this work opens the possibility for hearing as a significant modality in the mosquito sensory world.

1313

HOW DO BITING DISEASE VECTORS FUNCTIONALLY RESPOND TO HOST AVAILABILITY?

Laith Yakob

London School of Hygiene & Tropical Medicine, London, United Kingdom

Advanced molecular methods in biological fingerprinting are uncovering new opportunities in disease vector incrimination and behavioral ecology through the rapid and sensitive analysis of arthropod bloodmeals. However, for this potential to be realized, the interpretation of the species composition of vector meals must be guided by sound ecological theory. Even modern, complex simulation models of vector-borne diseases assume a simplistic, linear relationship between host species blood source and host availability. In ecological terminology, this constitutes a Type I Holling's functional response - a response type that is atypical of invertebrates in relation to their resource consumption. A new model is proposed that expands upon the classic functional responses to accommodate more qualitatively distinct disease vector behaviors. The substantial consequences of non-linear responses of biting disease vectors to human host availability are described for pathogens with three distinct transmission routes: falciparum malaria (strict anthroponotic competence), Chagas disease (anthroponotic and zoonotic competence) and Lyme disease (strict zoonotic competence).

1314

TARGETING *TRYPANOSOMA BRUCEI* METHIONYL-TRNA SYNTHETASE FOR NOVEL TREATMENT OF HUMAN AFRICAN TRYPANOSOMIASIS

Frederick S. Buckner, Ranae M. Ranade, John R. Gillespie, zhongsheng Zhang, Ximena Barros, Sayaka Shibata, Wenlin Huang, Christophe L. Verlinde, Wim G. Hol, Erkang Fan

University of Washington, Seattle, WA, United States

Human African trypanosomiasis (HAT) threatens populations in 36 countries of sub-Saharan Africa. New drugs with improved safety, efficacy, and ease of use are needed to replace the antiquated drugs that are currently available. A validated drug target in ***Trypanosoma brucei*** (the etiologic agent of HAT) is the methionyl-tRNA synthetase (MetRS). Inhibitors of this target were identified with potency as low as 4 nM (EC50) on bloodstream trypanosomes, but lacked the necessary permeability properties for oral uptake and brain permeability, the latter necessary for treating late-stage HAT. Guided by structure-based drug design, over 500 analogs to the original aminoquinolone scaffold were synthesized including a new series of fluorinated imidazo-pyridines and additional variants. The new compounds demonstrate potent inhibitory activity against ***T. brucei*** MetRS (IC50s <2 nM), ***T. brucei*** EC50s as low as 0.4 nM, improved blood-brain barrier permeability, and good oral bioavailability (88% in rats). A compound in the optimization pathway cures an acute ***T. brucei*** rhodesiense mouse model with an oral dose as low as 8 mg/kg (>20 days parasite free) and partially cures chronic ***T. brucei*** mouse model (>70 days parasite free). These studies serve as proof of concept that methionyl-tRNA synthetase inhibitors are viable drug candidates for HAT.

1315

RNAI OF *TRYPANOSOMA BRUCEI* CYTOSOLIC HSP83 AND MITOCHONDRIAL TRAP-1 REVEALS ROLES FOR THESE HSP90 HOMOLOGUES IN CYTOKINESIS AND KINETOPLAST DIVISION

Kirsten J. Meyer, Theresa A. Shapiro

Johns Hopkins University School of Medicine, Baltimore, MD, United States

17-AAG, an Hsp90 inhibitor, has potent activity against ***Trypanosoma brucei***. We found 17-AAG causes rapid and severe cell cycle defects, including delayed cleavage furrow ingression and delayed kinetoplast segregation. To compare the cell cycle effects of 17-AAG treatment with knock-down of Hsp83, the trypanosomal Hsp90, or TRAP-1, the mitochondrial Hsp90, we generated separate RNA interference (RNAi) cell lines with a tetracycline inducible stem-loop hairpin construct for Hsp83 and tbTRAP-1. For Hsp83 RNAi nine independent clones were obtained, and all displayed a severe growth defect by 24 h after addition of tetracycline (tet). Northern blot analysis demonstrated a decrease in Hsp83 RNA levels, and western blot analysis with anti-hHsp90 antibody showed a decrease in an 83kDa band, the expected size of Hsp83. Microscopy examination of the tet-treated cells revealed an accumulation of cells containing two nuclei and partially ingressed cleavage furrows, a cytokinesis defect. For tbTRAP-1 RNAi, ten independent clones were obtained, and all displayed normal growth until 62 h after addition of tet, when growth stopped and populations began to decline. Northern blot analysis demonstrated a loss of tbTRAP-1 RNA. Cell cycle analysis by microscopy revealed a loss of cells with two kinetoplasts from 62 h onwards, and an increase in cells with no kinetoplasts. Southern blot analysis of kinetoplast free-minicircle DNA revealed defects in minicircle replication, with the appearance of abnormal catenated forms. This work provides genetic evidence for functions of Hsp83 and TRAP-1 in cytokinesis and kinetoplast replication respectively. The cell cycle defects seen with 17-AAG are a combination of those seen by RNAi of Hsp83 and TRAP-1, suggesting 17-AAG may be inhibiting both proteins in ***T. brucei***, consistent with its specificity for the unique ATP binding pocket of Hsp90s. Overall we have confirmed that ***T. brucei*** Hsp83 is essential and a promising drug target.

1316

COMPARATIVE GENOMIC ANALYSIS BETWEEN *LEISHMANIA (VIANNIA) PERUVIANA* AND *LEISHMANIA (V.) BRAZILIENSIS*

Hugo Oswaldo Valdivia[1], João L. Reis-Cunha[1], Gabriela F. Rodrigues-Luiz[1], Rodrigo Babtista[1], Gerald C. Baldeviano[2], Robert V. Gerbasi[2], Deborah E. Dobson[3], Francine Pratlong[4], Patrick Bastien[4], Andres G. Lescano[2], Stephen M. Beverley[3], Daniella Bartholomeu[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]U.S Naval Medical Research Unit - 6, Lima, Peru, [3]Washington University in St. Louis, St. Louis, MO, United States, [4]Université of Montpellier, Montpellier, France

The ***Leishmania (Viannia) braziliensis*** complex is responsible of many cases of New World tegumentary leishmaniasis. This complex includes two closely related species, ***Leishmania (Viannia) peruviana*** (***LVP***) and ***L. (V.) braziliensis*** (***LVB***), that present different geographic distribution and disease phenotypes including the risk of mucocutaneous disease. However, the genetic basis of these differences is not well understood and the status of ***LVP*** as distinct species has been questioned by some. We

sequenced the genomes of two ***LVP*** isolates (LEM-1537 and PAB-4377) using Illumina high throughput sequencing at approximately 40x coverage. ***LVP*** is sufficiently close to ***LVB*** that we were able to map more than 90% ***LVP*** reads on the ***LVB*** M2904 reference genome. Comparative analyses were focused on the detection of Single Nucleotide Polymorphisms (SNPs), insertions and deletions (INDELs), aneuploidy and gene copy number variations. We found 92,698 SNPs between ***LVP*** and ***LVB*** M2904 reference genome while only 26,853 variants were detected between the two ***LVPs***. Analysis in coding sequences revealed 26,750 SNPs and 1,513 INDELS in both ***LVP*** isolates and two ***LVB*** pseudogenes that appear to have coding function in ***LVP***. Allele frequency profiling showed a highly heterogeneous pattern of chromosome ploidies with an overall disomic tendency in both ***LVP*** isolates in contrast with a trisomic pattern in the ***LVB*** M2904 reference. Read depth analysis allowed us to detect more than 368 gene expansions and 14 expanded gene arrays in ***LVP*** that are not present in ***LVB***. The presence of extensive variation in chromosome and gene copy numbers as well as high SNPs and INDELs between ***LVP*** and ***LVB*** support maintaining their classification as distinct species. The absence of expanded amastin gene arrays in ***LVP***, the presence of different genes in array expansions in ***LVP*** and extensive polymorphism in coding sequences could result in different expression profiles potentially influencing parasite development and host interactions possibly related to its differences in phenotype versus ***LVB***.

1317

IMPLICATION OF APOL1 EXPRESSION AND CODING POLYMORPHISMS IN DETERMINING RESISTANCE/ SUSCEPTIBILITY TO *TRYPANOSOMA BRUCEI GAMBIENSE* INFECTION IN GUINEA

Hamidou Ilboudo[1], Vincent Jmonneau[2], Mathurin Koffi[3], Sophie Ravel[4], Mamadou Camara[5], Jacqueline Milet[6], Oumou Camara[5], Annette MacLeod[7], Bruno Bucheton[8]

[1]Centre International de Recherche-Développement sur l'Elevage en zone Subhumide, Bobo-Dioulasso, Burkina Faso, [2]Centre International de Recherche-Développement sur l'Elevage en zone Subhumide/Institut de Recherche pour le Développement, Unité Mixte de Recherche IRD-CIRAD 177, Bobo-Dioulasso, Burkina Faso, [3]Université Jean Lorougnon Guédé de Daloa, Côte d'Ivoire, Daloa, Côte D'Ivoire, [4]Institut de Recherche pour le Développement, Unité Mixte de Recherche IRD-CIRAD 177, Montpellier, France, [5]Programme National de Lutte contre la Trypanosomose Humaine Africaine, Conakry, Guinea, [6]Institut de Recherche pour le Développement, UMR 216 Mère et enfant face aux infections tropicales, Paris, France, [7]Wellcome Center for Molecular Parasitology, Glasgow, United Kingdom, [8]Programme National de Lutte contre la Trypanosomose Humaine/Institut de Recherche pour le Développement, Unité Mixte de Recherche IRD-CIRAD 177, Conakry, Guinea

Most African trypanosome species are sensitive to trypanolytic factors present in human serum. Trypanosome lysis was demonstrated to be associated with apolipoprotein L-1 (APOL1). ***Trypanosoma brucei*** gambiense (***T. b. gambiense***) and ***T. b. rhodesiense*** have evolved distinct mechanisms to escape lysis from APOL1 and are able to infect humans. In T. b. gambiense, resistance seems to be in part controlled by a reduced capacity to internalize APOL1, thus limiting the lytic effects. Interestingly, APOL1 variants (G1 and G2) were shown to be associated with the development of kidney disease in African Americans and it was suggested that they may have been positively selected in African population because they provide some degree of protection against human African trypanosomiasis. In this study led in Guinea, the most affected country in West Africa, we have studied APOL1 expression levels as well as APOL1 coding sequence genetic variant in (i) unaffected endemic controls, (ii) HAT patients and (iii) seropositive subjects that are apparently able to control infection. We show that APOL1 expression appears to be induced by T. b. gambiense infection (in both seropositive and HAT patients) and that significant genetic association (with G1 and G2 but not others) were observed in seropositive subjects but not in HAT patients when compared to controls. These results suggest that these APOL1 polymorphisms may indeed provide a certain degree of resistance against T. b. gambiense infections but protection is far from complete.

GENETIC DIVERSITY IN THE NATURAL *TRYPANOSOMA CONGOLENSE* POPULATION

Eliane E. Tihon, Hideo Imamura, Frederik Van den Broeck, Jean-Claude Dujardin, Jan Van den Abbeele

Institute of Tropical Medicine, Antwerp, Belgium

Trypanosoma congolense is one of the major pathogens responsible for animal African Trypanosomiasis (AAT), a disease affecting about 10 million km^2 of the sub-Saharan region on the African continent. Isometamidium Chloride (ISM) is the principal drug used to counteract ***T. congolense*** infection in livestock, both as a prophylactic as well as curative treatment. Here, numerous cases of ISM resistance in different African regions have been reported, representing a serious problem in the battle against AAT. An important step in the fight against AAT is to monitor the level and distribution of genetic diversity in ***T. congolense*** populations, to reveal the biologically relevant structural variations present in their genomes that influence pathogenesis, virulence, and mechanisms leading to drug resistance. Using Next-Generation Sequencing technology, we sequenced 54 ISM-resistant and -sensitive field-isolated strains sampled between 1971 and 2010 in 9 countries where the disease is endemic. A total of 614859 SNPs were identified and long deletions were detected in both coding and non-coding regions, revealing a high genetic diversity. Interestingly, analyses of linkage disequilibrium decay suggested that genetic recombination and complex genetic exchanges are frequent between ***T. congolense*** parasites. Additional phylogenetic and structure analysis highlighted a geographically asymmetric distribution of genetic diversity across Africa. Parasites collected within a short period of time in Zambia showed a higher diversity compared to the strains sampled over a period of 30 years in the other countries. The factors resulting in this asymmetric diversity remain speculative but we suggest that the close proximity to wildlife observed in this region as well as the presence of specific tsetse fly vectors are playing a key role. This last hypothesis is currently being tested by studying the capability of several tsetse species to develop a mature ***T. congolense*** infection.

TRACHOMA ELIMINATION IN AN ENDEMIC ISLAND SETTING IN WEST AFRICA: ARE TWO DOSES OF ORAL AZITHROMYCIN BETTER THAN ONE?

Anna Last[1], Eunice Cassama[2], Ebrima Bojang[3], Meno Nabicassa[4], Sarah Burr[3], Katie Thompson[5], Danny Haddad[6], David Mabey[1], Martin Holland[1], Robin Bailey[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Ministerio de Saude Publica, Bissa, Guinea-Bissau, [3]Medical Research Council - UK, The Gambia Unit, Fajara, Gambia, [4]Ministerio de Saude Publica, Bissau, Guinea-Bissau, [5]University of Birmingham Medical School, Birmingham, United Kingdom, [6]Emory University, Atlanta, GA, United States

Trachoma is caused by ocular ***Chlamydia trachomatis*** (Ct) infection. The remote Bijagós Archipelago is trachoma-endemic. The WHO recommends community mass drug administration (MDA) of azithromycin if follicular trachoma (TF) prevalence in 1-9 year olds > 10% to achieve elimination (TF<5%). Single dose oral azithromycin MDA has significantly reduced TF prevalence and in some populations eliminated Ct infection. In trachoma-endemic communities, despite high coverage MDA, infection and disease persist. Optimal MDA frequency is unknown and may vary between settings. We evaluated the efficacy of single versus dual dose azithromycin MDA in this setting to evaluate options for effective trachoma control on the islands. A census of all 1-9 year olds was conducted in all communities on 3 study islands. Each of 39 settlements was randomized to a study

arm. MDA was given to all community members. Arm 1 received the 'intervention' (single observed height-based dose of oral azithromycin on day 1 and day 7) and Arm 2 was the control arm (single observed height-based dose of oral azithromycin on day 1 (WHO policy)). Study teams and participants were masked to trial arm assignment until after the first dose of treatment. Prior to MDA, all enrolled children were examined for TF and a conjunctival swab was taken for Ct DNA PCR. The census was updated at one year and children aged 1-9 years were re-examined for TF and Ct infection. 1714 1-9 year olds were enrolled into the study at baseline. 1482 were examined and had conjunctival swabs taken. TF prevalence was 10% (147/1482)(95% CI 8.5-11.5%). Ct infection prevalence was 13% (193/1482). At one year, 1270 1-9 year olds were followed up. 1152 had repeat examinations and swabs taken. TF prevalence was reduced to 2.3% (27/1152) (95% CI 1.43-3.17%). Preliminary cluster-summarized TF prevalence at follow-up suggests a difference between treatment arms. We will present cluster-summarised mean TF and infection prevalence between study arms. Results from this study may inform trachoma elimination activities on these islands, where infrastructure is lacking and trachoma is prevalent.

1320

CAN ONE ROUND OF MASS DRUG ADMINISTRATION WITH AZITHROMYCIN IN A HYPOENDEMIC DISTRICT REDUCE THE PREVALENCE OF TRACHOMA TO LESS THAN 5%? RESULTS FROM THREE DISTRICTS IN UGANDA

Patrick Turyaguma[1], **Anne Heggen**[2], Ambrose Onapa[2], Alexis Serna[3], Edridah M. Tukahebwa[1]

[1]Ministry of Health, Kampala, Uganda, [2]RTI International, Kampala, Uganda, [3]RTI International, Washington, DC, United States

The Uganda Ministry of Health Neglected Tropical Disease Program is working towards the elimination of blinding trachoma in Uganda by 2020 using the SAFE strategy (S= surgery; A= antibiotics given during Mass Drug Administration (MDA) with azithromycin; F=Facial cleanliness promotion; E= environmental sanitation improvement). In 2006, baseline prevalence of trachoma follicular (TF) in children 1-9 years in Buyende, Kamuli and Iganga districts of Uganda was found to be above 10% (33.6%, 33.6% and 20.1%, respectively), the intervention threshold for MDA with azithromycin. All three districts have carried out 3-5 rounds of MDA as recommended by World Health Organization, followed by impact assessments in 2013. Impact assessment results showed a substantial decrease in prevalence of active trachoma (5.9%, 6.4%, and 5.8% respectively). The new WHO treatment guidelines recommend a single round of MDA for districts under the treatment threshold of 10%, yet above the elimination goal of 5% TF in children aged 1-9 years. One round of mass drug administration with azithromycin was implemented in Buyende, Kamuli and Iganga districts in 2014 with varying levels of coverage (83.8%, 49.7%, and 87.4%, respectively). A second round of district-level impact assessments will be carried out in all three districts in May 2015. Results from these prevalence assessments are expected in June 2015, and will be used to guide programmatic implementation in Uganda and to provide valuable information to the global trachoma community about the validity of the new treatment guidelines for achieving elimination of blinding trachoma.

1321

THE ITI FLYING GENEXPERT: BRINGING NAAT DIAGNOSTICS FOR TRACHOMA TO THE END OF THE ROAD TO ACCELERATE RESEARCH, REDUCE COSTS, AND IMPROVE TRACHOMA PROGRAMS

Huub C. Gelderblom[1], Andrea I. Zambrano[2], Shekar Sharma[3], Sailesh K. Mishra[3], Birgit Bolton[1], PJ Hooper[1], Sheila West[2], Paul M. Emerson[1]

[1]Emory University, Atlanta, GA, United States, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Nepal Netra Jyoti Sangh, Kathmandu, Nepal

Studies are ongoing to evaluate Nucleic Acid Amplification Techniques (NAAT) as an indicator of infection in trachoma control programs, in addition to clinical signs of trachoma, and antibody serology. NAAT tests cannot always be done in the countries where the eye swab samples are collected. International transport of samples is costly and time consuming, requires material transfer agreements, and prohibits the building of laboratory and research capacity in trachoma endemic countries. To address these issues, we purchased a GeneXpert IV 4-module portable PCR machine and GeneXpert CT tests for the high-burden developing countries (HBDC) reduced price (Cepheid, Sunnyvale, CA, USA). The GeneXpert is a cartridge based test with minimal sample processing. Partners can borrow the "ITI Flying GeneXpert" to test eye swab samples for ***C. trachomatis***, in settings where there is no access to NAAT, for whatever reason. The GeneXpert IV can be checked-in as luggage on commercial flights, and is exempt of tax in customs, with appropriate documentation. To further reduce costs, 4-5 samples are usually pooled per test. The ITI Flying GeneXpert went from Atlanta to two remote settings in Nepal for a trachoma surveillance study. In 36 days, we tested 1543 samples in 310 PCRs (5 samples pooled per test). We tested samples within 5 days of collection. While survey teams collected samples, a technician processed samples at a make-shift laboratory. The ability to test in the field meant that we had results within days rather than weeks or months. In addition, we could identify positive clinical cases that were truly infected with ***C. trachomatis***, and discuss the results with the local authorities. The ITI Flying GeneXpert reduces the cost of research because 1) partners need not purchase a machine for temporary use, 2) there is no international transport of samples and associated regulatory procedures, and 3) laboratory staff salaries in developed countries are higher. The ITI Flying GeneXpert will increase the use of the GeneXpert platform for trachoma research, and will facilitate and accelerate the generation of data to inform and improve trachoma control programs.

1322

ACANTHAMOEBA SPP. AS POSSIBLE RESERVOIR AND VECTOR FOR THE TRANSMISSION OF *MYCOBACTERIUM ULCERANS* IN CAUSING BURULI ULCER (BU) DISEASE: PROOF OF PRINCIPLE

Bright K. Azumah[1], Phyllis G. Addo[1], Alfred K. Dodoo[1], Gordon Awandare[2], Lydia Mosi[2], Daniel A. Boakye[1], Michael D. Wilson[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]West African Centre for Cell Biology of Infectious Pathogens, Department of Biochemistry, Cell and Molecular Biology, University of Ghana, Accra, Ghana

The route of ***Mycobacterium ulcerans*** (MU) transmission in causing Buruli ulcer (BU) disease in humans (mammal) remains poorly understood although a number of possible routes have been proposed. Since ***Acanthamoeba*** species is capable of harboring the closely related ***Mycobacterium leprae*** and ***Mycobacterium marinum***, we hypothesized that ***Acanthamoeba*** spp. may be natural reservoirs and possible vectors for ***M. ulcerans*** transmission. To test this hypothesis, intact or shaved-pinpricked rumps of ICR mice were treated with either: (i) ***M. ulcerans alone;*** (ii) a co-culture of ***A. polyphaga*** and ***M. ulcerans***

or (iii) ***A. polyphaga*** only. To investigate differences in virulence, two additional groups of mice were injected in their footpads with identical concentrations of either ***M. ulcerans alone*** or ***M. ulcerans*****-**infected ***A. polyphaga.*** All groups were observed daily for development of lesions. Fine needle aspirations were performed on lesions from live animals, while infected parts of dead animals were excised and homogenized, decontaminated, Zeihl-Neelsen acid-fast (ZN) stained for acid fast bacilli and then inoculated on Lowenstein-Jensen (LJ) plates for growth of ***M. ulcerans*** for six weeks incubation at a temperature of 32°C. Both topically applied ***M. ulcerans*** only and ***A. polyphaga:M. ulcerans*** elicited inflammation (Day 31), edema (Day 45 and Day 44 respectively) and ulcers (Day 49) at infected sites for pinpricked but not intact skin groups. Also, for the same concentrations of ***M. ulcerans, M. ulcerans*****:*****A. polyphaga** caused early inflammation in mice footpads by day 3 compared to day 14 of ***M. ulcerans*** only. The aspirates and homogenized tissues of ulcers were all positive for acid-fast bacilli (MU) and showed growth of ***M. ulcerans*** when cultured. Evidence provided by this study supports the hypothesis that ***A. polyphaga*** may be a possible reservoir and a vector in BU transmission and also suggests that ***Acanthamoeba*** may enhance the virulence of ***M. ulcerans*** in the environment. This study also confirms the possibility of passive infection by ***M. ulcerans*** as a likely transmission route and also provides another mouse model, other than BALB/c, for BU studies.

1323

GLOBAL COMPARATIVE STUDY OF BACTERIAL MENINGITIS DYNAMICS

Angelica Chen[1], Hélène Broutin[2], Juliette Paireau[1], Bryan Grenfell[3], Nicole Basta[4]

[1]Princeton University, Princeton, NJ, United States, [2]MIVEGEC, Centre de Recherche Institut de Recherche pour le Developpement, Montpellier, France, [3]Department of Ecology and Evolutionary Biology, Princeton University, Princeton, NJ, United States, [4]University of Minnesota, School of Public Health, Division of Epidemiology and Community Health, Minneapolis, MN, United States

Bacterial meningitis, caused primarily by invasive infection with ***Neisseria meningitidis***, ***Haemophilus influenzae*** type b, and ***Streptococcus pneumoniae***, inflicts a significant disease burden in numerous countries around the world, often resulting in mortality rates of as high as 15-20% of cases. In the African meningitis belt, a group of countries in sub-Saharan Africa that experiences some of the highest bacterial meningitis incidence rates in the world, cases of bacterial meningitis exhibit a distinct seasonality wherein outbreaks only occur during the dry season. However, little is known about the seasonal dynamics of bacterial meningitis outside of this region. To generate the data necessary to investigate these trends, we created a global database of weekly and monthly bacterial meningitis incidence data from 63 countries, including 44 countries outside the African meningitis belt, 27 of which possessed meningococcal meningitis incidence data for the 10-year time period between 2003 and 2012. Of these 27, Brazil, Ireland, and Iceland exhibited the highest average annual meningococcal meningitis incidence whereas Japan, Thailand, and Hong Kong exhibited the lowest rates. Using wavelet analysis methods, we analyzed the time series data from these 27 countries to assess periodicity and seasonality, and compared pathogen-specific time series to determine if synchronicity could be observed between the relative frequencies of cases caused by these pathogens. We found that meningococcal meningitis exhibited significant seasonality in 14 of the 27 countries tested, but we observed no significant synchronicity between the three pathogens. In general, meningitis incidence was frequently the highest during the winter months and the lowest during the summer months. These results provide some of the first key steps toward evaluating possible environmental, demographic, social, and immunological factors driving these patterns.

1324

GENOMIC ANALYSIS OF CARRIED AND INVASIVE SEROGROUP A *NEISSERIA MENINGITIDIS* FROM THE 2011 EPIDEMIC IN CHAD

Kanny Diallo[1], Kadija Gamougam[2], Lodoum Mbainadji[2], Maxime Narbe[2], Cyriaque Ngadoua[3], Doumagoum Moto Daugla[2], Dominique Caugant[4], Jay Lucidarme[5], Moussa Hassan-King[6], James Stuart[6], Caroline Trotter[7], Olivier Manigart[6], Brian Greenwood[6], Martin M. Maiden[8]

[1]Centre pour le développement des vaccins, Bamako, Mali, [2]Centre de Support en Santé Internationale, Ndjamena, Chad, [3]Ministere de la Santé Publique, Ndjamena, Chad, [4]Norwegian Institute of Public Health, Oslo, Norway, [5]Public Health England, Manchester, United Kingdom, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom, [7]University of Cambridge, Cambridge, United Kingdom, [8]University of Oxford, Oxford, United Kingdom

Serogroup A ***Neisseria meningitidis*** (NmA) was the most common cause of meningitis in the African meningitis belt before the introduction of the TT-PsA vaccine (MenAfriVac). This bacterium, often carried asymptomatically is considered to be an 'accidental pathogen'. The mechanisms driving the transition from carriage to disease remain poorly understood. This study examined possible roles of bacterial genome diversity in this transition by comparing the genomes of geographically and temporally matched invasive and carried isolates. Purified DNA was obtained from 10 carried NmA collected by MenAfriCar and 14 invasive NmA identified during the Chadian meningitis surveillance in 2011. Whole genome sequence (WGS) data were collected, de novo assembled and submitted to the PubMLST/Neisseria website for automated annotation and analysis. Genomes were compared at 3 different levels: 7 MLST genes, 53 ribosomal MLST (rMLST) genes and 2070 whole genome MLST (wgMLST) using the Genome Comparator module. Phylogenetic networks were generated using the NeighborNet algorithm. One serogroup X isolate was found and not analyzed further. Of the 23 remaining isolates, 21 were ST7 and one was ST9021. One isolate had no ST assigned due to a deletion including gdh, one of the MLST loci. There were 6 distinct rSTs. 242 variable genes and 1542 identical genes were identified among all isolates with wgMLST; the isolates clustered into three distinct groups, but no systematic clustering by disease or carriage source was observed. wgMLST provided a high-resolution view of the genetic diversity of these NmA isolates, which were indistinguishable at lower resolution. The invasive meningococcus population circulating during the epidemic was not homogeneous. Instead our results show that a variety of closely related but distinct clones were circulating in the human population and no systematic genetic differences were found between carriage and disease isolates. This supports the idea that it is a change in the host-pathogen interaction and/or the nasopharynx environment that drives the bacteria invasive phenotype, rather than solely bacterial factors.

1325

IMMUNOGENICITY FOLLOWING THE INTRODUCTION OF A NOVEL MENINGOCOCCAL B VACCINE TO CONTROL AN OUTBREAK AT A U.S. UNIVERSITY IN 2013

Nicole E. Basta[1], Adel Mahmoud[2], Peter Johnsen[2], Robin Izzo[2], Bryan Grenfell[2], Alexander Ploss[2], Brigitte Heller[2], Jamie Findlow[3], Xilian Bai[3], Ray Borrow[3]

[1]University of Minnesota, Minneapolis, MN, United States, [2]Princeton University, Princeton, NJ, United States, [3]Public Health England, Manchester, United Kingdom

An outbreak at a New Jersey University in 2013 caused by ***Neisseria meningitidis serogroup B*** (MenB) ST-409 from the 41/44 clonal complex led to eight cases and one death. After months of sustained transmission, the FDA approved the use of a novel meningococcal B vaccine 4CMenB (Novartis), which was not licensed in the US. Overall,

98% of undergraduates received the first dose and 93% received the second dose. We aimed to understand the impact of 4CMenB on population-level immunity against the outbreak strain, immunity against the vaccine strains, and reasons for vaccine refusal. To address these questions, we conducted a cross-sectional seroprevalence survey in April 2014. Six hundred and seven students enrolled. Sixty-six percent (95% CI: 62-70%) of students who received two doses of vaccine in December and February, 59% (33-82%) of those who received one dose only in December, and 21% (6-46%) of those who remained unvaccinated had serum bactericidal antibody (hSBA) titers using human complement ≥4 against the outbreak strain. Students vaccinated with two doses had statistically significantly higher GMTs against the outbreak strain compared to unvaccinated students (7.6 (6.7-8.5) versus 2.8 (2.3-3.5), p=0.0015). The 7% of participants who remained unvaccinated or did not complete the series cited concerns about possible side effects, a lack of concern about MenB, and a lack of time as reasons. In the fall of 2014, we conducted a pre/post-vaccination immunogenicity study among incoming students who were also offered 4CMenB. The pre-vaccination survey enrolled 140 students; 75% returned for the post-vaccination survey four weeks after the second dose, of which 61 had received two doses and 33 remained unvaccinated. An additional 88 students who had received two doses were enrolled post-vaccinated. Preliminary analyses are underway. Our investigation of immunity following the introduction of 4CMenB is the first evaluation of this vaccine in the context of an outbreak and the first study among young adults in the US. Our results are key to informing public health policy and strategies for better preventing and controlling future outbreaks.

1326

THE CHALLENGES OF MAINTAINING GOOD CLINICAL LABORATORY PRACTICES IN LOW-RESOURCE SETTINGS: A HEALTH PROGRAM EVALUATION FRAMEWORK CASE STUDY FROM EAST AFRICA

Helen L. Zhang[1], Michael W. Omondi[2], Augustine M. Musyoka[3], Isaac A. Afwamba[3], Remigi P. Swai[3], Francis P. Karia[3], Charles Muiruri[2], Elizabeth A. Reddy[4], John A. Crump[5], Matthew P. Rubach[1]

[1]Division of Infectious Diseases and International Health, Department of Medicine, Duke University Medical Center, Durham, NC, United States, [2]Duke Global Health Institute, Duke University, Durham, NC, United States, [3]Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, [4]Division of Infectious Diseases, Department of Medicine, State University of New York Upstate, Syracuse, NY, United States, [5]Centre for International Health, University of Otago, Dunedin, New Zealand

Limited capacity and quality of laboratory services remain critical barriers to healthcare improvements in low-resource settings. The objective of this study was to characterize challenges faced by clinical laboratories in East Africa. Using the US Centers for Disease Control and Prevention framework for program evaluation in public health, we evaluated the laboratory sections of the Kilimanjaro Clinical Research Institute managed by the Kilimanjaro Christian Medical Centre-Duke University Health Collaboration in Tanzania, a full-service clinical laboratory that supports clinical research studies and abides by Good Clinical Laboratory Practice standards. Review of records from November 2012 through October 2014 revealed that the laboratory experienced 23 serious malfunctions among 8 instruments, of which 7 (30.4%) precluded testing of study protocol-required analytes. The median (range) time elapsed until vendor-contracted engineers arrived on-site for instrument repair was 9 (1-55) days. Of the laboratory's 21 reagent and consumable suppliers, 16 (76.1%) were based outside Tanzania. International reagent and consumable shipments were held in Tanzanian customs for a median (range) of 9 (1-51) days, and customs clearance charges accounted for US$22,980.11 (7.1%) of all reagent and consumable expenditures (US$321,801.82) over a two-year period. Monthly test throughput among laboratory sections was a median (range) of 0.6% (0.2%-2.7%) of instrument capacity. Of 9 laboratory technologists employed during the review period, 5 (55.6%) left during this period. This evaluation highlights key challenges for maintaining high quality clinical laboratory services in low-resource settings. Improved timeliness of instrument repair services, expanded local supply of reagents and consumables, reduction of customs barriers, and workforce retention represent necessary steps towards establishing quality-assured laboratory capacity in East Africa. Progress in these areas will require coordinated, goal-directed partnerships between national and international stakeholders, donor agencies, and biomedical industries.

1327

IMPROVING EFFICIENCY AND QUALITY IN CLINICAL TRIALS IN SUB-SAHARAN AFRICA

Nerina Vischer, Constanze Pfeiffer, Christian Burri

Swiss Tropical and Public Health Institute, Basel, Switzerland

Clinical research is indispensable for efficient health systems. Research centers in sub-Saharan Africa face particular constraints through increasing trial related workload and administration paired with capacity limitations. We therefore investigated the main challenges in the conduct of clinical trials to optimize processes for resource-effective and high quality trials in low-resource settings. The working hypothesis was that the main difficulty was that existing regulations are not adapted to these particular situations and that the possible leeway for interpretation was not sufficiently exploited. Semi-structured individual interviews were performed in 2014 and 2015 in three English- and two French-speaking African countries (Kenya, Tanzania, Ghana, Burkina Faso and Senegal). The interviews were conducted in two clinical research centers per country with a total of 69 clinical trial staff. For data triangulation, various staff levels were interviewed and additional informal information was gathered. The interview guide consisted of general questions about quality, guidelines, challenges, and perceived inefficiencies in clinical trials. The interviews were transcribed verbatim. Thematic analysis was then performed to identify themes relevant both across settings and positions. Poorly developed protocols, patient management and ineffective trial management are the themes that emerged: Protocols are often poorly adapted to the respective research settings ignoring capacity limitations and local culture and values. This together with unrealistic deadlines contributes to time loss in trials. Unclear delegation was another frequently described challenge. In turn, unexpectedly, the administrative burden resulting from the guidelines has never been mentioned as a difficulty; rather, researchers were grateful for having guidance in their daily work. To avoid protocols unsuitable for the context, we suggest better and earlier involvement of local staff. We also encourage careful and realistic planning with regular exchange and a test run before the enrolment of the first patient.

1328

THE FEASIBILITY USING OF HOSPITAL LOGBOOKS TO MEASURE BASELINE PERIOPERATIVE MORTALITY RATES IN ETHIOPIA

Lucy C. Unger[1], Malena A. Outhay[1], Isa I. Wismann-Horther[1], Elizabeth T. Drum[2], Miliard Derbew[3], Kelly McQueen[1]

[1]Vanderbilt University School of Medicine, Nashville, TN, United States, [2]Temple University, Philadelphia, PA, United States, [3]Addis Ababa University, Addis Ababa, Ethiopia

Ethiopia is a low-income country on the Horn of Africa with a developing healthcare infrastructure. Currently, there is no benchmark for the safety of surgery and anesthesia in Ethiopia that can be used to drive and track quality improvement. A recent consensus meeting held between representatives of Surgical and Anaesthetic Colleges and Societies supported the use of perioperative mortality rates (POMR) as a regional and national health indicator. The POMR is defined as total number of surgical deaths divided by total number of operations in a given year. POMR is measured at two time periods: death within 24 hours of surgery (or on the day of surgery) or within 7 days of surgery or prior to

hospital discharge. We examined the feasibility of measuring the baseline perioperative mortality rate (POMR) in Ethiopia using in a combination of intraoperative, anesthesia, and surgical ward logbooks at two hospital sites in Addis Ababa. A total of 7162 operations and 7 deaths were recorded, with 1 death occurring at the time of surgery and the remaining 6 in the surgical ward or ICU. The POMR was measured at .097%. We encountered limitations in the form of missing logbook pages, illegible entries, and misplaced logbooks that may serve to underestimate the POMR. Furthermore, only the anesthesia logbooks recorded ASA status and cause of death, which was not kept at one of the sites. In conclusion, the methods used to establish the baseline POMR through logbook analysis will vary across hospital sites until a standardized system of surgical record keeping is established in Ethiopia.

1329

ONE ENVIRONMENT, MANY ETHNIC HEALTH DISPARITIES

Peter Kunstadter[1], Alba Amaya-Burns[2]

[1]Program for HIV Prevention & Treatment, A. Muang, Chiang Mai, Thailand, [2]Duke-Kunshan University, Kunshan, Jiangsu, China

Members of many different ethnic groups including Thai citizens and trans-border migrants live in close proximity in relatively homogeneous ethnic communities in rural northwestern Thailand, near the border with Myanmar. Most of the people in all communities farm crops such as maize and peanuts for the international market. All Thai citizens and many trans-border migrants have government-provided health insurance and all share a common government health care system with low cost to patients. All pregnant women and their husbands are eligible for low cost antenatal care including HIV counseling and testing. Despite living in the same natural and health care environment, Hmong, Lahu, Tai Yai, and especially Chinese ethnic minorities compared with Northern Thai ethnic majority have significantly less knowledge of HIV transmission, prevention and treatment, greater stigmatization of HIV/AIDS, report more constraints that delay or prevent use of health facilities and make less use of health facilities. Statistical controls for citizenship, Thai language ability, education, health insurance, economic status and presence of a motor vehicle in household reduce but do not eliminate highly significant disparities in these variables. Ethnic-specific tailoring to reduce disparities in health knowledge, HIV stigmatization, and effective use of health service includes training and using bi-lingual community members as translator-interpreters in clinics and as community health educators.

1330

USE OF COMMUNITY HEALTH VOLUNTEERS TO INCREASE COVERAGE FOR INTEGRATED COMMUNITY CASE MANAGEMENT IN BONDO, KENYA

Savitha Subramanian[1], Mark Kabue[2], Dyness Kasungami[1], Makeba Shiroya-Wadambwa[3], Dan James Otieno[4], Charles Waka[3]

[1]John Snow, Inc., Rosslyn, VA, United States, [2]Jhpiego, Baltimore, MD, United States, [3]Jhpiego, Nairobi, Kenya, [4]John Snow, Inc., Nairobi, Kenya

Bondo County is located in the Western region of Kenya. It has an IMR of 110 and an U5MR of 208 per 1,000 live births which is thrice the national U5MR of 74/1000. There continues to be limited access to and use of health services in some rural areas that are underserved by health facilities. This provided the impetus for advocating for the implementation of integrated Community Case Management (iCCM) as a way to address these health disparities. An 18-month study is underway in Bondo to test whether community health volunteers (CHVs) can effectively deliver an iCCM package in the context of the existing community health strategy platform. The study is a quasi-experimental design with intervention and comparison groups of four community units each. Fifty-eight intervention group CHVs were trained on iCCM and health promotion, provided with iCCM commodities, and a monthly stipend of $23. In the comparison group CHVs were only trained in health promotion and receive a similar stipend. Baseline survey was done in October 2013 and midline in July 2014; the latter was limited to the intervention group only. An endline survey is planned for June 2015. Overall introduction of iCCM resulted in over 100% increase in iCCM cases managed from baseline compared to midline (2,367 vs. 4,868), with the CHVs' share being 56%. In terms of performance, the CHVs demonstrated good ability to follow the iCCM algorithm from the identification of signs to the classification of illness, and deciding whether to treat at home or refer to the health facility. The greatest improvement was in the ability to examine or "look" for signs of illness (average of 3% at baseline vs. 74% at midline), $p < 0.05$. Key stakeholders reported that there were various benefits of iCCM in Bondo such as improved access to health services, improved health behaviors at individual and community level, community empowerment, and increased trust of the CHVs by the community. Based on these results so far, CHVs can effectively provide iCCM services and thus contribute to reducing childhood morbidity deaths in Bondo, Kenya.

THE ROLE OF SOCIAL NETWORKS IN INTERVENTION STRATEGIES TO CONTROL TUBERCULOSIS: A CASE STUDY OF TWO COMMUNITIES IN LUSAKA, ZAMBIA

Lara J. Iverson

State University of New York – University of Buffalo, Buffalo, NY, United States

The global burden of tuberculosis (TB) currently is estimated to be 30-50% and is on the rise. In Zambia, as well as throughout the developing world, persons infected with TB often are stigmatized within their communities. Additionally, information about the disease is transmitted via informal networks. This research explores the structural mechanics of social networks in two low-resource communities in Lusaka, Zambia to understand the role of these networks in creating sustainable health behavior change after the implementation of intervention strategies that targeted tuberculosis-infected persons and their families. The project uses social network analysis to study how interpersonal networks in these communities operate with the goal of measuring the efficacy of intervention strategies aimed at reducing tuberculosis-related stigma. Social network analysis is an effective tool in which to examine the role of relationships within communities since relationships reflect emergent dimensions of complex social systems that cannot be captured in statistical models of health and demographic data. Analyzing network structures can highlight the flow of information among its members and the likelihood of subsequent behavior change. In low-resource settings, sustainable cost-effective intervention strategies are necessary to encourage TB-infected persons to seek treatment. Therefore, understanding these social networks potentially may allow for more effective program planning by harnessing the processes of information exchange within similar communities worldwide.

DETERMINATION OF WEANING FOODS USED IN THE DOMINICAN REPUBLIC, EL SALVADOR AND HONDURAS AND THE IMPACT THEY HAVE UPON GASTROINTESTINAL PARASITIC INFECTIONS IN CHILDREN

James Palmieri, Susan Meachum, **Sarah Stokes**, Jenna Warehime, Magdalena Bax, Janie Ogle, Dezarae Leto

Edward Via College of Osteopathic Medicine, Blacksburg, VA, United States

Contaminated weaning foods account for a substantial portion of parasite-induced diarrheal diseases among infants and young children in developing countries. The sources of food contamination are numerous and without appropriate food safety measures and hygienic quality control of infant foods including drinking water, parasitic infections will remain

high in both infants and children. In a published study by Childers and Palmieri (2014) on the prevalence of gastrointestinal parasites in children from Verón, a rural city of the Dominican Republic, they examined 128 fecal samples of children ranging from 2-15 years and found 127 positive for one or more parasites. Percent infection rates were 43.8% for Ascaris lumbricoides, 8.5% for ***Enterobius vermicularis***, 21.1% for ***Entamoeba histolytica***, and 22.7% for ***Giardia duodenalis***, and with 7.8% of the children examined having double infections. The extremely high infection rate of gastrointestinal parasitic diseases in the Punta Cana-Bávaro-Veron-Macao municipal district in young children may be attributed to what the local population use for weaning foods and how the weaning foods are prepared. Presently, there are not published reports on weaning foods in this area. In this study approximately 250 women with children in Honduras, El Salvador, and the Dominican Republic will be interviewed to determine breastfeeding practices, age at which weaning took place from breast milk or formula, what the weaning foods are, and how the weaning foods were prepared, and to correlate this information with transmission cycles for the known parasitic diseases in children in the area.

1333

ADVANCEMENTS AND CHALLENGES IN DESIGNING ACCURATE, POINT-OF-CONTACT, INFRASTRUCTURE-FREE MOLECULAR RAPID DIAGNOSTIC TESTS

Dylan Guelig, Robert Burton, Steven Diesburg, David McAdams, Paul LaBarre

PATH, Seattle, WA, United States

Currently, most clinically relevant nucleic acid amplification tests (NAATs) require laboratory or electrical infrastructure, preventing accurate infectious disease diagnostics in low-resource settings (LRS). Although simple and ubiquitous at the point-of-contact (POC), antigen based rapid diagnostic tests (RDTs) may lack the sensitivity required for diagnosing acute or low density infections. In an effort to extend the reach of molecular diagnostic tools, PATH has previously demonstrated the versatile, non-instrumented nucleic-acid amplification (NINA) reusable platform across HIV-1, Buruli ulcer, and ***Plasmodium*** spp. isothermal amplification assays. NINA provides precise temperatures required for isothermal NAATs by coupling an exothermic reaction to a phase change material (PCM) to create an energy dense, low-cost, consistent heat source. Furthering this technology, PATH has developed a single-use disposable miniature format, enabling low-cost diagnosis free from reusable components or infrastructure. This hardware advancement enables molecular diagnostics in an easy-to-use form factor, taking accurate diagnostics further into LRS. Significant engineering and manufacturing challenges encountered in device miniaturization include thermal management, performance repeatability, ambient operating range, and temperature precision. We have met these challenges through PCM composite engineering, paper microfluidic reagent delivery, computational modeling, and batch manufacturing methods. Here, we discuss design strategies and challenges in the manufacture of 150 miniature alpha prototypes to support evaluation by the US Center for Disease Control and Prevention (CDC) of a point-of-contact RT-LAMP HIV-1 NAAT. These recent developments show progress toward our vision of simple, sample-to-results molecular RDTs, capable of being used anywhere in the world.

1334

THE ANALYSIS OF CO-MORBIDITIES AND THE PROMISE OF IMPROVED DIAGNOSTICS FOR A HIGH DISEASE-BURDEN COMMUNITY

Paul W. Fenimore[1], Benjamin H. McMahon[1], Nicolas W. Hengartner[1], Ruy M. Ribeiro[1], Norman A. Doggett[1], Momchilo Vuyisch[1], Harshini Mukundan[1], James M. Hyman[2], Carrie A. Manore[2], Prakash Kempaiah[3], Douglas J. Perkins[3]

[1]Los Alamos National Laboratory, Los Alamos, NM, United States, [2]Tulane University, New Orleans, LA, United States, [3]University of New Mexico, Albuquerque, NM, United States

The most effective path to substantial improvements in public health and medicine in high-disease burden areas is unclear in part because the effect of changes in diagnostics or treatment options are difficult to anticipate. Co-morbidities radically alter the progression and outcome of disease relative to solitary infection and play a major role complicating medicine and public health, making the necessary analysis difficult. Well-documented examples of altered progression and outcome include HIV disease, tuberculosis, and malaria, which jointly influence progression and the outcome of concomitant acute bacterial infections. Several mechanisms tie changes in disease progression to epidemic progression and endemic state, including the maintenance of subclinical infections, and modulation of immunity. While disease progression and contagion are moderately well-characterized for these diseases in isolation, mathematical epidemiology of co-morbidities is not well-established. Relying on extensive clinical data from Siaya, Kenya, we analyze the model sensitivities for simultaneous disease progression and contagion models in the context of holoendemic malaria and co-morbidities in Siaya. The problem of constraining several simultaneous disease progression and contagion models (two acute bacterial infections, malaria, tuberculosis) including their co-morbidities is challenging and we report the co-varying uncertainties in the parametrization of our model's interactions between co-morbidites, and in the parametrization of contagion. Models such as the one reported here promise to improve our ability to understand co-morbidities and their complex interactions with medicine and public health.

1335

KEY SUCCESS INDICATORS OF A COMMUNITY ENGAGEMENT STRATEGY: THE CASE OF A TROPICAL MEDICINE RESEARCH UNIT ON THE THAI-MYANMAR BORDER

Phaik Yeong Cheah[1], Khin Maung Lwin[2], Francois Nosten[2], Michael Parker[3]

[1]Mahidol Oxford Tropical Medicine Research Unit, University of Oxford, Bangkok, Thailand, [2]Shoklo Malaria Research Unit, Mae Sot, Thailand, [3]The Ethox Centre, University of Oxford, Oxford, United Kingdom

Community engagement is increasingly promoted to strengthen the ethics of medical research in low-income countries. One strategy is to use community advisory boards (CABs), however there is a paucity of data on how to evaluate it. The Shoklo Malaria Research Unit (SMRU) has been conducting research in tropical medicine e.g. malaria in a population of refugees, migrant workers, and displaced people on the Thai-Myanmar border for nearly 30 years. In 2009 SMRU facilitated the establishment of the Tak Province Community Ethics Advisory Board which consists of members from the border community in an effort to formally engage with the local people both to obtain advice and to establish a participatory framework within which studies and the provision of health care can take place (https://www.youtube.com/watch?v=HFYJWfGoVeQ). Six years on, we wonder if the CAB been successful, which begs the question "what are the key success indicators of a CAB and how do we evaluate it?" Based on our experience facilitating the CAB, attending its meetings and conducting formal interviews with relevant stakeholders, we have

identified the following indicators, both qualitative and quantitative: (1) key factors that motivate members who serve on the CAB (2) the level of trust among the members, and between researchers and members (3) the nature and depth of discussions in CAB meetings (4) the number and the quality of suggestions and changes in research studies recommended by CAB members, and the extent they have been taken on board by SMRU researchers and collaborators (5) the extent of the CAB protecting the interests of the community it serves e.g. preventing exploitation (6) the representativeness of the CAB members (7) the sustainability of the CAB (8) the ability of the CAB to identify significant ethical issues and (9) the perception of the CAB by community members and researchers. These indicators are crucial for us to conduct a formal evaluation of the CAB and to design our community engagement strategy in years to come.

1336

MATERNAL SCREENING TO PREVENT CONGENITAL TOXOPLASMOSIS IN AUSTRIA: MODELING THE COST-MINIMIZING OPTION

Eileen Stillwaggon[1], Andrea-Romana Prusa[2], Evelyn Walter[3], Larry Sawers[4], Michael Hayde[2], Arnold Pollak[2], David C. Kasper[5]

[1]Gettysburg College, Gettysburg, PA, United States, [2]Department of Pediatrics and Adolescent Medicine, Toxoplasmosis Reference Laboratory, Medical University of Vienna, Vienna, Austria, [3]Institute for Pharmaeconomic Research, Vienna, Austria, [4]American University, Washington, DC, United States, [5]Department of Pediatrics and Adolescent Medicine, Research Core Unit for Pediatric Biochemistry and Analytics, Medical University of Vienna, Vienna, Austria

Toxoplasma gondii is a protozoal parasite that infects a significant proportion of humans globally, although prevalence varies widely among and within world regions. Mothers infected during pregnancy may exhibit no symptoms, but there is about a 50% risk of transmission to the fetus and possibility of mild to profound injury to the unborn child. Consequences of fetal infection include chorioretinitis, encephalitis, hydrocephaly, cerebral calcifications, hearing loss, and fetal death. In the USA, 91% of children with no prenatal or postnatal treatment had visual and/or cognitive impairment by age 12. In Europe, 3 countries have systematic prenatal screening programs for early intervention to prevent or reduce fetal injury and have seen large reductions in maternal infection, fetal infection, and fetal injury. The Austrian protocol for prenatal testing and medication was initiated in 1992. Using historical data from the Austrian Toxoplasmosis Register, which records serology history and birth outcomes for 1 387 680 pregnancies from 1992 to 2008, we compare lifetime societal costs of the Austrian protocol as implemented with lifetime societal costs in a hypothetical scenario without prenatal screening. In a decision-analytic model using a societal perspective, we include costs of treatment, lifetime care and accommodation of injuries, and lost productivity that would have occurred in a No Screening scenario with actual costs of screening, treatment, lifetime care and accommodation, and lost productivity in Austria from 1992 to 2008. Lifetime societal costs of the No Screening option would have been €198 per birth, for all Austrian births in the period, resulting in total costs of about €275 million for treatment and accommodation for children without early diagnosis and treatment. Maternal screening according to the Austrian protocol as implemented over the period, including costs of screening, maternal treatment, infant treatment, and lifetime costs for those children with CT in spite of the protocol cost €58 per birth, or roughly €80 million. The Screening option is cost-minimizing, saving €140 per birth, or about €200 million euros.

1337

TRANSLATING DATA FOR POLICY ACTION: ASSESSING HEALTH FACILITY CAPACITY FOR MALARIA CASE MANAGEMENT IN GHANA, KENYA, AND UGANDA

Nancy Fullman[1], Alexandra Wollum[1], Benjamin Brooks[2], Evelyn Anash[3], Jane Achan[4], Caroline Kisia[5], Emmanuela Gakidou[1]

[1]Institute for Health Metrics and Evaluation, Seattle, WA, United States, [2]Zillow, Seattle, WA, United States, [3]Ghana Health Service, Accra, Ghana, [4]Medical Research Council Unit, The Gambia, Serrekunda, Gambia, [5]Action Africa Help-International, Nairobi, Kenya

To further accelerate gains made against malaria, more efforts that link research to local policy priorities are needed. This work is particularly important as more countries aim to improve their malaria case management guidelines. Most countries stipulate that parasitological confirmation for all suspected cases of malaria occurs before first-line antimalarials can be prescribed. Thus, assessing whether health facilities concurrently stock artemisinin-based combination therapies (ACTs) and malaria diagnostics (laboratory testing or rapid diagnostic tests [RDTs]) provides critical information about a country's overall capacity for malaria case management. Drawing from nationally representative facility-level data collected through the Access, Bottlenecks, Costs, and Equity (ABCE) project, we analyzed the availability of both ACTs and malaria diagnostics across levels of care in Ghana, Kenya, and Uganda. In 2012, nearly all hospitals had the capacity for both diagnosing and treating malaria. Among primary care facilities, however, results varied more by country. Ghana recorded the largest proportion of public primary care facilities which lacked diagnostics (47% of health centers and 68% of community-based planning and services [CHPs]). By contrast, public facilities in Uganda were more frequently limited by stock-outs of ACTs than deficiencies in testing (91% either had a microscope or RDTs). At the lowest levels of care in Kenya, dispensaries and clinics, availability of malaria testing was the primary constraint to proper case management (15% stocked ACTs but lacked diagnostics); however, over 90% of public and private health centers in Kenya had concurrent capacity for malaria testing and treatment. These findings show that the policy interventions for improving malaria case management are likely to vary across countries and levels of care. As more national guidelines require parasitological confirmation of malaria and call for universal access to ACTs, it is crucial to identify where specific gaps exist within a country's health system and then use these data to tailor evidence-informed strategies against malaria.

1338

USING STORIES TO SUPPORT MASS DRUG ADMINISTRATION FOR THE ELIMINATION OF LYMPHATIC FILARIASIS IN AGAM DISTRICT AND DEPOK CITY, INDONESIA

Alison Krentel[1], Rita Damayanti[2], Christiana R. Titaley[2], Nugroho Soeharno[2], Mark H. Bradley[3], Timothy Lynam[4]

[1]Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Centre for Health Research, Faculty of Public Health, Universitas Indonesia, Jakarta, Indonesia, [3]Global Health Programs, GlaxoSmithKline, London, United Kingdom, [4]Society Reflecting Pty Ltd, Townsville, Australia

In 2013, we developed a tool and process to support the implementation of mass drug administration (MDA) for lymphatic filariasis (LF) elimination in two districts in Indonesia where additional rounds of MDA were required. We aimed to understand MDA from the perspective of the recipients (community members) and the deliverers. In both locations (Depok City (urban) and Agam District (rural)), more than six rounds of MDA had been completed by 2012. In 2013, Agam District did not pass the Transmission Assessment Survey (TAS) and Depok City did not qualify for TAS. District stakeholders reported feeling discouraged when required to continue additional MDA rounds. In order to assist with this prolongation of MDA we developed a tool using a novel approach in social

data collection whereby people were asked to tell their direct experiences with MDA. Based on these narratives, respondents then provide insight into the influences and motivations for the reported behavior. In December 2013 and January 2014, 805 community members were interviewed following the last MDA round. Over 78% of the total sample had ever received the MDA, and 65% of those receiving the drugs, complied. Positive influences on compliance included being given the LF drugs outside of the house (AOR 2.74, p=0.004), exposure to informative media (AOR 2.10, p=0.002), perceived common goodness (AOR 1.5, p=0.019), being healthy (AOR 10.74, p=0.000) and knowing that others have complied (AOR 2.27, p=0.03). At the same time, 204 drug deliverers were surveyed. 58% of deliverers had participated in MDA more than 3 times and 93% reported previous MDA compliance. Results showed that MDA eligibility criteria were misunderstood; meaning less people were being offered LF drugs. This research demonstrated that specialized guidance could assist those districts that must prolong MDA past six rounds. The use of stories provided a more reliable prediction of compliance than the standard behavior survey data. The narrative capture tool developed in this study could be used to assess and advise districts struggling to reach sufficient coverage levels to achieve LF elimination.

1339

PREDICTING THE USE OF ORAL REHYDRATION SOLUTION (ORS) FOR CHILDREN WITH DIARRHEA: AN APPLICATION OF LOGISTIC REGRESSION AND CLASSIFICATION TREES

Jay Park, John McLennan, Alberto Nettel-Aguirre

University of Calgary, Calgary, AB, Canada

Child diarrhea is a critical concern, for which oral rehydration solution (ORS) is a key management method. Logistic regression (LR) is one of the most common statistical methods used for prediction of key behaviours such as ORS use. With the large number of potential variables that could be included, variable selection is often a problem in LR. Classification trees (CT), a form of binary recursive partitioning, have been suggested as an alternative. CT can be used to identify complex interactions between predictors and present them in a tree diagram that is easy to interpret. Thus, CT may be used to build a predictive model as accurate and interpretable (or more) than LR. The aim of this study was to build and compare predictive models for ORS use using LR and CT, using data from the 2007 and 2013 Demographic Health Surveys of the Dominican Republic. Purposeful selection, which relies on univariate analyses to select variables, was chosen for LR. CT was used as a predictive model itself, and the variables in the tree output were used to build a LR. Purposeful selection and CT models ended up with almost the same list of predictors. Five of the six predictors in the CT were present in the purposeful LR (caregiver education, child age, feeding response, whether sought treatment/advice and whether used public health care for diarrhea), which may explain comparable prediction accuracy between the models. The CT had accuracy (Ac, 95% CI) of 67.9% (63.1-72.4), the tree LR had Ac of 71.9% (67.6-75.5), and the purposeful LR had Ac of 71.4% (66.8-75.5). The sensitivity and specificity were also similar between these models. Despite having similar performances, the CT approach was arguably more useful as the tree diagram better illustrated the order of hierarchy and interactions among the predictors, and how they collectively affected ORS use. While limited to two cross-sectional datasets, this study is one of the first to compare the utility of CT as a predictive model versus conventional method of LR for ORS use, and as a method to select variables for LR. This approach may be useful in identifying predictors in other health behavior studies.

1340

FACTORS ASSOCIATED WITH THE NON-USE OF INSECTICIDE TREATED NETS IN RWANDAN CHILDREN

Monique Murindahabi Ruyange[1], Corine Karema[1], Rukundo Alphonse Rukundo[1], Eric Tongren[2], Kaendi Munguti[3], Agnes Binagwaho[4], Jeanine Condo Jeanine[5]

[1]Malaria and Other Parasitic Diseases Division, Rwanda Biomedical Center, Ministry of Health, Kigali, Rwanda, [2]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention/U.S President's Malaria Initiative Rwanda, Atlanta, GA, United States, [3]United States Agency for International Development/U.S President's Malaria Initiative, Kigali, Rwanda, [4]Ministry of Health, Kigali, Rwanda, [5]School of Public Health, University of Rwanda, Kigali, Rwanda

Insecticide treated bed nets (ITNs), when used properly, have shown to be highly effective in reducing malaria morbidity and mortality. However, factors related to individual, household and community may influence how ITNs are used. Our study examined factors associated with non-use of ITNs non-use among children under five years in Rwanda. We conducted a secondary data analysis of 2010 Rwanda Demographic Health Survey (DHS) data using multilevel logistic regression analysis. Responses from a total of 6,173 women aged 15-49 years living in 492 villages were included in the analysis. The ITN non-use among children under five years was 25%. Risk factors for ITN non-use included household with more than 5 members (OR=1.42; 95% CI=1.23-1.63), employed mother (OR=1.33; 95% CI=1.06-1.66), and lower village altitude (OR=1.36; 95% CI=1.14-1.61). Risk factors for ITN use included households with more than 3 nets (OR=0.39; 95% CI=0. 33-0.47), women with one to four visits to antenatal clinic (ANC) (OR=0.45;95% CI=0.29-0.69) and more than 4 ANC visits (OR=0.39; 95% I=0.21-0.70), mother married or living with partner (OR=0.43; 95% I=0.36-0.52), mother with any education (OR=0.77; 95% CI=0.65-0.91), and higher community wealth quintile (OR=0.71; 95% CI=0.59-0.84). Proper use of ITNs can decrease the burden of malaria in Rwanda. Factors related to ITN non-use at individual, household and community levels, including mother marital status, mother occupation, education, ANC attendance, number of mosquito bed nets, number of household members and, socio-economic status need to be addressed to ensure that ITNs continue to be effective in preventing malaria.

1341

BETEL OR ARECA NUT CONSUMPTION IN YAP, FEDERATED STATES OF MICRONESIA

Mawuli Nyaku[1], Ashley Tippins[1], Rosemary B. Duda[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Yap State Department of Health Services, Colonia, Federated States of Micronesia

The areca or betel nut (AN), the fruit from the palm ***Areca catechu*** is the fourth most commonly used psychoactive drug after tobacco, alcohol, and caffeine globally. Worldwide, an estimated 600 million people of all age groups and social classes consume AN. Oral cancer mortality rates of up to 80% associated with AN consumption have been reported in the Western Pacific Region. Other adverse health effects associated with AN use include esophageal, pharynx, lung, pancreatic, and cervical cancers. Yap, one of the four islands that comprises the Federated States of Micronesia (FSM) has the most traditional and persistent AN practices. Oral cancer rates in Yap are the highest in FSM at 31.8 cases per 100,000 people. This study sought to characterize current AN consumption, preparation and health attitudes among the Yapese population. The surveys were conducted by trained Public Health staff, who randomly interviewed 524 Yapese using a standardized data collection instrument. The interviews were conducted from October 1-December 31, 2014. Demographic information, AN consumption practices, and smoking and drinking habits among AN consumers were collected. The survey participants comprised of a total of 524 individuals including 297 (56.7%) females. The mean age for all participants was 33.52 (range 13-90 years). 5.4% of participants

had completed professional education, 30.4% college education, and 48.7% high school. 87.9% of females and 90.7% of males responded yes to current AN consumption. The mean age at which participants started consuming AN regularly was 17.77 years (range: 2-53 years). Of all the participants, 22.1% indicated smoking tobacco and 48.5% indicated drinking alcohol. Of the current AN users, 81.4% agreed to stop consuming AN if they knew it was harmful to their health. According to the World Health Organization, AN alone is a cancer causing agent. Because a substantial number of participants indicated they would stop AN consumption if they were aware of harmful health effects, public health education on the adverse health effects of consuming AN should be an initial step implemented in Yap to reduce AN consumption in the population.

1342

USE OF INTERNET APPLICATIONS IN DATA MANAGEMENT OF THE DENGUE VACCINE INITIATIVE FIELD STUDIES

Lee Kang Sung, Lim Jacqueline, Mabel Carabali, Park Jin Kyung

International Vaccine Institute, Seoul, Republic of Korea

The data management in epidemiological studies implemented in developing countries faces many challenges in communication with different language, imbalance of proficiency among the data team staff at study sites, differences in terms of cultural background and past experience, and so on. Adequate communication through training with the local site staff is a key component in proper data management and successful execution of the field project. Hence, relevant training should be taken in advance to avoid delay of the study launch as well as to minimize potential errors. However, some studies experienced substantial delayed with inevitable reasons, such as travel restriction to the site with natural disasters and political instability. From the experience of launch and management of the data system, we report the learning lessons obtained from data management training using internet applications and its utilization on relevant studies. Two types of internet application were implemented for the data management training. WebEx includes functions requisite for training through the video conferencing and sharing the computer screen. TeamViewer allows us control remotely the main computer of study site and able to implement the data management system and to resolve the unexpected problems. The pilot study after the on-line data management training has been done and the on-line training was also compared with offline training.In DVI with multiple field sites with different local characteristics with standardized study designs, the DM could gain experience and learning lessons from various data management systems implemented. As many information techniques have been adopted in such kinds of field studies, many methods for the data management from paperless data collection to web-based system became available. Accordingly, an intensive relevant training needs to be complemented. The best way to manage data staffs of the study sites is a face-to-face training with monitored practice. However, proper use of the on-line alternatives for communication and training could be taken to overcome long international travels and cost issues.

1343

YOUTH TRAUMA TRAINING - EXPLORING THE FEASIBILITY OF TRAINING ETHIOPIAN YOUTH IN BASIC TRAUMA PRE-HOSPITAL CARE

Isa I. Wismann-Horther, Malena Outhay, Lucy Unger, Amina Merchant, Kelly McQueen, Miliard Derbew

Vanderbilt School of Medicine, Nashville, TN, United States

Trauma continues to be a leading cause of death, globally accounting for approximately 11% of the global burden of disease. Low and middle income countries (LMIC) report an annual injury death rate due to trauma nearly double those of high income countries. Accordingly, trauma is a leading cause of morbidity and mortality in the LMIC Ethiopia. Many deaths occur in the pre-hospital setting due to airway compromise, respiratory failure, or uncontrolled hemorrhage and can be managed by basic first-aid techniques. Several studies have demonstrated the significant potential to decrease trauma morbidity and mortality through training laypersons in basic trauma resuscitation. In collaboration with Ethiopian academic partners, we piloted a basic trauma resuscitation course targeted towards Ethiopian youth as a proof of concept study. Classes of approximately 20 voluntary students aged 14-21 were given a multiple choice pre-test, taught a three hour course and then given an identical post test with a qualitative, free response survey attached. The course content was based off ATLS principles of ABCD (Airway, Breathing, Circulation and Disability) interventions modified for a low resource setting. We hypothesized that young adults are an effective layperson population that could easily learn and apply these techniques and can be targeted for future trauma education interventions in order to increase the number of first responders in Ethiopia. Following education intervention the students demonstrated improvement in test scores with a post test average score of 81.78% (SD=12.04, N=83) increased from a pre test average score of 49.17% (SD=13.73, N=83). A dependent t test demonstrated significant difference between pre and post intervention scores ($p < 0.01$). The trauma courses were well received by students and increased the number of capable responders in Ethiopia. This study encourages further trauma education interventions targeted towards youth in order to establish an organized trauma triage system in a resource challenged country.

1344

COMPARISON OF VISUAL INSPECTION WITH ACETIC ACID AND PAP TEST IN THE PREVENTION OF CERVICAL CANCER IN RURAL HAITI

Nicole Tarui[1], Andrea Walker[2], Susan Partovi[3]

[1]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States, [2]University of California Los Angeles Department of Obstetrics and Gynecology, Los Angeles, CA, United States, [3]David Geffen School of Medicine at University of California Los Angeles, Founder and President of H.E.A.L. Haiti, Los Angeles, CA, United States

Cervical cancer has the highest incidence and mortality rate of all cancers in women in Haiti. Unlike many cancers, it is preventable to a large extent by effective screening programs. Papanicolau (Pap) tests are not readily available in resource-limited areas and require multiple steps prior to treatment. In a rural setting where the incidence of cervical cancer is high, visual inspection with acetic acid (VIA) provides a one step method to diagnose and treat cervical dysplasia in high risk patients in low resource settings and has been shown to decrease cervical cancer mortality by 31%. This technique is widely studied and shown to be an effective and safe way to prevent cervical cancer in rural settings and may also be used to provide early identification and treatment of cervical dysplasia in rural Haiti. Outpatient mobile clinics in Haiti were established in the rural village of Mussotte in March and April 2015. A total of 243 patients sought gynecologic care. VIA was performed by medical students supervised by physicians on patients ages 21-60 years of age. VIA screening and Pap tests were performed on 165 patients. A log was kept of all patients who received medical treatment, and the log was retrospectively analyzed. The purpose of this descriptive analysis is to compare the results of VIA and Pap test in the detection of cervical cancer. Of the 165 women screened with VIA and Pap test, 4 women had positive VIA results and were treated with cryotherapy. 1 woman had invasive cervical cancer. Pathologic analysis of Pap tests will be performed in the United States, and patients will be notified of their results. VIA positively identifies cervical dysplasia at least as often as Pap. The key advantages of VIA over Pap are a lower cost of testing and the ability to administer treatment contemporaneously. Given the relatively higher prevalence of cervical cancer in the rural setting, VIA is recommended as a cost-effective way to screen for cervical cancer in rural Haiti.

1345

EXPERIENCE USING FREE CLOUD SOFTWARE AS A MEDICAL TOOL ON A TROPICAL MEDICINE CLINIC

Ricardo A. Vega, Jose A. Suarez, Ana I. Jimenez, Franz D. Barnes, Betsi L. Ortiz, Zeuz Capitan, Jessica Rodriguez, Geraldo Daring, Feny Abrego, Juan M. Pascale, Nestor R. Sosa

Instituto Conmemorativo Gorgas de Estudios de La Salud, Panama, Panama

Electronic records are currently changing the way epidemiology is gathering information. In tropical medicine the demand for such products is huge, as this group of diseases affects more than one billion people. Starting to use electronic records on a tropical medicine clinic in a small country in Central America such as panama does not need a lot of monetary resources. There are many different software that are offered for free or paid that can provide medical records or data base registry. On our clinic we are currently managing electronic tools such as: Electronic Medical Records with a data base, a photo library indexed for each patient, georeferencing system and various forms for reporting to the health authorities; they are all offered for free from google drive and fusion tables, they are easily accessed from the cloud and are exportable to other programs. Our clinicians have all the information about their patients available in any device and readably accessible. The patients are easily georeferenced to the fusion table map and easily filtered by diagnosis making this tool indispensable for monitoring the epidemiology of different infectious diseases. These kind of systems allow an easier data collection, patient's follow-up, data analysis, and also provide information to the medical community, health authorities and scientific societies. We have seen the many advantages of these tools in our clinical setting and we strongly believe that this model can be easily adopted by other clinics. In today's world it is necessary to take advantage of the technology we have at hand and every physicians should familiarize with the wide spectrum of tools at their disposal.

LOGISTICS RELATED TO AN EBOLA TREATMENT STUDY IN WEST AFRICA

Joe Sgherza

Clinical Research Management, Hinckley, OH, United States

With rapid response to the 2014 Ebola outbreak in West Africa, ClinicalRM initiated a treatment study for Ebola in West Africa, utilizing convalescent plasmapheresed plasma. Given the nature of this study, and the need for rapid response, logistical issues were overcome by providing rapid protocol development, mobility of personnel, equipment, including ***HopeMobiles*** (bloodmobiles), and the ability to leverage strong international partnerships to ensure effective and rapid study start-up. Preplanning involved consideration of personnel needed in the U.S. and Africa for effective execution of the study. ClinicalRM and partners provided full-time investigators, program and project managers, and a full research team. Challenges faced in Africa, from the lack of site Standard Operating Procedures (SOPs), training, as well as enhanced communication between the U.S. and Africa. These issues were overcome by utilizing ClinicalRM's extensive template library and by providing continuous SOP review by ClinicalRM project managers and quality specialists. Site communications and telephone line capacities were inadequate for large studies and international, daily conference calls. These issues were rectified with an appropriate carrier and a new platform for hosting meetings. Remote Data Capture could not be accomplished electronically due to internet bandwidth. We were required to use paper CRFs. One of the largest problems to overcome was that of transportation of the ***HopeMobiles*** from the manufacturing site in North Carolina to the destination in West Africa. With careful planning and one-of-a-kind international synergy, we were able to supply and ship our ***HopeMobiles*** to the study sites using a FedEx AN-124 transport aircraft and drive them directly to the sites. A U.S. engineer oversaw the setup of site equipment on board the ***HopeMobiles***, ensuring the technical efficiencies. Moreover, because ELISA could not be performed at the site in Africa, specialized labs at U.S. Army Medical Research Institute for Infectious Diseases (U.S.) committed to the study by providing RT-PCR and ELISA test methods. Along with our partners, we managed all aspects of operations and study startup.

1347

PRIVATE SECTOR PROVIDERS, KEY PARTNERS IN IMPROVING QUALITY OF FEVER CASE MANAGEMENT-INSIGHTS FROM MADAGASCAR

Rova Ratsimandisa[1], Cristina Lussiana[2], Victor Lara[2], Purity Njagi[2], Nikki Charman[2], Stephanie Dolan[2]

[1]Population Services International, Antananarivo, Madagascar, [2]Population Services International, Nairobi, Kenya

In Madagascar, the private health sector distributes 80% of antimalarial drugs, primarily through drug stores, pharmacies and retailers. Diagnostic services, however, are practically non-existent in the private health sector, often leaving potentially life- threatening febrile illnesses mistreated. Population Services International is implementing a project to improve fever case management in the private sector. In addition to training private providers to correctly manage fever cases using Rapid Diagnostic Tests (RDTs), the project has built a dynamic system to supervise providers and improve their performance to ensure they meet international standards of Quality of Care (QoC). Private provider behavior is regularly assessed by a team of quality assurance officers (QAOs), using an assessment checklist approved by the Ministry of Health and WHO. The checklist provides QAOs with an overall QoC score, based on a series of critical steps that providers need to complete, from evaluating danger signs to making correct treatment decision according to diagnostic test results, as well as providing counseling and follow-up care through a referral system. It is used not only to track progress over time and plan next assessment visits, but also to identify specific gaps that can be addressed during each assessment visit, or through refresher training. Early results from the project show that monitoring for performance improvement can be achieved in the private health sector, and that tailored support to private health providers ensures high level of quality of care. Since the beginning of the project in Madagascar, 60 private providers have been trained on the use of RDTs, representing over 9,000 fever cases managed at 52 private facilities between April and December 2014. During that time, testing rate increased from 69.2% to 92.7%. The overall QoC score rose from 38% in late 2014 to 71.4% in early 2015. This project represents the first time such a system has been set up to monitor performance in the private sector.

1348

DELIVERING SEASONAL MALARIA CHEMOPREVENTION TO CHILDREN UNDER TEN AT SCALE IN CENTRAL SENEGAL: COSTS AND COST DETERMINANTS

Catherine Pitt[1], Mouhamed Ndiaye[2], Lesong Conteh[3], Ousmane Sy[4], El Hadj Ba[1], Badara Cisse[1], Oumar Gaye[2], Jean Louis NDiaye[2], Paul J. Milligan[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Universite Cheikh Anta Diop, Dakar, Senegal, [3]Institute for Global Health Innovation, Imperial College London, London, United Kingdom, [4]Université Cheikh Anta Diop, Dakar, Senegal

The World Health Organization (WHO) recommends seasonal malaria chemoprevention (SMC) for children under 5 in areas of highly seasonal transmission. Extending the age range could protect older children. We analysed the incremental financial and economic costs of delivering SMC to 180,000 children aged 3 months to 10 years from a health service perspective in 2010, the third year of implementation in rural and semi-urban central Senegal. In addition to analysing project accounts, we prospectively collected data from a representative, systematic sample of 405 community health workers (CHWs); all 46 health posts; and all

four district headquarters by introducing questionnaires in advance and administering them after each of three monthly rounds of SMC. Key informant interviews were used to understand CHW opportunity costs and data sources were triangulated to arrive at best estimates. Coverage estimates reflect a comprehensive analysis of administrative records and a cross-sectional household survey. Increasing the age range for SMC from under-5s to under-10s virtually doubled the target population, however, it only increased the target number of households by 13%; high coverage was achieved in both groups. The financial cost over one malaria season at average monthly coverage of 90% was $234,462, $0.50 per monthly course administered, or $0.32 per resident (all ages) in the catchment area. The economic costs were 19% higher at $278,407 or $0.59 per course administered. The average cost per course administered varied widely between health posts, with the smallest incurring substantially higher costs. Key determinants of variation between health posts in the total and average costs of SMC delivery were analysed with ordinary least squares regression, but neither previous experience with SMC nor geographic variables were consistent determinants. At a financial cost per capita of 1% of Senegal's general government expenditure on health per capita, SMC may be affordable. Costs were lower than estimated and projected in previous, smaller studies conducted only in under-5s, indicating economies of scale and/or scope in an extended age range.

1349

IMPROVING TRAUMA CARE SYSTEMS IN EAST AFRICA: AVOIDING THE BANDAID APPROACH

Harvey Hawes, Andre Isaac, Abdullah Saleh, Jessica Hogan, Badeia Jawhari, Abraam Isaac

Innovative Canadians for Change, Edmonton, AB, Canada

Trauma is the leading cause of death in the first four decades of life worldwide, with an annual mortality rate higher than that of HIV, malaria, and TB combined. This burden falls disproportionately on Low Income Countries (LICs), where the rate of deaths secondary to trauma is the highest in the world. In LICs, there is severely limited access to adequate trauma care due to inconsistent quality of care, inappropriate distribution of resources, inadequate training, and poor infrastructure. Solutions to this problem must address multiple levels of a fragmented health system, rather than any one aspect alone. The Kenya Trauma and Injury Program (KTIP) is the Innovative Canadians for Change (ICChange) approach to addressing the burden of trauma in LICs. KTIP is working to develop and implement a national trauma framework and build the necessary administrative and technical capacity to train, implement, oversee, certify, and support selected existing and new infrastructure in all facets of trauma care in Kenya. The goal of KTIP is to collaborate with local experts to develop a thorough approach to trauma care, including preinjury policy work, prehospital, hospital, and rehabilitation services, which would be supported by a national trauma registry, trauma Geographic Information System (GIS) and trauma education systems such as Advanced Trauma Life Support (ATLS). Firstly, an assessment of the incident data of trauma regionally and nationally will improve the decision making of which sites on the GIS can act as a trauma "hub." Secondly, infrastructure and clinic readiness surveys will be done to gain a better understanding of the capacity and feasibility of bringing a facility to a standard that is adequate for essential trauma care. Incorporating a national trauma registry will increase understanding of the epidemiology of trauma, guide policy development and the monitoring and evaluation of interventions such as training of clinic staff in the handling of trauma on trauma morbidity and mortality outcomes. Using the model of KTIP, this presentation will explore the strengths, risks, and criticisms of innovative trauma care in East Africa.

1350

EVOLUTION AND FUNCTION OF THE DUAL-AFFINITY AMINO ACID TRANSPORTER, AASLIF IN *AEDES AEGYPTI*

Hitoshi Tsujimoto[1], Dmitri Y. Boudko[2], Immo A. Hansen[1]

[1]New Mexico State University, Las Cruces, NM, United States, [2]Rosalind Franklin University, North Chicago, IL, United States

Aedes aegypti is the major vector of dengue, yellow fever and Chikungunya viruses, which put hundreds of millions of people at risk each year in endemic areas. Blood feeding is required for both virus transmission and mosquito reproduction. Amino acid transporters play critical roles in sensing blood-meal nutrients and transporting building blocks for egg development. We analyzed the arrangement of SLC7-family transporter genes in ***Ae. aegypti*** genome and found that these genes are tightly clustered in a specific genomic region. Homology modeling revealed that putative substrate-interacting residues are strictly conserved among insect Slif orthologs. Electrophysiological studies uncovered that AaSlif is a dual-affinity amino acid transporter that functions in a sodium-dependent and -independent manner. This property allows AaSlif to function in a wide dynamic range of substrate concentrations (from micromolar to high milimolar for L-argenine) and allows mosquitoes to quickly react to varied nutritional environments they encounter during their life history. Our study shows that AaSlif is a high-value-target for the development of novel mosquito control strategies.

1351

EFFECTS OF DIAPAUSE ON THE EXCRETORY PHYSIOLOGY AND EXPRESSION OF AQUAPORINS IN THE WEST NILE VECTOR *CULEX PIPIENS*

Liu Yang[1], David L. Denlinger[2], Peter M. Piermarini[1]

[1]The Ohio State University, Wooster, OH, United States, [2]The Ohio State University, Columbus, OH, United States

The northern house mosquito ***Culex pipiens*** is the primary vector of West Nile Virus in North America. Only female adults survive winter in a dormant phase called diapause. Infected female mosquitoes can serve as reservoirs for the pathogens to overwinter, leading to potential disease outbreaks in the following spring. Desiccation is one of the biggest physiological challenges for insects that over-winter. A previous study found that diapausing ***C. pipiens*** conserve water by increasing the accumulation of cuticular lipids, thereby reducing evaporative water loss. However, it is not known if ***C. pipiens*** modulates its excretory system during diapause. My study aims to fill this gap of knowledge. Malpighian tubules (MTs) are the primary excretory tissues of insects. Water transport across MTs is mediated by a family of membrane-bound water channels called aquaporins (AQPs). I have measured the whole animal excretory capacity and mRNA levels of five AQP genes in diapausing (D) and non-diapausing (ND) mosquitoes. The D mosquitoes exhibit a significantly lower excretory capacity than ND mosquitoes. Moreover, the expression levels of some AQP mRNAs were significantly lower in D mosquitoes compared to ND mosquitoes. The results provide new insights into the molecular physiology of water balance in diapausing mosquitoes, and may also validate AQPs as targets for developing novel vector control methods that disrupt mosquito diapause and their transmission of pathogens.

1352

OXIDATIVE STRESS "MANAGEMENT" IS ESSENTIAL FOR *ANOPHELES* SURVIVAL POST *PLASMODIUM* INFECTED BLOOD MEAL INGESTION

Brian B. Tarimo

Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania

Anopheles mosquitoes like other dipterans lack the flavoenzyme glutathione reductase (GR) of the GSH pathway and therefore utilize

instead a Thioredoxin (Trx) system for "stress management". ***Anopheles gambiae*** and ***Anopheles*** stephensi mosquitoes have been shown to regulate proteins of the Trx system to protect midgut epithelial cells against reactive oxygen/nitrogen species (ROS/RNS) associated with ***Plasmodium berghei*** infection. However, this mosquito vector-parasite combination is not natural and may not necessarily reflect human malaria transmission biology in the field. Despite its importance, a complete understanding of the Trx pathway at the molecular level is missing. We used an ***ex vivo*** assay to examine the Trx response pathway following midgut exposure to ROS/RNS by measuring both protein and transcript expression levels of Thioredoxin-1 (AgTrx-1) by western blot analysis and qRT-PCR, respectively. We observed that protein levels of AgTrx-1 increase in midgut epithelial cells exposed to increased concentrations of a ROS inducer, tert-Butyl hydroperoxide, and transcript levels of AgTrx-1 and other genes of the Trx system were also up-regulated. Since it has been shown that ***P. berghei*** induces midgut cell damage in An. stephensi and An. gambiae, we anticipated the observed Trx pathway gene up-regulation at 24 hours post-infection with ***P. berghei***. We then compared this spectrum of responses to oxidative stress in a more natural vector-parasite combination of An. gambiae-***P. falciparum***. Transcriptomics and proteomics profiles were consistent with cells undergoing extensive redox regulation. Since it is known that ***P. falciparum*** does not induce marked midgut destruction in An. gambiae, these data suggest that ***An. gambiae*** must regulate ROS/RNS in response to an infected bloodmeal, that Trx system is crucial to this regulation, and that the cause of ROS/RNS is independent of midgut cell damage or apoptosis. We are now exploring approaches to perturb mosquito Trx regulation, which we predict will lead to unmanageable levels of ROS/RNS exposure to the parasite in the midgut, yet still allowing the mosquito to survive the dysregulation.

1353

A NOVEL SUPPLEMENT TO REDUCE *PLASMODIUM* DISEASE SEVERITY AND TRANSMISSION

Elizabeth Glennon[1], Derrick Hicks[1], Katayoon Dehesh[1], Bryan Greenhouse[2], Shirley Luckhart[1]

[1]University of California Davis, Davis, CA, United States, [2]University of California San Francisco, San Francisco, CA, United States

Nearly half of the world's population is at risk for malaria. Increased drug and insecticide resistance have demonstrated the need for novel methods of control, including treatments with dual therapeutic and transmission-blocking properties. We have established that a natural compound with roles metabolism and immunity in a wide variety of eukaryotes has significant therapeutic benefit in malaria. In our studies, oral supplementation of mice significantly reduced Plasmodium yoelii parasitemia and gametocytemia. Addition of the compound to Plasmodium falciparum-infected blood also reduced infection prevalence in exposed mosquitoes. Preliminary data indicate that this compound is perceived as a signal in the mosquito but not the parasite and thereby alters mosquito physiology to indirectly affect parasite development. Our data suggest that this natural compound affects the physiology of mammalian and mosquito hosts to reduce malaria parasite infection and transmission.

1354

MOSQUITOCIDAL PROPERTIES OF IGG AGAINST ESTABLISHED INSECTICIDE TARGETS IN THREE MOSQUITO DISEASE VECTORS

Jacob I. Meyers, Meg Gray, Brian D. Foy

Colorado State University, Fort Collins, CO, United States

Mosquito-borne diseases account for an estimated 1,434,000 deaths annually and 60,056,000 disability adjusted life years. The most successful strategy to control disease transmission is by targeting mosquito vectors through the use of chemical insecticides. As an alternative to chemical insecticides, we tested the effects of purified IgG against the extracellular domain of the glutamate-gated chloride channel (GluCl; the target of the insecticide ivermectin) on the survivorship of three mosquito disease vectors, ***Anopheles gambiae*** s.s., ***Aedes aegypti*** and ***Culex tarsalis***. Anti-AgGluCl IgG mixed in a single blood meal significantly reduced the survivorship of ***An. gambiae*** (LC_{50}=2.82mg/mL), as did serial blood feeds containing 1/10th of the LC_{50}. Anti-AgGluCl IgG blood meals did not affect the survivorship of ***A. aegypti*** or ***C. tarsalis***. However, injection of anti-AgGluCl IgG into the hemocoel equally reduced the survivorship of all three mosquitoes. Dot blot measurements of anti-AgGluCl IgG in the mosquito hemolymph following blood feeding revealed anti-AgGluCl IgG only in the hemolymph of ***An. gambiae***, suggesting that anti-AgGluCl IgG sensitivity requires antibody diffusion across the midgut. To analyze anti-AgGluCl IgG's mode of action, we fed ***An. gambiae*** blood meals containing both anti-AgGluCl IgG and ivermectin (IVM, GluCl agonist). Anti-AgGluCl IgG attenuated the mosquitocidal effects of IVM, suggesting that it acts as a GluCl antagonist. Our proof of concept showing the mosquitocidal properties of blood meals containing IgG against the target of IVM has prompted research into the mosquitocidal effects of IgGs against other insecticide targets. We have designed antibodies against the GABA-gated chloride channel (target of chlorinated cyclodienes) and the voltage-gated sodium channel (target of pyrethroids). Initial experiments suggest that blood meals containing IgGs against these insecticide targets also have mosquitocidal properties. Future studies will quantify the toxicity of these IgGs, both individually and in combination, as well as the mosquitocidal effects of blood meals taken directly from immunized cattle.

1355

IDENTIFYING SEMINAL PROTEINS THAT INDUCE REFRACTORY BEHAVIOR IN MATED *AEDES AEGYPTI* FEMALES

Susan M. Villarreal, Frank W. Avila, Mariana F. Wolfner, Laura C. Harrington

Cornell University, Ithaca, NY, United States

Mosquito mating biology has important consequences for vector-borne disease transmission and control. The transfer of male seminal fluid to female mosquitoes during mating initiates a suite of physiological and behavioral changes in the female. By understanding the molecules responsible for these changes in the mated female we can identify potential targets for novel control strategies of mosquitoes, such as the dengue vector ***Aedes aegypti***. Injecting female ***Ae. aegypti*** with a homogenate of male seminal fluid proteins, extracted from the accessory gland tissue, causes the female to lay eggs sooner, lay more eggs, take more blood meals, become refractory to mating and live longer than virgin females. We narrowed the range of refractory-behavior-inducing candidates in ***Ae. aegypti*** to select proteins ranging from 6-30 kDa. We present this work, as well as our studies using RNAi to assess the functional significance of individual candidate proteins on female refractory behavior.

1356

THE ROLE OF THE MOSQUITO IMMUNE SYSTEM AND PFS47 IN THE ADAPTATION OF *PLASMODIUM FALCIPARUM* TO DIFFERENT ANOPHELINE VECTORS

Alvaro Molina-Cruz

National Institutes of Health, Rockville, MD, United States

Plasmodium falciparum, the most fatal of the human malaria parasites, originated in Africa. It was dispersed relatively recently to other continents by humans, where it encountered diverse anopheline mosquito species. In order to obtain evidence of natural selection during the adaptation of ***P. falciparum*** to different vectors, we studied the compatibility between major malaria vectors from Africa (***Anopheles gambiae***), Southeast Asia (***A. dirus***) and the Americas (***A. albimanus***) with ***P. falciparum*** isolates collected in those regions. ***P. falciparum*** isolates from a given geographic region presented higher compatibility (i.e. higher infection intensity and

prevalence) with the anopheline of the same region, suggesting that *P. falciparum* underwent natural selection while adapting to different vectors. We tested the role that the mosquito immune system and the parasite gene Pfs47 may have had in the adaptation of *P. falciparum* to evolutionary distant anophelines. Disruption of the mosquito complement-like system by RNAi rescued infections in less compatible anopheline-parasite combinations. We have shown previously that *P. falciparum* can evade the complement-like system of some anophelines through its Pfs47 gene, which shows signatures of positive selection and a strong continent-level geographic population structure. Replacement of the Pfs47 haplotype in an African *P. falciparum* line with Pfs47 haplotypes that are frequent in other geographic regions was sufficient to change the compatibility of *P. falciparum* to evolutionarily diverse anopheline vectors by allowing the parasite to evade the mosquito complement-like system. The mosquito immune system appears to have been an important barrier for adaptation of *P. falciparum* to different anopheline species through selection of Pfs47, and this may have influenced the parasite's population structure and malaria epidemiology.

1357

DNA BARCODING OF ANOPHELINE MOSQUITOES FROM REMOTE MALARIA-ENDEMIC AREAS IN LORETO, NORTHERN PERUVIAN AMAZON

Yvonne-Marie Linton[1], Fanny Castro-Llanos[2], Marisa Lozano[2], Victor Lopez-Sifuentes[2], Karin Escobedo-Vargas[2], Carmen Flores-Mendoza[2], Edson Maguiña[2], Juan F. Sanchez[2], Craig Stoops[2], Frederick M. Stell[3], Andrés G. Lescano[2], **Gissella M. Vásquez**[2]

[1]Walter Reed Biosystematics Unit, Suitland, MD, United States, [2]U.S. Naval Medical Research Unit - 6, Callao 2, Peru, [3]Armed Forces Pest Management Board, Silver Spring, MD, United States

Loreto is the most affected malaria endemic region in Peru; yet studies characterizing *Anopheles* species in high incidence areas are limited. Thus, we collected anophelines in the highest malaria risk areas in Loreto from February-May 2014. *Anopheles darlingi* was the most abundant species (1,649 adults; 95%) in nine communities surveyed in eastern Loreto; yet it was completely absent in seven communities in western Loreto where *An. benarrochi* was the most abundant species (224 adults; 96%). To further confirm our taxonomical identification results, we compared the morphological identification of a subset of specimens with their differentiation based on mtDNA cytochrome C oxidase I (*COI*) barcode. We analyzed 222 specimens from eastern Loreto comprising 5 species (*An. darlingi*, *An.* nr. *forattinii*, *An. mattogrossensis*, *An. nuneztovari*, *An. oswaldoi* s.l.) and unidentified *Anopheles*; and 58 specimens from western Loreto identified as *An. benarrochi*. *COI* sequences were compared with expertly identified specimens in the Mosquito Barcoding Initiative databank (Barcode of Life Database). Almost all *An. darlingi* specimens (99%) were molecularly verified; only one specimen was identified as *An. dunhami*. All *An.* nr. *forattinii* were confirmed as *An. forattinii; An. mattogrossensis* specimens were identified as *An. mattogrossensis* 1 (20%) and *An. mattogrossensis* 2 (80%). *Anopheles nuneztovari* and *An. oswaldoi* s.l. were all identified as *An. dunhami* except for one *An. oswaldoi* s.l. specimen identified as *An*. sp. nr. *konderi*. Unidentified *Anopheles* specimens (45) comprised *An. darlingi* (71%), *An. dunhami* (11%), *An. forattinii* (11%), *An. mattogrossensis* 2 (4%) and *An. mattogrossensis* 1 (2%). All *An. benarrochi* were identified as *An. benarrochi* B. We report two new country records for *Anopheles* in Peru: *An. mattogrossensis* 1 and *An. mattogrossensis* 2. Our results corroborate that *An. darlingi* is the dominant anopheline species and primary malaria vector in eastern Loreto, yet not found in western Loreto where *An. benarrochi* B is dominant. *COI*-based DNA barcoding proved useful in verifying and discovering anopheline species in the Peruvian Amazon.

1358

SILENCING OF XANTHINE DEHYDROGENASE (XDH1) SEVERALLY AFFECTS THE SURVIVAL OF BLOOD-FED *AEDES AEGYPTI* MOSQUITOES

Natthida Petchampai[1], Jun Isoe[2], Yurika Isoe[2], Katrina Co[1], **Patricia Y. Scaraffia**[1]

[1]Tulane Unversity, New Orleans, LA, United States, [2]University of Arizona, Tucson, AZ, United States

Xanthine dehydrogenase (XDH) is involved in uric acid synthesis in mosquitoes. This nitrogen compound serves as a depot for excess ammonia produced during the digestion of blood meal. Uric acid can be excreted directly or metabolized to allantoin, allantoic acid and urea through an amphibian-like uricolytic pathway. Surprisingly, we have recently observed that mosquitoes with alanine aminotransferase deficiency increase XDH1 transcript levels in mosquito tissues, and store provisionally high uric acid concentrations in the midgut as a strategy for survival. To better understand this metabolic regulation, we began to explore the effect of XDH disruption in *A. aegypti*. Two genes encoding XDH (XDH1 and XDH2) are present in the genome of *A. aegypti.* We analyzed XDH1 and XDH2 gene and protein expression by qRT-PCR and western blotting analysis in tissues from sugar- and blood-fed females. A differential XDH1 and XDH2 gene and protein expression was observed in mosquito tissues dissected during a time course. Next, we exposed females to blood meals supplemented with high doses of allopurinol. The effect of injecting dsRNA against XDH1 or XDH2 was also evaluated. The disruption of XDH by high allopurinol concentrations, as well as the silencing of XDH1 by RNAi caused a high mortality in *A. aegyti*. However, no mortality was registered in those blood-fed mosquitoes injected with dsRNA against XDH2 when compared with dsRNA-firefly luciferase-injected control. Surviving mosquitoes treated with allopurinol or injected with dsRNA-XDH1 showed a significant disruption in blood digestion, excretion and reproduction. Western blotting analysis indicated that surviving dsRNA-XDH1-injected mosquitoes showed a persistence of the major serine proteases in the midgut at 48 h after blood feeding and a significantly reduction in the uptake of vitellogenin by the ovaries of females with XDH1 deficiency. These data demonstrate that XDH1 plays a critical role during blood meal digestion and that nitrogen metabolism in blood-fed mosquitoes is much more complex than previously thought.

1359

AUTOPHAGY AS A FACTOR FOR DENGUE INFECTION IN THE VECTOR MOSQUITO, *AEDES AEGYPTI*

Matthew W. Eng, David W. Severson

University of Notre Dame, Notre Dame, IN, United States

The *Aedes aegypti* mosquito is the primary vector for transmitting dengue virus (DENV). DENV causes dengue fever, resulting in over 500,000 hospitalizations people worldwide annually. Programmed cell death (PCD) is often induced in virus-infected cells to limit infection in the host. In *Ae. aegypti*, PCD is activated by an initiator caspase, Dronc, which cleaves and activates other caspases including Casps7, responsible for activation of targets further downstream. However, our previous study found that upon knockdown of *Dronc*, DENV-refractory females showed decreased disseminated infection, and in those mosquitoes infected, lower titers of DENV-2. Further analysis revealed that Dronc also has a novel role in controlling a cellular recycling process, known as autophagy. During this process, the autophagy-related protein 8 (ATG8) is lipidated to double-membrane vesicles, known as autophagosomes. These vesicles surround cellular cargo and then fuse with lysosomes to degrade any contents. Using western blot analysis, we observed upregulation and lipidation of ATG8 following a blood meal, not only in fat body as previously shown, but also in midgut tissue. DENV must infect the midgut epithelium to become transmissible. Silencing *Dronc* and *Casps7*, resulted in decreased activation and lipidation of ATG8, suggesting that these caspases can control autophagy. Furthermore, to determine whether autophagy was

crucial to DENV-2 infection, we silenced several ATG genes involved in initiation and progression of autophagy. Preliminary silencing showed decreased levels of DENV genomic RNA detectable by qPCR, suggesting autophagy may influence DENV-2 infection. We also begin evaluation of the potential for this pathway to be targeted by chemical inhibition in order to inhibit DENV infection of the vector host.

1360

PROTEOMIC ANALYSIS OF MOSQUITO BLOOD CELLS REVEALS DISTINCT PHAGOCYTIC HEMOCYTE PROFILES AND IMMUNE ACTIVATION IN THE ABSENCE OF PARASITE CHALLENGE

Ryan C. Smith[1], Jonas G. King[1], Dingyin Tao[1], Oana A. Temescu[2], Clara Brando[1], Gerhard Thallinger[2], Rhoel R. Dinglasan[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Graz University of Technology, Graz, Austria

Insect blood cells (or hemocytes) are essential components of the innate immune response. Implicated in both cellular and humoral responses, hemocytes mediate pathogen clearance by phagocytosis or encapsulation and are responsible for the production of soluble immune factors. In addition, recent evidence suggests that hemocytes play critical roles in malaria parasite survival. However, despite their importance, critical aspects of their biology in mosquitoes remain uncharacterized. Using a novel method of enrichment, we isolated the phagocytic subset of hemocytes known as granulocytes (phagocytes) in the African malaria vector, ***Anopheles gambiae***, and quantified their proteomic profiles during homeostasis, blood-feeding, and following malaria parasite challenge. Integrating existing hemocyte transcriptional profiles, we demonstrate a high degree of similarity between our proteomic data and provide new information regarding hemocyte gene regulation. We observe that phagocytosis, blood-feeding, and ***Plasmodium falciparum*** infection promote dramatic shifts in phagocytic granulocyte protein expression indicative of changes in feeding status, cellular proliferation, and innate immune response priming. Of interest, we identified large numbers of hemocyte immune proteins induced in response to blood feeding alone, suggesting that these phagocytic blood cells may play an integral role in immune priming prior to pathogen challenge. Current experiments aim to address the role of candidate genes in blood cell proliferation/differentiation and ***Plasmodium*** development using dsRNA-mediated silencing. Together, these data provide a rich resource for hemocyte biology in ***An. gambiae*** and provide new insight into their biological roles that will serve as a foundation for their future study.

1361

DISSECTING THE ROLE OF MALE ACCESSORY GLAND TRANSCRIPTION FACTORS IN SHAPING THE REPRODUCTIVE SUCCESS OF *ANOPHELES GAMBIAE*

Enzo Mameli[1], Paolo Gabrieli[2], Adam South[3], Matthew J. Peirce[1], Flaminia Catteruccia[3]

[1]University of Perugia, Perugia, Italy, [2]University of Pavia, Pavia, Italy, [3]Harvard T.H. Chan School of Public Health, Boston, MA, United States

In the fight against malaria, control strategies aimed at inducing sexual sterility in ***Anopheles*** populations are an attractive alternative to the use of insecticides due to evolution of resistance in mosquitoes. However, the development of these strategies is hampered by a profound lack of knowledge regarding many elements of ***Anopheles*** mating ecology. During mating in ***An. gambiae***, males synthesize a gelatinous, rod-shaped mating plug in their reproductive accessory glands (MAGs) that contains a complex cocktail of seminal fluid proteins, steroid hormones and lipids. Female receipt of this plug induces a suite of physiological and behavioral changes including increased oogenesis, stimulation of oviposition and refractoriness to further mating attempts. While our lab group has recently demonstrated that these changes are mediated in part by the steroid hormone 20-hydroxyecdysone, the role of additional ejaculate components in activating this female post mating response (PMR) remains largely unknown. Here we present evidence suggesting that highly expressed MAG transcription factors (TF) are a critical part of female PMR. Given their regulatory role in the complex protein expression network of MAGs, the targeting of TFs allows for a simplified identification of candidate genes critical for ***An. gambiae*** reproductive success. To determine the role these TFs play, we targeted them in males via RNAi mediated knockdown, and looked for post mating reproductive phenotypes in mated females. Compared to their counterparts mated to controls, females mated to TF knockdown males experienced a significant increase in egg infertility. Interestingly, this increase in infertility did not emerge until the second gonotrophic cycle, suggesting a possible time dependent impairment of sperm activation/storage mechanisms due to TF mediated alterations of male ejaculate components. Further characterization of this striking phenotype through transcriptional and morphological analyses is ongoing. This work represents a first step into identifying additional ejaculate components underlying the reproductive fitness of a major disease vector.

1362

HEMOLYSIN GENE EXPRESSION UNDER VARIABLE IRON REGIMES OF *ELIZABETHKINGIA ANOPHELIS*, A COMMENSAL BACTERIUM OF THE *ANOPHELES* MIDGUT

Shicheng Chen, Edward D. Walker

Michigan State University, East Lansing, MI, United States

Elizabethkingia anophelis predominates in the bacterial community in the ***Anopheles*** mosquito midgut and its presence may influence important mosquito physiological processes. Owing to hemolytic activity, ***E. anophelis*** may participate in erythrocytic lysis in in the mosquito midgut. The highly variable mosquito midgut conditions, particularly extreme fluxes in iron concentration and temperature before and after a blood meal, require that ***E. anophelis*** withstand stresses and efficiently regulate gene expression. However, iron uptake mechanisms such as sense and scavenge iron processes in this species and other related bacteria in the phylum Bacteroidetes are poorly known. Therefore, we investigated responses of ***E. anophelis*** responses to environmental iron status and explored the molecular mechanisms that these bacteria utilize to cope with iron alternation using high throughput, deep sequencing of mRNA transcripts (RNAseq). The differential regulated genes under low and high iron were analyzed and compared. A sensitive reporter analysis based on NanoLuc was utilized for studying representative gene regulation (such as hemolysins). Expression of hemolysin genes was significantly repressed when ***E. anophelis*** was grown under the iron-replete and high temperature (37 degrees C). ***E. anophelis*** cells increased more than three-fold in blood-fed mosquito than those in sucrose-fed ones. Furthermore, the hemolysin gene expression was down-regulated by the blood meal, indicating that it was actively involved in erythrocyte lysis ***in vivo***. Our results provide new insights into how ***E. anophelis*** responds and adapts to the midgut environment and reveals new functions impacting its mosquito host.

1363

GENES ASSOCIATED WITH REFRACTORINESS OR SUSCEPTIBILITY TO DENGUE-2 VIRUS INFECTION IN *AEDES AEGYPTI* FROM COLOMBIA, USING COMPARATIVE MICROARRAY-BASED ANALYSIS

Paola A. Caicedo Burbano[1], Carl Lowenberger[2], George Dimopoulos[3], Idalba M. Serrato[1], Yenifer Orobio[1], Neal Alexander[1], Clara B. Ocampo[1]

[1]Centro Internacional de Entrenamiento e Investigaciones Médicas-CIDIEM, Cali, Colombia, [2]Simon Fraser University, Vancouver, BC, Canada, [3]Johns Hopkins University, Baltimore, MD, United States

In recent years there has been considerable progress in our knowledge of dengue, particularly in vaccine development, the characterization of the immune responses and molecular properties of the virus. However, there are still many aspects that must be investigated in terms of its transmission by the principal vector, ***Aedes aegypti***. We have elucidates Dengue virus-vector relationships, specifically the innate immune response of ***A. aegypti*** to dengue virus infection. For this, we identified and selected two strains of ***A. aegypti***, from Cali, Colombia with different susceptibility to dengue infection: Susceptible (Cali-S, 96%) and refractory with midgut infection barrier (Cali-MIB, 50%).We used micro arrays to compare the global gene expression of the midguts of Cali-S and Cali-MIB after ingestion of sugar, a bloodmeal, or a bloodmeal containing Dengue-2 virus. A total expression of 3761 genes were observed. A differential expression between the two strains exposed to DENv-2 included genes in different functional groups: immunity, metabolism, proteolysis, redox, replication, transport, and unknown function. We have selected 12 genes to evaluate their differential expression at different time points (0, 8, 24, 36 and 48h) by qPCR. The qPCR analysis confirmed the predominance of down regulated genes in Cali-MIB in comparison with Cali-S strain, observed in the microarray at 30 hours post infection (h.p.i). However, early in the infection (at 0, 8 and 24 h.p.i), several of this genes were up regulated suggesting an early response to eliminate the virus in refractory strain. Finally, we used RNAi assays to evaluated the role of 4 genes from 12 selected before (Gram Negative Binding Protein-GNBP (AAEL009176), Niemann-Pick Type C-2 (AAEL015136), Galectin (AAEL009842) and Cathepsin-b (AAEL007585)) in DENv infection. We observed that the silencing of down regulated genes, GNBP, Cathepsin-b and Galectin, changed the phenotype of Cali-S strain from 96% to 8, 20 and 12% respectively. The up regulated gene, Niemann, changed the phenotype of Cali-BIM strain from 50% to 18%. This study validate the use of our field derived strains as a biological model.

TARGETED DELIVERY OF MOLECULAR CARGO INTO THE MOSQUITO GERMLINE

Duverney Chaverra-Rodriguez[1], Grant L. Hughes[2], Yasutsugu Suzuki[1], David Peterson[1], Jason L. Rasgon[1]

[1]Pennsylvania State University, University Park, PA, United States, [2]University of Texas Medical Branch, Galveston, TX, United States

Genetic manipulation is a powerful technique for addressing research questions in arthropods of medical importance. Current approaches rely upon delivering DNA or endonucleases to preblastoderm embryos via embryonic microinjection. However, embryonic microinjection is technically challenging, is limited to a small number of arthropod taxa, and is inefficient even in optimized species. As such, there is a critical need to develop methods for arthropod genetic manipulation that are simple, accessible for many researchers and generally compatible for a large variety of arthropod species. During oogenesis, insects transfer molecules to developing oocytes by receptor-mediated endocytosis (RME). We are developing tools exploiting this phenomenon to specifically target DNA and protein cargo into the mosquito germline for heritable modification of the chromosomal genetic sequence. We will discuss progress in optimizing this technique and in transferring the technology to multiple mosquito species.

1365

STIMULATION OF A SERINE PROTEASE TARGETING THE LRIM1/APL1C COMPLEX REVEALS SPECIFICITY IN COMPLEMENT-LIKE PATHWAY ACTIVATION IN *ANOPHELES GAMBIAE*

Michael Povelones[1], Katie V. Farrant[2], George K. Christophides[2]

[1]University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA, United States, [2]Imperial College London, London, United Kingdom

The complement-like pathway of the African malaria mosquito ***Anopheles gambiae*** provides protection against infection by diverse pathogens including bacteria, fungi, and rodent and human malaria parasites. Detailed analysis of complement activation in response to the Gram-negative bacterium ***Escherichia coli*** and ***Plasmodium*** showed that activation of the complement-like pathway is triggered by protein complex containing $TEP1_{cut}$, a processed form of the C3-like protein TEP1, and the leucine-rich repeat proteins LRIM1 and APL1C. Binding of $TEP1_{cut}$ results in the activation of a TEP1 convertase through the recruitment of a non-catalytic serine protease SPCLIP1. It is unknown how other pathogens are recognized by the mosquito's immune responses and if activation of the TEP1 convertase is a general requirement for eliminating all infections. In this study, biochemical and functional assays were performed to analyze the complement-like pathway responses to the Gram-positive bacterium ***Staphyloccocus aureus***. Western blot analysis revealed that like ***E. coli***, ***S. aureus*** also activates the TEP1 convertase. However, striking differences in the initial immune reactions promoted by the different Gram type bacteria were observed. In particular, it was found that ***E. coli*** specifically activates a protease that cleaves the C-terminus of APL1C. This study shows initial pathogen-specific reactions in the mosquito complement-like pathway. These unique responses converge on the same core mechanism involving the TEP1 convertase triggering pathogen neutralization.

1366

EVALUATION OF INNATE IMMUNE RESPONSE MECHANISMS ASSOCIATED WITH SUSCEPTIBILITY TO DENGUE VIRUS IN DIFFERENT FIELD POPULATIONS OF *AEDES AEGYPTI*

Idalba M. Serrato[1], Paola A. Caicedo burbano[1], Yenifer Orobio[1], Carl Lowenberger[2], **Clara B. Ocampo**[1]

[1]CIDEIM, Cali, Colombia, [2]Simon Fraser University, Vancouver, BC, Canada

Dengue is an infectious viral disease transmitted by mosquito vectors, for which there is no available vaccine or specific medical treatment. The main vector of dengue virus (vD) is ***Aedes aegypti***, a mosquito species extremely well adapted to the human urban environment. The ability of ***Ae. aegypti*** populations to become infected and transmit the virus (vector competence-VC) varies among populations and depends on genetic and environmental characteristics. Understanding the genetic basis of VC may help to identify potential targets and strategies to inhibit virus replication and transmission. Preliminary studies on differential expression in D-2 selected strains from field collected individuals in Cali, susceptible (Cali-S) and refractory (Cali-MIB), suggest that immune response genes associated with apoptosis play a role in the virus replication. This study evaluated if VC of the select strains is similar compared to the other serotypes. And assessed if the molecular mechanisms identified in select strains are a characteristic of field populations. The VC of the selected strains compared to the 4 virus serotypes was measured by artificial infection and immunofluorescence. The VC of ***Ae. aegypti*** collected from 6 locations in Cali was measured to D-2. Populations with different VC were selected to evaluate the expression by qPCR of Dronc, Caspase-16, Cathepsin-B and Niemann genes at 0, 24, 36, 48h post-infection. No statistically significant differences in the VC of the selected strains against the four serotypes

were observed. The mosquitoes collected in Cali showed differences on VC . Differential expression of the evaluated genes were observed among the evaluated times. The most refractory strain showed significant differences in gene expression between the treatments blood Vs blood +virus especially in Caspase -16.

1367

BASELINE SUSCEPTIBILITY OF *LUTZOMYIA VERRUCARUM* COLLECTED IN ANCASH, PERU TO THREE CLASSES OF INSECTICIDES BY CDC BOTTLE BIOASSAY

Carmen Flores-Mendoza[1], Nelson Solorzano[2], Gissella Vasquez[1], Craig Stoops[1], Frederick Stell[1]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]Universidad San Pedro, Ancash, Peru

Lutzomyia verrucarum is a vector of cutaneous leishmaniasis and bartonellosis in the Peruvian Andes. Since no effective vaccines exist for either disease, reduction of the burden of these diseases is accomplished through sand fly vector control using insecticides applied by thermal fog or Indoor Residual Spraying; however, there is no knowledge of susceptibility of sand flies, including ***Lu. verrucarum***, to commonly-used insecticides in Peru. The objective of this study was to determine the baseline susceptibility of ***Lu. verrucarum*** to three classes of insecticides using the CDC bottle bioassay method. Sand flies were manually collected with mouth aspirators in resting sites in Huichi and Choquechaca (Caraz, Peru) where bartonellosis and cutaneous leishmaniasis are endemic. Field-collected ***Lu. verrucarum*** adults were transferred live to the insectary; blood meals were provided to unengorged females using membrane feeding. Wild and artificially fed, blood-engorged females were individually placed into oviposition containers to obtain F1 progeny. Unfed, 3-5 day-old F1 and wild adult females were assayed with these three classes of technical-grade insecticides diluted in 100% ethanol: two pyrethroids, one organophosphate, and one organochlorine. On average, 23 females/bottle were tested and a minimum of three replicates/insecticide were performed. Diagnostic dosages (µg) standardized for ***Aedes aegypti*** by CDC (2010) were adapted for sand flies. Mortality was 99% for wild females from Huichi for deltamethrin (10 µg/40 min), permethrin (15 µg/30 min), fenitrothion (50 µg/40 min), and DDT (75 µg/30 min). For wild and F1 females from Choquechaca, mortality was 99% percent for deltamethrin (10 µg/30 min), permethrin (15 µg/30 min), fenitrothion (50 µg/40 min), and DDT (75 µg/30 min). Sand flies from both field sites in were susceptible to the three classes of insecticides tested, information which is critical to establish baseline insecticide susceptibility for management of ***Lu. verrucarum*** in this region. Our results show that the CDC bottle bioassay is a useful method to establish baseline insecticide susceptibility in sand flies in Peru

EFFECT OF SPATIAL REPELLENTS ON DENGUE VECTOR ATTRACTANCY BEHAVIOR

Diane B. Choi, Nicole L. Achee, John P. Grieco

University of Notre Dame, Notre Dame, IN, United States

The ***Aedes aegypti*** mosquito is considered to be the principal vector of Dengue virus (DENV), which causes dengue fever, an arthropod-borne disease of global burden with incidence growing to estimates of approximately 50-100 million infections worldwide annually. Similarly, the expansion of ***Aedes albopictus*** has increased the risk of both DENV and Chikungunya transmission in temperate zones. Although efforts are underway for development of a DENV vaccine, current prevention relies on vector control through use of indoor and outdoor application of insecticides, specifically pyrethroids, through fogging and/or spray applications. However, pyrethroids that are characterized as spatial repellents – those that are highly volatile at ambient temperatures – have received interest as a novel delivery system for adult vector control. Understanding the behavioral effects these volatile pyrethroids have on target mosquito species will be critical to understanding the overall impact on vector populations and therefore expectations of efficacy against DENV transmission. This includes attraction to oviposition sites, which will influence next generation population densities. A significant decrease in ***Aedes spp.*** attractancy to potential oviposition sites after repellent exposure would indicate that there is considerable probability of impacting the overall vector population, human-mosquito contact and DENV transmission over time. This study quantified baseline levels of gravid ***Ae. aegypti and Ae. albopictus*** attractancy to oviposition containers in the laboratory using a 'sticky-screen' bioassay and established bacterial infusions, then repeated experiments following exposure of test cohorts to the volatile pyrethroid transfluthrin – a chemical widely used in mosquito coils and other household control products. Findings from this study will be used to begin defining implications of using spatial repellents for broader vector population effects.

1369

QUANTIFYING LLIN BIOEFFICACY: CAN COLORIMETRIC FIELD TEST (CFT) REPLACE THE WHO CONE BIOASSAY TEST?

Judith Hedje[1], Sanjiarizaha Randriamaherijaona[2], Sebastien Boyer[2], Annett H. Cotte[1], Sixte Zigirumugabe[3], Mike Green[1], Ray Beach[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Institut Pasteur Madagascar, Antananarivo, Madagascar, [3]United States Agency for International Development, Antananarivo, Madagascar

Under normal use, long-lasting insecticidal (mosquito) nets (LLIN) are expected to last up to three to five years. This is now recognized as an estimate since significant variation in durability has been observed. Programs implementing LLIN interventions are encouraged to conduct field monitoring of indicators such as LLIN survival, LLIN fabric integrity and LLIN insecticidal activity or bio-efficacy, to assess the actual rate of LLIN durability following distribution and use. World Health Organization (WHO) guidance recommends the use of a bioassay, the WHO cone test, to monitor bio-efficacy of the insecticide on LLINs. However, cone test accuracy depends on the capacity to routinely produce a high number of physiologically-uniform and insecticide-susceptible female mosquitoes, a challenging task. A non-mosquito alternative for measuring insecticide levels on the surface of a net is desirable. One possibility is the Colorimetric Field Test (CFT), a chemical method to estimate surface concentration of deltamethrin insecticide on LLINs. We used the CFT on 21 LLINs collected from the field in Madagascar, and compared results with standard cone test outcomes (five cone test positions / LLIN tested). By comparing classical bioassay and CFT results, we determined that CFT can distinguish between a LLIN with 'acceptable bio-efficacy' based on cone test criteria (mosquito mortality > 80%) and a LLIN scored as 'not acceptable' (mortality <80%). Using a CFT cut off value of 0.35 µg / sample (equivalent to 14% of deltamethrin content of a new net with a concentration of 55 mg/m2) we were able to correctly predict the WHO cone test results for 20/21 LLINs included in the comparison. Test accuracy was evaluated using Receiver Operating Characteristic (ROC) curve analysis. The area under the ROC curve was 0.954 and assay sensitivity and specificity were 0.92 and 1.00 respectively, indicating the CFT to be an excellent predictor of LLIN insecticidal content. We believe that the CFT is an easier and more economical option for programs seeking to monitor LLIN insecticidal activity loss as it allows for a larger number of nets to be tested using lower testing costs.

1370

INDOOR RESIDUAL SPRAYING (IRS) OF CLOTHIANIDIN IN COMBINATION WITH DELTAMETHRIN OR ALONE FOR THE CONTROL OF PYRETHROID-RESISTANT *ANOPHELES GAMBIAE* IN EXPERIMENTAL HUTS IN BENIN AND CÔTE D'IVOIRE

Raphael N'Guessan[1], Augustin Fongnikin[2], Ludovic Ahoua Alou[3], Corine Ngufor[1], Karin Horn[4], Mark Rowland[1], Alphonsine A. Koffi[3]

[1]Disease Control Department, London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, [3]Institut Pierre Richet, Bouake, Côte D'Ivoire, [4]Bayer CropScience AG, Monheim, Germany

One way to manage pyrethroid resistance in malaria vectors is to combine insecticides with unrelated modes of action so that insects resistant to one insecticide will succumb to the other. For IRS, identifying residual insecticides that can cover long transmission seasons from a single application is a research priority. The neonicotinoid, clothianidin represents a class of chemistry new to public health. IRS with Clothianidin alone or in a mixture with deltamethrin was evaluated in experimental huts in Benin and Côte d'Ivoire where ***Anopheles gambiae*** populations are resistant to pyrethroids. Monthly bioassays were carried out on substrates of mud, cement and plywood. On top of immediate mortality, clothianidin induced delayed mortality ***of An. gambiae;*** taking up to 120 hours to show full effect. Mortality among mosquitoes entering huts in Benin was 37% after 24h but reached 91% after 120h. Clothianidin applied alone or in mixture with deltamethrin gave high mortality (>80%) of resistant ***An. gambiae*** for ~9 months in cement and mud huts in Benin but produced marginal control (<40%) of pyrethroid-resistant ***An. gambiae*** in Côte d'Ivoire. In both areas, deltamethrin alone failed to achieve control of ***Anopheles*** mosquitoes entering the huts. Cone bioassays showed improved residual activity of the mixture over either insecticide applied alone in Côte d'Ivoire: the mixture killed >95% of both susceptible and resistant ***An. gambiae*** over 10 months whereas a drop below the WHO threshold (80% mortality) was observed just 2 months post spray with the single components. The differences between cone assay and hut observations will be subject for further investigation. Clothianidin shows promise as a new mode of action for malaria vector control when delayed mortality effects are taken into account. A mixture of clothianidin with deltamethrin showed very good activity in standard WHO Cone bioassays independent of any delayed mortality effects. The introduction of this new mode of action could be a timely addition to the limited portfolio of IRS insecticides.

1371

THE EFFICACY OF CHLORFENAPYR, DELIVERED AS A LONG-LASTING INDOOR RESIDUAL SPRAY, AGAINST PYRETHROID-RESISTANT *ANOPHELES ARABIENSIS* IN NORTHERN TANZANIA

Matthew J. Kirby[1], Jovin Kitau[2], Chacha Mataro[2], Franklin Mosha[2], Mark Rowland[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania

There is an urgent need for insecticides with novel properties and modes of action to combat pyrethroid-resistant mosquitoes. Additionally, there is a serious shortage of insecticides for indoor residual spraying that have a duration of effective action of 6 months or greater. Chlorfenapyr (CFP) is a pyrrole insecticide, which unlike neurotoxic pyrethroids, has a distinct mode of action targeting oxidative pathways in insect mitochondria and disrupting cellular respiration. Highly stable CFP formulations have been developed with an anticipated duration of efficacy of at least 6 months. In a succession of experimental hut trials and complementary laboratory bioassays the duration of the bioefficacy of CFP was assessed on both concrete and plywood-treated surfaces, and contrasted with the performance of a commercial formulation of Alphacypermethrin. Whilst the hut trials are on-going, at 3 months the mortality of unfed ***An. arabiensis*** caught from the CFP-sprayed hut is >80% 72h post-exposure, and in the laboratory the same level of mortality is observed after 6 months for several different CFP formulations. The results of the hut trials at 9 months will be presented and interpreted in the context of the distinctive house-entering, resting and exiting behaviour (and therefore insecticide exposure time) of ***An. arabiensis*** in the area.

1372

HIGH LEVELS OF *ANOPHELES GAMBIAE* S.L. RESISTANCE TO PYRETHROIDS, DDT AND MALATHION AND INDICATIONS OF REDUCED SUSCEPTIBILITY TO CARBAMATES IN OROMIA REGION - ETHIOPIA

Dereje Dengela[1], Alemayehu Getachew Tesfaye[2], Gedeon Yohannes Anshebo[1], Lena Kolyada[1], Christen Fornadel[3], Kristen George[3], Gunawardena Dissanayake[4], Sheleme Chibsa[4], Yemane Yeebiyo[2]

[1]Abt Associates Inc, Bethesda, MD, United States, [2]Abt Associates Inc, Addis Ababa, Ethiopia, [3]U.S. President's Malaria Initiative, United States Agency for International Development, Arlington, VA, United States, [4]U.S. President's Malaria Initiative, United States Agency for International Development, Addis Ababa, Ethiopia

The insecticide susceptibility status of ***Anopheles gambiae*** s.l. (presumably ***An. arabiensis,*** the major malaria vector in Ethiopia) was assessed in 8 in Oromia region where indoor residual spraying (IRS) operations are supported by the President's Malaria Initiative. Mosquitoes were exposed to diagnostic dosages of DDT, deltamethrin, lambda-cyhalothrin, permethrin, alpha-cypermethrin, etofenprox, fenitrothion, pirimiphos-methyl, malathion, bendiocarb and propoxur using the standard WHO tube tests. Tests were conducted on 2- to 3-day-old, non-blood fed, adult female mosquitoes reared from larvae and pupae collected from different breeding habitats. Based on the mortality counts after a 24-hour holding period, the vector population was classified as susceptible, possibly resistant or resistant to an insecticide following the WHO criteria. Resistance to DDT (3-16% mortality), deltamethrin (12-51%), lambda-cyhalothrin (4.3-25.7%), permethrin (2.9-66%), alpha-cypermethrin (5-61%), etofenprox (8.7-55%), and malathion (26-93.7%) was reported in all eight sites. The vector was susceptible to bendiocarb in 7 of 8 sites and resistant in one site (mortality 87%). Propoxur resistance was also recorded in one site with a 75% mortality rate. The mortality rate to fenitrothion was 97% (possible resistance) in one site and ranged from 98 to 100% (susceptible) in the remaining sites. ***An. gambiae*** s.l. from all eight sites were susceptible to pirimiphos-methyl with a mortality rate of 100%. The findings of the study show that (1) the Ethiopian IRS program now has limited options of insecticides for public health use; (2) rational use of available insecticides and implementation of an appropriate insecticide resistance management strategy is critical; (3) a strong system for monitoring vector resistance to the insecticides in use should be part of the vector control program. The information generated from this study will contribute to the development of an insecticide management strategy and selection of alternative options for the Ethiopian IRS program. Overall, the study indicates that new insecticides are urgently needed for IRS.

1373

INCREASE LEVEL OF PYRETHROID AND DDT RESISTANCE IN THE MAJOR MALARIA VECTOR *ANOPHELES FUNESTUS* IN NORTHERN SENEGAL

Badara Samb[1], Jacob M. Riveron[2], Lassana Konate[1], Ousmane Faye[1], Charles S. Wondji[2]

[1]Laboratoire d'Ecologie Vectorielle et Parasitaire, Département de Biologie Animale, Université Cheikh Anta Diop de Dakar, Dakar, Senegal, [2]Vector Biology Department, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Insecticide resistance in ***Anopheles funestus***, one of the main malaria vectors, is threatening malaria control in Africa, notably in Senegal. Evaluation of the resistance profile and the mechanisms implicated are crucial to implement suitable resistance management strategies. Here, we explored the dynamic and evolution of insecticide resistance profile of ***Anopheles funestus*** populations in Northern Senegal and investigated the molecular basis of resistance observed. Insecticide susceptibility assays were carried out using 2-5 day old F1 adults generated from indoor-collected blood-fed female of ***An. funestus*** from Northern Senegal in 2014 and compared to 2011 samples. WHO bioassays revealed an increased level of pyrethroid and DDT resistance in ***Anopheles funestus*** population in 2014 with mortality to permethrin and DDT of 68.75% and 62% respectively compared to 91.19% and 83.36% in 2011. In addition, insecticide resistance was also observed to lambdacyhalothrin (89.82% mortality) and deltamethrin (88.23% mortality). However, this population remains fully susceptible to bendiocarb, dieldrin and malathion. Our results also show a reduced efficacy of the insecticide-treated bed net Permanet 2.0 (76%) on this ***An. funestus*** population whereas full efficacy was observed with Net Permanet 3.0, Olyset Net and Olyset Plus. The synergist assay with PBO suggests that while the cytochrome P450s genes have little involvement in DDT resistance they play the major role in the pyrethroid resistance, as a full recovery of susceptibility was observed after PBO pre-exposure. The increase level of pyrethroid and DDT resistance in Senegalese ***An. funestus*** populations represents a challenge to the control of this vector. However, the observed carbamate and organophosphate susceptibility offers alternative solutions for resistance management. Further molecular characterizations are on going to characterise the molecular mechanisms driving this increased resistance.

1374

EFFICACY OF A PYRIPROXYFEN-AUTODISSEMINATION STATION AGAINST *AEDES ALBOPICTUS* IN RESIDENTIAL AREAS

Devi Suman[1], Yi Wang[1], Kshitij Chandel[1], Isik Unlu[2], Gregory M. Williams[3], Randy Gaugler[1]

[1]Rutgers University, New Brunswick, NJ, United States, [2]Mercer County Mosquito Control, West Trenton, NJ, United States, [3]Hudson County Mosquito Control, Secaucus, NJ, United States

The Asian tiger mosquito, ***Aedes albopictus,*** is an anthropophilic mosquito transmitting chikungunya and dengue. Suppression of ***Ae. albopictus*** populations is a challenge for mosquito control programs because immatures are found in numerous peridomestic artificial containers that are difficult to detect, access, and eliminate. ***Ae. albopictus*** uses cryptic habitats such as corrugated extension gutters, fence pots etc. as larval habitats, which are nearly invulnerable to penetrating by conventional pesticide spray. Our study was assessed the effectiveness of autodissemination stations to target the ***Ae. albopictus*** larval habitats in urban areas. This pull-and-push technology attracts gravid females to autodissemination stations, contaminates them with pyriproxyfen (juvenile hormone analogue), and disseminate the insect growth regulator to larval habitats using skip oviposition behavior. We assessed station efficacy in residential hot spots of ***Ae. albopictus***. Four treatment and four control plots (~ 3 acres each site) with >5 adult mosquitoes per BGS trap (hot spot) were selected for seasonal efficacy of the stations. Autodissemination stations were deployed in treatment plots for 8-12 weeks. Population density of eggs, larvae and adults of ***Ae. albopictus*** in controls and treatment areas were compared to assess the effect. Pupal mortality in the field samples assessed with 3rd instar ***Ae. albopictus*** bioassay were considered as another efficacy parameter. The findings may be helpful to develop a better management approach against container inhabiting mosquitoes.

1375

SMARTPATCHES: EXPLOITING MOSQUITO BEHAVIOR TO BUILD A BETTER BED NET

Eleanore Sternberg, Matthew Thomas

Pennsylvania State University, University Park, PA, United States

When used correctly, bed nets can provide personal and community protection against ***Anopheles*** mosquitoes and consequently, against malaria. When nets fall short as a vector control tool, it can be attributed broadly to one of two issues: inequitable distribution due to cost of bed nets, and insecticide resistance in mosquitoes. To address these constraints, we have developed the SmartPatch. In its simplest form, the SmartPatch is a small piece of insecticide-treated fabric or netting that can be placed on top of an existing bed net. Because contact with host-seeking ***Anopheles gambiae*** is focused on this region, the SmartPatch should maximize protective effects while minimizing treated area. Because of the size and placement of the patch, it is less expensive and could be replaced more frequently than a full long-lasting insecticidal net (LLIN). It is also relatively protected from daily contact and as a result, the SmartPatch could potentially be treated with a wider range of actives than currently available for use on bed nets. As a proof-of-concept test and to better understand the relationship between treated area and efficacy, we have tested pyrethroid-treated patches ranging in size from 31 x 61 cm2 to the entire top of a bed net. We carried out these tests under laboratory and semi-field conditions using susceptible ***An. gambiae*** and measuring mosquito knock down and blood feeding relative to an untreated control and a full LLIN. We find intermediate levels of protection associated with all patch sizes. We also find that protection does not scale linearly with covered area and thus, the effects of the patch area greater than might be expected based on treated area relative to total area of a bed net. To follow up on these experiments, we are using mathematical models to explore the relationship between bed net efficacy and coverage. The goal of these simulations is to determine what conditions might favor the use of less expensive, less effective bed nets. Lastly, we are conducting trials with insecticide-resistance mosquitoes and non-pyrethroid patches, to evaluate the SmartPatch as a resistance-breaking tool.

1376

REDUCED EFFICACY OF LONG-LASTING INSECTICIDAL NETS IN AREA WITH PYRETHROID-RESISTANCE POPULATIONS OF *ANOPHELES GAMBIAE* S.L IN NE TANZANIA: AN EXPERIMENTAL HUTS STUDY

Patrick K. Tungu

National Institute for Medical Research, Tanga, United Republic of Tanzania

The success of malaria vector control is threatened by widespread pyrethroid resistance. The extent to which insecticide resistance and underlining mechanisms impact the malaria vector insecticidal control is not clearly known. This study comparatively assessed the bio-efficacy of washed and unwashed PermaNet 2.0 long-lasting insecticidal nets (LLINs) against wild free flying pyrethroid-resistant ***Anopheles gambiae*** s.l. field populations in North Eastern Tanzania before and after development of insecticide resistance by the local vectors. Evaluation of the efficacy of PermaNet 2.0 LLINs was conducted in laboratory and in semi field (Experimental huts) following the standard WHOPES Protocol (WHO/CDS/NTD/WHOPES/GCDPP/2006.3). The evaluation criteria were

percentage mortality, blood feeding inhibition, exophily and deterrence effects. WHO method was used to detect resistance in wild ***Anopheles*** mosquitoes exposed to 0.05% deltamethrin. PCR based molecular diagnostics were used to identify mosquitoes to species and to detect kdr alleles. ***Anopheles*** mosquitoes were resistance to deltamethrin with mortality rate of 81.2% [95% CI: 76.8-84.9%]. Mortality rates induced by unwashed PermaNet 2.0 and PermaNet 2.0 washed 20x in this trial against An gambiae was 31%, 30% and 27% respectively. By contrast the mortality induced by unwashed and 20 washed PermaNet 2.0 nets against An gambiae in a trial conducted in this same area employing same huts when the vectors were fully susceptible to pyrethroids was 96% and 95% respectively. The reduced LLINs efficacy reported in this study indicates that resistance in Tanzania is capable of undermining the bio-efficacy of pyrethroid insecticide-based vector control interventions, especially LLINs. This emphasizes the need to identify alternative insecticides to replace or supplement pyrethroids also emphasizes the need for the development and implementation of effective and sustainable resistance management strategies.

1377

NEW MODE-OF-ACTION CHEMISTRIES FOR VECTOR CONTROL: SMALL MOLECULE INHIBITORS OF ARTHROPOD GPCRS

Catherine A. Hill[1], Andrew B. Nuss[1], Karin F. Ejendal[1], Jason M. Meyer[1], Jason M. Conley[1], Monika Gulia-Nuss[1], Tarsis Brust[1], Trevor B. Doyle[1], Larissa Avramova[1], Sergey Savinov[2], Val J. Watts[1]

[1]Purdue University, West Lafayette, IN, United States, [2]University of Massachusetts, Amherst, Amherst, MA, United States

New, safer mode-of-action chemistries are needed to control the arthropod vectors of infectious diseases. Continued control is threatened by the emergence of insecticide resistant populations of vectors and no new public health pesticides have been developed in recent decades. The Purdue Invertebrate Receptor Group (PIRG) is a collaborative effort to develop novel chemistries as interventions for the control and elimination of arthropod-borne diseases. G protein-coupled receptors (GPCRs) represent promising targets for insecticide discovery because of their critical role in the neurological processes of arthropods. We are pursuing rational drug design to discover small molecule inhibitors of arthropod GPCRs for vector control. To date, multiple arthropod vector genomes have been mined to identify suitable candidate GPCR targets. Using high-throughput chemical library screening and hit-to-lead optimization, we have identified potent antagonists of the D_1-like dopamine receptors (DARs) from the yellow fever mosquito, ***Aedes aegypti (AaDOP2),*** the malaria mosquito, ***Anopheles gambiae*** (***Ag***DOP2), the northern house mosquito, ***Culex quinquefasciatus*** (***Cq***DOP2) and the Lyme disease tick, ***Ixodes scapularis*** (***Is***DOP2). These chemistries exhibit greater than 100-fold selectivity for mosquito and tick DARs versus orthologous human and honeybee receptors ***in vitro***, and are highly toxic to mosquito larvae and adults ***in vivo***. Transcriptome analyses suggest that these antagonists disrupt GPCR-mediate signaling processes and operate via modes-of-action that are distinct from existing insecticides. Structure activity relationship studies are ongoing to explore multiple chemical scaffolds, develop a preliminary pharmacophore and identify leads for development. These studies demonstrate proof of concept for a target-based approach to deliver novel classes of vector-selective insecticides. Activities to expand the discovery pipeline via the development and incorporation of other GPCR targets from other species of arthropod vectors will be presented.

MAPPING INSECTICIDE RESISTANCE IN MALARIA VECTORS: LATEST UPDATES FROM IR MAPPER®

Melinda P. Hadi[1], Elijah O. Juma[1], Helen Pates Jamet[2]

[1]Vestergaard Frandsen (EA) Ltd, Nairobi, Kenya, [2]Vestergaard Frandsen Inc, Washington, DC, United States

The emerging and rapid spread of resistance to major classes of public health insecticides threatens current malaria vector control efforts. Deployment of the most appropriate tools must be informed by up-to-date data on insecticide resistance in target malaria vector species. Launched in 2012, IR Mapper® (www.irmapper.com) is an online geospatial mapping platform built on a systematic review of peer reviewed, published literature to visualize insecticide resistance trends in ***Anopheles*** vectors. IR Mapper® utilizes an ArcGIS for JavaScript API platform and is updated monthly with newly published data from peer reviewed scientific publications on phenotypic (WHO susceptibility test and CDC bottle assay data) and resistance mechanisms (target site and overexpressed metabolic enzymes) data. Additional data meeting standard WHO or CDC test criteria from PMI, National Malaria Control Programmes, and other reputable sources are also included. The filter tools on IR Mapper® enable filtering by year, vector species, insecticide class, and resistance mechanisms. As of January 2015, IR Mapper® consisted of 9,433 unique field records from 57 countries and 48 ***Anopheles*** species or species complexes. 81.5% of countries have reported resistance to at least one of the four classes of insecticides; 76.0% have reported testing of resistance mechanisms. Filtering by time period highlighted that three times more reports of insecticide resistance in ***Anopheles*** were reported between 2000 and 2014 compared with the previous 45 years. IR Mapper® highlighted gaps in resistance monitoring, particularly in high burden countries like Democratic Republic of Congo and Nigeria. While insecticide resistance testing has increased in recent years, IR Mapper® is able to identify where data gaps on insecticide resistance exist in malaria vectors. IR Mapper® is a useful tool for visualizing temporal and spatial trends in ***Anopheles*** insecticide resistance and associated resistance mechanisms, and can be used to assist rational decision making on the deployment of vector control interventions and design of vector monitoring programs.

SUSCEPTIBILITY OF *ANOPHELES GAMBIAE SENSU LATO* TO MALARIA CONTROL INSECTICIDES- RWANDA, 2011 AND 2013

Emmanuel Hakizimana[1], Corine Karema[1], Dunia Munyakanage[1], Eric Tongren[2], John Githure[3], Ray Beach[4], Constantianus J. Koenraadt[5], Willem Takken[5], Jean Baptiste Mazarati[6], Agnes Binagwaho[7]

[1]Malaria and Other Parasitic Diseases Division, Rwanda Biomedical Centre, Ministry of Health, Kigali, Rwanda, [2]Centers for Disease Control and Prevention/U.S. President's Malaria Initiative, Atlanta, GA, United States, [3]Abt Associates Inc. Integrated Vector Management Project/U.S. President's Malaria Initiative, Kigali, Rwanda, [4]Division of Parasitic Diseases and Malaria/Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Laboratory of Entomology, Wageningen University, Wageningen, Netherlands, [6]National Reference Laboratory, Biomedical Services Department, RBC, Kigali, Rwanda, [7]Ministry of Health Rwanda/ Harvard Medical School, Boston, MA, Kigali, Rwanda

Insecticides are important malaria vector control tools, with pyrethroids being the most widely used class to treat nets and spray interior walls of homes.Widespread pyrethroid resistance emergence is a major threat to malaria control gains in Rwanda and throughout Africa. In 2011 and 2013, Rwanda conducted insecticide resistance monitoring of local malaria vectors at 12 sentinel sites in high malaria transmission districts with high LLIN and IRS coverage. Collected larvae were reared to adults and examined for knock-down and mortality using WHO tube bioassay. We analyzed a sample of female adults from field larval collections for the

kdr-east mutation (L1014S), a known resistance gene. We characterized 1,406 mosquitoes by polymerase chain reaction and identified 1,165 (82.9%) as ***Anopheles arabiensis*** and 241 (17%) as ***An.gambiae s.s***. We compared mortality rates observed in 2011 to 2013 and found a significant increase in resistance to lambda-cyhalothrin (98% vs. 63%%; p=0.0001), permethrin (86% vs. 66%, p=0.002), deltamethrin (100% vs. 87%, p=0.0003) and DDT (100% vs. 89%, p=0.001). Bendiocarb showed variable susceptibility with 58% of sites tested showing full susceptibility. No sentinel site had mosquitos resistant to fenitrothion. We genotyped 134 A***n. gambiae s.s*** mosquitoes for ***kdr***-east mutation and discovered 67 (50%exhibited homozygous sensitive (SS) alleles, while 35 (26%) and 32 (24%) mosquitoes exhibited heterozygous (RS) and homozygous resistance (RR) alleles, respectively. Of the 591 ***An.arabiensis*** genotyped, 425 (72%) exhibited homozygous sensitive (SS) alleles while 158 (27%) and 8 (1.4%) expressed heterozygous (RS) and homozygous resistance (RR) alleles, respectively. The results of this first insecticide resistance study in Rwanda reveal decreased pyrethroid and DDT susceptibility in 2013 compared to 2011 and susceptibility to carbamates and organosphosphates. These results demonstrate the need for Rwanda to continue monitoring insecticide resistance to inform effective insecticide management and sustain the gains made in malaria control as we approach pre-elimination.

MODELING THE SPREAD OF *AEDES ALBOPICTUS* IN LOS ANGELES, CALIFORNIA

Christopher M. Barker, Diego Montecino

University of California, Davis, Davis, CA, United States

The Asian tiger mosquito, ***Aedes albopictus***, is among the world's most invasive species. Its spread has been facilitated by rapid global transport of cargo, and it is now established on every continent except Antarctica. This species represents a "triple threat" to human health, being a day-biting pest, a competent vector of globally important dengue and chikungunya viruses, and a potential bridge vector of several zoonotic arboviruses. As a result of its importance, the biology of ***Ae. albopictus*** is also well-studied, but the fine-scale processes by which it becomes established in a given location are poorly understood. This is because even intensive surveillance systems yield limited information during the early phase of invasions when densities are low, and detection often occurs after populations are relatively widespread. Fine-scale spatial models for mosquito dynamics and movement offer a way forward, marrying our understanding of ***Ae. albopictus*** biology with surveillance paradigms and detailed data on the real landscapes where invasions occur. Here, we consider the ongoing invasion and establishment of ***Ae. albopictus*** in Los Angeles since 2011. We have used hierarchical modeling to account for heterogeneities in household-level suitability, then we modeled the stochastic dynamics of ***Ae. albopictus*** on this landscape using the suitability surface and a temperature-dependent, dynamical model for reproduction and spread. We then use the model to answer policy-relevant questions related to detection, control, and the feasibility of local eradication efforts.

1381

AEDES ALBOPICTUS MOSQUITO MICROBIOTA ASSEMBLIES: ROLE OF DEVELOPMENTAL STAGES AND LARVAL HABITATS

Xiaoming Wang[1], Daibin Zhong[2], Jiabao Xu[2], Guofa Zhou[2], Xiaoguang Chen[1], Guiyun Yan[2]

[1]Department of Pathogen Biology, School of Public Health and Tropical Medicine, Southern Medical University, Guangzhou, China, [2]University of California Irvine, Irvine, CA, United States

Aedes albopictus is a major vector of dengue and other arbovirus worldwide and a sole vector for dengue in southern China. It's highly invasive and spreads rapidly. Microbiota-mosquito holobiont may play an important role in different aspects of mosquito life history, but the relationship between vector environments and vector microbiome assemblies is largely unknown. This study examined the hypothesis that microbiota of aquatic habitats is a key determinant of microbiota and larval and adult mosquitoes, and mosquito microbiota is modulated by sugar feeding, blood feeding, and exposure to environmental microbes. Using Miseq pyrosequencing of 16S rRNA gene V4 hyper-variable region, mosquito microbiota was examined from five natural larval habitats, and from adult mosquitoes of various ages and life histories. The results indicated that microbiota of water in different larval habitats and resulting mosquitoes differed significantly. Bacterial diversity generally decreased from aquatic stage to adults, while blood feeding reduced microbial community diversity. In mosquito larvae, bacterial species common to the five natural habitats were less than 30% of the total bacterial species OTU identified. Interestingly, we found that Wolbachia abundance was low in larvae, and increased with adult mosquito age. The relative densities of two main Wolbachia strains (wAlbA and wAlbB) in adult mosquitoes were examined by qPCR assays. The ratio of wAlbB to wAlbA gene copy number was around 106~108. Other bacterial taxa associated with human and pathogen vectorial capacity were also identified. The information obtained from this study would help to establish a metagenomic foundation for better understanding the impact of environmental microbial on vector development and disease transmission.

1382

TRANSCRIPTOME PROFILING BETWEEN PYRETHROID RESISTANT AND SUSCEPTIBLE POPULATIONS OF *AEDES ALBOPICTUS*

Jiabao Xu[1], Daibin Zhong[2], Mariangela Bonizzoni[2], Xiaoming Wang[1], Xiaoguang Chen[1], Guiyun Yan[2]

[1]Key Laboratory of Prevention and Control of Emerging Infectious Diseases of GD Higher Education Inst, Guangzhou, China, [2]Program of Public Health, University of California Irvine, Irvine, CA, United States

The Asian tiger mosquito, ***Aedes albopictus***, is highly invasive mosquito species. It vectors a number of important human pathogens. The extensive usage of insecticides for public health vector control and agricultural pest control has posted strong selection pressure for increased resistance. However, very limited genomic information on ***Ae.albopictus*** insecticide resistance is available, hindering the development of sensitive molecular surveillance tools for insecticide resistance. In this study, we performed pyrethroid resistance bioassay in two field populations of ***Ae. albopictus*** from Southern China. We found one population from Shenzhen, southern China highly resistant to pyrethroid. With this population, the transcriptome profiling was conducted in 12 resistant individuals and 12 susceptible individuals using the Illumina HiSeq v4 PE100 technique. The transcriptome sequencing yielded more than 674 million clean paired end reads, with an average of 53 million reads per individual mosquito. A total of 19,733 (98.2% of the reference transcripts) transcripts were expressed in the tested mosquitoes. Among these, 742 transcripts were differentially expressed between deltamethrin resistant and susceptible mosquitoes collected from the same field site. Among these, top 50 differentially expressed genes included detoxification enzymes, cuticle protein and immune genes. A total of 439,306 non-synonymous variants were identified, among those, 5,245 SNPs differed significantly between resistant and susceptible populations in frequencies, and distributed in 1,925 genes. The most differential SNPs were found in cytochrome P450 detoxification genes. The transcriptome databases provide a valuable genomic resource for further genetic studies of this important dengue virus vector species. The differentially expressed genes associated with insecticide resistance identified in this study lay an important foundation for further functional analysis. The identified SNP markers will provide useful tools for future population genetic and comparative genomic analyses of ***Ae. albopictus*** vectors.

1383

GENOMIC ANALYSES OF DELTAMETHRIN RESISTANT AND SUSCEPTIBLE MOSQUITOES IN *ANOPHELES SINENSIS*

Daibin Zhong[1], Xiaoming Wang[1], Mariangela Bonizzoni[1], Jiabao Xu[1], Liwang Cui[2], Guiyun Yan[1]

[1]University of California Irvine, Irvine, CA, United States, [2]Department of Entomology, Pennsylvania State University, University Park, PA, United States

Anopheles sinensis is a major malaria vector in Southeast Asia. Resistance to pyrethroid insecticides is becoming a common problem in this species. Previous study identified the ***An. . sinensis*** populations from Yunnan, China, showing high level resistance to deltamethrin, but total absence of knockdown resistance (kdr) mutation, suggesting resistance mechanisms other than kdr resistance in ***An. sinensis***. The aim of this study was to identify genomic variants, including single nucleotide polymorphisms (SNPs), multiple nucleotide variants (MNV), and insertion/deletion polymorphisms (INDELs) in ***An. sinensis***. Using massively parallel paired-end DNA sequencing, we generated 108 Gb of DNA sequence data from pooled deltamethrin resistant and susceptible mosquitoes, resulting in an average of 83.3X sequence coverage. Reads were mapped to approximately 94% of the ***An. sinensis*** reference genome. Using a stringent filtering method, we identified a total of 7.7 million variants, including 0.46 million variants located in codon regions. Over 140 thousand non-synonymous variants were identified. Approximately 6,000 differential SNPs were identified between deltamethrin resistant and susceptible population. Among those, 26 genes with the highest percentage of differential SNPs were identified, including detoxification genes, immune genes, cuticular protein, ordant protein, and ribosomal genes. We confirmed the finding by genotyping 40 mosquitoes at 20 highly differential SNPs. Furthermore, the two cytochromes P450 genes, CYP6Z3 and CYP4J10 previously identified with overexpression in resistant ***An. sinensis*** mosquitoes, were found having higher mutation frequencies at A513D of CYP4J10 and at G363S of CYP6Z3, respectively, in the resistant mosquitoes. The genomic variation described here will be a useful resource for future studies of genetic mechanisms of insecticide resistance.

1384

AN ANALYSIS OF CHROMOSOMAL INVERSIONS WITHIN THE *ANOPHELES* 1000-GENOMES PROJECT - MARKERS OF POPULATION STRUCTURE IN DISEASE VECTORS FROM THE PAST TO THE FUTURE

Seth N. Redmond[1], Tiago Antão[2], Nora Besansky[3], Samantha O'Loughlin[4], Ag1000g Consortium[5]

[1]Broad Institute, Boston, MA, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]University of Notre Dame, South Bend, IN, United States, [4]Imperial College, London, United Kingdom, [5]Ag1000G Consortium affiliations are listed at www.malariagen.net/ag1000g, Oxford, United Kingdom

The ***Anopheles*** 1000-genomes project has generated, in it's first phase, full-genome sequences for 765 individual mosquitoes. Samples collected cover two different species and sampling sites across the whole of Sub-Saharan Africa and genotypes have been called for more than 52m SNPs, enabling investigations of population structure and selection at an unprecedented scale. Yet despite the breadth of this dataset and the broad utility of SNP markers, it has been challenging to place this work in the context of the many decades of prior studies of the ***Anopheles*** species cluster. Work in the pre-genomic era frequently involved large structural variants; chromosomal inversions that can identify population structure, facilitate adaptation to differing ecological conditions, and can both prevent and facilitate genetic transfer between members of the species cluster. However, though inversions are readily identifiable via analysis of polytene chromosomes, they are difficult to call from the short-insert illumina sequence that makes up the Ag1000g data. Using multiple methods, including breakpoint identification, LD-clustering and admixture analysis, we have investigated chromosomal inversions in all sample groups of the ag1000g dataset, generating karyotypes for five of the seven major inversions that are thought to be represented in the Ag1000g dataset, and including additional rare inversions found on chromosomes 2 and 3. SNP markers have been identified for all of these inversions enabling future investigations of karyotype using cost effective genotyping methods. We will present a detailed analysis of the distribution of these inversions within the Ag1000g dataset, illuminating population structure at both intraspecific and interspecific levels. This will include sites showing reproductively isolated ***Anopheles gambiae*** / coluzzii, admixed ***A. gambiae*** / coluzzii,and evidence of allopatric structured populations within ***Anopheles gambiae*** s.s.

1385

CORRECTING GENOME MISASSEMBLIES IN MALARIA VECTORS BY PHYSICAL MAPPING

Igor V. Sharakhov[1], Ashley Peery[1], Anastasia Naumenko[1], Xiaofang Jiang[1], Brantley Hall[1], Maria V. Sharakhova[1], Zhijian Tu[1], Gleb Artemov[2], Vladimir Stegniy[2]

[1]Virginia Tech, Blacksburg, VA, United States, [2]Tomsk State University, Tomsk, Russian Federation

The recently sequenced and assembled genomes of 16 anophelines allowed researchers to investigate the genomic basis of vectorial capacity. However, unmapped scaffolds may conceal gaps and misassemblies, which could cause incorrect or incomplete annotation of genomic sequences. Anchoring scaffolds onto chromosomes can correct these mistakes and can facilitate the development of high-quality reference genome assemblies that could be used for studying chromosome evolution and gene-order phylogeny. Using a combination of cytogenetic and bioinformatics approaches we mapped the genomic scaffolds to chromosomes of ***Anopheles*** arabiensis, An. stephensi, An. atroparvus, and An. albimanus. Each of the species was individually compared to An. gambiae. The comparative positions of genes within mapped scaffolds based on orthology relationships were plotted using the R program genoPlotR. Orientation of scaffolds on chromosomes was obtained from physical mapping data. This effort identified and corrected scaffold misassemblies in several species and developed chromosome-based genome assemblies. We estimated the number of chromosomal inversions between ***An. gambiae*** and each of the species and found that rearrangement rates are ~3 times higher on the X chromosome than on autosomes. The fast rate of X chromosome rearrangements is in sharp contrast with the paucity of polymorphic inversions on the X in anophelines. This finding could be indicative of a greater role of the X chromosome rearrangements in speciation of malaria mosquitoes.

VECTORBASE: COMMUNITY RESOURCES FOR VARIATION, POPULATION AND COMPARATIVE GENETIC DATA ANALYSIS

Gareth Maslen[1], James Allen[1], Mikkel Christiansen[1], Robert M. MacCallum[2], Scott J. Emrich[3], Gregory R. Madey[3], Frank H. Collins[3], VectorBase consortium [(1,2,3)]

[1]European Molecular Biology Laboratory - European Bioinformatics Institute, Cambridge, United Kingdom, [2]Imperial College London, London, United Kingdom, [3]University of Notre Dame, Notre Dame, IN, United States

VectorBase is a NIAID-funded Bioinformatic Resource Center that provides resources to investigate vectors of human pathogens. Over the last year VectorBase has expanded to incorporate data from several species clusters (for a total of 22 ***Anopheles*** and 6 ***Glossina*** genomes) as well as the genomes of other insects supplying a total of 37 genomes representing 35 species. The availability of genomic, transcriptomic and proteomic data from multiple species permits a comparative approach to identify and characterize regulatory and biochemical pathways involved in diverse

phenotypes such as insecticide resistance, pathogen-host interactions and immunity, and arthropod phylogenetic relationships. Gene models and metadata are curated for all VectorBase species, and are used to recalculate gene trees for all updated organisms with each database release (bimonthly). Phylogenetic trees are constructed for all coding and ncRNA genes, orthologs and paralogs are identified, and gene and species trees are reconciled to identify duplication and speciation events. In addition to comparative omics information, variation data from a variety of wild populations and laboratory research strains are available for 14 species (12 ***Anopheles***, ***Aedes aegypti*** and ***Ixodes scapularis***). Variation data sets relating to insecticide resistance, host immune response to infection, and SNP chips used for large scale sample genotyping can be visualised in their genomic context using the VectorBase gene browser, and are linked to population and geodata for the originating samples via the Population Biology browser (PopBio) application. Since access to experimental sample metadata is a key requirement for efficient querying and visualization of large variation and population data sets VectorBase provides linkage to public repositories of reference sample metadata such as BioSamples to permit the provenance of samples to be determined, and provide convenient links to related sample data such as NCBI/ENA sequencing and expression data. All data provided by VectorBase are freely available at www.vectorbase.org.

1387

THE CREATION AND CHARACTERIZATION OF A TRANSGENIC *ANOPHELES GAMBIAE* LINE DYSFUNCTIONAL FOR SEXUALLY TRANSFERRED 20E

Andrea L. Smidler[1], Enzo Mameli[2], Evdoxia Kakani[1], Flaminia Catteruccia[1]

[1]Harvard University, Boston, MA, United States, [2]University of Perugia, Perugia, Italy

Recent findings have demonstrated the importance of the insect hormone, 20-hydroxyecdysone (20E), in coordinating ***Anopheline*** reproductive biology. In the ***Cellia*** sub-genus of anophelines male-transfer of 20E during mating has been implicated in fertility, fecundity, mating refractoriness, and has been suggested to play an indirect role in ***Plasmodium*** development. Elucidating the downstream effects of male 20E transfer can therefore provide valuable insight into the biology of both reproduction and parasite development within the mosquito. Generation of 20E-depleted males is crucial to facilitate studies of this biological system. Unfortunately the tissue in which 20E is synthesized, the male accessory glands (MAGs), is generally difficult to target with RNAi based approaches; therefore targeting genes involved in 20E-synthesis is problematic. Here we present the characterization of an ***An. gambiae*** MAG specific promoter from the mating plug protein, Plugin, and demonstrate that this regulatory region is capable of driving MAG-specific expression of tdTomato. Further, we use this promoter to create a transgenic line in which expression of a 20E-deactivating enzyme is driven specifically in the MAGs. Males from this transgenic line, which we named Me2, are successfully depleted of 20E within their MAGs and transfer significantly less 20E to females during copulation. We are currently employing Me2 males to explore the role of male-transferred 20E in the female post-mating response, and its potential influence on ***Plasmodium falciparum*** development within ***An. gambiae.***

1388

THE EFFECT OF HYBRIDIZATION ON GENE EXPRESSION IN THE *ANOPHELES GAMBIAE* COMPLEX

Kevin C. Deitz[1], Willem Takken[2], Michel A. Slotman[1]

[1]Texas A&M University, College Station, TX, United States, [2]Wageningen University, Wageningen, Netherlands

The accumulation of genetic incompatibilities that cause hybrid sterility and/or inviability between diverged populations is an important step in the formation and maintenance of species boundaries in the face of hybridization. While some chromosomal incompatibilities that cause hybrid sterility and inviability between ***An. gambiae*** and ***An. arabiensis*** have been identified, little is understood about the nature of these incompatibilities. Divergence in gene regulation, rather than genetic differences, is thought to account for a large proportion of phenotypic differences between species, and could also play a large role in hybrid sterility and inviability. Therefore, we analyzed gene expression in sterile F1 hybrid male pupae and compared it to parental males in crosses between ***An. gambiae, An. arabiensis,*** and ***An. quadriannulatus***. By analyzing genome-wide, allele-specific gene expression, we explored the roles of ***cis*** and ***trans*** regulatory divergence in the hybrid male sterility phenotype. The relationship between allele-specific expression, patterns of sequence evolution, and known hybrid sterility QTL was also explored. Our analysis provides insight into the divergence of the ***An. gambiae*** complex.

1389

SPECIATION, HYBRIDIZATION AND INTROGRESSION IN NATURAL *ANOPHELES GAMBIAE* AND *A. COLUZZII* POPULATIONS FROM THE AG1000G PHASE-1 DATA

Alessandra della Torre[1], Giordano Botta[1], Alistar Miles[2], Kirk Rockett[2], Beniamino Caputo[1], Martin Donnelly[3], Dominic Kwiatkowski[2], The Anopheles gambiae 1000 genomes consortium

[1]University of Rome SAPIENZA, Rome, Italy, [2]University of Oxford, Oxford, United Kingdom, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The ***Anopheles gambiae*** 1000 genomes (Ag1000g) project is opening unprecedented perspectives in the analysis of genome variation in natural populations of Afrotropical malaria vectors by providing high throughput sequence data on natural vector populations to be exploited to characterize patterns of diversity, linkage disequilibrium and recombination, population structure and gene flow, signals of recent selection, and demographic history. As a first step toward the full exploitation of the genetic data made available by Phase-1 of Ag1000g project, we focused on the SNPs that were found to show high allele frequencies difference (>0.9) between ***A. gambiae*** and ***A. coluzzii*** populations from Mali. Screening for variation in these SNPs in the first 765 wild-caught sequenced specimens from 8 sub-Saharan countries (i.e. Guinea-Bissau, Guinea-Conakry, Burkina Faso, Cameroon, Gabon, Angola, Uganda, Kenya) revealed evidence of: i) putative ***A. coluzzii/A. gambiae*** ancestral polymorphisms in an ***A. gambiae*** population out of its range of sympatry with ***A. coluzzii***; ii) ongoing gene flow between ***A. gambiae*** and ***A. coluzzii*** in the "far west" of their sympatric range, where a secondary contact region has been previously hypothesized; iii) introgression of mutations conferring insecticide resistance across species and between geographically distant populations. In order to facilitate large-scale and straightforward genotyping of additional ***A. gambiae*** and ***A. coluzzii*** populations, we developed a nucleic acid mass spectrometry assay based on a selection of the most informative SNPs and tested the novel approach on the initial 765 wild-caught sequenced specimens first, and on additional populations next.

1390

ANOPHELINE TRIGGERS OF FEMALE POST-MATING PHYSIOLOGY IN ABSENCE OF SEXUALLY TRANSFERRED ECDYSONE AND IMPLICATIONS FOR MALARIA TRANSMISSION

Sara N. Mitchell, Evdoxia G. Kakani, Adam South, Flaminia Catteruccia

Harvard T. H. Chan School of Public Health, Boston, MA, United States

The ability of anophelines to transmit malaria is influence by their sexual reproduction, with female fecundity, longevity and immunity shaped by post-mating physiological changes. In ***Anopheles gambiae,*** male sexual traits - transfer of a mating plug containing the steroid hormone

20-hydroxyecdysone (20E) - triggers major physiological events in females including loss of receptivity to mating and increased egg development. Correlated coevolution has driven the adaptation of these male traits in anophelines, with transfer of both a mating plug and 20E occurring exclusively in extant species of the subgenus ***Cellia***. We employed RNAseq to determine possible alternative triggers of female reproductive behaviors in other anophelines; focusing on the 20E-less and plugless ***Nyssorhynchus*** vector ***An. albimanus.*** We transcriptionally profiled the male accessory glands before and after mating as fluctuations in individual semen components my indicate factors crucial for mating success, and identified a number of unique proteins regulated by sex. Through reciprocal sequencing of the female uterus we identified potential interacting partners to these male peptides as well as pathways controlled by mating in the female. RNAi demonstrates a role for these male-female interactions in regulating ***An. albimanus*** female reproductive physiology and behavior. Furthermore, we show evidence of potential interplay between this divergent 20E-independent mating system and female physiology after blood feeding with implications for malaria transmission. Our data help elucidate the biological aspects relevant for vectorial capacity in different anophelines, and may facilitate control strategies aimed at reducing mosquito reproductive success.

1391

LANDSCAPE GENETICS OF *ANOPHELES ARABIENSIS* MOSQUITOES ACROSS KENYA

Elizabeth Hemming[1], Daibin Zhong[1], Eugenia Lo[1], Harrysone Atieli[2], Yaw Afrane[2], Andrew Githeko[2], Guiyun Yan[1]

[1]University of California, Irvine, Irvine, CA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya

Malaria transmission is affected by the movement of mosquitoes (over short distances) and people (over any distance). Active mosquito dispersal may depend on environmental and ecological factors, such as availability of blood meal source and larval habitats, suitability of ambient climate, and geographic distance and barriers. ***Anopheles*** arabiensis mosquito is presently one of the most widespread and important malaria vectors in Africa. Using a landscape genetics approach, we aimed to determine the relative contribution of geographic and ecological factors to genetic structure of ***An. arabiensis*** across Kenya. ***An. arabiensis*** larvae were collected from twelve sites in four ecological regions (Western Kenya highlands, Western Kenya lowlands, Great Rift Valley and Eastern Kenya coast). Ten microsatellite markers were used to genotype these mosquito populations. We are currently analyzing the population genotype data using the Bayesian Estimation of Differentiation in Alleles by Spatial Structure and Local Ecology (BEDASSLE) program to quantify the contributions of geographic and ecological factors to mosquito genetic structure. Understanding factors that promote and prevent gene flow of malaria vectors is critical to predicting the spread of insecticide resistance.

1392

ANOPHELES SPECIES DIVERSITY, BEHAVIOR AND SPOROZOITE RATES IN SIX STATES OF NIGERIA

A survey of adult anopheline mosquito diversity was conducted from March through October 2014 in six States (Enugu, Plateau, Rivers, Jigawa, Nasarawa and Lagos) across different ecological zones of Nigeria. Monthly sampling was carried out over a 10-month period using human-baited CDC LT hourly cup-change method placed indoors and outdoors to measure mosquito biting-time and location from 18:00hrs to 06:00hrs. PSCs were used to sample indoor-resting mosquitoes. PCR identification was carried out on a subset of samples from each site. ***An. gambiae*** s.l. was tested for ***Plasmodium falciparum*** sporozoite infection using ELISA. A total of 23,740 ***Anopheles*** mosquitoes were collected between March and October 2014. 14,001 (58.98%) were caught using PSCs. Using CDC LT, 5,000 (51.3%) were caught indoors, while 4,739 (48.7%) were caught outdoors. Significantly higher numbers of anopheline mosquitoes were collected indoors than outdoors (χ^2=6.995; df =1; p= 0.0082). A total of 19,699 (83.2%) were ***An. gambiae*** s.l., 1,749 (7.4%) were ***An. funestus,*** 1767 (7.4%) were ***An. coustani,*** 162 (0.68%) were ***An. nili.*** and 6 (0.03%) were ***An. moucheti.*** The difference between the two major vectors was statistically significant (p<0.0001). ***An. gambiae*** s.l. was distributed across all the sites, while ***An. funestus*** was only found in Enugu, Plateau, Jigawa and Nasarawa States. ***An. nili*** was only present in Enugu, Jigawa, and Nasarawa States, with significantly higher densities in Enugu (p<0.0001). PCR analysis revealed that of the 2,984 samples analyzed from all the sites, 2,787 (93.4%) were ***Anopheles gambiae*** s.s., while 197 (6.6%) were ***An. arabiensis.*** The highest sporozoite infection rate of 5.5% was recorded in Rivers state, in ***Anopheles gambiae*** collected using both methods, followed by Enugu (3.7%). The predominance of ***An. gambiae*** s.l. in all the sentinel sites has been established. High diversity of ***Anopheles*** vectors was found in Plateau while ***An. gambiae*** s.l. was the only species found in the Rivers state. ***Anopheles moucheti***, was found only in Enugu. This shows the differences in the complexity of vectors and malaria transmission in the different ecological zones.

MAJOR MALARIA VECTORS, *ANOPHELES FUNESTUS* AND *AN. ARABIENSIS*, BITE AT DIFFERENT TIMES OF THE NIGHT IN TWO VILLAGES IN NORTHERN MALAWI: IMPLICATIONS FOR MALARIA CONTROL

Themba Mzilahowa[1], Steve Gowelo[2], John Chiphwanya[3]

[1]University of Malawi, Blantyre, Malawi, [2]University of Malawi, Zomba, Malawi, [3]National Malaria Control Program, Lilongwe, Malawi

The deployment of both long-lasting insecticidal nets and indoor residual spraying (IRS) has potential to alter vector behavior through selection or toxic effects. There are no recent data to indicate the behavioral patterns of major malaria vectors in Malawi. Therefore, human landing catches were carried out at one village each in Nkhata Bay and Karonga districts to investigate the biting behavior of ***Anopheles arabiensis*** and ***An. funestus*** from January to July 2014. At monthly visits, three houses were randomly selected, and teams of four people worked in pairs at each house, one person inside and the other outside. Using a flashlight and mouth aspirator, mosquitoes were collected as they landed on bare legs from 6:00 PM to 12:00 midnight. Another team of two continued from 12:00 midnight to 6:00 AM to complete the night's collection. Each hourly collection was placed in a separate paper cup, labeled by house, location and collection time. On a second night teams were rotated between houses and time period. An. ***funestus*** was predominant in Nkhata Bay (91.2%; n = 2567) compared to ***An. arabiensis*** (8.8%; n = 249). The latter species was predominant in Karonga (95.2%; n = 440) compared to An. ***funestus*** (4.8%; n = 22). ***An. arabiensis*** was active from 8 PM until 6 AM with peak biting between 1 - 2 AM, while An. ***funestus*** was active from 11 PM until 6 AM with peak biting at 5 AM. An. ***funestus*** predominantly was collected indoors while biting (65.8%; n = 1704) compared to outdoors (34.2%; n = 884), whereas ***An. arabiensis*** bit more outdoors (57.0%; n = 393) than indoors (42.0%; n = 296).

1394

ANTI-SALIVARY ANTIBODIES AS A MEASURE OF PROTECTIVE EFFICACY OF LONG-LASTING PERMETHRIN-IMPREGNATED CLOTHING AGAINST MOSQUITO BITES

Berlin L. Londono[1], Jaymin Patel[2], Meagan Vaughn[3], Sheana Funkhouser[2], Loganathan Ponnusamy[4], Crystal Grippin Grippin[1], Samuel Jameson[1], Charles Apperson[4], Christopher N. Mores[5], Dawn M. Wesson[1], Tonya M. Colpitts[1], Steven R. Meshnick[2]

[1]Tulane University, New Orleans, LA, United States, [2]Department of Epidemiology, Gillings School of Global Public Health, Chapel Hill, NC, United States, [3]Rho, Inc., Chapel Hill, NC, United States, [4]Department of Entomology, North Carolina State University, Raleigh, NC, United States, [5]Louisiana State University, Baton Rouge, LA, United States

Mosquitoes are vectors of many infectious pathogens. Because mosquito bites may be unnoticed, it is difficult to monitor efficacy of mosquito avoidance measures in the field. However, mosquito saliva contains immunogenic proteins which elicit antibodies in humans and these are a direct measure of the exposure to mosquito bites. We have previously shown that long-lasting permethrin-impregnated clothing protects against tick and chigger bites in a double-blind randomized controlled trial in North Carolina outdoor workers. Here, we evaluated whether this clothing is protective against mosquito bites by measuring changes in antibody titers to mosquito salivary gland extracts. Paired serum samples were obtained from 64 participants. Antibody titers to ***Aedes atlanticus*** and ***Ae. albopictus*** salivary gland extracts were measured by ELISA. Antibody titers increased 10-fold between March 2011 and September 2012. The difference was 2-2.5 fold lower in subjects wearing treated uniforms than in control subjects. This suggests that long-lasting permethrin impregnated clothing provides protection not only against ticks but also against mosquito bites.

1395

TARGETING ECDYSONE SIGNALLING IN THE MOSQUITO: AN EFFECTIVE APPROACH FOR MALARIA CONTROL

Evdoxia G. Kakani[1], Lauren M. Childs[2], Francisco Cai[2], Sara N. Mitchell[2], Paolo Gabrieli[1], Caroline O. Buckee[2], Flaminia Catteruccia[2]

[1]University of Perugia, Perugia, Italy, [2]Harvard T. H. Chan School of Public Health, Boston, MA, United States

Chemical control of mosquito populations remains the most effective method to defeat malaria. New tools are however needed as malaria elimination is threatened by the spread of insecticide resistance. As ***Anopheles*** females typically mate only once in their lifetime, interfering with mosquito reproduction offers an exciting opportunity to interrupt malaria transmission. Besides the crucial role of 20-hydroxyecdysone (20E) in oogenesis, we have recently shown that in ***Anopheles gambiae***, male 20E transferred during copulation induces oviposition and refractoriness to further mating. Based on the multiple profound effects of 20E on the reproductive physiology of ***Anopheles*** females, we investigated the potential use of hormone agonists as mosquito chemosterilants against ***An. gambiae*** females. Here, we show that disrupting 20E signalling has a remarkable impact on a number of biological traits that are relevant to vectorial capacity; it significantly reduces longevity, completely abolishes egg development and drastically decreases insemination rates. By fitting our data into a mathematical model of the mosquito lifecycle, we demonstrate that manipulating hormonal balance significantly impacts mosquito population dynamics and malaria transmission; reducing mosquito population size and shifting its age structure. These results demonstrate that disruption of 20E signaling is an effective, new and complementary approach to the existing tools for mosquito control, and may provide the additional effort required to achieve malaria elimination. Importantly, as the role of 20E in reproduction is conserved among most anopheline vectors, applications based on this hormone could also translate to other important ***Plasmodium*** vectors.

1396

CHARACTERIZATION OF ANOPHELINE SPECIES COMPOSITION ALONG THE BHUTAN-INDIA BORDER REGION

Wan Nurul Naszeerah[1], Nima Wangdi Gyeltshen[2], Rinzin Namgay[2], Leonard E. Munstermann[1], Sunil Parikh[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Vector-borne Disease Control Program, Gelephu, Bhutan

Bhutan is aggressively embarking on a path towards malaria elimination. Despite substantial progress, Bhutan remains vulnerable to imported malaria. The majority of cases are in Sarpang District, which shares a border with the state of Assam in India, and from where most cases likely originate. However, the anopheline species responsible for autochthonous malaria transmission have not been well characterized. Therefore, a comparison of the vector species in Sarpang was made with published vector records in neighboring Assam. An assessment of the anopheline species composition was undertaken from May to July 2014 in four Sarpang villages adjacent to the Assam border. Five sampling methods were employed: (1) human landing catches, (2) cattle-baited catches, (3) CDC light traps, (4) indoor resting catches and (5) resting boxes. Female anopheline mosquitoes were identified to species using a morphologic key. These results were compared to published literature on anopheline ecology and vectorial roles in Assam. The two suspected malaria vectors in Bhutan, ***Anopheles*** culicifacies (n=189) and An. pseudowillmori (n=205), were abundant in the Sarpong villages. However, in Assam, only An. culicifacies species B, a relatively incompetent vector, has been documented. In contrast, the primary malaria vectors of Assam, ***An. minimus*** and ***An. baimaii***, were absent in the Sarpang collections. If ***An. culicifacies*** is not a competent vector in Sarpang, the other recovered species--***An. pseudowillmori, An. maculatus*** and others may be the responsible vectors for malaria transmission in Sarpang. Nonetheless, molecular

methods are required to identify members of several of the sibling species in this region; however as yet, adequate equipment and trained personnel are not available to address this difficulty.

1397

UTILITY OF BARRIER SCREENS TO SAMPLE OUTDOOR MOSQUITOES IN AN AREA TARGETED FOR MALARIA ELIMINATION

Jennifer C. Stevenson[1], Limonty Simubali[2], Harry Hamapumbu[2], Neil F. Lobo[3], Douglas E. Norris[1], for the Southern Africa ICEMR

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Choma, Zambia, [3]University of Notre Dame, South Bend, IN, United States

Malaria elimination strategies, employing reactive case detection and mass distribution of treated bednets, are being rolled out in southern Zambia. Entomological surveillance is essential to not only monitor the impact on vectors but also to identify where transmission may still occur. Two years of surveillance in Macha, southern Zambia indicate that vector densities indoors are very low, with high spatio-temporal heterogeneity, but recent data on outdoor transmission is lacking. To assess the utility of barrier screens for sampling outdoor vectors, eight households with above mean indoor densities of the vector ***Anopheles arabiensis*** were selected. Two barrier screens, set between houses and either mosquito breeding sites or animal enclosures, were rotated randomly though the households for a period of 40 nights during the rainy season of 2015. Barriers measuring 2 meters high and 5 meters long were constructed from polyester shade netting attached to poles, with a 'roof' to create 'eaves'. Mosquitoes were collected by mouth aspiration from each side of the barrier hourly from 18:00 to 06:00, recording the height of collection. More than 75% of anophelines caught were morphologically identified as ***An. gambiae s.l.,*** similar to the species composition indoors***.*** Molecular identities will determine whether these are indeed the vector species ***An. arabiensis***. Blood feeding rates were higher than that of indoor light trap catches. Human blood indices, infectivity and parity rates will be estimated. Whilst the majority of ***An. gambiae s.l.*** were collected between 22:00 and 05:00, when most people were recorded to be indoors and protected by bednets, almost 20% were caught between 19:00 and 22:00. A larger study surveying more houses over time would indicate the extent of this outdoor exposure. This study demonstrated that barriers screens can be used in an area of low vector density to collect anophelines outdoors and that densities are comparable to that of indoor host-seeking collections. This tool could be used to quantify residual transmission, estimations of which are essential in an area where elimination employs only indoor vector interventions.

1398

MALARIA TRANSMISSION IN TWO DIFFERENT RURAL ECOLOGICAL SETTINGS IN MALI

Mamadou B. Coulibaly[1], Moussa Kieta[1], Sidy Doumbia[1], Nafomon Sogoba[1], Seydou Doumbia[1], Sekou F. Traore[1], Donald J. Krogstad[2]

[1]University of Science, Technologies and Techniques, Bamako, Mali, [2]Tulane University, New Orleans, LA, United States

Malaria transmission varies widely across divergent ecological settings. Here we compare entomological parameters for malaria transmission between two ecologically divergent zones in Mali: 1] one with distinct rainfall-based (seasonal) transmission (Dangassa) and 2] another with virtually year-round transmission (Koïla Bamana) because of irrigation to grow rice in the inner delta region of the Niger River. Standard control measures are used at both sites with the difference that their implementation and effectiveness have been monitored by the Millennium Villages Project (MVP) in Koïla Bamana, whereas in Dangassa, the only control measures are those provided by the government. Five entomological surveys were performed at each of the study sites simultaneously to collect mosquitoes using pyrethrum spray catches (PSCs) and human landing catches after obtaining ethical approvals. ***Anopheles gambiae*** s.l. was the major vector found in both localities and represented 99% (N=5466) of the mosquitoes collected. Overall, the mean density of mosquitoes per house from the PSCs (mean=15.0, 95% CI [14.4-15.6]) was higher in the rice growing area of Koïla Bamana than in the seasonal transmission setting of Dangassa (mean=5.9, 95% CI [5.5-6.3]). In contrast, the human blood index (HBI=percent of mosquito blood meals from human subjects) and the monthly entomological inoculation rate (EIR) were 6.2 (80.0% vs 13.6%) and 3.7 (1.43 vs 0.39) times higher, respectively, in Dangassa than Koïla. The higher ***An. gambiae*** s.l. densities in the rice growing area of Koila Bamana and the higher HBIs and EIRs in Dangassa may have resulted from a combination of: 1] intense implementation and monitoring of vector control measures by the MVP in Koila Bamana and 2] longer vector survival and less intense vector control in Dangassa.

1399

CHANGING VECTOR POPULATION DYNAMICS WITH AN EMERGING POPULATION OF *ANOPHELES FUNESTUS* IN A SETTING OF HIGH MALARIA CONTROL INTERVENTIONS IN THE GAMBIA

Musa Jawara[1], Dr Julia Mwesigwa[1], Mathurin Daitta[1], Majidah Hamid Adiamoh[1], Muna Affara[1], Archibald Worwui[1], Gian Luca Di Tanna[2], Dr Jane Achan[1], Prof Umberto D'Alessandro[1]

[1]Medical Research Council Unit, The Gambia, Banjul, Gambia, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom

The scale-up of key malaria control interventions like indoor residual spraying, use of insecticide treated bed nets and provision of artemisinin-based combination therapy has greatly reduced the burden of malaria in The Gambia. There is limited data on how these interventions have altered the ecology of major vectors in the country. Entomological sampling was conducted in the setting of an ongoing longitudinal cohort study in twelve villages across the country. In each village, fourteen houses were selected and indoor and outdoor mosquito collections were done using human landing catches and CDC light traps. Mosquito species were identified using morphological characteristics and by PCR. During the 2013 transmission seasons (June to December); a total of 12,815 adult ***Anopheles*** mosquitoes were collected. ***Anopheles gambiae*** s.l.complex was the predominant species (81.2%) in most villages. Significant densities of ***An.funestus*** species were identified for the first time in the country but only limited to the Central River region. There was significant heterogeneity in vector abundance between regions. Villages in central river region and the West coast had the highest mosquito densities despite having lower malaria parasite prevalence, whereas villages in the upper river region with higher malaria parasite prevalence had significantly lower vector densities. The peak vector density was in September and the peak biting time was at dawn (5:00 am). Significant outdoor feeding and resting behaviour was also observed. The overall sporozoite rate was 0.1 with the highest rates observed in the west coast (0.8) and upper river region (0.6). Mosquito survival (98% parity) and EIR (21 infective bites per person per year) were highest in the upper river region. In conclusion these observed changes in key entomological indices especially the emergence of ***An. fenestus*** species in this region have important implications for the epidemiology and control of malaria in The Gambia. Additional vector control strategies utilising both indoor and outdoor tools may be beneficial.

1400

A DIFFERENT ANGLE OF *AEDES AEGYPTI* PUPAL PRODUCTIVITY: SOCIAL AND BIOLOGICAL FACTORS IN TWO DENGUE HYPER-ENDEMIC CITIES

Diana R. Higuera-Mendieta, Juliana Quintero

Fundación Santa Fe de Bogotá, Bogotá, Colombia

Behaviors, beliefs and ecologic conditions in a community are of particular importance to dengue control given ***Aedes aegypti*** anthropophilic behavior. Since the reduction of household breeding sites is a key control measure available for dengue vector control, the objective of this study was to determine the social and ecologic factors related to pupal productivity in households of two hyperendemic cities in Colombia (Armenia and Arauca). 4000 households were randomly selected using cluster sampling with replacement after three attempts to contact. In each household a survey including knowledge, attitudes and practices about dengue; a characterization of all the potential breeding sites and subsequently counting of pupae was performed. Two statistical models were designed: a logistic model between absence/presence of pupae in a household and social and behavioural factors, and a negative binomial model for the counts of pupae per breeding site and the ecologic and behavioural factors. Risk factors in Armenia were the location of the household in areas of less altitude and more temperature (OR 6.2 p 0.02), having seen larvae in the household (OR 4.4 p 0.001), and not knowing about vector oviposition places (OR 1.8 p 0.001) was related with presence of pupae. Containers in which no frequency of emptying was reported or were filled with rain water were associated with a higher number pupae but those not having sediments, having the nearest tree further than 180 cm and a capacity of <20 liters, decrease significantly the number of pupae. In Arauca, hearing about dengue from parents and friends (OR 2.6 p0.03), report water storage for cooking or cleaning the house (OR 3.2 p0.001) and have washing machine (OR 1.5 p0.001) was associated with household positivity. Containers emptied 4 days or longer, not reporting this information and having less than half of the container filled with water was associated with a higher number of pupae. The related factors to pupal positivity and productivity within households are dependent on each environment and attention should be focused on the convergence of biological and social forces that drive productivity.

SPACE-TIME CLUSTER ANALYSIS OF DENGUE FEVER OCURRENCE AND VECTOR DETECTION BY MOSQUITRAP IN SINCELEJO-COLOMBIA

Erwin Camacho Burgos, Merab Manjarrez, Juan Mercado, Pedro Blanco

Investigaciones Biomédicas - Universidad de Sucre, Sincelejo, Colombia

Dengue is the most common arthropod-borne viral disease in tropical and subtropical areas of the world and one of the most important in terms of morbidity, mortality and economic impact. In Colombia, the disease is considered a major public health problem. The main strategy to control the disease worldwide remain in the vector control and surveillance however, low correlation have been described between the infestation levels from different surveillance methods and the risk of dengue transmission. In the present study we describe a space-time cluster analysis of the dengue occurrence and the vector abundance in the city of Sincelejo-Colombia, in addition to infection rate estimations with dengue virus (DENV) in the mosquitoes. From May to August 2014, dengue vector ***Aedes aegypti*** was captured bi-weekly by MosquiTRAPs in seven districts of Sincelejo urban area. Captured mosquitoes were used for DENV detection and typing by RT-PCR. Space-time scans with SaTScan software, were used for detection of dengue cases and vector abundance clusters. Intersections were detected with Dengue cases and vector clusters, suggesting specific risk areas within district 5 of the city. District 5 captured mosquitoes represented 20.76% of the total amount of vectors, which is the highest percentage compare to the other districts. The general minimum infection rate was 24.4 per 1000 mosquitoes, but the highest value was estimated in district 5 with 32.1 per 1000 mosquitoes. All four serotypes were detected with DENV-3 (63%) as the most frequent. The simultaneous circulation of DENV serotypes and the high vector abundance within a specific zone suggest that this could potentially be a hotspot for dengue transmission in the city.

1402

SPATIO-TEMPORAL MECHANISMS OF COEXISTENCE IN URBAN MOSQUITOES

Megan E. Saunders[1], Shannon LaDeau[2], Paul T. Leisnham[1]

[1]University of Maryland, College Park, College Park, MD, United States, [2]Cary Institute of Ecosystem Studies, Millbrook, NY, United States

Competitive asymmetry is the expected outcome of interspecific competition among mosquito species that utilize water-filled containers. But inconsistent with the expectations of competitive exclusion, mosquito species often co-occur with superior competitors within the same individual container in urban areas. Understanding the mechanisms behind species coexistence can provide insight into processes governing vector distributions and guide public health management efforts. Several important vector species, including ***Culex pipiens***, ***Cx. restuans***, and the competitively superior invasive ***Aedes albopictus***, coexist across neighborhoods that vary in socio-economic status (SES) in southwest Baltimore, Maryland. We tested predictions that temporal and spatial habitat segregation fosters coexistence of these species. Oviposition cups were deployed every three weeks in four neighborhoods of differing SES in Baltimore between May and November of 2014. ***Ae. albopictus***, ***Cx. restuans***, and ***Cx. pipiens*** constituted 80.4%, 10.9%, and 7.9% of the 61,534 total mosquito larvae collected, respectively. Coexistence of two or more species was seen in 19.9% (n=627) of ovicups. Abundances of both ***Ae. albopictus*** and ***Cx. pipiens*** peaked in late summer, whereas ***Cx. restuans*** abundances peaked in early summer. ***Aedes albopictus*** abundances in the highest SES neighborhood were approximately half that of the other three neighborhoods, while ***Cx. pipiens*** abundances varied among neighborhoods. ***Culex restuans*** abundances in the two highest SES neighborhoods were twice that of the two lower SES neighborhoods. These results suggest that both spatial and temporal habitat segregation may foster coexistence of ***Culex*** species with ***Ae. albopictus*** in southwest Baltimore, but the mechanism of coexistence (spatial vs. temporal) varies between species, even though they are ecologically similar. SES may affect abundances of all species through changes in larval habitat types. The coexistence of ***Ae. albopictus*** with at least one ***Culex*** species likely have real implications for disease risk and transmission due to differences in adult biting behaviors.

1403

EFFECT ON *AEDES AEGYPTI* FEEDING BEHAVIOR FOLLOWING PRE-EXPOSURE TO DEET

Victor A. Sugiharto[1], John P. Grieco[2], Michael J. Turell[3], Edgar D. Rowton[4], Michelle G. Colacicco-Mayhugh[5], Cara H. Olsen[1], V. Ann Stewart[1], Nicole L. Achee[2]

[1]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Department of Biological Sciences, Eck Institute for Global Health, University of Notre Dame, Notre Dame, IN, United States, [3]Department of Vector Assessment, Virology Division, U.S. Army Medical Research Institute for Infectious Diseases, Fort Detrick, MD, United States, [4]Division of Entomology, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [5]Preventive Health Services Department, Medical Education and Training Campus, Fort Sam Houston, TX, United States

DEET is the most widely used topical insect repellent in the world. Substantial evidence has documented DEET to provide effective protection against mosquito bites. Despite its substantial use, the exact mechanism

of action of DEET has yet to be fully elucidated. Moreover, reports from experimental studies indicate that mosquitoes can become less responsive to the chemical, thereby being less repelled. Either a genetic change or direct learning/habituation could be responsible for this altered sensitivity. As such, it is important to determine if previous exposure to DEET can alter mosquitoes' subsequent attempts at blood-feeding behavior. Here we pre-exposed cohorts of ***Aedes aegypti*** mosquitoes to various concentrations of DEET (0.10%, 0.12%, 0.14%, and 0.16%) or to ethanol as a control for a standard time period. The mosquitoes were then provided a blood meal source either immediately following exposure or after defined holding periods (one, three, six, and 24 hours post DEET exposure). The landing and probing rates were recorded every 30 seconds for the first five minutes and the engorgement level was assessed at the end of the 20 minutes blood feeding time. Results indicate that the mosquitoes that had been pre-exposed to DEET displayed no difference in landing and probing rates compared to mosquitoes that were pre-exposed to ethanol. However, 0.16% DEET caused test mosquitoes to imbibe significantly (van Elteren's test ***P***-value < 0.05) less blood as compared to the control population. This effect was observed in mosquito cohorts held for one, three, and six hours after exposure but disappeared when the test mosquitoes were allowed to blood feed at 24 hours post DEET exposure. Findings from this study indicate that DEET exposure can alter the ability of ***Ae. aegypti*** mosquitoes to imbibe blood to engorgement up to six hours post exposure. As the landing and probing rates were not affected, this result suggests that there is a possibility of short term increased vector capacity following DEET exposure that needs to be further evaluated.

1404

DOG HEARTWORM (*DIROFILARIA IMMITIS*) EXTRINSIC INCUBATION, MOSQUITO ECOLOGY, AND PUBLIC KNOWLEDGE: OPPORTUNITIES FOR IMPROVED MESSAGING AND RISK MANAGEMENT

Nicholas Ledesma[1], Phillip E. Kaufman[2], Rui-De Xue[3], Laura C. Harrington[1]

[1]Cornell University, Ithaca, NY, United States, [2]University of Florida, Gainesville, FL, United States, [3]Anastasia Mosquito Control District, St. Augustine, FL, United States

We present ***Dirofilaria immitis*** in a broad context of its extrinsic incubation period, vector ecology, and community impact. ***Aedes aegypti*** were infected with ***D. immitis*** to monitor extrinsic incubation period under temperature fluctuation near and above the ***D. immitis*** development threshold, 14°C. Infected mosquitoes were kept at 19 ± 9°C, 22 ± 4°C, 26 ± 4°C, and compared with constant temperature controls. ***D. immitis*** stages were identified under dissection and L3 development was compared between treatments. The ability of the standard Heartworm Development Unit (HDU) model to predict L3 development was tested against our novel hourly temperature model. L3 development differed between fluctuating and constant temperature treatments. HDU models underestimated L3 stage development at temperatures fluctuating around 14°C; hourly temperature models more accurately predicted L3 development. We then performed a community-level study to analyze vector species, infection rate, and residents' knowledge, attitudes, and practices in two counties of historical high and low ***D. immitis*** prevalence. Questionnaires regarding mosquito-borne disease and heartworm prevention were administered to consenting adults (n=100), and their yards were surveyed for mosquito breeding sites and larvae. Adult mosquitoes were collected in both communities for the duration of the study. Mosquito larvae and adults were identified, and ***D. immitis*** prevalence in adult mosquitoes was determined by PCR. Many residents (59.4%) were unaware that mosquitoes transmit ***D. immitis***; most owners (71.2%) administered heartworm preventive to their pets; and most non-compliant owners were unaware of the risk or decided that preventive was unnecessary. Mosquito species diversity was used to determine the role of key vector species in each community. We propose an updated model for spatiotemporal determination of dog heartworm risk, and describe a comprehensive approach to evaluate ***D. immitis*** vector and transmission dynamics in residential habitats. We use residents' responses to identify areas for improved messaging by public health officials and veterinarians.

1405

DISTRIBUTION AND SPECIES COMPOSITION OF THE *ANOPHELES CRUCIANS* COMPLEX IN SOUTH GEORGIA, USA

Eric W. Chambers, Richard West, Corey D. Anderson, Mark S. Blackmore

Valdosta State University, Valdosta, GA, United States

Anopheles crucians Wiedmann (sensu lato) is an anopheline species complex that is distributed broadly across North America, Central America, and the Caribbean. It is a potential vector of ***Plasmodium falciparum*** and ***Plasmodium vivax***, as well as a potential vector of several arboviruses including EEE, VEE, SLE, WNV, and Tensaw virus. It has also been implicated as a vector of ***Dirofilaria immitis***, a filariod nematode that is a serious veterinary health problem among canines. Although the members of this species complex are morphologically indistinguishable as adults, it is possible to assign individuals at the species level within the complex using a previously described polymerase chain reaction (PCR) assay based on amplification of the internal transcribed spacer 2 region (ITS2). An understanding of species composition and distribution could be critical in elucidating the role that this complex may play as a disease vector as it is possible that each member of this complex may exhibit unique ecological and behavioral traits. Here we describe our initial efforts to determine the distribution and composition of the ***An. crucians*** complex within a community in the Southeastern United States. We employed PCR amplification of the rDNA ITS2 sequence to differentiate over 200 individuals from the ***An. crucians*** complex collected from 10 different sample locations in Lowndes county GA, USA. We observed individuals of this complex in sympatry in five of ten locations throughout the county with several of these locations exhibiting three of the species (A, C, D) in sympatry. Spatial and temporal distributions of members within this complex were explored. This work represents a first step in understanding ***An. crucians*** ecology in the state of Georgia. An understanding of species distribution and vector competence within the ***An. crucians*** complex could allow for the development of improved vector control strategies.

1406

DENGUE VACCINE INITIATIVE PROJECT: BURDEN OF DENGUE FEVER IN CHILDREN AND ADULTS OF PIEDECUESTA - SANTANDER, COLOMBIA

Mabel Carabali[1], Jacqueline K. Lim[1], Diana Palencia[2], Kang Sung Lee[1], Jung Seok Lee[1], Anyela Lozano[2], Victor M. Herrera[2], Elsa Rojas[2], Luis Angel Villar[2]

[1]International Vaccine Institute, Seoul, Republic of Korea, [2]Clinical Epidemiology Unit, Universidad Industrial de Santander, Bucaramanga, Colombia

Dengue infection is a major public health problem in Colombia, likely to be interested in early adoption of dengue vaccines. The largest dengue outbreaks in the past decade were in 2010 and 2013 with incidences of 587.7 and 473.2 cases per 100,000 inhabitants, respectively. Santander is a state in the northeastern Colombia, with significantly high incidence reported in 2013 as 979 cases per 100,000 inhabitants. In preparation for the upcoming dengue vaccine introduction, Dengue Vaccine Initiative (DVI) and the Universidad Industrial de Santander conduct the passive facility-based surveillance with a cost-of-illness (COI) survey to determine the true burden of dengue fever in Piedecuesta, Santander in Colombia. The passive fever surveillance was launched in August 2014 in the public hospital and the private clinic of Piedecuesta. From febrile patients between 1-55 years-of-age from the Piedecuesta area, acute and convalescent blood samples were collected 10-21 days apart. All subjects were tested using a rapid test (NS1/IGM/IgG) and IgM/IgG Capture ELISA. Subjects with dengue positive results on any of the tests were further

tested with RT-PCR. Since the launch, there were 407 subjects enrolled as of February 2015, from which 175 (43%) were found to be positive on the rapid test for dengue. About half (53%) of the subjects were female and 60% were under 24 years-of-age. From the sub-sample with complete lab-results (n=255) up to February, we have 130 (51%) subjects confirmed with dengue, including 66 (51%) primary and 64 (49%) secondary infections. Among the 130 cases with dengue confirmation, 93 (71.5%) were clinically diagnosed with dengue, 21 (16.2%) with severe dengue (DHF), and the rest with undifferentiated fever. Among 175 patients with NS-1 positive results, 99 patients agreed to participate in our COI survey. Once the needed sample size of 150 cases is reached, data analysis will begin and more data will be available for presentation by October, 2015. The data generated on dengue disease burden in Colombia would aid the policy makers for their decision making for upcoming dengue vaccine introduction in the country.

STUDY OF ANTI-ENVELOPE ANTIBODIES IN POLYCLONAL SERA AFTER PRIMARY DENGUE VIRUS INFECTION

Chih-Yun Lai[1], Wen-Yang Tsai[1], Allison Imrie[2], **Wei-Kung Wang**[1]

[1]JABSOM, University of Hawaii at Manoa, Honolulu, HI, United States, [2]School of Pathology and Laboratory Medicine, University of Western Australia, Perth, Australia

The four serotypes of dengue virus (DENV) cause the most important and rapidly emerging arboviral diseases in humans. The envelope (E) protein is the major target of neutralizing antibodies (Abs). Previously, we and others reported that a significant proportion of anti-E Abs after primary DENV infection are cross-reactive to other flaviviruses, known as flavivirus group-reactive (GR), and recognize the highly conserved fusion loop residues of E protein. However, the characteristics of type-specific (TS) anti-E Abs, which is believed to account for the monotypic neutralization activity after primary infection, remain largely unknown. In this study, we investigated anti-E Abs in 10 individuals who experienced primary DENV1 infection during the 2001 outbreak in Hawaii. Depletion of cross-reactive Abs including complex-reactive (CR) and GR Abs did not affect the DENV1 neutralizing activities, whereas depletion of DENV1 TS Abs greatly reduced the DENV1 neutralization activities. Based on the endpoint titers to virion-ELISA after depletion, TS Abs were found to constitute 16% to 41 % of anti-E Abs and account for the TS neutralizing activity after primary DENV infection. In addition, the requirement of virions rather than solubilized E protein alone to deplete the neutralizing activities suggests the importance of neutralizing epitopes present on virions, which is in agreement with recent reports of potent TS neutralizing Abs recognizing quaternary epitopes on virions. These findings add to our understanding of antibody responses after primary DENV infection and have implications for dengue vaccine development.

1408

EVALUATION OF HUMORAL AND INNATE RESPONSES FOLLOWING A LIVE ATTENUATED DENGUE VACCINE IN FLAVIVIRUS-EXPERIENCED VOLUNTEERS

Sean A. Diehl[1], Kristen K. Pierce[1], Erick Maclean[1], Tess Solomon[1], Benjamin D. McElvany[1], Ellen A. Fraser[1], Marya P. Carmolli[1], Adrienne P. Jarvis[1], Gillian Naro[1], Catherine J. Larsson[1], Cassandra Ventrone[1], Cecelia Tibery[2], Dorothy Dickson[1], Janece Lovchik[2], Matthew Jo[2], Tama Grier[2], Beulah Sabundayo[2], Stephen S. Whitehead[3], Anna P. Durbin[2], Beth D. Kirkpatrick[1]

[1]University of Vermont, Burlington, VT, United States, [2]Johns Hopkins School of Public Health, Baltimore, MD, United States, [3]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

The four mosquito-borne dengue viruses (DENV1-4) collectively cause nearly 100 million symptomatic dengue infections annually worldwide. Current dengue vaccine development is focused on tetravalent candidates that elicit a balanced immune response against all four serotypes since all cause disease but with unpredictable circulation patterns. In the United States, live attenuated tetravalent dengue vaccine (LATV) candidates with 3' UTR deletions developed at NIAID have been tested primarily in flavivirus-naïve (FV-) individuals. Since areas endemic for dengue and other flaviviruses are of importance for LATV use, we evaluated the safety and immunogenicity of a candidate, TV003, in healthy flavivirus-experienced (FV+) individuals. Neutralizing antibody responses to three of four DENV serotypes after a single dose of TV003 were significantly higher in FV+ subjects compared to FV- subjects. Interestingly, post-TV003 titers in individuals presenting as FV+ due to yellow fever (YF) vaccination were similar or greater to those in subjects who were FV+ due to prior vaccination with monovalent live attenuated dengue candidates or through prior apparent natural exposure. In both groups, a second dose of LATV within 6 months did not boost neutralizing antibody titers. These results are consistent with a cross-flavivirus anamnestic memory akin to what has been described for Japanese encephalitis virus and YF vaccinations. The basis for anamnestic flavivirus memory is not well understood. We hypothesize that the early plasmablast response to TV003 may differ in both kinetics and magnitude in FV+ compared to FV- subjects. Since early innate immunity plays a key role in establishing robust humoral responses to vaccination, we monitored blood cell differentials in FV+ and FV- subjects after a single dose of TV003. While neutrophils dropped after TV003 in FV- subjects, these cells remained stable after TV003 administration to FV+ subjects. Both phenotypes tracked with a select subset of serum cytokines. These results introduce new parameters that can be used to monitor LATV immunogenicity in addition to serum neutralizing antibodies.

1409

EBOLA VIRUS DISEASE PREPAREDNESS AND RESPONSE STRATEGIES IN ETHIOPIA AND LESSONS LEARNED FROM WEST AFRICAN COUNTRIES

Netsanet H. Dadi[1], Mesfin T. Manyazewal[2]

[1]Menilik II Referral Hospital, Addis Ababa, Ethiopia, [2]Ethiopian Public Health Institute, Addis Ababa, Ethiopia

Shocking the world Ebola virus disease has claimed more than 10,000 lives during the current epidemic in West Africa making it the deadliest outbreak since Ebola was discovered in 1976. Evidently it has a global repercussion and response to contain spread of the epidemic .On 8 August the World Health Organization declared Ebola outbreak as a public health emergency of global Concern. The Ebola outbreak in West Africa is unprecedented in terms of its geographical scope. It began in Guinea in early 2014 and quickly spread to the neighboring countries. Inadequate health infrastructure and overall fragile health system has fuelled rapid spread of the outbreak in West Africa. The severity of the outbreak is exacerbated by lack of understanding about the disease by communities and lack of experience among health-care workers .Lack of adequate treatment facilities, rumor, fear and stigma has in turn led families to keep sick patients at home, risking further spread of the virus. Resistance to proposed response measures as well as traditional burial practices further aggravated high transmission of the outbreak with devastating economic and livelihood implications. Ethiopia by the virtue of its geographic position and being political capital of Africa and being a major transport hub in the east Africa region is very prone to the deadly virus due to importation from Ebola riddled countries. Hence it has swiftly enhanced its domestic preparedness to respond in a predictable manner in the event of Ebola outbreak .It has employed state of the art screening measures at main entry ports and has also been engaged in fighting the outbreak at its source by sending medical teams to Ebola-stricken nations. This paper reviews the current Ebola preparedness and response strategies in Ethiopia, challenges and crucial lessons learnt from West African countries and map out the strategies that are in place for improvement preventing future outbreaks.

1410

EXPRESSION OF NKG2D AND DNAM-1 LIGANDS DURING DENGUE INFECTION *IN VITRO*

Davis A. Beltran[1], Arcelys Pitti[1], Simona Zompi[2], Yamilka Diaz[1], Eva Harris[3], Lewis Lanier[2], Sandra López-Vergès[1]

[1]Gorgas Memorial for Health Studies, Panama City, Panama, [2]University of California San Francisco, San Francisco, CA, United States, [3]University of California Berkeley, Berkeley, CA, United States

The first response against dengue virus (DENV) infection is regularly mediated by the innate immune response. Natural Killer (NK) cells are an important cell population that could be implicated in the response during the early stage of DENV infection, controlling DENV replication, resulting as a mild manifestation of the disease. NK cells usually recognize the surface of infected cells coated by antibodies using its CD16 receptor, and therefore capable of performing antibody dependant cytotoxicity (ADCC). However ***in vitro*** experiments suggest that they are also capable of direct recognition of DENV-infected cells in the absence of antibodies. Ligands of NK cells activating receptors such as NKG2D receptor could be induced during early establishment of DENV infection. A role of NKG2D and its ligands in DENV immune response is supported by genetic studies that showed the association of some alleles of MICB and MICA, two NKG2D ligands, and dengue disease severity. To verify if the ligands of some NK activating receptors, like NKG2D and DNAM-1, were altered by DENV infection, we performed ***in vitro*** experiments in which immature dendritic cells derived from peripheral blood monocytes from healthy volunteer donors were infected with a DENV-2 isolate from Panama. Expression of mRNA of NKG2D and DNAM-1 ligands was assessed by qPCR in non infected cells versus infected cells at 24 hours and 48 hours post infection. All currently described NKG2D (ULBP 1-6, MICA and MICB) and DNAM-1 (PVR and Nectin2) ligands were included in our analysis. Expression of surface protein ligands was evaluated by flow cytometry. Preliminary assays of Lamp1 expression as a marker of degranulation and intracellular IFNɣ production were also evaluated. Our preliminary results suggest that NKG2D and DINAM-1 ligands are induced during DENV infection ***in vitro***, the mechanisms of induction are yet to be identified and that this could allow for recognition of infected cells by NK cells.

1411

ASSESSMENT OF THE AGE-SPECIFIC BURDEN OF DENGUE IN MIRPUR, DHAKA: A CROSS SECTIONAL STUDY

Marya P. Carmolli[1], Rashidul Haque[2], Mohammad Shafiul Alam[2], Mohammad Golam Kibria[2], Dorothy M. Dickson[1], Elizabeth R. Colgate[1], Caroline E. Lyon[1], Sean Diehl[1], Firdausi Qadri[2], Kristen K. Pierce[1], Beth D. Kirkpatrick[1]

[1]University of Vermont, Burlington, VT, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Dengue is the most significant mosquito born virus world-wide, with over two billion persons at risk for infection. In the summer of 2000, the first outbreak of 5000 cases dengue fever (serotype 3) occurred in Dhaka, Bangladesh. Since this outbreak, dengue fever has had a continued presence throughout Bangladesh. While previous studies have found that seroprevalence of dengue in Dhaka is currently approximately 80% in adults, the details of circulating serotypes and age at infection remain unknown. These data are necessary to assess the need and strategy for the introduction of dengue vaccines in Bangladesh, in particular into the extremely densely populated city of Dhaka (12 million persons). Specifically, this study determines the age-specific seroprevalence of dengue, the currently circulating serotypes, and quantitative neutralizing antibody titers in Mirpur, a densely-populated area of Dhaka. A cross sectional design is employed enrolling 700 individuals in four separate age categories: 6 month to 4 years, 4-10, 11-17, and 18-60 years. Individuals are randomly selected from household census and information on dengue risk exposure is obtained through a structured questionnaire. Dengue prevalence, serotype and antibody titer will be determined. Dengue seroprevalence is determined by IgG/IgM antibody testing; serotype and antibody level is determined by Plaque Reducing Neutralizing Antibody Titer (PRNT) assay. Differences in antibody titer among circulating serotypes and age strata will also be analyzed by analysis of variance methods according to the data distribution. Knowledge of which dengue serotypes are circulating in Dhaka, confirmation of previous exposure by age and intensity of infection will help determine burden of disease and guide safe introduction of a tetravalent live attenuated dengue vaccine in this population.

1412

NS1 CAPTURE ELISA WITH A SERUM HEAT DENATURATION STEP TO IMPROVE TEST SENSITIVITY IN PERSONS WITH SECONDARY DENGUE VIRUS INFECTION

Tesfaye Gelanew, Elba Caraballo, B. Katie Poole-Smith, **Elizabeth Hunsperger**

Centers For Disease Control and Prevention, San Juan, PR, United States

There is no licensed effective vaccine or anti-viral drug against dengue, and early diagnosis is important means to improve patient care as well as improve public health surveillance. The detection of dengue virus (DENV) non-structural protein 1 (NS1) in serum is widely used for the diagnosis of suspected dengue, worldwide. One of the limitations of the NS1 test is the reduced sensitivity in secondary DENV infections. Immune complex formation between DENV NS1 antigen and anti-DENV NS1 IgG antibodies is thought to be the cause for the decreased sensitivity of commercially available NS1 antigen capture enzyme-linked immunosorbent assays (ELISAs) observed in secondary DENV infections. Heat treatment of the serum sample could release complexed NS1 antigen by irreversible denaturation of antibodies and may improve the sensitivity of NS1 detection assays. However, this requires an assay that captures and detects heat-denatured NS1antigen. We have developed a NS1 capture ELISA using two serotype-cross-reactive, anti-NS1 monoclonal antibodies (MAbs) that bind specifically and efficiently to the heat-denatured DENV NS1. The performance of this assay was evaluated in a small panel of serum samples from patients with secondary DENV infection (n=15) and dengue negative cases (n=20), with and without heat treatment. Notably, heat treatment increased the optical density (OD) at least three-fold in dengue-positive serum samples and there was no increased OD in dengue-negative serum samples. Additionally, a considerable higher OD value was observed following heat treatment of artificially formed NS1-rabbit anti-DENV NS1 immune complexes compared to untreated ones. These findings suggest that our NS1 capture ELISA can be used to improve dengue diagnosis especially in patients with secondary DENV infections. Further evaluation of this assay in large panel of clinical samples is currently undergoing.

DENGUE COHORT STUDY, ARARAQUARA, BRAZIL, 2015, BASELINE SEROPREVALENCE

Expedito J. Luna[1], Gerusa M. Figueiredo[1], Jose E. Levi[1], Walter M. Figueiredo[2], Angela A. Costa[2], Sergio R. Campos[1], Alvina C. Felix[1], Ana C. Souza[1], Nathalia C. Souza[1], Maria R. Cardoso[1], Claudio S. Pannuti[1]

[1]Universidade de Sao Paulo, Sao Paulo, Brazil, [2]Universidade de Sao Paulo, Araraquara, Brazil

The number of reported cases does not fully represent the dengue burden. Access to health care, misdiagnosis and underreporting are factors that may influence dengue cases reporting. More accurate data on incidence are needed to support the evaluation of novel control strategies. A cohort study to assess the incidence of dengue among children and adolescents, from 2 to 16 years of age, in a low endemic setting has started in August, 2014. Data on the baseline seroprevalence will be addressed here. A random sample of children and adolescents was selected from the population of Araraquara, a city in Central-Western São Paulo State. Home visits were made to the families of selected children, to present the study and invite them to participate. The ones who agreed

to participate signed an Informed Consent Form. An interview on socio-demographic characteristics was carried out and blood samples from the selected children were drawn for dengue baseline serology. Dengue IgG antibodies were tested by enzyme-linked immunosorbant assay (ELISA). Families are being contacted weekly for fever surveillance. Fever cases are submitted to dengue diagnosis tests. 3,514 children and adolescents agreed to participate in the study. 50.5 % are girls. Their mean age is 7.9 years of age. The distribution according to age groups is 27.6% from 2 to 4 years of age; 36.7% from 5 to 9; 22.7% from 10 to 13; and 12.9% from 14 to 16. The baseline prevalence of IgG antibodies was 15.2%. There was no difference in prevalence according to gender. Regarding age groups, there was no difference in prevalence among the younger groups (from 2 to 13 years of age). Prevalence in the age group 14 - 16 was higher (18.6%), when compared to the younger group ($p = 0.047$). Despite the observed dengue transmission since 2000 in Araraquara, the seroprevalence among children and adolescents remains low. Surprisingly there was no increase in prevalence from 2 to 13 years of age, as observed in hyperendemic settings in Brazil. The state of São Paulo is facing its largest dengue epidemic ever in the 2015 transmission season. The follow up of the cohort will allow the assessment of incidence, as well as changes in prevalence.

1414

SPATIAL-TEMPORAL PATTERNS OF DENGUE AND CHIKUNGUNYA TRANSMISSION IN APARTADO, ANTIOQUIA, COLOMBIA. A PILOT CLUSTER STUDY

Catalina Alfonso-Parra, Berta N. Restrepo Jaramillo, Wilber Gomez, Leidy D. Piedrahita

Instituto Colombiano de Medicina Tropical, Sabaneta, Colombia

Dengue and Chikungunya are two important arboviruses in tropical and subtropical urban and semi-urban areas. Of these arboviral threats, dengue is considered the most important, affecting an estimated 390 million people per year, with 500,000 episodes of severe dengue and >20,000 dengue related deaths. In Antioquia, department of Colombia, 26,027 cases of dengue were reported in 2010, 300 of which resulted in hemorrhagic fever. Chikungunya is now a threat in the Americas_as of January 2015, >1,135,000 suspected cases have been recorded in the Caribbean, Latin America and the United States. In Colombia, 249,013 cases have been confirmed since September 2014. Transmission of the dengue and chikungunya viruses is determined by factors related to their hosts, virus biology, their vectors (***Aedes aegypti*** and ***Ae. albopictus***) and the environment. With no effective vaccine and no treatment for dengue or chikungunya, control of these diseases is focused on suppresing their mosquito vector populations through environmental managment strategies and insecticide use. Examining patterns of viral transmission, and the factors that cause those patterns, will improve disease prevention and surveillance, ultimately reducing the burden of human infection. To gain insight into the patterns of dengue and chikungunya infection and the behavior of their vectors, we are conducting a pilot study of viral transmission in neighborhood clusters in Apartado, Antioquia, Colombia, a population endemic for dengue. This clustering method allows for the fine resolution of viral transmission dynamics within small geographic spaces during a short temporal scale. Data on human and mosquito infection, mosquito density and biometrics will be shown. These results will contribute to our knowledge of spatial-temporal patterns of dengue and chikungunya transmission, as well as the demographic and entomologic factors important for the spread of the virus. Our goal is to aid the local government in planning and applying strategies for vector and disease control.

1415

ESTIMATING THE SUPPLY AND DEMAND OF A BUTANTAN DENGUE VACCINE USING DIFFERENT INTRODUCTION STRATEGIES IN BRAZIL

Cristina R. Garcia[1], Marta Wilson-Barthes[1], Giovanini E. Coelho[2], Carla Domingues[3], Dagna Constenla[4]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]National Dengue Control Program, Ministry of Health, Brasilia, Brazil, [3]National Immunization Program, Ministry of Health, Brasilia, Brazil, [4]Johns Hopkins Bloomberg School of Public Health and Dengue Vaccine Initiative, Baltimore, MD, United States

We modeled the vaccine demand, total implementation costs, and economic impact of Butantan's one-dose tetravalent dengue vaccine in Brazil for different introduction strategies in Brazil, using an integrated model approach. Input parameters on vaccine pricing, production capacity, introduction strategies, and related costs were derived from local Brazilian stakeholders. Country-specific epidemiological data were obtained from disease reporting systems. Thirty-year population projections were made with Brazil adopting by 2019. Brazil's highest dengue burden is among adults 19-46 years, and strategies targeting adults and children were modeled based on existing immunization age groups. Initial strategies targeting all ages or ≥18 year olds exceeded capacity and were considered not feasible. The demand for strategies targeting children ≤18 years was within capacity, but for adults 18-59 years, demand exceeded capacity by year 2024 except when stratifying by ages 19-31 (93.4M) and 31-46 (96.2M). At $5 per dose, the average annual cost of introduction ranged from $21.1-405.8M in the first 10 years to $52.6-810.4M in the last 10 years. The most affordable scenario was children aged 1-2 years, but this scenario had little disease burden impact (34% case reduction in last 10 years). Stakeholders prioritized vaccinating ages 7-60 years in the first 3 years followed by routine immunization in ages 2-6 years, but the expected capacity can only meet 76% of the demand over the first 3 years. Focusing on ages 2-46 years and staggering introduction over the first 5 years was feasible and had the greatest impact on reducing cases (90%) and deaths (79%) and on treatment cost savings (84%). Vaccinating adults followed by children yields the greatest vaccine impact. Vaccine price, introduction strategies, age, and production capacity are major drivers of the demand and require consideration when deciding vaccine introduction. Dengue vaccine has the potential to reduce cases and associated costs substantially based on various introduction scenarios.

1416

TRANSPLANTATION OF A COMPLEX QUATERNARY ANTIBODY EPITOPE FROM DENV3 INTO DENV4 REVEALS DETERMINANTS OF SEROTYPE-SPECIFIC NEUTRALIZATION AND DETAILS OF THE HUMORAL RESPONSE TO DENGUE INFECTION IN NON-HUMAN PRIMATES

Douglas G. Widman[1], Scott R. Royal[1], Jesica A. Swanstrom[1], Boyd L. Yount[1], Petraleigh Pantoja[2], Idia V. Rodriguez[2], Aravinda M. de Silva[1], Carlos A. Sariol[2], William B. Messer[3], Ralph S. Baric[1]

[1]University of North Carolina Chapel Hill, Chapel Hill, NC, United States, [2]University of Puerto Rico, San Juan, PR, United States, [3]Oregon Health and Science University, Portland, OR, United States

Despite an incidence of nearly 400 million infections per year, no approved therapeutics or vaccines exist to treat or prevent dengue virus (DENV) infection. Vaccination against DENV is complicated by the existence of 4 serotypes. Infection with one serotype does not confer immunity against heterologous serotypes. In fact, people exposed to secondary infections have an increased risk of severe disease thought to be a result of antibody-dependent enhancement of infection and aberrant cellular immune responses to the initial infecting serotype. As such, vaccination must induce a balanced protective response to all 4 serotypes simultaneously. To date this has been a challenge leading live-

attenuated tetravalent vaccine candidates have struggled with, indicating that new vaccine strategies may be needed. We recently reported on the discovery of a potent DENV3 human mAb (5J7) that recognizes a complex quaternary epitope present on the DENV3 virion. Using reverse genetics and structure-guided modeling, we have transplanted increasingly larger regions of the DENV3 mAb footprint into DENV4, to generate 3 recombinant DENV (from smallest transplant to largest: DENV4 M12, M14, and M16). These 3 rDENV4 were viable and demonstrated slight to moderate attenuation in cell culture systems. Importantly, the DENV3 mAb 5J7 bound and neutralized both DENV4 M14 and M16, indicating successful transplantation of the DENV3 epitope. Immune sera from people exposed to primary DENV4 and DENV3 neutralized DENV4 M14 and M16, demonstrating bivalent neutralization sensitivity of these viruses. Neutralization sensitivity was specific as DENV1 and DENV2 antisera did not neutralize rDENV4 M14 and M16. Inoculation of Rhesus macaques with DENV4 M14 or M16 resulted in detectible serum viremia in 3 of 4 animals receiving M14 and 1 of 4 animals receiving M16, and detectible DENV-specific IgM and IgG in a subset of animals. Taken together these results provide a more complete understanding of the development of complex antibody responses following DENV infection and have the potential to inform future vaccine design.

1417

GENERATING SUPPLY AND DEMAND ESTIMATES TO INFORM DENGUE VACCINE INTRODUCTION IN MEXICO, HONDURAS AND EL SALVADOR: A STRATEGIC DEMAND FORECAST

Grace A. Morgan[1], Jorge Martin del Campo[1], Ali Greenberg[1], Cristina Garcia[1], Marta Wilson-Barthes[1], Dagna Constenla[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Johns Hopkins Bloomberg School of Public Health and Dengue Vaccine Initiative, Baltimore, MD, United States

Mexico, Honduras and El Salvador have recently reported growing incidence and mortality attributed to dengue hemorrhagic fever in the Americas. The growing burden of dengue in these countries has drawn attention to the need for an equitable dengue vaccine introduction. Currently, there are no studies that quantify the demand and supply of the dengue vaccine to inform the value of dengue vaccine introduction in Mexico, Honduras or El Salvador. Dengue strategic demand forecasts are a valuable decision-making tool that can evaluate the temporal demand of dengue vaccination, estimate the purchase costs of vaccination, and approximate the funding requirements for the vaccine according to different introduction scenarios. This study aims to generate new evidence on the potential demand and supply of two dengue vaccine candidates in Mexico, Honduras and El Salvador. We adopted an existing strategic demand forecast model to assess the potential demand of the vaccine candidates and estimate the purchase costs and disease impact of this demand in the three countries. Early results from extensive stakeholder consultations, including local government policymakers, program managers and vaccine researchers, indicate that, for a number of different scenarios, average national annual demand could be up to 105 million doses (entire endemic area) over 5 years. These levels of demand could result in substantial annual revenues over the same period. Higher vaccine demand requires increased capacity. Results rest on price, supply constraints, and timing of licensure. Governments in the three countries can increase their vaccine uptake by strengthening their national regulatory systems, expanding their healthcare infrastructure and programs to reach high-risk populations, and negotiating vaccine prices. Dengue strategic demand forecasts can aid overall strategic planning for vaccine introduction in the three countries.

1418

COST OF DENGUE VACCINE INTRODUCTION IN THE AMERICAS

Jorge Martin del Campo, Grace Morgan, Marta Wilson-Barthe, Cristina Garcia, Dagna Constenla

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Planning for introduction of a novel vaccine relies heavily on financial considerations related to vaccine price, cost of production, and vaccine funding. Seven Latin American countries - Argentina, Brazil, Colombia, Ecuador, Mexico, Nicaragua and Venezuela - were selected to estimate the implementation cost of the Sanofi Pasteur three dose dengue vaccine and the potential financial impact at the national level. An economic supply and demand model was used to assess vaccine impact over a 30 year forecast. Country-specific data on age stratified case rates, treatment costs, vaccine coverage, and immunization costs was collected through national disease reporting systems and stakeholder interviews. Three survey versions were developed to align model inputs with stakeholder expertise. A variance range was applied to model parameters to account for differences across scenarios. Costs ranged from US$5-$15 per dose with the initial introduction strategy targeting children 2-14 year olds based on trends in disease burden. Results demonstrate that at highest potential price per dose, total cost of introduction to most countries was less than US$ 20M in the first three years. Highest cost was seen in Brazil and Mexico for the same time frame (US$1B; US$500M). At the lowest price per dose of US$5 over 3 years, highest introduction cost was for Brazil (US$419M) and less than US$ 2M for remaining countries. Vaccine purchasing costs had the highest financial impact in larger countries, estimated between US$460-$1370 for Brazil in the first five years and US$290-$870 in Mexico. Vaccine price represented the greatest portion of total production costs, with a difference of US$1.3 B between a US$5 per dose and US$15 per dose in the first three years in select countries. Understanding the financial requirements of a novel vaccine and the economic impact will service in accelerating uptake and increasing future health impact.

1419

CONSENSUS-BUILDING TO SUPPORT NOVEL VACCINE INTRODUCTION: METHODS AND LESSONS LEARNED FROM A STRATEGIC DEMAND FORECAST OF A DENGUE VACCINE IN BRAZIL

Marta Wilson-Barthes[1], Cristina Garcia[1], Giovanini Coehlo[2], Dagna Constenla[3]

[1]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [2]National Dengue Control Program, Federal Ministry of Health, Brasilia, Brazil, [3]International Vaccine Access Center, Johns Hopkins University, Dengue Vaccine Initiative, Baltimore, MD, United States

We present methods used to model vaccine demand of a one-dose tetravalent dengue vaccine in Brazil. Understanding the potential demand and associated impact of this vaccine will inform introduction decisions and strategies. Public sector demand estimates were based on demographic, epidemiologic, and vaccine uptake assumptions derived from local stakeholder surveys, disease reporting systems and national and state-level census data. Using a combination of the above sources along with multi-level vetting and validation of model parameters, consensus was reached on a number of model parameters, including state-level age distribution of cases, vaccine coverage, and appropriate proxy vaccines. Consensus depended heavily on the strength of stakeholder survey questions and prioritization of stakeholder interests. Other factors that contributed to consensus agreement were early stakeholder involvement during data collection and participation of stakeholders with multidisciplinary backgrounds to reduce stakeholder bias. Disagreement remained on parameters related to target population and vaccine price.

Immunization program experts supported vaccine introduction through routine immunization in 1-2 year olds while vaccine manufacturers supported initial introduction in adults 15-49, the population considered high risk in Brazil. Disagreement remained regarding the public sector vaccine price and their willingness to pay. Where consensus was not reached, parameters were varied over multiple model iterations. Estimates of dengue vaccine demand are driven largely by supply constraints, vaccine price, timing of licensure, vaccine uptake after introduction, and population at highest risk for infection. Consensus was the result of a collaborative effort between investigators, internal staff, and participating stakeholders. Ongoing validation between parties was necessary to ensure plausibility of introduction strategies at every stage of analyses. Creating consensus around model parameters is critical for an impact study with a high level of unknown parameters and informs decision-making processes.

1420

CASE REPORT: ACUTE MYOCARDITIS CAUSE DEATH IN DENGUE PATIENT

Jean N. Hernandez

University of Puerto Rico, San Juan, PR, United States

Dengue is a mosquito borne viral disease affecting 50-100 million people yearly. Despite global efforts neither an effective vaccine nor drug treatment are available. Infection with any of the four dengue virus serotypes 1-4 can cause outcomes that range from asymptomatic or mild disease to fatal dengue hemorrhagic fever/dengue shock syndrome. Typical signs and symptoms associated with most symptomatic infections include fever, headache, malaise, and body aches depending of the dengue serotype and the host immunological response. Severe manifestations are usually associated with subsequent infections and very rarely with first dengue infection. A 32 years old female was admitted to the clinic with fever, headache, body aches and malaise. No travel history, prior disease and no previous history of cardiac disease reported. The patient was previously treated at two outpatient health centers with medications to ameliorate fever and headache. She was admitted to the emergency room with hypotension, headache which increase by the hours, and immediately transferred to the Intensive Care Unit. Hypotension 80/60 mmHg of BP, cardiac frequency 120/min and breathing 32/min. Broad spectrum antibiotic treatment, antimalarial drugs and inotropics was administered inmediately. Results revealed Ig M positive reaction for dengue, hematocrit 41%, and platelets 35,000/ml. An abdominal ultrasound revealed evidence of cholecystitis and free liquid in the Douglas compartment, Leptospira test negative and smear for malaria negative. A cardiac ultrasound evidenced myocarditis and 25% of flow ejection. The patient clinical evolution was decreasing and in 36 hours after her admission to the clinic died, with multi organic dysfunction.The final diagnosis was myocarditis, pericardical effusion, and dengue shock syndrome, as the main cause of death. This is the first case of myocarditis due to acute dengue infection reported. It is important to educate individuals about the treatment and monitoring of vector borne virus disease and is convenient to perform the treatment in the same health facilit.

1421

PHYLOGENETIC ANALYSIS OF THE FOUR DENGUE VIRUS SEROTYPES THAT HAVE CIRCULATED IN PANAMÁ FROM 1993 TO 2014

Yamilka Y. Díaz[1], Jean Paul Carrera[1], Leticia Franco[2], Robert Tesh[3], Sandra Lopez-Verges[1]

[1]Gorgas Memorial Laboratory, Panama, Panama, [2]Instituto de Salud Carlos III, Spain, Spain, [3]University of Texas Medical Branch, Galveston, TX, United States

After 50 years of absence, Dengue virus (DENV) reemerged in Panama in 1993. Until 2014, a total of 55,970 Dengue cases with a case severity rate of Dengue Hemorrhagic fever (DHF) of 0.3% and of 48 deaths were reported. There is no information about the dynamic of the introduction, circulation and phylogenetic of the four serotypes of DENV in Panama. Since its reemergence, Dengue is endemic and all of the serotypes have circulated, with DENV-4 been reported only in 1999-2001. The reintroduction and replacement of serotypes has been associated with outbreaks. DENV-2 reemergence was responsible of the 1993 outbreak; during 1995 outbreak DENV-1 and DENV-2 co-circulated; in 2011 DENV-1 and 3 co-circulated and the reintroduction of DENV-2 was associated with an increase of the cases and the severity of the disease. Since then, DENV-2 is the main serotype in the country with the 90% of the PCR detected cases, and was also responsible of the 2013-2014 outbreak. Here we present the phylogenetic analysis of representative strains of each region of Panama from 1993 to 2014 of all four serotype of DENV and analyze the relationship with strains circulating in neighbor countries. We sequenced the coding region of the E envelope protein of at least two isolates by year of circulation for each serotype: 83 isolates for DENV-1; 38 for DENV-2; 15 for Denv-3 and 6 for DENV-4. Preliminary results show that the isolates of DENV-1 belonged to American/African genotype, DENV-2 to Southeast Asian/American genotype and DENV-3 to genotype III, DENV-4 isolates are still under analysis. Our data also show that the reintroduction of some of the serotypes included the circulation of different clades, related with clades circulating in neighbor countries. This suggests that because our geographic position, Panama could be a bridge between strains circulating in the North, South American and Caribbean regions. Future studies will evaluated the phylogeography dynamic of the Panamanian Dengue strains in the rest of the American continent to allow a better comprehension of the exchange and movements of DENV across the continent.

FINDINGS FROM AN ACUTE FEBRILE ILLNESS ENHANCED SURVEILLANCE STUDY IN PUERTO RICO

Luisa I. Alvarado[1], Aidsa Rivera[2], Olga D. Lorenzi[2], Gladys González[2], Doris Andújar-Pérez[1], Tyler Sharp[2], Janice Pérez-Padilla[2], Jorge Muñoz[2], Elizabeth Hunsperger[2], Steve Oberste[2], William A. Nix[2], Elizabeth Henderson[2], Renee Galloway[2], Mindy Glass Elrod[2], Demetrius Mathis[2], Carlos García-Gubern[1], William Santiago[1], Jesús Cruz-Correa[1], Domingo Ortiz[3], Gerson Jiménez[3], Robert Munsosa[3], Harold S. Margolis[2], Kay M. Tomashek[2]

[1]Ponce School of Medicine of the Ponce Health Sciences University/Saint Luke's Episcopal Hospital, Ponce, Puerto Rico, [2]Dengue Branch, Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, San Juan, Puerto Rico, [3]Saint Luke's Episcopal Hospital Guayama, Guayama, Puerto Rico

Dengue has been endemic in Puerto Rico for four decades, but little is known about other acute febrile illnesses (AFI) on the differential diagnosis of dengue. The Sentinel Enhanced Dengue Surveillance System (SEDSS) was implemented in two hospitals in southern Puerto Rico. Patients with fever or history of fever for <7 days were enrolled and followed through their illness. Blood, urine, nasopharyngeal, and oropharyngeal specimens were collected at enrollment and tested by RT-PCR and immunodiagnostic methods as appropriate for dengue viruses 1-4 (DENV); Influenza virus A and B; ten other respiratory viruses (ORV) including adenovirus, respiratory syncytial virus, metapneumovirus and parainfluenza viruses 1 & 3; enteroviruses; ***Leptospira*** spp., ***Burkholderia pseudomallei,*** and chikungunya virus (CHIKV). Of 31,525 AFI patients presenting from May 7, 2012 through September 30, 2014, 7,491 (24%) were enrolled. Of these, 26% were hospitalized, 50% were female, and the median age was 14 years (range: 0-103 years). An etiologic agent was identified in 46% (3,510), including DENV (13%), Influenza A or B (12%), ORV (10%), CHIKV (9%), enteroviruses (0.8%), Leptospira spp. (0.1%), and B. pseudomallei (<0.1%). In addition, 83 co-infections were confirmed by PCR, more than forty percent (42%) included DENV. Most (92%) of the 718 DENV PCR positive cases were DENV-1. Dengue patients were slightly older than other enrolled patients (median age: 15 versus 14 years, respectively), but younger than influenza patients (median age: 17 years). Dengue patients were more likely to be admitted than other

enrolled patients (OR = 2.89, 95% CI: 2.54-3.33) and influenza patients (OR = 3.57, 95% CI: 2.88-4.43). Almost half of all cases had a pathogen detected and most were caused by either a DENV, a respiratory virus (Influenza or ORV), or an enterovirus. Leptospirosis and melioidosis cases were sporadic and focal; study of these diseases may require study sites in high risk areas. Reasons for why dengue cases were more likely to be hospitalized will be studied further. We expect to use the SEDSS platform to conduct clinical research and evaluate current management practices.

HIGH BURDEN OF DENGUE FEVER IN SOUTHERN COASTAL ECUADOR: EPIDEMIOLOGY FROM A PROSPECTIVE STUDY IN MACHALA IN 2014

Anna M. Stewart Ibarra[1], Christine A. King[2], Arturo Barbachano-Guerro[2], Efraín Beltrán-Ayala[3], Mercy J. Borbor-Cordova[4], Washington B. Cárdenas[5], Cinthya K. Cueva[1], Renato León[6], Julia L. Finkelstein[7], Christina D. Lupone[1], Saurabh Mehta[7], Sadie J. Ryan[8], Mercy Silva[3], Timothy P. Endy[1]

[1]SUNY Upstate Medical University, Center for Global Health and Translational Science, Syracuse, NY, United States, [2]SUNY Upstate Medical University, Center for Global Health and Translational Science, Department of Microbiology and Immunology, Syracuse, NY, United States, [3]Ministry of Health, Machala, Ecuador, [4]Facultad de Ingeniería Marítima, Ciencias Biológicas, Oceánicas y Recursos Naturales, Escuela Superior Politécnica del Litoral, Guayaquil, Ecuador, [5]Laboratorio de Biomedicina, Escuela Superior Politécnica del Litoral, Guayaquil, Ecuador, [6]Laboratorio de Entomología Médica and Medicina Tropical, Universidad San Francisco de Quito, Quito, Ecuador, [7]Division of Nutritional Sciences, Cornell University, Ithaca, NY, United States, [8]Department of Geography and Emerging Pathogens Institute, University of Florida, Gainesville, FL, United States

Comprehensive epidemiological studies that integrate passive and active surveillance of the dengue virus and vector are needed to inform the development of effective local control programs and novel interventions, including testing and licensure of new vaccines. Here we report the findings from the first year of a prospective study of dengue transmission conducted in Machala, Ecuador, a key surveillance site located near the Ecuador-Peru border. Individuals who presented with suspected dengue fever (index cases) at four sentinel clinics and the central hospital of the Ministry of Health were recruited into the study (n=204, mean age 21y, 48% female). Index cases with acute dengue infection (NS1 rapid strip positive) triggered an investigation of dengue cases in the index household and four neighboring households (n=329, 9-10 people per cluster, mean age 35y, 64% female). The primary endpoint was acute dengue infection, indicated by positive NS1 rapid strip, NS1 ELISA, or RT-PCR; secondary endpoints were recent secondary (IgG ELISA positive) and primary (IgM ELISA positive) dengue infections. Cases were deemed febrile if ear temperatures were >37°C. Dengue transmission peaked in mid-May following the onset of the hot, rainy season and an increase in adult female ***Ae. aegypti*** densities; the weekly incidence of acute cluster and index cases was significantly correlated ($p<0.05$). Children 10 to 14 years of age had the highest burden of dengue. In index cases, the prevalence of afebrile and febrile acute dengue infections was 11.1% and 20.2%; recent secondary and primary infections were detected in 46.1% and 57.2% of cases. In cluster cases, the prevalence of afebrile and febrile acute dengue infections was 11.8% and 4.4%, with recent secondary and primary infections detected in 37.9% and 25.2% of cases. DENV-2 was the dominant serotype, although all four serotypes (DENV1-4) were detected. Findings indicate that there is a high burden of symptomatic and inapparent dengue infections in this region, highlighting the need for improved surveillance and disease control interventions.

1424

PERSISTENT SYMPTOMS OF DENGUE: SYSTEMATIC REVIEW AND ESTIMATES OF THE INCREMENTAL ECONOMIC BURDEN IN MEXICO

D. Carolina Tiga[1], Eduardo A. Undurraga[2], José Ramos-Castañeda[1], Ruth Martinez-Vega[3], Yara A. Halasa[2], **Donald S. Shepard**[2]

[1]Instituto Nacional de Salud Publica, Cuernavaca, Mexico, [2]Brandeis University, Waltham, MA, United States, [3]Universidad Industrial de Santander, Bucaramanga, Colombia

Dengue imposes a substantial disease burden to health systems in most tropical and subtropical countries worldwide. Symptomatic dengue infections are considered as mainly acute illnesses with three phases: a 1-7 day febrile phase, a critical phase affecting a small share of patients with possible hemorrhagic manifestations, and a 2-3 day recovery phase leading to a quick improvement of symptoms. But some dengue patients present persistent symptoms including profound fatigue, depression, and weight loss, a possibility acknowledged by WHO since 1997. If persistent symptoms affect a non-negligible share of the population, previous studies probably underestimate the burden of dengue. We performed a systematic review of literature of primary studies in English, Spanish, and Portuguese, in PubMed, Web of Science, LILACS, and SciELO since 1980. We identified a total of 31 articles, 11 of which (from Brazil, Cuba, Peru, and Singapore) satisfied our criteria (full-text available, empirical data, scientifically valid approach, and external validity). Persistent symptoms were usually associated with female and older age, and additional medical expenses. We found a significant relation between the share of patients (s) reporting persistent symptoms that may result in work loss (fatigue, asthenia, or difficulty working) and time (in months, t): $s=\exp(3.12-.38*\ln(t))$, $p=.03$, $r2=.24$. Using these predicted values, we updated recent estimates of the economic burden of dengue in Mexico, addressing uncertainty in the loss of productivity and additional expenses using Monte Carlo simulations. Our estimates suggest that persistent symptoms represent about US$38.2 (US$19.3-US$57.0) million annually in additional costs (US$0.35 per capita), or a 23% increase over previous estimates of economic burden in Mexico (US$170 million, US$1.56 per capita). While there is uncertainty in our estimates due to limited data, our results show a substantial neglected economic burden of dengue due to persistent symptoms. Given the breadth of the literature by continent and demographics, similar patterns likely extend to other dengue endemic countries.

1425

MIR-34A IS AN ANTI-FLAVIVIRAL MICRORNA THAT ENHANCES THE INNATE IMMUNE RESPONSE THROUGH REPRESSION OF THE WNT PATHWAY

Jessica L. Smith, Alec J. Hirsch

Oregon Health and Sciences University, Portland, OR, United States

MicroRNAs (miRNAs) are small, noncoding RNAs that modulate gene expression post-transcriptionally and have been demonstrated to regulate a broad range of cellular processes. Our research is focused on identifying pro- and anti-flaviviral miRNAs as a means of elucidating cellular pathways that support or limit viral replication. To this end, we have screened a library of known human miRNA mimics for their effect on replication of three flaviviruses--dengue (DENV), West Nile virus (WNV), and Japanese encephalitis virus (JEV)--using a high throughput immunofluorescence screen. Of more than 1200 miRNA mimics screened, 61, 117, and 217 miRNA mimics were found to significantly inhibit infection of DENV, WNV, and JEV, respectively, with 23 blocking replication of 2 or more viruses. Members of the miR-34 family--miRNAs that have been extensively characterized for their inhibitory effects on the Wnt/β-catenin signaling pathway--demonstrated strong anti-flaviviral effects. Previous research has suggested that crosstalk occurs between the Wnt signaling and type I interferon (IFN) pathways. Therefore, we investigated the role of type I

IFN induction in the inhibitory effect of miR-34a and confirmed that miR-34a enhances the activation of IRF3 phosphorylation and translocation to the nucleus, induction of IFN-responsive genes, and release of type I IFNs from transfected cells. Importantly, enhancement of innate immune signaling by miR-34a does not occur in the absence of a stimulus, such as viral infection. This characteristic, along with the extensive ***in vivo*** characterization that has already been performed on miR-34a mimics as anti-cancer agents, makes this miRNA an attractive candidate for investigation as an ***in vivo*** antiviral treatment. Current research is focused on investigating the effect of miR-34a against WNV infection a mouse model. These findings highlight the opportunities for using miRNAs to discover novel cellular pathways and factors involved in supporting or limiting virus replication.

RECRUITMENT AND CHARACTERIZATION OF A LOCAL DENGUE IMMUNE COHORT IN PORTLAND, OR

Adam Brady, Justine E. Sunshine, Sarah Gabriel, William Messer

Oregon Health & Sciences University, Portland, OR, United States

Dengue virus (DENV) is the most important arthropod-borne virus affecting humans worldwide. The specific correlates and determinants of natural long-term DENV immunity are not known, without which designing and evaluating candidate DENV vaccines must proceed in the absence of reliable targets and endpoints. Large cohorts of naturally dengue immune individuals are vital resources for defining the critical correlates of dengue immunity. While investigators have recruited international DENV immune cohorts to study natural DENV immunity, local DENV immune cohorts offer several advantages over internationally based cohorts, including: 1) recruited individuals are unlikely to be confounded by repeat infection, with only long-term immunity present, 2) adult recruits can provide large volume serum and cell samples serially can be taken and processed locally and contemporaneously, 3) given time, a local cohort is expected to include donors with diverse DENV exposures that vary over time, geography, and DENV serotype. Here we present the design, execution and initial characterization of a DENV immune cohort based at Oregon Health & Sciences University in Portland, OR. We use previously validated recruitment approaches including traditional media, social media, email and direct physician contact to identify and recruit DENV immune individuals from local college student populations, cultural centers, and medical clinics expected to serve populations enriched for DENV exposure. Additionally, we focused recruitment efforts in the Portland VA Medical Center, which has a patient population expected to be enriched for very remote DENV exposure. From this cohort we expect to subsequently develop a baseline understanding of the correlates of long-term DENV immunity, specifically rates of neutralizing antibody decay and persistence of DENV immune cells. This cohort will provide new high-value immune sera and cells for both dissecting components of protective DENV immunity and validating targets and correlates of long-term DENV immunity.

TOWARDS REFINING THE GLOBAL DENGUE MAP: SEROPREVALENCE VS. CASE DATA

Isabel Rodríguez Barraquer, Derek A. Cummings

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Good understanding of the transmission dynamics of infectious diseases is important to design effective control strategies. In particular, good estimates of the force of infection (the per capita hazard of infection), and of the basic reproductive number (R0) are critical because they give insight into the level of control that is required to reduce incidence and eventually block transmission. Given that population based serological studies (the gold standard) are very scarce, recent efforts to generate a global dengue map have been based on crude case counts and occurrence (presence/absence) data. However, inference from case counts is often misleading due to the poor correlation that exists between infection and symptomatic disease, and to differences that exist between and within surveillance systems. Here, we build on existing frameworks to estimate yearly forces of infection and R0 from age-specific incidence data and census data. We then use publicly available data to produce detailed updated maps of the transmission hazard and R0 of dengue in Thailand, Brazil, Mexico and Colombia. Preliminary analyses show very good agreement between our estimates and those obtained from age-stratified serological surveys from a range of settings. These include historically hyperendemic settings (Rayong, Thailand) and settings where dengue more recently re-emerged (Recife, Brazil; and Piedecuesta, Colombia). Furthermore, when applied to data from re-emergent settings, model estimates correctly the date of re-emergence. Additional analyses will include comparisons to additional serological data and to previously published estimates. Good characterization of dengue epidemiology will be fundamental to design optimal vaccination strategies and control interventions. This framework provides an opportunity to reconstruct recent dengue trends at a local scale and to refine the global dengue map using data that is readily available from multiple surveillance systems.

DENGUE INFANT COHORT STUDY IN BRAZIL

Renata Saraiva Pedro, Vania Girianella, Mayumi Wakimoto, Stephanit Penetra, Luana Santana Damasceno, Liege Carvalho, Denise Cotrim, Jennifer Braathen Salgueiro, **Patricia Brasil**

Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil

Dengue disease is the most prevalent arthropod-borne viral disease in humans and is a global and national public health concern in Brazil. Prospective studies are important to estimate incidence and to guide control measures. The aim of this study was to estimate the prevalence of dengue in pregnant women and the incidence in infants from a community in Rio de Janeiro (RJ). Prospective study of 0-2 years-old children who live in Manguinhos, an urban slum community in RJ, going on since May 2012. Pregnant women at third semester followed by the local Family Health Program were recruited. Epidemiological, clinical data and blood samples were obtained for dengue serological survey. The infants had programmed pediatric visits for evaluation of fever history and blood collection for serological tests (IgM). Mothers were instructed to contact the study staff, in case of infant´s fever. Active febrile surveillance was made by telephone calls, facebook and home visits. Pediatric visit is scheduled within 7 days after the onset of fever. The study was approved by the local Ethical Board No. 308/2011 CAAE: 0048.0.009.031-11. In two years, 502 pregnant women were included in the study with median age of 25 years-old (15 to 44). 90.5% tested positive for dengue IgG. There were 8 stillbirths, resulting in a total of 494 newborns eligible for follow-up. Until March 2015, 25.5% were lost for follow-up, most of them due to address change. From 374 infants on followed-up, 33.3% were infected by DENV in the 1st year of life. The high prevalence of positive IgG in young women is expected in hiperendemic areas as RJ where DENV circulates since 1986. The high incidence of dengue observed in infants in the 1st year of life raises the question about the protection to dengue by the maternal transmission of neutralizing antibodies. However, it can also be a result of the recent introduction of DENV-4 in Rio. The maintenance of this cohort is important to confirm our preliminary results and to determine the ideal age of life for vaccine trials. It also enables the study of environmental and individual factors associated to dengue infection.

DYNAMIC EXPANSION FACTORS ENABLE REAL-TIME USE OF SURVEILLANCE DATA

Krzysztof Sakrejda[1], Nick Reich[1], Stephen Lauer[1], Derek Cummings[2], Paphanij Suangtho[3], Soawapak Hinjoy[3], Sopon Iamsirithaworn[4], Suthanun Suthachana[5], Hannah Clapham[2], Justin Lessler[2]

[1]University of Massachusetts, Amherst, MA, United States, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Bureau of Epidemiology, Bangkok, Thailand, [4]Office of Disease Prevention and Control I, Bangkok, Thailand, [5]Communicable Disease Section, Nonthaburi, Thailand

Surveillance systems generate data on disease incidence at a delay but public health decisions require current data. Recent work has focused on reducing reporting delays by converting to electronic records and centralized databases. For large systems these changes are expensive and time consuming, and there will always be some delays as records are reviewed for quality and updated based on laboratory tests. We propose a method to adjust case counts for under-reporting resulting from delays in the surveillance process. Our approach estimates dynamic expansion factors from statistical models of the surveillance system based on either individual case data or aggregated counts. We demonstrate the large-scale application of these methods using data from the Thai passive notifiable disease surveillance system (R506) for the years 2013-2015. To generate dynamic expansion factors we construct a country-wide contaminated Weibull model of reporting times with time-specific and province-specific parameters. We will present results from the 2015 dengue season and characterize the ability of dynamic expansion factors to accurately predict finalized case counts. Key lessons from this exercise are that 1) dynamic expansion factors increase the utility of reported surveillance data; 2) in a system with multiple reporting units creating accurate dynamic expansion factors requires characterizing surveillance process variation among units and over time; and 3) a model-based characterization of the reporting system can be an important resource for the management of the surveillance system. Future work will focus on integrating reporting and population dynamics into joint forecasts.

ANTIGENIC IMPACT OF GENOTYPIC VARIATION WITHIN THE DENGUE 1 ENVELOPE PROTEIN

Jessica A. Plante, Mary A. Bone, Scott R. Royal, Jesica A. Swanstrom, Boyd L. Yount, Ralph S. Baric

University of North Carolina, Chapel Hill, NC, United States

Dengue virus is a mosquito-borne human pathogen with four serotypes, each consisting of multiple genotypes. These genotypes tend to be broadly associated with different geographical regions, but do co-circulate in some cases. Despite the immense effort being made toward the development of a vaccine capable of protecting against all four serotypes, relatively little has been done to investigate the importance of genotypic variation. To address this issue, a panel of dengue 1 viruses was generated consisting of a West Pac 74 backbone with envelope sequences derived from representative strains within the other dengue 1 genotypes swapped for that of West Pac 74. Replication kinetics were assessed in Vero 76, C6/36 and U937+DC-SIGN cells, and virulence was assessed in a type I/II interferon receptor knockout mouse model. A panel of human monoclonal antibodies and dengue immune sera was used to assess the impact of genotypic variation in a U937+DC-SIGN neutralization assay. Combined, these results indicate that the genotypic variation in the envelope protein had minimal impacts on viral replication. There, was, however, a noticeable impact on antigenicity, indicating that geographical differences in the prevailing genotype of dengue 1 may need to be taken into account when designing a vaccine or interpreting the results of clinical trials.

1431

MODELING POPULATION SUSCEPTIBILITY TO DENGUE INFECTION USING A "MEMORY" TERM

Nicholas G. Reich[1], Krzysztof Sakrejda[1], Hannah Clapham[2], Derek Cummings[2]

[1]University of Massachusetts, Amherst, MA, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Models for interacting multi-pathogen systems are challenging to analyze. Dengue, a viral pathogen estimated to cause 400 million infections each year worldwide, has four identifiable serotypes. Infection with one serotype is thought to confer permanent immunity to that serotype and temporary cross-protection against infection with other serotypes. A central challenge in modeling dengue fever is accurately estimating the (largely unobservable) population of individuals who are susceptible to infection. We propose a new approach to accounting for the susceptible population over time based on observed dengue case data. We use standardized weighted sums of prior case counts (a.k.a. ``memory terms", since they retain a memory of recent level of relevant infections) for all serotypes as an approximation to deviations from mean susceptibility. This method provides a simple way to include complex dynamics in otherwise standard statistical time-series models. We apply and evaluate this method in two contexts. First, we use memory terms to predict dengue hemorrhagic fever outbreaks in Thailand. Including the memory term in prediction models results in modest improvements in the average cross-validated prediction errors. Second, we use memory terms to draw inference about the existence and duration of cross-protection between dengue serotypes. Using simulated data, we demonstrate that our method can detect the presence of cross-protection in a wide array of four-strain disease settings with sensitivity ranging between 65% and 95%.

1432

ASSOCIATED FACTORS TO DENGUE INFECTION FROM A COHORT OF NAÏVE SUBJECTS IN AN ENDEMIC AREA

Ruth A. Martínez-Vega[1], Irma Y. Amaya-Larios[2], Fredi A. Díaz-Quijano[3], José Ramos-Castañeda[2]

[1]Universidad de Santander, Bucaramanga, Colombia, [2]Instituto Nacional de Salud Pública, Cuernavaca, Mexico, [3]Organización Latinoamericana para el Fomento de la Investigación en Salud, Bucaramanga, Colombia

Dengue is a public health problem in Mexico. The study of factors that contribute in dengue infection is important to optimize the promotion and prevention programs. However underreporting of cases and the asymptomatic infections makes it difficult. Objective: To determine associated factors to DENV infection in naïve subjects from two Mexican dengue endemic localities. Between August and November of 2014, we visited naïve subjects from a Mexican cohort enrolled between June and November 2011. We interviewed and took blood sample from subjects who accepted to participate in this follow-up. ELISA IgG indirect (Panbio) was performed to evaluate DENV infection during this period. Binomial regression was performed to evaluate associated factors to the seroconversion. An adjustment of standard errors was made considering the 125 houses as cluster units. 196 (79.4%) of 247 naïve subjects from original cohort agreed to participate. 90 were IgG positive (45.9%) and 1 was IgG indeterminate. Only 16 subjects remembered to have a dengue medical diagnosis (17.8%), and only 3 subjects were detected by the surveillance system. The associated factors were age (Prevalence Ratio 0.97; IC95% 0.95-0.99; p=0.016) and the occupation; compared with the students, the independent workers (PR 1.93 IC95% 1.46-2.56, <0.001) and the subjects who stay at home the majority of time (housewife, unemployed, retired, and disabled) (PR 1.62; IC95% 1.01-2.59, p=0.047) had more risk to get DENV infected; the employed workers were marginally associated (PR 1.41 IC95% 0.85-2.34, p=0.183). Also, the exposition to a cohabitant with a medical dengue diagnostic was marginally associated (PR 1.37 IC95% 0.98-1.93, p=0.07). Other variables like gender, education, locality, work/study out side the locality were not

associated. There was a high rate of DENV infection in these localities during 2.5 years of follow-up. The occupation factor could be related with the time that subjects spend in places where the infection is occurring (home or workplace).

1433

A HIGH-THROUGHPUT MICROASSAY FOR DETERMINING ANTIBODY RESPONSES TO 15 CLINICALLY IMPORTANT SPECIES OF FLAVIVIRUSES

Christine Pugh, Emily Cisney, Cyra Ranji, Stefan Fernandez, Robert G. Ulrich

U.S. Army Medical Research Institute for Infectious Diseases, Frederick, MD, United States

Flaviviruses, such as dengue virus (DENV) and West Nile virus (WNV), are arthropod-borne RNA viruses that are infectious disease risks to half of the human global population. Viruses within the Flaviviridae family share a similar genomic organization and replication strategy, yet are able to cause a wide range of clinical disease in humans, from undifferentiated febrile illness to the more severe forms, hemorrhagic fever and encephalitis. Serological assays for diagnosis and surveillance are generally directed towards one specific virus and disregard the potential for antibody cross reactivity between nearest neighbors. Here, we developed a comprehensive assay for flaviviruses that includes whole virus preparations and recombinant antigens from several clinically significant species. The antigens include capsid, pre-membrane/membrane, envelope, NS1, and NS3 proteins from 15 species that may co-circulate within the same geographic region. Using the microarrays, we examined serum IgG and IgM responses from humans infected with DENV serotypes 1-4, WNV, and Japanese encephalitis virus in order to examine specificity and cross reactivity of antibody responses among the viral antigens. We further employed sera from dengue vaccine studies to demonstrate the utility of using multiple viral antigens for obtaining a detailed analysis of antibody responses to vaccines. The small test volume requirement (1-10 microliters), multiplexing capacity, and high-throughput nature are all valuable features of this microassay. We propose that the data obtained from these flavivirus-focused protein microarray assays will provide a wealth of information into the human antibody response during natural infections and in response to vaccination.

DENGUE VACCINE INITIATIVE: OVERVIEW OF THE FIELD OPERATION

Jacqueline K. Lim, Mabel Carabali, Kang Sung Lee, Sl-Ki Lim, Jung Seok Lee

International Vaccine Institute, Seoul, Republic of Korea

IVI within the Dengue Vaccine Initiative (DVI) consortium handles the field operation of the program. From 2011 to 2013, DVI conducted field studies in Colombia, Thailand, and Vietnam, likely early adopter countries of dengue vaccine. A complete package of the study including the passive fever surveillance, serological survey, cost-of-illness survey (COI), willingness to pay survey (WTP), and healthcare utilization survey (HUS) is conducted in Thailand and Colombia. In Vietnam, the COI and WTP surveys were conducted in 2011-2012. Since 2014, DVI has shifted the focus from the middle-income countries to the lower-income countries in Africa and Asia. The recent publication of the WHO Global Strategy for Dengue Prevention and Control in 2012-2020 emphasized the need for true burden of dengue by 2015. While there are documented disease transmission and vector presence, not much data from population-based studies are available, especially from Africa. Dengue may be considered for the GAVI vaccine investment strategy. Three countries, Burkina Faso, Gabon, and Kenya in Africa, as well as Vietnam and Cambodia, were selected for field studies. Most of these countries are GAVI-eligible with some documented disease transmission or outbreak history with existing infrastructure and local commitment for dengue research. In Vietnam, the study of the passive fever surveillance and the serosurvey are launched in Nha Trang in Aug. 2014 and data are forthcoming. In Burkina Faso, the set of DVI study including the passive fever surveillance with the COI survey embedded, HUS to complement the surveillance, and the serosurvey, was launched in Ouagadougou in Dec. 2014. In Gabon, the same set of study is launched in April of 2015 in Lambaréné. In Cambodia, launch of similar work package with the serosurvey in a community-based cohort design is planned in May, 2015. The similar work package is also in plan in Kenya. More information on the progress made in these sites of DVI field operation will be presented at the conference. By conducting DVI study in these sites, we hope to generate further evidence on burden of dengue for low-income countries.

1435

DETECTION OF DENGUE VIRUS IN EGG-HATCHED MOSQUITOES COLLECTED IN A CITY OF THE CENTRAL PORTION OF SÃO PAULO STATE, BRAZIL

Adriano Mondini[1], Felipe Guioti[2], Talita Motta Quiarim[2], Eduardo Sterlino Bergo[3], Walquer Vinicius Pereira[2], Roberta Vieira Bronzoni[4], Mauricio Lacerda Nogueira[5]

[1]UNESP - São Paulo State University, Araraquara , São Paulo, Brazil, [2]UNESP - São Paulo State University, Araraquara, São Paulo, Brazil, [3]SUCEN - SR06, Araraquara, São Paulo, Brazil, [4]UFMT- Universidade Federal do Mato Grosso, Mato Grosso, Brazil, [5]Faculdade de Medicina de São José do Rio Preto, São Paulo, Brazil

Dengue is a viral disease transmitted by ***Aedes*** mosquitos, which affects nearly 390 million people worldwide. It is endemic in more than 100 countries and the infections result in 500,000 hospitalizations and 20,000 deaths each year. Dengue is an arbovirus that belongs to ***Flaviviridae*** family, genus ***Flavivirus***, and presents four antigenically distinct serotypes (DENV 1-4). Virus surveillance in mosquitoes is important to track the spread of a virus after its introduction. ***Ae. aegypti*** and ***Ae. albopictus*** mosquitoes were obtained from ovitrap collected eggs. Traps were installed monthly in Araraquara, São Paulo/Brazil, from February 2014 to January 2015. Mosquitoes were grouped according to collection site, species and gender, and tested for the presence of four dengue serotypes using Hemi-Nested-Multiplex-RT-PCR. Field-collected eggs produced 8,667 ***Aedes*** mosquitoes, which were grouped in 1,114 pools. The presence of DENV was detected in 26 pools among the 187 that were analyzed. There were 25 amplifications that indicate the presence of DENV-1, DENV-2, DENV-3 and DENV-4 in pools of ***Ae. aegypti***. Among them were 15 male and 10 female pools. There was one pool of ***Ae. albopictus*** that was positive for DENV-1. Apparently, the four dengue serotypes are circulating in Araraquara. However, for complete confirmation of these results, our next step is viral isolation and nucleotide sequencing of the positive samples. But our results seem to be in accordance with the recent outbreaks in Brazil, caused by serotypes 1 and 4. The verification of vertical transmission in Araraquara seems to confirm a global trend and can be related with the maintenance of virus transmission in less favorable periods for the vectors and disease transmission.

SPATIAL AND TEMPORAL HETEROGENEITY IN DENGUE SEROTYPE CIRCULATION AND DYNAMICS OF RISK ACROSS PERU

Karen M. Campbell[1], Chris Lehnig[1], Kristin Haldeman[1], Cesar V. Munayco[2], Eric S. Halsey[3], V. Alberto Laguna[4], Martin Yagui[4], Paquita Garcia-Mendonza[5], Jake Talley[1], Mark Wilson[1], Amy C. Morrison[6], Thomas W. Scott[6]

[1]San Diego State University, San Diego, CA, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]U.S. Naval Medical Research Unit - 6, Lima, Peru, [4]Dirección General de Epidemiología, Lima, Peru, [5]Instituto Nacional de Salud, Lima, Peru, [6]University of California Davis, Davis, CA, United States

Dengue is one of the most aggressively expanding mosquito-transmitted viruses approaching 400 million infections annually. Complex transmission dynamics pose challenges for predicting location, timing, and magnitude of risk or spatial scale of risk when an outbreak occurs; thus models are needed to guide prevention strategies and policy development locally and globally. Empirical data needed to guide model development and a better understanding of risk dynamics suffer from critical gaps. Weather regulates transmission-potential via its effects on vector dynamics, yet an empirical perspective clarifying how weather impacts transmission in diverse ecological settings is lacking. Four antigenically related but distinct virus serotypes co-circulate in hyperendemic regions causing (1) short-term heterologous immunity and long-term homologous immunity against re-infection; (2) wide range in clinical disease from asymptomatic to self-limiting dengue fever to life-threatening dengue hemorrhagic fever- a spectrum that varies across serotypes/strains and with number, sequence, and relative timing of sequential infections from different serotypes; and (3) a general lack of serotype-specific information in surveillance data. This lack of data obstructs an understanding of spatial scales and networks of virus spread beyond community cohort studies. We developed a high-resolution empirical profile of (1) the local weather-disease connection, (2) serotype-specific dengue disease, human susceptibility, and force of infection, and (3) serotype-specific transmission networks across Peru, a country with considerable ecological diversity. For 1990-2012, we tracked the introduction and spread of the 4 dengue serotypes across Peru, examining serotype-specific spatial dynamics amidst the role of weather in regulating transmission, heterogeneity in spatial networks, and factors that regulate cycles in serotype replacement spatially. Results provide new insights regarding the spatial scales and dynamics of risk that will enable more effective strategies for separate or integrated delivery of vector control and vaccines.

1437

POTENTIAL IMPACT OF DENGUE VACCINATION IN DENGUE ENDEMIC AREAS: INSIGHTS FROM TWO LARGE-SCALE EFFICACY TRIALS

Laurent Coudeville, Nicolas Baurin

Sanofi Pasteur, Lyon, France

With about 4 billion people living in endemic areas and 100 million apparent infections occurring each year, dengue is a major international public health concern. To date, no specific treatment is available for this disease but the Sanofi Pasteur vaccine candidate has in 2014 successfully demonstrated its protective efficacy against symptomatic dengue during the 25 month active phase of two Phase 3 efficacy trials performed in five Asian countries (Indonesia, Malaysia, Philippines, Thailand, Vietnam) and 5 Latin American countries (Brazil, Colombia, Honduras, Mexico, Puerto Rico), based on the observations obtained from a total of 31,144 subjects. In order to best use this vaccine, it is important to evaluate its ability to reduce dengue burden in endemic areas and mathematical models of transmission can provide valuable insights on the matter. Results observed during the active phase 3 efficacy trials were used to fit an age-structured, host-vector and serotype-specific compartmental model previously developed. The estimation was performed using Approximate Bayesian Computation (ABC) method based on Sequential Monte Carlo. Several scenarios of cross-interactions between serotypes and vaccine efficacy were tested. We notably considered vaccine efficacy based on: 1) difference in efficacy between serotypes; 2) increase in efficacy after subsequent doses; 3) protection conferred to naïve and primed populations. The results obtained provide insight on the optimal age for vaccination for the 10 countries included in the two trials. We also considered the impact over time of different vaccination programs including routine and catch-up vaccination. In conclusion, the analysis performed on the basis of these two large vaccine efficacy trials suggests that the dengue vaccine candidate has the potential to significantly impact dengue burden in endemic countries.

1438

SEROLOGICAL AND VIROLOGICAL INVESTIGATION OF YELLOW FEVER OUTBREAK IN SOUTH OMO ZONE, ETHIOPIA

Mesfin M. Tsegaye[1], Abrham Lilay[1], Million Wendabeku[1], Negga Asamene[1], Yonas Wuletaw[1], Workenesh Ayele[1], Gelila Demissie[1], Almaz Abebe[1], Berhane Beyene[1], Israle Tareke[2], Abyot Bekele[1], Daddi Jimma[1], Amadou Sall[3]

[1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]World Health Organization, Addis Ababa, Ethiopia, [3]Pasteur Institute of Dakar, Dakar, Senegal

South Ari district of South Omo zone reported unknown illness with clinical presentations of fever, headache, nausea and bloody vomiting since December 2012. On the basis of clinical symptoms, a viral hemorrhagic fever was suspected and outbreak investigations were carried out. This abstract presents findings of the serological part of the outbreak investigation. A total of 30 serum samples were collected either from in-patients admitted at the Zonal Hospital as a result of having at least two of the clinical manifestations typical of the outbreak or active searches of suspected cases and contacts in the affected areas. As part of further investigation of the outbreak and elucidating if possible expansion of the yellow fever outbreak exists in the neighbouring/nearby districts/zones to the affected area, 42 serum samples collected from patients of acute febrile illness (AFI) seen at a health facility and Hospitals in these areas were also also investigated. The 30 serum samples were screened for yellow fever IgM by ELISA and 7 cases (23.3 %) were found to be positive. Differential diagnoses for other flavi viruses (Dengue, West Nile and Zika viruses) and also for RVF, CCHF and Chikungunya viruses showed no positivity. None of the samples were positive by PCR . Two samples (6.6%) had a positive IgG test for flavi viruses. Of the 42 serum samples from AFI patients in the neighbouring/nearby district/zones to the affected area, 3 (7.14%) were positive for west Nile IgG and 2 (4.76%) were positive for yellow fever IgG. The serological and virological investigation revealed that the cause of the outbreak to be a yellow fever virus. IgG positivity for falviviruses in adjacent/nearby districts and zones to the affected area necessitates identifying which specific virus of the flavi virus group is circulating and may require determining yellow fever epidemic risks as well as strengthening of surveillance in the broader vicinity of the affected area.

1439

CDC WEB-BASED YELLOW FEVER VACCINE COURSE: USE BY STATE AND TERRITORIAL HEALTH DEPARTMENTS IN THE UNITED STATES

Rhett J. Stoney[1], Theresa E. Sommers[2], Mark J. Sotir[1], Nancy M. Gallagher[1], Emily S. Jentes[1], Gary W. Brunette[1], Mark Gershman[1]

[1]Travelers' Health Branch, Division of Global Migration and Quarantine, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Department of Conflict Resolution, Global Governance, and Human Security, College of Advancing and Professional Studies, University of Massachusetts-Boston, Boston, MA, United States

In 2010, the Centers for Disease Control and Prevention (CDC) Travelers' Health Branch (THB) launched the free web-based course, ***Yellow Fever: Information for Health Care Providers Advising Travelers,*** to provide state and territorial health departments (STHDs) with an effective training tool to educate health care providers about yellow fever (YF) and best practices for YF vaccination. To purchase and administer YF vaccine (YFV) in the United States, a nonfederal provider must possess a STHD-issued YF stamp or practice in the same clinic as a YF stamp owner. However, practices for authorizing use of YF stamps vary among STHD YF stamp designation programs. We examined characteristics of these programs and their use of CDC's web-based course. THB invited 53 STHDs to participate in a survey during December 2011. Topics covered included eligibility for YF stamp ownership; training requirements for first-time stamp applicants, renewing stamp owners, and non-stamp-owning YFV providers. Survey response data were analyzed using SAS Enterprise Guide 5.1. Overall, 31 (58%) of 53 STHDs participated in the survey. Among the 31, 28 (90%) are aware of CDC's YFV course. All 31 responding STHDs issue stamps to physicians, 11 (35%) to nurse practitioners, 9 (29%) to pharmacists, and 7 (23%) to physician assistants. Thirteen (43%) of 30 STHDs that responded to the question require current stamp owners to renew their stamp yearly or less frequently. Ten (32%) of 31 responding STHDs require training in YF or travel medicine before issuing a YF stamp; 9 specifically require completion of CDC's YF course. Six (20%) of 30 STHDs require non-stamp-owning YFV providers to complete the course. Most responding STHDs are aware of CDC's YFV course but do not require proof of YF training from first-time stamp applicants or from non-stamp-owning YFV providers. However, among STHDs requiring proof of YF vaccination training, CDC's YF course is the most often utilized resource. With a revised course in development, THB plans to re-administer the survey and assess changes in YF programs and in STHD use of the course as a training requirement for health care providers who administer YFV.

1440

GLOBAL DISTRIBUTION AND ENVIRONMENTAL SUITABILITY FOR CHIKUNGUNYA VIRUS

Moritz U. Kraemer[1], Elaine O. Nsoesie[2]

[1]University of Oxford, Oxford, United Kingdom, [2]University of Washington, Seattle, WA, United States

Chikungunya is an acute febrile illness caused by the Chikungunya virus (CHIKV), which is transmitted to humans by Aedes mosquitoes. Although Chikungunya is rarely fatal, patients can experience debilitating symptoms that last from months to years. Despite expanding worldwide geographical distribution, knowledge of the global burden and extent of CHIKV remains alarmingly sparse. Here we exhaustively assess and map the global occurrence of Chikungunya using an established modeling framework previously used for dengue. We also predict the global environmental suitability and estimate population at risk of CHIKV transmission. We identified 89 countries with good evidence for CHIKV occurrence and several countries with environmental suitability and previous reports of CHIKV but with a general lack of reliable data and poor surveillance leading to indeterminate conclusions on presence or absence. We estimate 1.3 billion people living in areas at-risk of CHIKV transmission. These observations provide a basis for assessing clinical surveillance and burden estimation of Chikungunya globally, and an initial evaluation on the global distribution that can be refined as CHIKV continues to expand.

1441

CHARACTERIZATION OF A GENETIC DETERMINANT FOR THE MOUSE NEUROVIRULENCE OF YELLOW FEVER VIRUS IN *AEDES AEGYPTI*

Yan-Jang S. Huang[1], John T. Nuckols[2], Stephen Higgs[1], Alan D. Barrett[3], Dana L. Vanlandingham[1]

[1]Kansas State University, Manhattan, KS, United States, [2]Medical Countermeasure Systems, Joint Vaccine Acquisition Program, Fort Detrick, MD, United States, [3]University of Texas Medical Branch, Galveston, TX, United States

The loss of neurovirulence of wildtype flaviviruses in vertebrate hosts has been considered as a critical phenotype for the development of live attenuated strains of flaviviruses as vaccine candidates. Using yellow fever virus (YFV) 17D vaccines as a model, one of the genetic determinants for mouse neurovirulence of YFV has been mapped to the wildtype specific epitope Thr^{173} in the envelope (E) protein. Whilst the functional importance of the E protein with respect to antibody neutralization and attenuation of the YFV 17D-204 strain in mice has been demonstrated ***in vitro*** and ***in vivo***, it is still unclear whether or not the E T173I genetic mutation contributes to the loss of the biologically transmissibility by mosquitoes that is a characteristic of the YFV 17D vaccine strain. We evaluated the phenotypic changes caused by the T173I mutation with the cDNA infectious clones of the Asibi strain and the 17D+Asibi M-E chimera in ***Aedes aegypti*** through ***per os*** infection. The Asibi E T173I mutant and the 17D+Asibi M-E E T173I chimeric mutant were orally administered with the control mosquito groups receiving either the Asibi strain alone, the 17D+Asibi M-E chimera, or the 17D strain. Mosquitoes were collected for analysis at 7, 10, and 14 days post-infection. Comparison of the percentage of infection and dissemination as well as the replication kinetics was performed between wildtype and mutant viruses by detection of infectious viruses using tissue culture infectious dose 50. The phenotypic change caused by the mutation on infection and dissemination in mosquitoes will be discussed.

1442

ARIPO VIRUS IS AN INSECT-SPECIFIC FLAVIVIRUS THAT CAN ENTER AND REPLICATE IN VERTEBRATE CELLS AND PRECLUDES SUPERINFECTION AND DISSEMINATION OF WEST NILE VIRUS *IN VIVO*

Albert Jonathan Auguste, Nicholas A. Bergren, Rose M. Langsjoen, Shannan L. Rossi, Bethany G. Bolling, Hilda Guzman, Vesvolod L. Popov, Michael Woodson, Michael Sherman, Robert B. Tesh, Scott C. Weaver

The University of Texas Medical Branch, Galveston, TX, United States

To date, at least 25 distinct insect-specific flaviviruses have been isolated from and/or detected in mosquitoes collected worldwide. Although insect-specific flaviviruses are abundant in nature, little is known about their ecological niche, their place in the evolutionary history of flaviviruses, genetic determinants that render them unable to replicate in vertebrate cells, or to what extent they affect transmission of vertebrate-pathogenic flaviviruses in nature. Herein we describe the isolation and characterization of a novel insect-specific flavivirus (tentatively named Aripo virus; ARPV) that was isolated from a pool of Psorophora albipes mosquitoes collected in Trinidad. The complete ARPV genome was determined and phylogenetic analyses showed that ARPV clusters with other insect-specific flaviviruses that fall within the pathogenic mosquito-borne flavivirus clade. ARPV antigen was significantly cross-reactive with Japanese encephalitis virus (JEV) serogroup antisera by both immunofluorescence assays and hemagglutination inhibition assays. Infection with ARPV significantly

reduces superinfection rates and prevents dissemination of West Nile virus ***in vivo*** in ***Aedes aegypti*** mosquitoes. Experimentally, we also determined that ARPV infection is efficiently transmitted vertically in ***Ae. aegypti*** mosquitoes at least to the F3 generation. A 2 nm single particle cryo-EM reconstruction revealed that ARPV is structurally similar to other flaviviruses, having a very smooth surface with envelope protein trimer-dimers oriented in a head to tail manner, across its surface. We also show using transmission electron microscopy, confocal microscopy, and PCR based molecular techniques, that ARPV can attach and enter vertebrate cells via clathrin mediated endocytosis, as well as replicate its genome in these cells. Preliminary data suggests this virus is restricted from replication in vertebrate cells because it is incorrectly assembled in these cells.

1443

INFERRING THE YELLOW FEVER FORCE OF INFECTION FROM THE OBSERVED AGE DISTRIBUTION OF CONFIRMED CASES

Tini Garske[1], Kevin Jean[1], Maria D. Van Kerkhove[2], Sergio Yactayo[3], William Perea[3], Joseph Biey[4], Amadou Sall[5], Christl A. Donnelly[1], Neil M. Ferguson[1]

[1]MRC Centre for Outbreak Analysis and Modelling, Imperial College, London, United Kingdom, [2]Centre for Global Health, Institut Pasteur, Paris, France, [3]World Health Organization, Geneva, Switzerland, [4]World Health Organization-AFRO, Ouagadougou, Burkina Faso, [5]Institut Pasteur, Dakar, Senegal

Yellow fever is an arboviral disease, transmitted between humans and non-human primates and mosquitoes of various Aedes spp. in Africa. Disease severity shows a broad spectrum with high rates of fatality amongst the more severe cases, but symptoms tend to be non-specific, particularly in milder cases leading to huge underreporting and highly uncertain disease burden. As yellow fever is a sterilising infection, the age distribution of observed cases can give clues to the yellow fever transmission intensity. Using data on confirmed human cases of yellow fever reported between 2005 and 2013 to the Yellow Fever Surveillance Database covering 20 countries in western and central Africa in conjunction with data on population demographics and age-dependent vaccination coverage we estimated the force of infection that could give rise to the observed age distribution of cases under a number of different assumptions regarding the age-dependence of the exposure. Point estimates of the force of infection were low, but comparison with estimates derived from other data suggest upper confidence bounds obtained might put useful bounds on the extent of transmission. Results were sensitive to the assumed age distribution of the population and vaccination coverage and strongly depended on the age-dependence of exposure assumed, highlighting the need for robust sensitivity analyses. Models assuming age-independent force of infection fitted better in western Africa, but a higher exposure in adults than children fitted better in central Africa. In western Africa, the annual risk of infection to a susceptible person was estimated to be below 2.3%, while the annual infection risk in central Africa was estimated to be below 0.5% for children and 1.2% for adults. The fact that in different areas different assumptions about the age-dependence of the infection risk gave the best fit to the data indicates an indiscriminate exposure in villages in western Africa, where the transmission intensity is highest, but more limited occupational exposure through activities such as wood clearing in central Africa with a lower overall transmission intensity.

1444

DISTINCT SPLENIC CELLULARITY IN WILD-TYPE YELLOW FEVER VIRUS AND 17D VACCINE STRAIN INFECTION AND ITS IMPLICATION ON IMMUNOGENICITY/PATHOGENESIS

LK Metthew Lam, Alan M. Watson, William B. Klimstra, Kate D. Ryman

University of Pittsburgh, Pittsburgh, PA, United States

Yellow fever virus (YFV) is a mosquito-borne flavivirus that causes hemorrhagic fever in humans and poses a serious health threat in developing countries. Control of YFV relies upon the live-attenuated 17D vaccine strain, derived in the 1930s. The mechanism for 17D attenuation and immunogenicity remains unclear. In our pathophysiologically relevant mouse model, WT-YFV infection causes severe viscerotropic disease in type I IFN receptor deficient mice whereas 17D vaccination induces long-term, protective immunity against WT-YFV challenge. CD169 (Siglec-1) is a glycoprotein expressed on tissue-resident macrophages such as splenic marginal zone macrophages (MZMs) and hepatic Kupffer cells. Immunologically active CD169+ macrophages play an important role in the capture of antigens, induction of innate immune responses and peptide presentation to T and B lymphocytes. Interestingly, the expression of CD169 was dramatically increased in 17D-infected mice, consistent with a role in the induction of effector and memory immune response. In contrast, after a transient upregulation, CD169+ cells disappeared following infection with WT-YFV. Parallel to this finding, GL-7, an activation marker for B and T cells, expression in splenic follicles is also different between the two. Together with the evidence for enhanced CD169 transcript levels in the PBMCs of human 17D-vaccinees, the stark differences in CD169+ cell populations and lymphocyte activation may infer a mechanism for pathogenesis for WT virus or strong immunogenicity of 17D which we are currently exploring.

1445

THE ROLE OF PIWI-INTERACTING RNAS IN *CULEX QUINQUEFASCIATUS* CELLS AND MOSQUITOES DURING WEST NILE VIRUS INFECTION

Claudia Rueckert[1], Abhishek N. Prasad[2], Reyes D. Murrieta[1], Gregory D. Ebel[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]University of Texas Medical Branch, Galveston, TX, United States

Arboviruses are maintained in an enzootic cycle between a vertebrate host and an arthropod vector and have evolved to cope with both the complex vertebrate immune system and arthropod antiviral defenses. In order to develop efficient preventive measures it is important to understand both virus-host and virus-vector interactions. Our understanding of arthropod antiviral defenses has increased immensely over the last 15 years, and RNA interference (RNAi) is considered the most important antiviral mechanism. There are three individual components of the RNAi system, namely the small interfering RNA (siRNA), the micro RNA (miRNA) and the PIWI-interacting RNA (piRNA) pathways. The siRNA pathway is predominantly considered an antiviral mechanism, while miRNAs have important roles in regulation of gene expression and piRNAs are important for the protection of germ line DNA from retrotransposons. While the siRNA pathway has been considered the most important antiviral response in mosquitoes, the antiviral role of piRNAs is becoming more and more evident. A number of studies have implicated virus-derived piRNAs in the control of alpha-, bunya- and flaviviruses in Aedes mosquitoes. Culex mosquitoes are important vectors of arboviruses, such as West Nile virus, but they are considerably less studied than ***Aedes*** mosquitoes, vectors of for example dengue virus. In the present study we investigated the role of the PIWI pathway in antiviral defenses of ***Culex*** mosquitoes. We characterized expression of putative Piwi pathway components in ***Culex quinquefasciatus*** and ***C. pipiens*** mosquito tissues, as well as ***C. quinquefasciatus*** Hsu cells. Interestingly, while all six PIWI genes were highly expressed in ovaries, only selected PIWI genes were expressed at high levels in mosquito midguts and Hsu cells, possibly indicating the importance of these PIWI proteins in antiviral defenses rather than just germ line protection. The putative antiviral role of individual PIWI proteins was then determined in Hsu cells by silencing of Piwi gene expression and subsequent virus infection. This is the first study to implicate the piRNA pathway in ***Culex*** antiviral defenses.

EXPERIMENTAL WEST NILE VIRUS EVOLUTION USING A NATURAL TRANSMISSION MODEL: DETERMINING THE ROLE OF VECTOR-HOST INTERACTIONS IN SHAPING VIRAL POPULATIONS

Nathan Grubaugh[1], Claudia Rueckert[1], Joseph R. Fauver[1], Alex Gendernalik[1], Selene Garcia-Luna[1], Reyes D. Murrieta[1], Darci R. Smith[2], Doug E. Brackney[3], Greg D. Ebel[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Southern Research Institute, Frederick, MD, United States, [3]The Connecticut Agricultural Experiment Station, New Haven, CT, United States

West Nile virus (WNV) is a dynamic, evolving entity that can adapt to a wide range of environments and infect many different host species. It is primarily maintained in an enzootic cycle by Culex species vectors and avian hosts. Microhabitat-specific aspects of WNV transmission, such as how often the vectors and hosts interact, may drive evolution on a local scale. We have developed an ***in vivo*** model for WNV transmission using ***Culex*** mosquitoes and young chickens to 1) characterize intrahost WNV evolution during transmission and 2) to determine the degree to which the frequency of transmission influences WNV population structure and infection phenotype. We will use next generation sequencing to track changes to the viral populations in mosquito saliva and chick serum during several rounds of transmission. Our data suggests that shorter durations of mosquito infection (7 vs 21 days post infection) leads to higher viremia in chicks upon mosquito bloodfeeding. Multiple cycles of more frequent mosquito-to-bird transmission may lead to the selection of WNV variants that can be transmitted sooner (i.e. decreased extrinsic incubation periods) and increase vectorial capacity. Ultimately, this could help determine how periods of rapid transmission can change the genetic foundation of a WNV population and give rise to new genotypes.

1447

THE IMPACTS OF CYCLING TEMPERATURE ON WEST NILE VIRUS TRANSMISSION IN CALIFORNIA'S CENTRAL VALLEY

Mary E. Danforth, Christopher M. Barker, William K. Reisen

University of California Davis, Davis, CA, United States

West Nile virus (WNV), a flavivirus from the family Flaviviridae, is of public health concern due to its ability to cause disease in both humans and animals. It is transmitted between birds by mosquitoes, typically those from the genus ***Culex***. The time from a mosquito's consumption of an infected blood meal until it becomes capable of transmitting the virus by bite is termed the extrinsic incubation period (EIP) and is temperature-dependent. The EIP can be expressed in terms of degree-days, a measure of the cumulative temperature above a zero-transmission threshold. The current model for WNV transmission in California was based on the assumption that the number of degree-days to transmission is the same under all conditions and that a model calculated using only constant temperatures accurately captures the effects of daily temperature cycling found in nature. However, research on other vector-borne pathogens, such as ***Plasmodium*** and dengue virus, has shown that extrinsic incubation rates and vector competence depend on the range of daily temperature cycles in addition to the daily mean temperature. We examined the impacts of daily temperature cycling on WNV transmission using temperatures typical of the viral amplification season from March-July in a hyperendemic area of California's Central Valley. In addition to the daily air temperature profiles, we considered the impact of realistic mosquito exposure temperatures for night-biting ***C. tarsalis***, which are sheltered from afternoon peak temperatures. We found that the combination of extrinsic incubation time and daily mean temperature explained temporal changes in vector competence, but when transmission was expressed as a function of degree-days, vector competence was consistently higher for the July temperature treatment. Taken together, these results suggests that extrinsic incubation rates depend on both cumulative temperature (degree-days) and other features of the diurnal temperature cycle.

1448

AVIAN VIRULENCE AND VECTOR COMPETENCE PROFILES OF EMERGENT LINEAGE 2 WEST NILE VIRUS STRAINS

Hannah Romo[1], Michael Anishchenko[2], Anna Papa[3], Greg D. Ebel[1], Aaron C. Brault[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Division of Vector-borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States, [3]Aristotle University of Thessaloniki, Thessaloniki, Greece

The continuing global dissemination of West Nile virus (WNV) has been highlighted by the recent geographic expansion of lineage 2 (L2) West Nile strains from sub-Saharan Africa into eastern and southern Europe. An NS3-H249P substitution, previously unassociated with L2 WNVs, was initially identified in L2 WNV isolates (NS10) made during a Greek 2010 human WNV disease outbreak. In L1 WNV strains, an NS3-249P substitution has previously been associated with increased viremia and mortality in corvids as a result of positive selection. In order to assess similar avian pathogenic associations with the NS3-249 loci in L2 WNV backbones, alternative polymorphisms (Pro/ His) were generated at the NS3-249 site in NS10 and South African 1989 (SA89) L2 WNVs. Resulting mutant viruses were assessed directly in a highly susceptible American crow (AMCR) model. The parental NS10 and SA89 strains displayed peak viremias of 9.5 and 7.5 log10 PFU/mL sera with 100% and 33% mortality, respectively. The NS10 mutant, NS10 NS3-249H, exhibited reduced peak viremia (8.7 log10 PFU/mL sera) and mortality (80%) relative to the parental NS10. Reciprocally, the SA89 NS3-249P virus exhibited a bolstered peak viremia (9.6 log10 PFU/mL sera) and an increase in mortality (100%) relative to the parental SA89 WNV. In order to assess if altered vector competence is associated with compensation for lower avian viremias elicited by polymorphisms at the NS3-249 loci and/or whether this loci could modulate vector competence, three parental L2 WNV isolates containing a His at the NS3-249 loci (SA89, Hungary 2004 and Uganda 2009) were compared to NS10 in colonized ***Culex pipiens*** and ***C. quinquefasciatus*** mosquitoes. Initial studies have indicated that all four L2 WNVs display similar vector competence profiles following oral exposure to varying doses of the viruses and extrinsic incubation periods in mosquito species were similar. These results suggest that the emergence of the L2 NS3-249P substitution has likely resulted from avian selection and its subsequent effect on modulating the force of transmission has been independent of inherent direct vector competence effects.

1449

RAPID DETECTION METHODS OF KOREAN SACBROOD VIRUS

Mi-Sun Yoo, Young-Ha Kim, Ha-Na Jung, Hee-Soo Lee, Seung-Won Kang

Animal and Plant Quarantine Agency, Anyang, Republic of Korea

Sacbrood virus (SBV) is one of the most serious honeybee viruses. The virus causes failure to pupate and death in both larvae and adult bees. Recently, Korean Sacbrood virus (KSBV) caused a great loss in Korean honeybee (Apis cerana) colonies. Although KSBV shows high homology with SBV strains, it has unique motifs and causes different symptoms. Therefore, a simple, sensitive and specific method for detecting KSBV is needed urgently. In this study a reverse transcription loop-mediated isothermal amplification (RT-LAMP) and a novel micro PCR-based detection method, termed ultra-rapid real-time PCR (URRT-PCR) were applied for rapid detection for korean sacbrood virus (KSBV) from honeybees (Apis cerana) infected with SBV in Korea. The LAMP could be detect the virus in RT-LAMP reactions containing 10^2copies of pBX-KSBV within 30 min, which was 10 times more sensitive than a RT-PCR assay. The URRT-PCR showed high sensitivities which were able to detect 10 copies in the standard

assays. In the application of URRT-PCR detection to an KSBV-infected honeybee, the shortest detection time was 10 min 12 sec, including reverse transcription. In addition, these methods could be distinguished between KSBV and other closely-related SBV strains, These rapid methods were rapid molecular-based diagnostic tools and useful tool for the rapid and sensitive diagnosis of KSBV infection of honeybees.

THE PREVALENCE AND GENETIC DIVERSITY OF SAPOVIRUS IN A NESTED CASE-CONTROL STUDY OF A PERUVIAN PERI-URBAN COMMUNITY

Xiaofang Liu[1], Holger Mayta[2], Robert H. Gilman[3], Michiko Okamoto[1], Lilia Cabrera[4], Jean E. Crabtree[5], Vitaliano Cama[6], **Mayuko Saito**[1], Hitoshi Oshitani[1]

[1]Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]Asociacion Benefica PRISMA, Lima, Peru, [5]Leeds Institute of Molecular Medicine, University of Leeds, Leeds, United Kingdom, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States

Human sapovirus (SaV) belongs to the caliciviridae family and a causative agent of acute gastroenteritis. Recently, occurrence of SaV has been increasing worldwide with emerging SaV GI.2, but its attribution and diversity among infant diarrhea has not been reported. A birth cohort study to look at infant diarrhea was conducted between June 2007 and May 2010 in a peri-urban shanty town in Lima, Peru. Stool samples from 300 diarrheal episodes and 300 age-season matched non-diarrheal samples were selected from archived specimen bank generated from this cohort study. The detection rate of SaV were 12.3% in diarrheal and 5.7% in non-diarrheal stool samples using real-time PCR. The attributable fraction of SaV was higher in the second year (13.1%) than that in the first year of life in children (2.6%). Ten known genotypes (8 GI.1, 2 GI.2, 2 GI.6, 7 GI.7, 2 GII.1, 4 GII.2, 2 GII.4, 1 GII.5, 2 GIV, and 5 GV.1) and one novel genotype in GII (n=5) were found. Symptomatic reinfection causing by different genogroups (n=5) and genotypes (n=3) were observed in eight children and it suggest SaV may develop genotype specific immunity. This study indicates SaV contributes to community acquired diarrhea, especially in the second year of life of infants in developing area. Multiple genotypes circulating in one community and possible genotype specific immune response could complicate the SaV vaccine development.

1451

DEVELOPMENT OF MOLECULAR ASSAYS FOR THE DETECTION OF SOUTH AMERICAN HEMORRHAGIC FEVER VIRUSES

Jessica M. Shifflett, Teresa M. Towle, Briana Benton, Glendie Marcelin, Sujatha Rashid

ATCC, BEI Resources, Manassas, VA, United States

Of the several viral hemorrhagic fevers (VHF) in South America, there are five that are caused by arenaviruses. Due to the necessity of higher biocontainment, a diagnosis is usually confirmed through reference laboratories. However, diagnosis can be complicated by other VHF such as those caused by dengue and yellow fever viruses, requiring the development of new molecular tools. Individual qRT-PCR virus-specific assays with synthetic RNA or DNA positive control standards were developed for ***Junin***, ***Chapare***, ***Guanarito***, ***Machupo***, and ***Sabiá*** viruses. In certain assays, DNA standards were utilized due to incomplete ***in vitro*** transcription of the target amplicon (RNA). Parameters tested during assay development included sensitivity, specificity as a function of melt curve, linearity, and reproducibility. Each assay was found to be sensitive enough to detect between 10 and 100 genome equivalencies per reaction and formed a single melt peak, indicating primer target specificity. To compare the assay performance of RNA versus DNA standards, both types of synthetic positive controls for the ***Junin*** assay were evaluated. Both standards showed comparable performance with respect to sensitivity of detection, specificity, PCR efficiency, linearity, and reproducibility. In separate studies, we demonstrated the utility of these assays for the detection of viral RNA content using a preparation made from irradiated inactivated virus as a surrogate to live virus. To test the effectiveness of viral detection from a clinically relevant matrix, inactivated ***Junin*** virus was serially diluted then spiked into normal human serum. Total viral RNA was extracted and analyzed using the established ***Junin*** qRT-PCR assay. The recovery of viral RNA from serum was within 0.5 logs of calculated genomic equivalencies to that of viral RNA recovered from positive controls. This demonstrates the applicability of the ***Junin*** qRT-PCR assay with clinically relevant matrices. Our findings show that these assays are a sensitive method for the detection of arenavirus causing VHF and could potentially be developed for diagnostic testing.

DETECTION OF CORONAVIRUSES IN BATS IN CAMBODIA AND LAO PDR

Audrey Lacroix[1], Veasna Duong[1], Vibol Hul[1], Sorn San[2], Holl Davun[2], Keo Omaliss[3], Roger Frutos[4], Sokha Chea[5], Watthana Theppangna[6], Damien O. Joly[7], Zoe Greatorex[8], Sarah H. Olson[7], Lucy Keatts[5], Philippe Buchy[1]

[1]Pasteur Institute of Cambodia, Phnom Penh, Cambodia, [2]National Veterinary Research Institute, Ministry of Agriculture Forestry and Fisheries, Phnom Penh, Cambodia, [3]Forest Administration, Ministry of Agriculture Forestry and Fisheries, Phnom Penh, Cambodia, [4]Université de Montpellier, Montpellier, France, [5]Wildlife Conservation Society, Phnom Penh, Cambodia, [6]National Animal Health Laboratory, Ministry of Agriculture Forestry and Fisheries, Vientiane, Lao People's Democratic Republic, [7]Wildlife Conservation Society, New York, NY, United States, [8]Wildlife Conservation Society, Vientiane, Lao People's Democratic Republic

South-East Asia has been identified as hot spot for emerging zoonotic diseases. Over the past decade, bats have been recognized as natural reservoir for an increasing number of zoonotic viruses such as SARS-coronavirus, or Nipah virus. Hence, there is the necessity to identify known and novel infectious diseases in bats which may constitute a risk to the human population. In our study, we assessed and characterized the presence of coronaviruses (CoVs) in bats at interfaces with human populations in Lao PDR and Cambodia. Bat samples (organs, swabs, urine, feces) were collected in several provinces of Cambodia and Laos from 2010 to 2014 and tested for the presence of coronavirus by RT-PCR targeting the RdRp gene. Positive samples were sequenced and phylogenetic analyses of RdRp fragments (430 bp and 1500bp) were conducted to determinate their relationship with other known coronaviruses. A total of 83 coronavirus positive samples were detected in microchiroptera and fruit bats, including 35 αCoV and 48 βCoV. All βCoV clustered with the group of bat βCoV-HKU9 strains (78 to 99% of nucleotide identity). Detected αCoV clustered with different αCoV bat strains and 2 samples were closely related to PEDV strains (93% and 96% of nucleotide identity respectively) responsible of severe diarrhea in pigs. Such results showed the presence and diversity of coronaviruses circulating in bat population in Cambodia and Lao PDR. This is the first report of coronavirus detection in bat population in these two countries. Further molecular epidemiological studies and complete genome sequencing, especially the spike protein gene, will shed more light on diversity of those coronaviruses and help to estimate the potential zoonotic risk.

DISTRIBUTION OF THE CIRCULATING ROTAVIRUS GENOTYPES BEFORE AND AFTER ROTARIX® VACCINATION AT SENTINEL SITES IN SUDAN

Hanan EL Mohammady[1], Rania A. Nada[1], Amani Mostafa[2], Rehab El Hag[2], Hinda Ahmed[3], Hossam Ashmony[3], Nadia Teleb[3]

[1]U.S. Medical Research Unit No. 3, Cairo, Egypt, [2]Central Public Health Laboratories, Khartoum, Sudan, [3]World Health Organization Regional Office for Eastern Mediterranean, Cairo, Egypt

Globally, rotavirus infection is responsible for 37% to 53% of hospitalizations due to diarrhea in children below 5 years of age where rotavirus vaccination is not routinely administered. In Sudan, rotavirus has accounted for 33% of diarrheal cases from 2008 to 2010. These data supported the decision of the Sudanese Ministry of Health to introduce rotavirus vaccine (Rotarix ®, monovalent G1P[8]) into the national immunization program (NIP) in July 2011. This study evaluated the impact of rotavirus vaccine on the distribution of rotavirus genotypes. Group A rotavirus EIA positive stool samples obtained prior (n=358; 2011) and post (n=120; 2013) vaccine introduction, were genotyped using two-step RT-PCR and DNA sequencing. Stool samples were collected from three sites in Sudan: SDKK, SDFO and SDGG. No significant change was observed in the prevalence of diarrhea after vaccination. However, Rotavirus G9 frequency increased from 0.3% to 67.5% post vaccination. Almost half of rotavirus G9 strains identified in mixed infections with rotavirus G2 strains. Post vaccination, the frequency of genotype G1 decreased from 9.5% to 5.8%. Additionally, rotavirus P[8] rate increased from 12.3% to 32.5% post vaccination. We noted change in the wild type sequence within 87.5% of the P[8] strains post vaccination. G1 completely disappeared from samples from SDKK and SDFO while G9 was predominant in both sites. At SDGG site, a dramatic decline in G2 was noted (82.9% to 6.1%), combined with an increase of G9 from 0.8% to 32.7%. For VP4,a reduction in P[4] (62% to 4.1%) in conjunction with increased P[8] (16.3% to 53.1%) was observed at SDGG. Rotavirus P[4] remained the dominating genotype at the other two sites. Out data suggests that the Rotarix ® vaccine did not reduce the overall prevalence of the virus in patients in Sudan. However, the selective pressure of vaccine administration resulted in the changes within circulating genotypes. Whether rotavirus G9 and mutated P[8] strains emerged as a result of vaccination and replaced endemic rotavirus G1 and P[8] strains in Sudan remains to be seen.

CO-INFECTIONS WITH MONKEYPOX AND VARICELLA ZOSTER VIRUSES, THE DEMOCRATIC REPUBLIC OF THE CONGO, 2010-2013

Christine M. Hughes[1], Lindy Liu[1], Andrea M. McCollum[1], Whitni Davidson[1], Benjamin Monroe[1], Darin Carroll[1], Kimberly Wilkins[1], Yu Li[1], Kay Radford[1], D. Scott Schmid[1], Joelle Kabamba[1], Beatrice Nguete[2], Robert Shongo Lushima[3], Toutou Likafi[2], Marcel Pie Balilo[2], Jean Malekani[4], Elisabeth Pukuta[5], Frida Nkawa[5], Stomy Karhemere[5], Jean-Jacques Muyembe Tamfum[5], Emile Wemakoy Okitolonda[2], Mary G. Reynolds[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [3]Ministry of Health, Kinshasa, Democratic Republic of the Congo, [4]University of Kinshasa - Department of Biology, Kinshasa, Democratic Republic of the Congo, [5]Institut National de Recherche Biomedicale, Ministry of Health, Kinshasa, Democratic Republic of the Congo

Monkeypox (MPX) is an acute febrile rash illness that is endemic in the Democratic Republic of the Congo (DRC). Human MPX is caused by a zoonotic orthopoxvirus (OPXV), monkeypox virus (MPXV). One febrile rash illness that can be mistaken for MPX is chickenpox, caused by varicella zoster virus (VZV). In 2010, Tshuapa District, DRC, implemented an enhanced surveillance system for human MPX, which incorporates the collection and laboratory testing of at least two lesion specimens per patient. Between December of 2010 and April of 2013, 611 suspect MPX patients were investigated. Of those, 216 (35.4%) patients were positive for MPXV and 405 (66.3%) were positive for VZV. 71 (11.6%) patients had specimens that were positive for MPXV and VZV, indicating a co-infection. Patients with co-infections ranged in age from 1-42 years (mean 13.8 years); 38 were male and 33 were female. Co-infections were observed in ten of the twelve Tshuapa health zones. The majority (n=47, 66.2%) of co-infected patients had a reported occupation of "child" or "student". In addition to rash and fever, the most common symptoms reported by co-infected patients were fatigue, headache, and chills. The rash burden for co-infected patients averaged to 97 lesions per patient with the thorax, arms, and legs being the sites with the highest lesion counts. The rash burden for these patients was higher than those seen with VZV alone (average=86) and lower than those with MPX alone (average = 129). While MPXV and VZV co-infections have been reported in the past, this is the first time these patients have been examined and documented to this extent. The surveillance protocol of collecting at least two specimens from distinct lesions may assist in the identification of co-infections. Laboratory results from these specimens show biological evidence for MPXV and VZV co-infection, where one distinct lesion yields one virus. Understanding and documenting differences in symptoms, disease severity, and diagnostic results for febrile rash illnesses will help guide case investigation procedures and clinical case management in areas where both viruses circulate.

1455

EVALUATION OF THE GENEXPERT FOR HUMAN MONKEYPOX DIAGNOSIS IN THE DEMOCRATIC REPUBLIC OF CONGO

Daniel Li[1], Kimberly Wilkins[1], Andrea McCollum[1], Joelle Kabamba[2], Toutou Likafi[3], Marcel P. Balilo[3], Robert S. Lushima[4], Jean Malekani[5], Inger Damon[1], Darin Carroll[1], Elisabeth Pukuta[6], Frida Nkawa[6], Stomy Karhemere[6], Jean-Jacques M. Tamfum[6], Emile W. Okitolonda[3], Yu Li[1], Mary Reynolds[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Kinshasa, Democratic Republic of the Congo, [3]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [4]Ministry of Health, Kinshasa, Democratic Republic of the Congo, [5]University of Kinshasa, Department of Biology, Kinshasa, Democratic Republic of the Congo, [6]Institut National de Recherche Biomedicale, Ministry of Health, Kinshasa, Democratic Republic of the Congo

Monkeypox virus (MPXV), a zoonotic ***Orthopoxvirus***, is endemic and causes human infections in the Democratic Republic of Congo (DRC). Molecular diagnostics for human monkeypox are currently limited to real-time quantitative PCR assays (qPCR) in sophisticated laboratory settings, and a simpler system designed to perform well in field conditions is needed to promptly diagnose new infections. Here, we evaluated the accuracy and utility of a multiplex MPXV assay using the GeneXpert platform, a portable rapid diagnostic device that may serve as a point-of-care test to diagnose infections in the endemic areas. The Multiplex MPXV assay includes a MPXV specific qPCR test, Orthopoxvirus (OPXV) generic qPCR test and an internal control qPCR test. In total, 106 diagnostic specimens (32 crusts, 74 vesicular swabs) were collected from suspect monkeypox cases in Tshuapa District, DRC under national surveillance guidelines. The specimens were tested with the GeneXpert MPXV assay and an OPXV qPCR assay at the Institut National de Recherche Biomedicale (INRB) in Kinshasa. Aliquots of each specimen were tested with a second GeneXpert system and a q-specific MPXV qPCR assay at the Centers for Disease Control and Prevention (CDC). The results of the MPXV qPCR were used as the gold standard for all analyses. The OPXV assay at INRB showed a sensitivity of 88% and a specificity of 51%. The GeneXpert MPXV assay at INRB had a sensitivity of 100% and specificity of 96%, and the GeneXpert MPXV assay at CDC similarly showed a sensitivity of 100% and specificity of 100%. The GeneXpert assay was equally sensitive with both crust and vesicle samples. The GeneXpert monkeypox test incorporates

a simple methodology and the results were sensitive and specific for monkeypox, suggesting its viability as a diagnostic platform that can be easily employed in established labs and/or field settings.

RUBELLA VACCINATION IN INDIA: IDENTIFYING BROAD CONSEQUENCES OF VACCINATION INTRODUCTION, KEY KNOWLEDGE GAPS AND RECOMMENDATIONS FOR ADDRESSING THEM

Amy K. Winter[1], Santanu Prahamanik[2], Justin Lessler[3], Bryan T. Grenfell[1], C. J. Metcalf[1]

[1]Princeton University, Princeton, NJ, United States, [2]Public Health Foundation of India, Delhi, India, [3]Johns Hopkins University, Baltimore, MD, United States

Rubella is a mild childhood disease, but infection during early pregnancy may cause fetal death, spontaneous abortion, or the birth of an infant with congenital rubella syndrome (CRS). In 2014, India announced their plan to introduce rubella-containing vaccine (RCV) into India's national measles immunization program. The success of India's rubella vaccination program will depend on maintaining a critical threshold of vaccination coverage. Empirical analyses have shown that `insufficient' levels of RCV coverage can result in an increase in CRS incidence in the short term, by increasing the age of infection without sufficiently reducing incidence of rubella cases. Using a deterministic age-structured model that accounts for state-specific demography and vaccination coverage levels, we simulated rubella dynamics across India in the presence and absence of the introduction of RCV into the public sector. We show that the effect of introducing the rubella vaccine at coverage levels equal to current measles coverage on the incidence of CRS is highly sensitive to the basic reproductive number for rubella in India. As the assumed basic reproductive number of rubella increases, the risk of an increase in CRS incidence post vaccine also increases. The basic reproductive number for rubella in India is an unknown parameter due to poor surveillance of rubella incident cases and a lack of rubella serological surveys among the general population in India. The second part of the analyses therefore uses simulation tools to explore optimal serological survey designs and analysis techniques to strengthen inference of rubella epidemiologic parameters in India. All results are conservative to model assumptions and limitations, and tend to underestimate of the benefits of public sector vaccine introduction.

THE SPEED AND DIRECTION OF EBOLA SPREAD IN GUINEA, LIBERIA AND SIERRA LEONE

Kate Zinszer[1], Kathryn Morrison[2], Aranka Anema[1], Maimuna S. Majumder[3], John S. Brownstein[1]

[1]Harvard Medical School, Boston, MA, United States, [2]McGill University, Montreal, QC, Canada, [3]Massachusetts Institute of Technology, Boston, MA, United States

In speed outpacing control efforts, the Ebola virus disease (EVD) epidemic in West Africa has spread across Guinea, Liberia, and Sierra Leone infecting an estimated 25,515 of individuals and claiming over 10,500 lives as of 5 April 2015. The outbreak likely began in early December 2013 in the southeastern district of Guéckédou, Guinea, and variety of risk factors have contributed to the human-to-human spread of EVD including caring for the infected, involvement in funeral preparations of infected corpses, and healthcare infrastructure. At the population level, mobile populations, porous borders, and commercial air travel patterns have influenced the frequency and breadth of EBV transmission. However, little is known about the speed and pattern of EVD spread in the current epidemic. The goal of our analysis was to calculate the velocity of spread of EVD in Guinea, Liberia, and Sierra Leone. Publically available data from the World Health Organization (WHO) were used for this analysis, which we restricted to confirmed cases of EVD. Using a surface trend analysis, the speed and direction of EVD diffusion was calculated for each district. The average speed of EVD spread across Guinea, Liberia, and Sierra Leone was 13.8 km/week, and varied from 1.9 km/week to 69.6 km/week. There was a radial pattern of diffusion from the initial EVD-affected districts that bordered Guinea and Liberia. Other spatial patterns of spread were present, which could likely be explained by the translocation of infected individuals. Understanding the movement of EVD is useful for identifying the timing and placement of treatment and containment efforts. These methods can be applied prospectively and also to other infectious diseases, to understand the broad pattern of spatial and temporal spread.

EXTRACELLULAR MICROVESICLES MEDIATE RECEPTOR-INDEPENDENT TRANSMISSION OF NOVEL TICK-BORNE BUNYAVIRUS

Jesus A. Silvas, Patricia Barrera, Adriana Paulucci-Holthauzen, Xuejie Yu, Vsevolod Popov, Patricia Aguilar

University of Texas Medical Branch, Galveston, TX, United States

Severe Fever with Thrombocytopenia Syndrome virus (SFTSV) is a newly recognized member of the family ***Bunyaviridae*** genus Phlebovirus. The virus was isolated from patients presenting with hemorrhagic manifestations and an initial case fatality rate of 12-30% was reported. Knowledge concerning exploitation of cellular processes by SFTSV is currently limited. Recently, we reported that the nonstructural NSs protein of SFTSV is a potent inhibitor of interferon (IFN) responses. We also found that SFTSV NSs relocalizes key components of the IFN pathway into SFTSV NSs-positive cytoplasmic structures and that these structures co-localize with the early endosomal marker Rab5 but not with Golgi or endoplasmic reticulum markers. In this study, we have investigated the role these structures play during SFTSV infection. We conducted live cell imaging studies in cells stably expressing the SFTSV NSs to gain further insight into the role and trafficking of these cytoplasmic structures during virus infection. Astonishingly, we found that some of the SFTSV NSs-positive cytoplasmic structures were secreted to the extracellular space and endocytosed by neighboring cells. Electron microscopy and biochemical analyses of secreted structures isolated from SFTSV NSs-expressing cells and SFTSV infected cells, revealed that these structures were positive for SFTSV NSs, and the host protein CD63, a protein associated with extracellular microvesicles. Our study also revealed that the isolated CD63-immunoprecipitated extracellular microvesicles produced during SFTSV infection contained high numbers of viral RNA copies and that the viral RNA was efficiently delivered to uninfected cells and were able to sustain SFTSV replication in the absence of infectious virus. Overall, our results suggest SFTSV exploits extracellular microvesicles to mediate viral RNA receptor-independent transmission to host cells. To our knowledge, this is the first report describing exploitation of microvesicles to mediate virus infection among members of the ***Bunyaviridae*** family and other arboviruses, and open the avenue for novel therapeutic strategies against SFTSV.

MEASLES OUTBREAK IN NAUGAON BLOCK, UTTARKASHI DISTRICT, UTTARAKHAND, INDIA, APRIL-AUGUST, 2014

Somashekar Dundaiah[1], Kapil Goel[1], Rajshree P[2], Umid Sharapova[3], James Goodson[3], Padmini Srikantaiah[4], Kayla Laserson[4], Jai P. Narain[1], Anil Kumar[1], L. S. Chauhan[1]

[1]National Centre for Disease Control, Delhi, India, [2]District Surveillance Unit, Health Department, Uttarkashi District, Uttarakhand State, India, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Global Disease Detection Centre, Centers for Disease Control and Prevention, Delhi, India

Although India is working toward measles elimination, measles still prevails as an outbreak prone disease reported with 310 outbreaks and 10059 cases till August, in the year 2014. There is a need to understand

the epidemiology of measles outbreaks to help achieve elimination. In June, 2014, Uttarakhand state reported 18 children with fever and rash, including one death in Naugaon block, Uttarkashi district. Suspecting measles, an outbreak investigation was conducted from July 30 - August 6, 2014. A suspected measles case was defined as onset of fever and rash with ≥1 of cough, coryza, or conjunctivitis during April 1-August 5, 2014 in a resident from either of two affected villages in Naugaon block. We did house to house survey for active case finding and assessed measles vaccination coverage among 9 -59 months old children. Measles vaccination status was determined by vaccination card or mother's history with record verification of at least one dose of measles vaccine. We assessed risk factors by 1:1 unmatched case-control study. Controls were persons aged <15 years from case-patient's house or neighbourhood without fever, rash, cough, coryza, or conjunctivitis. Case management with vitamin A was also assessed. We performed serologic test using ELISA for measles-specific IgM antibodies. There were 65 cases with one death; median age was 4 years (range: 8 months-21 years). Age specific attack rates were highest in 1-4 (23/49, 41%) and 5-9 years groups (21/70, 30%). Measles vaccination coverage was 51% (37/73). 75% (44/58) of cases and 57% (33/58) of controls not being vaccinated for measles (OR: 2.36, 95% CI: 1.07-5.34) and sharing the room with > 2 children (OR: 5.1, 95%CI: 1.1-35.9) were significant risk factors. Among cases, 14 (21.5%) were managed with vitamin A. Among 17 serum samples tested, 14 were positive. Low vaccination coverage and close contact with the cases led to propagation of this outbreak. Outbreak response immunization, case isolation, case management with vitamin A and > 95% coverage with two doses of measles vaccine are needed.

1460

ARTESUNATE-AMODIAQUINE IS ASSOCIATED WITH REDUCED EBOLA MORTALITY

Etienne Gignoux[1], Andrew S. Azman[2], **Iza Ciglenecki**[3]

[1]Epicentre, Paris, France, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Médecins sans Frontières, Geneva, Switzerland

Malaria treatment is recommended for all suspected cases of Ebola virus disease (EVD), either presumptively or based on malaria diagnosis. In Foya Ebola Treatment Center (ETC), Lofa County, Liberia, the first-line anti-malarial, artemether-lumefantrine (AL), ran out for a two-week period in August 2014; during this time patients received artesunate-amodiaquine (ASAQ), which includes amodiaquine, a compound with anti-Ebola virus activity ***in vitro***. With standardized line-list data we estimated the relative risk of mortality in confirmed EVD patients prescribed ASAQ compared to either AL or no anti-malarial therapy, using unadjusted and adjusted regression models. Between 5 June_21 October 2014, 382 patients with confirmed EVD were admitted to the Foya ETC, with 194 prescribed AL and 71 prescribed ASAQ at admission. Patients prescribed ASAQ were similar to those prescribed AL or no anti-malarial therapy. Sixty-four percent (125/194) of patients prescribed AL died, compared to 51% (36/71) for ASAQ. In adjusted analyses, ASAQ prescription reduced mortality risk by 31% (risk ratio 0.69, 95% confidence interval, 0.54_0.89) compared to AL, with a stronger effect in individuals without malaria. Age, cycle threshold value at admission, total number of ETC inpatients on the day of patient admission, and IV rehydration were associated with risk of dying in the adjusted model. Artesunate-amodiaquine may provide substantial protection against EVD mortality compared to AL. While more pre-clinical and clinical research is needed to understand these biologically plausible findings, health policy makers should consider recommending ASAQ for all EVD patients regardless of malaria status.

1461

A TENTATIVE NEW PHLEBOVIRUS ASSOCIATED WITH A DENGUE-LIKE FEVER ILLNESS IN PANAMA

Jean Paul Carrera[1], Yamilka Díaz[2], Davis Beltran[2], Brechla Moreno[2], Juan M. Pascale[2], Robert B. Tesh[3], Sandra Lopez-Verges[2]

[1]Gorgas Memorial Institute and School of Medicine, Columbus University, Panama, Panama, [2]Gorgas Memorial Institute, Panama, Panama, [3]University of Texas Medical Branch, Galveston, TX, United States

The genus Phlebovirus (Phlebovirus, Bunyaviridae) is composed of approximately 70 viruses that are classified into two broad groups: the Sandfly fever group and the Uukuniemi group. Recently, a third distinct group within the genus was described and is composed of two mosquito-specific viruses. In Panama only two members of the Sandfly fever group, Chagres and Punta Toro Viruses, has been related with human disease. In order to detect the circulation of both members we develop a human retrospective cross-sectional survey from samples collected through the dengue surveillance program in 2009 to 2014. Viral RNA was extracted from acute sera samples, with a previous dengue negative results, and tested using phlebovirus genus-specific RT-PCR as described previously. Amplicons generated were purified directly and sequenced in both directions with the RT-PCR primers. The segment analyzed is based in a higly conserved gene thougth the pheblovirus genus. After its identification using Basic Local Alignment Search Tool Software consensus sequences from the partial L gene of the phleboviruses, sequences of interest were aligned with representative homologous sequences from the GenBank library using the MUSCLE program as amino acids. An optimal maximum likelihood tree was then generated with GTR+G model. One thousend bootstrap replicates were calculated. Phylogenetic analyses were conducted using MEGA*, version 6. Four samples from 2009 and two from 2014 were RT-PCR phlebovirus positive. Phylogentic analysis from the partial L segment detected in human samples indicated that the virus belongs to the Naples serocomplex that had not been previously detected in Panama. Because 30% of received acute samples from the dengue surveillance program are negative for dengue virus, it seems likely that human infections with other arboviruses, specially with Phlebovirus Sandfly fever members are more frequent than is now being recognized. More studies to sequence the completed genome of the virus and increased the resolution of evolutionary analysis are being conducted.

1462

SAFETY AND IMMUNOGENICITY OF THE HETEROLOGOUS PRIME-BOOST EBOLAVIRUS VACCINE REGIMEN CHAD3-EBO Z AND MVA-BN® FILO IN HEALTHY UK ADULTS

Tommy Rampling[1], Katie Ewer[1], Georgina Bowyer[1], Danny Wright[1], Navin Venkatraman[1], Egeruan B. Imoukhuede[1], Ruth Payne[1], Felicity Hartnell[1], Alfredo Nicosia[2], Julie E. Ledgerwood[3], Nancy J. Sullivan[3], Barney S. Graham[3], Vasee Moorthy[4], Stephan Becker[5], W Ripley Ballou[6], Simon Draper[1], Alison Lawrie[1], Sarah Gilbert[1], Adrian Hill[1]

[1]University of Oxford, Oxford, United Kingdom, [2]ReiThera, Rome, Italy, [3]National Institutes of Health, Bethesda, MD, United States, [4]World Health Organization, Geneva, Switzerland, [5]Philipps University Marburg, Marburg, Germany, [6]GlaxoSmithKline Biologicals, Rixensart, Belgium

Viral vectored vaccines using chimpanzee adenoviruses and Modified Vaccinia Ankara (MVA) vectors have demonstrated efficacy against Ebolavirus challenge in non-human primates. This Phase 1 trial was designed to assess the safety and immunogenicity of 2 novel Ebolavirus vaccines in healthy UK adults: the monovalent chimpanzee adenovirus 3 vector encoding Zaire Ebolavirus glycoprotein (ChAd3-EBO Z) and the multivalent MVA encoding multiple filoviral proteins (MVA-BN® Filo). 60 healthy adult volunteers were recruited in Oxford, UK and vaccinated with a single dose of the ChAd3-EBO Z vaccine at three dose levels (groups 1-3): $1x10^{10}$ viral particles (vp), $2.5x10^{10}$ vp and $5x10^{10}$ vp (n = 20 per group). Of these subjects, 30 received a heterologous boost 3 to 10

weeks later with MVA-BN® Filo at 2 dose levels: 2.2x10^8 TCID50s (n=18) and 4.4 x 10^8 TCID50s (n=12). Safety was assessed over the subsequent 4 weeks. Antibodies were measured by ELISA, T cell responses by ELISpot and flow cytometry assays were performed. The trial was then extended to include 4 additional groups (groups 4-7) to assess the effect of a reduced prime boost interval (either 1 or 2 weeks), and the effect of a further reduced dose of MVA-BN® Filo (4.4 x 10^7 TCID50s). In groups 1-3, both ChAd3-EBO Z and MVA-BN® Filo were well tolerated in all subjects, with short-lived, predominantly mild adverse events, and a low rate of febrile reactions. Both ChAd3-EBO Z alone, and the heterologous prime boost regimen were immunogenic at all dose levels with induction of both antibodies and T-cells on ELISpot and flow cytometry. Vaccination in the extension groups 4-7 is ongoing. Safety and immunogenicity data from these groups will be presented. Initial assessment of ChAd3-EBO Z and MVA-BN® Filo show these vaccines to be safe and immunogenic. These results suggest that this regimen is suitable for further evaluation as a tool to protect healthcare workers, and aid control of Ebola outbreaks.

1463

COMPARISON OF IMMUNOLOGICAL MEDIATORS IN DENGUE PATIENTS OF TWO ANCESTRAL GROUPS, COLOMBIA

Berta N. Restrepo[1], Ivony Y. Agudelo[1], Carlos A. Sariol[2], Petraleigh Pantoja[2], Leidy D. Piedrahita[1], Gonzalo Alvarez[3]

[1]Instituto Colombiano de Medicina Tropical-Universidad CES, Sabaneta, Colombia, [2]Universidad de Puerto Rico, San Juan de Puerto Rico, Puerto Rico, [3]Universidad CES, Medellin, Colombia

Colombia is a country with endemic transmission of dengue; besides its population has racial mixture diversity. On the other hand, studies shown that host genetic susceptibility can contribute in clinical outcomes. We developed a cross sectional study and we compared serum levels of immunological mediators between two Colombian populations: Afro-Colombians and Mestizos each group with 48 individuals. In the acute serum sample were measured the following cytokines: IL-1β, IL-1ra, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, TNF-α, IFN-γ; chemokine: MCP-1, MIP-1α, MIP-1β, RANTES, IP-10, Eotaxin and growth factors: basic FGF, G-CSF, GM-CSF, PDGF-BB, VEGF. We found that dengue hemorrhagic fever and thrombocytopenia were more frequent in mestizo that in Afro-Colombian patients. Levels of IL-2, IL-5, IL-7, IL-9, IL-12 IFN-γ and IL-17 were statistically significant higher in Mestizo with dengue virus infection. The current study shown differences in levels of cytokines with pro-inflammatory function or related to cellular and humoral immune responses. These are important findings because can contribute to knowledge about the immunological response to dengue infection according to the diversity racial.

1464

COMPARISON OF SEROPREVALENCE OF TETANUS COMPARED TO REPORTED VACCINATION STATUS AMONG CHILDREN AGED 6-59 MONTHS IN THE DEMOCRATIC REPUBLIC OF CONGO, 2013

Nicole A. Hoff[1], Sue Gerber[2], Reena H. Doshi[1], Patrick Mukadi[3], Jean-Jacques Muyembe-Tamfum[3], Emile Okitolonda-Wemakoy[4], Anne W. Rimoin[1]

[1]University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, [2]Bill & Melinda Gates Foundation, Seattle, WA, United States, [3]National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, [4]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Previous demographic surveys have determined immunization status through vaccination cards and maternal recall, however this may not be the most reliable method for obtaining vaccination status in children. We proposed a novel method for adding a seroprevalence study in conjunction with the 2013 Demographics and Health Survey (DHS) in DRC, to assess population immunity. We screened 8,117 children aged 6 - 59 months for IgG antibodies against tetanus using dried blood spots (DBS) collected during the study. These results were compared to reported data on vaccination status. The data was broken down by sex and age to explore differences between reported rates and seroprevalence. Overall for tetanus immunity, we found a seroprevalence of 36.0%, children with reporting complete tetanus vaccination (3 doses) by cards or maternal recall was 60.5%. Children with vaccination cards seen had the highest rates of positive antibody response compared to those with a card not seen and maternal recall (55.6% vs. 37.8% vs. 27.4%, respectively). Additionally, as number of doses received increases (1 to 3), there was a slight increase in seroprevalence results for results reported by card and maternal recall (56.3% to 58.6%, respectively, and 41.9% to 44.6%, respectively). Children reporting never vaccinated had a 15.6% seropositivity, if the received 1 or 2 doses (considered drop-outs), they conferred slightly higher immunity (19.5% and 24.4%). Similar results were seen when looked at by sex. Children 12-23 months had slightly higher immunity, but had a greater range between if reported by card or maternal recall. The immunity for tetanus was higher for those with vaccination cards compared to those that had maternal recall. However, overall maternal recall and vaccination status, both overestimated the seroprevalence of tetanus. This data should be used to show the improved information on coverage rates and where immunity gaps exist that could be obtained using seroprevalence studies in place of or in coordination with reported coverage surveys.

MOLECULAR CHARACTERIZATION OF THREE VIRUS BELONING TO GUAMÁ SEROGROUP (ORTHOBUNYAVIRUS, *BUNYAVIRIDAE*)

Valéria L. Carvalho, Márcio Roberto T. Nunes, Daniele B. Medeiros, Clayton P. Lima, Sandro P. Silva, Jedson F. Cardoso, João L. Vianez, Davi T. Inada, Pedro F. Vasconcelos

Evandro Chagas Institute, Belém, Brazil

The Guamá virus serogroup (***Bunyaviridae***: ***Orthobunyavirus***) is among the first groups of viruses identified in the Brazilian Amazon, in Belém, Brazil, in the 1950s. The prototype, the Guamá virus (GMAV, strain BE AN 277) was isolated from the blood of a sentinel monkey ***Cebus apella*** in the Oriboca Forest (Pará State, Brazil) in 1955. The Bimiti virus (BIMV), originally isolated in Port of Spain, Trinidad in 1955, after some years, it was isolated in Brazil (Utinga Forest, Belém municipality, Pará State) in 1966 from ***Proechimys guyannensis*** (prototype BE AN 100519). The Moju virus (MOJUV, strain BE AR 12590) was initially isolated in 1959 in a forest area of the "Agronômico do Norte" Institute (nowadays EMBRAPA - Brazilian Agricultural Research Corporation), in Belém, Pará, Brazil from a pool of ***Culex*** (***Melanoconion***) sp. mosquitoes. GMAV has relevance for public health because it causes acute febrile disease in humans characterized by fever of sudden onset, headache, arthralgia, myalgia, photophobia and asthenia. This study aimed to perform the genetic characterization of the three prototype virus strains of the Guamá virus serogroup isolated in the Brazilian Amazon: GMAV, BIMV, MOJUV. These viruses were sequenced and we got complete sequences of the S-RNA, M-RNA and L-RNA segments of them. The genomic organization of these viruses is compatible with the organization of members of ***Orthobunyavirus***, except for the absence of the NSs protein. It was identified for the Guamá group conserved motifs for the N gene of other ***Orthobunyaviruses***, some even involved with viral replication, as well as, conserved motifs for L-RNA segment called I, II, III and IV regions and the motifs of the Region III (Pré-A, A, B, C, D, and E). Based on nucleotide- and aminoacid- sequences of the three RNA segments, the higher degree of genetic similarity exhibited occurred between the GMAV and BIMV. The most divergent for all genomic segments evaluated was the MOJUV. This relationship is according to phylogenetic analysis for S-RNA, M-RNA, and L-RNA segments. Moreover, the findings of this study agree with the serological analysis previously described for the Guamá virus serogroup.

EXAMINING DISCREPANCIES IN MEASLES VACCINATION AND IGG SEROPOSITIVITY AMONGST CHILDREN AGED 12-23 MONTHS IN THE DEMOCRATIC REPUBLIC OF CONGO

Adva Gadoth[1], Reena H. Doshi[1], Patrick Mukadi[2], Nicole A. Hoff[1], Sue Gerber[3], Elisabeth Pukuta[2], Emile Okitolonda[4], Jean-Jacque Muyembe[2], Anne W. Rimoin[1]

[1]University of California, Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, [2]National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, [3]Bill & Melinda Gates Foundation, Seattle, WA, United States, [4]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Steady monitoring and evaluation of national immunization programs is vital to uncovering discrepancies in coverage that leave populations susceptible to vaccine-preventable diseases. In countries with weak surveillance programs, examination of biomarkers for antigen exposure may provide insights into the reach and effectiveness of vaccination campaigns, as well as the baseline immunity conferred upon unvaccinated groups via passive or active immunization. Using dried blood spots collected during the 2013 Demographics and Health Survey (DHS), we compared the seroprevalence of anti-measles IgG with survey responses regarding vaccination history for 1,766 children aged 12-23 months in the Democratic Republic of Congo (DRC). Of those children with reported measles vaccination from either vaccination card or maternal recall, 62.1% tested positive for measles antibodies (n= 1,155). Within this group, 69.2% of children with vaccination cards (n= 362) and 58.8% of children with maternal declaration of vaccination (n= 793) tested positive for measles antibodies. IgG seropositivity was 36.6% amongst those children reporting no measles vaccination (n= 543). These data suggest high background exposure of young children in DRC to measles, as well as a large discrepancy between measles vaccination and the presence of anti-measles IgG. It is difficult to discern whether the presence of antibodies in vaccinated children in the study is due to effective vaccine response or other unverified exposure to measles, considering the high seroprevalence observed amongst unvaccinated children. Given the high efficacy of the measles vaccine in controlled settings, our results implicate the potential for haphazardly filled vaccination cards, poor maternal recall, inadequate vaccine storage conditions, and interference of preexisting conditions (malaria, malnutrition, immunocompromised state) on the effectiveness of the vaccine to elicit an immune response. Intervention strategies should focus on improvements in cold-chain maintenance alongside general activities to improve vaccine coverage in DRC.

PLASMODIUM FALCIPARUM AND BLOOD BRAIN BARRIER: LOCAL ADHESION-INDEPENDENT EFFECTS

Chidinma B. Okafor

Armstrong State University, Savannah, GA, United States

This presentation intends to analyze the effects of ***Plasmodium falciparum*** on the Blood Brain Barrier leading to cerebral malaria through adhesion independent events. ***Plasmodium falciparum*** prevails to be one of the leading causes of mortality and morbidity in sub-Saharan Africa. In its severe form, this infection can lead to a severe case of morbidity called cerebral malaria. This exposition addresses the following question: What is the working mechanism of the blood brain barrier? What are local adhesion-independent activities in relationship with ***Plasmodium falciparum***? What are the effects of these activities on the blood brain barrier? To answer these questions, this study critically examines research works and literatures concerning this problem. Moreover, it will offer recommendations for possible elimination of malaria in sub-Saharan Africa.

1468

INVESTIGATING THE MECHANISMS MEDIATING IMPROVED OUTCOMES FOR S-NITROSOGLUTATHIONE REDUCTASE (GSNOR) NULL MICE IN EXPERIMENTAL CEREBRAL MALARIA

Robyn E. Elphinstone[1], Eric Shikatani[2], Mansoor Husain[2], Jonathan S. Stamler[3], Kevin C. Kain[1]

[1]Sandra Rotman Centre for Global Health, University Health Network-Toronto General Hospital, Tropical Disease Unit, Department of Medicine and Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, [2]Toronto General Research Institute-University Health Network, Department of Medicine and Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, [3]Institute of Transformative Molecular Medicine, Harrington Discovery Institute, Case Western Reserve University and University Hospitals, Cleveland, OH, United States

Severe and fatal malaria are associated with decreased nitric oxide (NO) bioavailability. NO bioavailability is mediated through both soluble guanylate cyclase and post-translational S-nitrosylation. Endogenous levels of S-nitrosothiols (SNOs) are negatively regulated, in part, by S-nitrosoglutathione Reductase (GSNOR). Therefore, we hypothesized that the increased levels of SNOs in the GSNOR knockout (KO) mice would lead to improved outcomes during experimental cerebral malaria (ECM). In support of this hypothesis, we have previously shown that GSNOR KO mice had improved survival in ECM. The GSNOR KO mice had improved Rapid Murine Coma and Behavioural Scores (RMCBS), and improved maintenance of the blood brain barrier. To further investigate the mechanisms mediating the improved outcomes, we first measured plasma levels of endothelial activation markers (VWF, Ang-2, sICAM-1, and sVCAM-1) throughout the course of infection. There were no significant differences between the GSNOR KO and wild type (WT) mice at any of the time points measured. However, there were significantly higher levels of IFN-Gamma on D4, and D5 post infection in the GSNOR KO mice compared to the WT mice ($p<0.001$). This suggested that the GSNOR KO mice had altered immune responses to ***Plasmodium berghei*** ANKA (PbA). In order to evaluate the role the hematopoietic compartment, specifically T cells, in mediating improved outcomes for the GSNOR KO mice, bone marrow transplants were performed. WT mice were irradiated and received either GSNOR KO or WT bone marrow. Eight weeks following the transplant, the mice were infected with PbA and followed for survival. There was no significant difference in survival between the mice receiving GSNOR KO or WT bone marrow. This suggests that a compartment outside of the hematopoietic system is mediating protection in the GSNOR KO mice. We are currently investigating this hypothesis using reciprocal bone marrow transplants. Although the mechanism mediating protection is still being investigated, these findings suggest a potential target for novel therapeutics for the treatment of cerebral malaria.

1469

PLASMODIUM FALCIPARUM FATTY ACID METABOLISM IN LIMITED GLUCOSE GROWTH CONDITIONS

Allison Demas[1], Erik Allman[2], Selina Bopp[1], Pamela Magistrado[1], Ulf Ribacke[1], Sarah Volkman[1], Manuel Llinas[2], Dyann F. Wirth[1]

[1]Harvard School of Public Health, Boston, MA, United States, [2]Pennsylvania State University, University Park, PA, United States

Despite the importance of fatty acid (FA) metabolism, relatively little is known about these pathways in ***Plasmodium falciparum***. Acyl CoA Synthetase (ACS) enzymes activate exogenous FAs, and these enzymes have expanded to a thirteen-member, polymorphic gene family in ***P. falciparum***, suggesting an important role for scavenged FAs. Previously, we have used [3H]-hypoxanthine incorporation assays to demonstrate restricted parasite growth in limited media conditions, including restricted glucose and limited fatty acids. Knockdown of individual ACS family members exacerbates this growth defect, suggesting a link between FA and carbon metabolism in the parasite. We determined that glucose-

deprived parasites exhibit FA oxidation (FAO), as measured by release of 3H20 from parasites grown in 3H labeled palmitic and oleic acid. Restricted glucose growth conditions induced a significant increase in FAO as compared to uninfected red blood cells, while parasites grown in the standard RPMI1640 did not exhibit FAO. We will update these initial findings with the results of metabolic labelling studies and metabolite profiling. In addition, we are using Seahorse XFe Bioanalyzer to better understand parasite carbon and FA metabolism under these restricted growth conditions. Fluorescent sensors detect changes in the pH and oxygen consumption of cells in real time, allowing us to measure parasite metabolic flux in response to specific substrates. Our observations of FA metabolism point to an important role for exogenous FAs and offer a potential explanation for the previously reported expansion and positive selection of the ACS gene family in ***P. falciparum***. Characterization of parasite growth under limited nutrient conditions offers insight into the parasite's metabolic flexibility and ability to survive in different host microenvironments.

PLASMODIUM FALCIPARUM EXPRESSES FEVER-INDUCED REGULATORS TO MAINTAIN PARASITE LOADS AT APPROPRIATE LEVELS FOR HOST AND PARASITE SURVIVAL

Papa Alioune Ndour[1], Uyen T Nguyen[2], Melanie Rug[2], Matthew MacKenzie[3], Alexander G. Maier[2], Pierre A. Buffet[1]

[1]INSERM – Paris 6 University, Paris, France, [2]Research School of Biology, The Australian National University, Canberra, Australia, [3]Monash Institute of Medical Research, Monash University, Melbourne, Australia

Plasmodium falciparum infection in a non-immune human host portends a significant risk of death. The human spleen mechanically clears a proportion of circulating ring-infected erythrocytes (rings). This innate process potentially favors host survival by reducing the pace at which initial steps of infection proceed. Because preventing death of infected hosts increases the chances of parasite transmission this should also favor parasite survival. Here, we show that ***P. falciparum*** expresses PIKA-1, a protein that associates with Ring Erythrocyte Surface Antigen to form a 390 kDa complex and changes the properties of late rings. PIKA 1-expressing rings are recognized and eliminated in the spleen more efficiently after exposure to febrile temperatures. As compared to wild-type PIKA-1-expressing parasites, αPIKA-1 mutants grew faster ***in vitro***. In addition, RBC infected with αPIKA-1 mutant rings were retained less effectively in biomimetic spleen-like filters and in human spleens perfused ***ex vivo***. These phenotypic traits were expressed only after exposure of rings at 41°C. Wild-type PIKA-1-expressing parasites were retained more effectively by the spleen when the parasite had been exposed to 41°C while there was no such difference after exposure of wild-type and mutants at 37°C. Phagocytosis of infected RBC was greater with wild type parasites than with αPIKA-1 mutants. We propose a model where parasite expansion is initially rapid until parasite loads are high enough for transmission then slowered down by PIKA-1 (probably in collaboration with other parasite components) when parasite loads reach fever-inducing levels associated with severe complications. PIKA-1 can thus be viewed as a fever-induced sensor of high parasite loads that reduces parasite expansion when death of the host becomes a short-term risk. PIKA-1 and RESA would thus confer ***P. falciparum*** a key selective advantage and may be original operators of parasite-host co-adaptation toward mutual survival.

MALARIA SYSTEMS BIOLOGY AT THE HOST-PATHOGEN INTERFACE

Regina Joice[1], Alberto Moreno[1], Jessica C. Kissinger[2], Mary R. Galinski[1], The MaHPIC Consortium

[1]Emory University, Atlanta, GA, United States, [2]University of Georgia, Athens, GA, United States

The Malaria Host-Pathogen Interaction Center (MaHPIC) is a large systems biology consortium that uses multi-'omic data integration approaches to study malaria infections and specifically the interactions of diverse ***Plasmodium*** species with their non-human primate (NHP) and human hosts. We are designing and implementing longitudinal investigations in NHPs, to build upon existing knowledge of host-parasite interactions for several primate species of malaria parasites with diverse biological characteristics. We are investigating which features (e.g. genes, transcripts, proteins, lipids, metabolites, immune profile) of the host and parasite during the course of experimental infections are associated with differences observed in malarial disease progression and severity. We are comparing different parasite species in the same host using ***P. cynomolgi*** and ***P. coatneyi*** infections of ***Macaca mulatta*** (rhesus monkey) to model ***P. vivax*** and ***P. falciparum***, respectively. We are also studying the same parasite (***P. knowlesi***) in two different hosts, using ***M. mulatta*** (susceptible) and ***M. fascicularis*** (refractory), to identify features that confer protection against disease. Finally, we are directly studying ***P. vivax*** and ***P. falciparum*** experimental infections using New World monkeys and conducting high-resolution metabolomics analyses involving natural human infections and clinical investigations being led from South America, Southeast Asia and Sub-Saharan Africa. Altogether, we aim to identify novel host and parasite factors involved in malaria disease progression in NHPs, and translate these findings to what is observed in humans. Furthermore, we aim to address biological questions using NHPs that for ethical reasons cannot be approached in clinical studies. The MaHPIC includes intensive informatics to generate and release datasets for use by the broad scientific community, and mathematical modeling and computational analysis to guide ongoing research and to integrate and make sense of the large amount of information being generated and compared. We will present the status of the project with data featured from a series of infections.

MALAWIAN CHILDREN WITH CEREBRAL MALARIA DO NOT HAVE MARKERS OF KIDNEY INJURY

Erika Phelps Nishiguchi[1], Dan Milner[2], Terrie Taylor[3], Karl Seydel[3]

[1]Michigan State University College of Human Medicine, East Lansing, MI, United States, [2]Brigham and Women's Hospital, Boston, MA, United States, [3]Michigan State University College of Osteopathic Medicine, East Lansing, MI, United States

Renal failure is a common manifestation of severe malaria in adults but is rarely reported in children. A recent study of children in 9 African countries found elevated blood urea nitrogen to be an independent predictor of mortality, and other studies have found that elevated creatinine is a marker for poor prognosis in children. None of these children were found to have frank renal failure. Because assessments of renal function are limited in resource-challenged settings, it is possible that clinically relevant kidney injury is more widespread in children with severe malaria than has been recognized. This study seeks to determine whether Malawian children with cerebral malaria (CM) had evidence of kidney injury. Creatinine concentration was measured in stored plasma samples from 79 children aged 6 months to 12 years who were enrolled in an autopsy study at the University of Malawi College of Medicine. Creatinine concentrations were compared between differently defined groups. Groups 1 and 2 were patients with clinically defined CM during life who either had malarial retinopathy (n=25) or did not (n=17). Groups 3 and 4 were patients with clinically defined CM during life and either with (n=31) or without (n=13)

sequestered parasites on autopsy. Only 2 patients, both with autopsy confirmed non-malarial encephalopathy, had creatinine concentrations meeting the WHO criteria for kidney injury. There were no statistically significant differences in the creatinine concentrations between Groups 1 and 2, or between Groups 3 and 4. These findings suggest that kidney injury is not common in Malawian children with cerebral malaria. However, because functional impairment is often significant before elevations in plasma creatinine manifest, we will be expanding this study to include novel early kidney injury biomarkers KIM-1 and NGAL.

1473

ATTEMPTS TO REVERSE ADAPT AOTUS DERIVED *PLASMODIUM VIVAX* TO *IN VITRO* CULTURE BY *EX VIVO* CO-CULTIVATION WITH HUMAN ERYTHROCYTES

Nicanor Iii Obaldia[1], Marlon Nunez[1], Sahir Dutary[1], Richard Thomson Luque[2], Kathryn Shaw Saliba[3], Manoj T. Duraisingh[3], John Adams[2]

[1]Center for the Evaluation of Antimalarial Drugs and Vaccines, Tropical Medicine Research/Instituto Conmemorativo Gorgas, Panama, Panama, [2]Center for Global Health and Infectious Diseases Research, Department of Global Health, University of South Florida, Tampa, FL, United States, [3]Department of Immunology and Infectious Diseases, Harvard, T.H. Chan School of Public Health, Boston, MA, United States

Plasmodium vivax malaria is widely distributed around the world. The lack of ***P. vivax*** continuous ***in vitro*** culture has limited the advance of research in this area. ***P. vivax*** has proven difficult to maintain in continuous culture, due in part to special culture conditions and its preference for invading reticulocytes. In the past, adaptation of malaria parasites to Aotus monkeys, have been carried out by replacing human by Aotus erythrocytes in a stepwise fashion. Moreover, it has long been known that Aotus serum does not support ***in vitro*** culture of ***P. falciparum***, and that leukocytes removal by filtration is important to avoid phagocytosis. However, during filtration, an important number of parasites are retained. In order to compare the use of filtered vs retained back-flush recovered parasites, on the effect of parasitemia of ex-vivo cultures, and test the hypothesis that co-cultivation of Aotus adapted ***P. vivax*** parasites with malaria naïve human RBCs, reverse adapts Aotus parasites to ***in vitro*** culture: First, we tested the effect of adding malaria naïve human or Aotus RBCs to ex-vivo cultures over parasitemia; then, tested the effect of media supplementation with or without 0.5 % glucose or 5 % lipids, and, lastly, the effect of adding reticulocytes at different time intervals over parasitemia. For this purpose, we used Aotus derived ***P. vivax*** SAL-1 parasites, filtered or retained by a Plasmodipur® device, re-suspended in McCoy's media at 5% HCT, plate it in 4 well plates and incubated under a 5% O2, 5% CO2, 90% N2 atmosphere at 37 Celsius. Thin smears were prepared and stained with Giemsa to determine % parasitemia and staging. Preliminary results indicated that Aotus ***P. vivax*** iRBCs co-cultivated with human RBCs or filter retained had higher and longer parasitemias when compare to Aotus RBCs alone or Plasmodipur® filtered respectively. In conclusion: Parasitemia in ***P. vivax*** Aotus derived ex-vivo cultures is enhanced by co-cultivation with human erythrocytes. In general Plasmodipur® filter retained parasites had higher and longer ex-vivo parasitemias with or without media supplementation.

1474

INTRINSIC VARIATIONS IN CULTIVABILITY OF *PLASMODIUM FALCIPARUM* MALARIA PARASITES

John White[1], Anjali Mascarenhas[2], Ligia Pereira[2], Jayashri Walke[2], Pooja Gawas[2], Ambika Sharma[2], Jennifer Guler[1], Jennifer Maki[1], Nagesh Dubhashi[2], Edwin Gomes[2], Ashwani Kumar[3], Jagadish Mahanta[4], Neena Valecha[5], Laura Chery[1], **Pradipsinh K. Rathod**[1]

[1]University of Washington, Seattle, WA, United States, [2]Goa Medical College and Hospital, Bambolim, India, [3]National Institute of Malaria Research, Panjim, India, [4]Regional Medical Research Center, Dibrugarh, India, [5]National Institute of Malaria Research, New Delhi, India

An understanding of variations in drug resistance, pathogenesis, and immune evasion in malaria often relies on culture-adapted ***Plasmodium falciparum*** parasites. Before making population-based inferences, parasite collections require standard methods and precise definition of successful ***in vitro*** adapted parasites to assure good representation. Patient blood was collected from 31 ***P. falciparum***-infected individuals at the Goa Medical College and Hospital (Bambolim, Goa, India) during the 2012-2013 malaria season. After dividing samples into whole blood or washed blood, they were further distributed in different media or at different hematocrit levels , in duplicate, to give 8 test flasks per original patient sample. ***In vitro*** adaptation was considered successful when two sequential 4-fold increases in parasitemia were observed within 96 hours, after culture for as long as 30 days. Later, separately, cryopreserved parasites from the day of patient contact were tested again for adaptability but this time in parallel using identical host RBC and culture media. Overall, 70% of the tested patient samples were successfully culture-adapted. Cultures setup at 1% hematocrit and 0.5% Albumax adapted most easily, even with whole blood inoculations. Success was not limited by low patient parasitemia, patient age, recent treatment with antimalarials, or even significant delays in sample processing. The speed to adaptability appeared to be an intrinsic property of the parasites. Microsatellite analysis confirmed that adaptation favored some clones over others. Our findings can help assure more complete descriptions of culture-adapted parasite collections. Such precision is expected to improve population-based extrapolations of findings from cultured parasites to questions of public health importance.

1475

RETINOPATHY-POSITIVE CEREBRAL MALARIA IS ASSOCIATED WITH GREATER INFLAMMATION, BLOOD-BRAIN BARRIER BREAKDOWN AND NEURONAL DAMAGE THAN RETINOPATHY-NEGATIVE CEREBRAL MALARIA

Chandler Villaverde[1], Gregory S. Park[2], Estela Shabani[2], Ruth Namazzi[3], Robert O. Opoka[3], Chandy C. John[4]

[1]The Warren Alpert Medical School at Brown University, Providence, RI, United States, [2]University of Minnesota, Minneapolis, MN, United States, [3]Global Health Uganda, Kampala, Uganda, [4]Indiana University, Bloomington, IN, United States

Cerebral malaria (CM) is the most severe neurological complication of malaria, and is associated with a case fatality rate of up to 15%, while 24% of survivors develop long-term neurocognitive sequelae. Examination of the ocular fundus in children with CM has revealed a characteristic retinopathy that has both diagnostic and prognostic significance. Children with CM can be characterized as retinopathy positive (RP) or retinopathy negative (RN), but little is known about the pathophysiologic differences between these two groups. Understanding the differences between RP and RN CM may help shed light on the pathophysiology of malarial retinopathy. We compared markers of endothelial activation, platelet activation, angiogenesis, oxidative stress, ischemia, inflammation, and neuronal damage in Ugandan children with CM admitted to Mulago Hospital, Kampala, Uganda who were RN (n=91) or RP (n=170). RP children had higher CRP (p=0.008) and ferritin (p<0.001) levels than RN children. RP children had an elevated CSF/plasma albumin ratio

(p<0.001) and elevated CSF tau protein levels (p=0.024) as compared to RN children. Additionally, RP children had significantly elevated total (p<0.001) and sequestered (p<0.001) parasite biomass levels compared to RN children, but there was no significant difference in circulating parasite biomass levels. RP CM is associated with greater parasite sequestration, inflammation, blood-brain barrier breakdown, and neuronal damage than RN CM.

1476

MATERNAL TO FETAL MICROCHIMERISM IS ASSOCIATED WITH PLACENTAL MALARIA AND RISK OF MALARIA DURING INFANCY

Whitney E. Harrington[1], Coline Gentil[2], Robert Morrison[3], Michal Fried[4], Patrick E. Duffy[4], J. Lee Nelson[5]

[1]Seattle Children's Hospital/Department of Pediatrics, University of Washington School of Medicine, Seattle, WA, United States, [2]Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA, United States, [3]Seattle Biomedical Research Institute, Seattle, WA, United States, [4]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, [5]Clinical Research Division, Fred Hutchinson Cancer Research Center/Division of Rheumatology, University of Washington, Seattle, WA, United States

Placental malaria (PM) is associated with increased risk of malaria during infancy, which may be the result of acquired ***in utero*** malaria-specific tolerance. Microchimerism (Mc) refers to the harboring of cells or DNA derived from a genetically disparate individual, a phenomenon most easily observed during pregnancy. We hypothesize that PM, with its associated damage to the trophoblast barrier, increases the prevalence and level of maternal to fetal Mc. In addition, we hypothesize that maternal Mc may increase malaria susceptibility in infancy via direct immune activity of maternally-derived microchimeric cells or a Mc-dependent increase in fetal tolerance to malaria antigens. We conducted a nested case-control study of women with (n=18) and without (n=21) PM and their paired infants, drawn from a larger birth cohort from Muheza, Tanzania. To investigate Mc, we first genotyped the women and infants for MHC class II alleles to identify an informative marker of maternal cells in the infant background, looking for a non-shared, non-inherited maternal allele (NIMA). We are currently assaying for presence and level of Mc in cord blood using a previously validated quantitative PCR-based method, targeting the NIMA for each maternal-infant pair. Among 8 controls and 10 cases thus far surveyed, PM is associated with presence of Mc (OR=10.5, p=0.07) as well as level of Mc (2/100,000 cells vs 2,647/100,000 cells, p<0.001). In addition, both presence and level of Mc predict risk of parasitemia during infancy independent of PM status (AOR=2.04, p=0.04; per 1% increase in Mc cells: AOR=1.08, p<0.001). This preliminary data suggests a possible association between PM and increased maternal to fetal Mc, as well as an association between maternal Mc and susceptibility to malaria during infancy.

1477

CHILDREN WITH SEVERE MALARIAL ANEMIA AND SICKLE CELL DISEASE HAVE DECREASED PARASITE BIOMASS AND INFLAMMATION BUT INCREASED ANGIOPOIETIN-2 LEVELS COMPARED TO CHILDREN WITHOUT SICKLE CELL DISEASE

Casey L. Sautter[1], Robert O. Opoka[2], Melvin T. Donaldson[1], Gregory S. Park[1], Chandy C. John[3]

[1]University of Minnesota Medical School, Minneapolis, MN, United States, [2]Makerere University School of Medicine, Kampala, Uganda, [3]Indiana University, Bloomington, IN, United States

Malaria is an important cause of morbidity and mortality among children with sickle cell disease (SCD, genotype HbSS) living in malaria endemic regions. While sickle cell trait (HbAS) has been shown to confer protection against infection by the ***Plasmodium falciparum*** parasite, and children with sickle cell trait or SCD have a lower risk of malaria infection than children without SCD (HbAA), children with SCD have higher rates of severe anemia and death when hospitalized for malaria. The reasons for increased morbidity and mortality from severe malaria in children with SCD are not known. In the present study, we assessed biomarkers associated with severe malaria pathogenesis in children with severe malarial anemia (SMA) admitted to Mulago Hospital in Kampala, Uganda and compared these biomarkers in children with SMA who had SCD (n=19) or did not have SCD (n=172). Children with SCD were older and had lower hemoglobin levels and higher leukocyte counts than children without SCD. Children with SCD also had significantly lower sequestered and circulating parasite biomass, and evidence of a significantly reduced inflammatory response, including decreased C-reactive protein and alpha-1-glycoprotein levels, and decreased levels of multiple pro-inflammatory cytokines (TNF-α, IL-1Rα, IL-10, IL-12, G-CSF) and chemokines (MCP-1, MIP-1α, RANTES). In contrast, as compared to children without SCD, children with SCD had significantly higher levels of angiopoietin-2, a marker of endothelial cell disruption and increased vascular permeability that has been associated with increased mortality in severe malaria. Children with SMA and SCD have decreased parasite biomass and a reduced inflammatory response when compared to children without SCD, but have evidence of increased endothelial cell disruption. Further study is required to assess whether the reduced inflammatory response and increased endothelial cell disruption correlate with increased morbidity or mortality in these children.

1478

ESTABLISHING AN *IN VITRO PLASMODIUM VIVAX* CULTURE FROM COLOMBIAN CLINICAL ISOLATES

Gustavo E. Quintero[1], Paula A. Avilés[1], Carolina Lopez[2], Manuel A. Patarroyo[2], Maria F. Yasnot[1]

[1]Grupo de Investigaciones Microbiológicas y Biomédicas de Córdoba, Universidad de Cordoba, Monteria, Colombia, [2]Fundación Instituto de Inmunología de Colombia, Bogota, Colombia

One problem, which has delayed better understanding of the host-parasite interaction for ***Plasmodium vivax***, has been the inability to maintain an ***in vitro*** culture for facilitating tests, such as drug susceptibility, red blood cell-parasite interaction and the evaluation of new vaccine candidates. It was proposed that an ***in vitro*** culture of this parasitic species isolated from patients living in an endemic area of the Córdoba department should be established due to high ***P. vivax*** incidence. Three variants of each RPMI 1640 and McCoy's 5A media were used; reticulocytes were obtained from cord blood and hemochromatosis patients for maintaining and growing cultures. Both cord blood reticulocytes and hemochromatosis patients' reticulocytes were enriched by 70% Percoll density gradient. Infected samples having more than 50% rings were processed and enriched by 46% Percoll density gradient and samples having more than 70% mature trophozoites by 70%. Parasitised erythrocytes were maintained in a 37°C anaerobic microenvironment using the candle jar system. Average starting parasitaemia observed per crop was 1.58%. Parasites were viable for up to 120h when RPMI-1640 culture medium was tested, whereas viability increased by up to 140h when culturing the same base medium modified in our laboratory. Twenty samples which were viable for up to 168h were processed once it has been established that our RPMI 1640 medium variant was as efficient as McCoy's 5A medium and more efficient than that proposed by Russell ***et al***., in 2011. A final 257.38% average reticulocyte efficiency was obtained once the samples from umbilical cord blood and hemochromatosis patients had been enriched by 70% Percoll gradient. Reticulocytes were viable until week 4 when they were kept at 4^0C (1.8% average daily loss). Two invasion assays were performed by adding reticulocytes to culture maintained at 6% haematocrit when schizonts were observed in culture samples; two possible erythrocyte invasion routes were observed in one of these two trials. Colombian ***P. vivax*** clinical isolates were thus susceptible to growth in the culture media tested and it was feasible to adapt them to laboratory conditions.

DRUG-INDUCED LIVER INJURY AFTER TREATMENT WITH ARTESUNATE-ATOVAQUONE-PROGAUNIL FOR UNCOMPLICATED *PLASMODIUM FALCIPARUM* INFECTION

Jessica Manning[1], Chanthap Lon[2], Sok Somethy[2], Worachet Kuntawunginn[1], Mali Ittiverakul[1], Soklyda Chann[1], Lek Dysoley[3], Dustin Harrison[4], David Saunders[1]

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [3]Centre Nationale de Malariologie, Phnom Penh, Cambodia, [4]Navy Army Medical Research Unit, Phnom Penh, Cambodia

Drug-induced liver injury (DILI) is a common phenomenon and often underreported in remote settings without laboratory monitoring, such as those found in malaria-endemic areas. Atovaquone-progaunil has been known to cause subclinical and transient elevation in liver enzymes in clinical trials of malaria prophylaxis, but reported liver injury is rare. Only one case report in the literature details an episode of hepatitis after atovaquone-proguanil prophylaxis. Given AP's otherwise excellent safety profile, the significance of an associated subclinical transaminitis is unknown but purportedly, there have been reports where liver function test abnormalities have limited treatment with AP. The mechanism by which atovaquone-progaunil may cause hepatic injury is unknown, but is of concern now that atovaquone-progaunil is being increasingly deployed at treatment doses in multidrug resistant settings of ***Plasmodium falciparum***. Here, we report an episode of drug-induced liver injury in a Cambodian farmer after taking a course of artesunate-atovaquone-progaunil and a single dose of primaquine for ***P. falciparum*** mono-infection. This incident serves as an important safety signal to remain pharmacovigilant, particularly if this efficacious combination regimen is more frequently deployed in settings of multidrug resistant ***P. falciparum*** such as Cambodia.

THERAPEUTIC EFFICACY OF ARTEMISININ-BASED COMBINATION THERAPY IN THE TREATMENT OF UNCOMPLICATED MALARIA IN TWO ECOLOGICAL ZONES IN GHANA AFTER EIGHT YEARS OF DEPLOYMENT

Benjamin Abuaku[1], Nancy Quashie[1], Neils Quashie[2], Keziah Malm[3], Lydia Quaye[1], Kwadwo Koram[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Centre for Tropical Clinical Pharmacology and Therapeutics, University of Ghana Medical School, Accra, Ghana, [3]National Malaria Control Programme, Public Health Division, Ghana Health Service, Accra, Ghana

Malaria remains a major public health problem in Ghana, accounting for 44% of all outpatient clinic visits, 37.6% of all admissions, and 22.3% of all under-five deaths in 2013. Case management based on prompt diagnosis and adequate treatment remains the main focus of malaria control in Ghana. Artesunate-amodiaquine (AA) combination was deployed in 2005 as first line drug for the treatment of uncomplicated malaria. This was followed in 2008 with artemether-lumefantrine combination (AL) and dihydroartemisinin-piperaquine (DHAP) as alternative first line drugs for patients unable to tolerate AA. Since 2005 ten sentinel sites, representing the ecological zones of Ghana, have been monitoring the therapeutic efficacy of artemisinin-based combination therapies (ACTs) in the country using the World Health Organization's (WHO) protocols for antimalarial drug efficacy assessment. After 8 years of ACT deployment in the country, per protocol analyses for two ecological zones studied (savannah and forest) showed significantly higher day-28 pcr-uncorrected cure rate for AA compared with AL. In the savannah zone, pcr-uncorrected cure rates were 97.3% (95% CI: 90.7, 99.7) for AA and 56.3% (95% CI: 37.7, 73.6) for AL (p<0.001). In the forest zone pcr-uncorrected cure rates were 98% (95% CI: 89.4, 99.9) for AA and 85.2% (95% CI: 77.7, 91.0) for AL (p=0.031). Kaplan-Meier survival analysis for the savanna zone showed day-28 pcr-uncorrected cumulative cure rates of 97.4% (95% CI: 89.9, 99.3) for AA and 60.1% (95% CI: 41.8, 74.3) for AL (p<0.001) whilst the forest zone showed cumulative cure rates of 98.1% (95% CI: 87.1, 99.7) for AA and 85.2% (95% CI: 77.6, 90.4) for AL (p=0.030). These preliminary findings suggest greater day-28 efficacy of AA over AL in terms of preventing treatment failures in the savannah and forest zones of Ghana after 8 years of ACT deployment.

1481

FITNESS LOSS AND COMPENSATION IN ANTIFOLATE AND ARTEMISININ RESISTANCE IN *PLASMODIUM FALCIPARUM*

Krittikorn Kumpornsin, Duangkamon Bunditvorapoom, Kesinee Chotivanich, Thanat Chookajorn

Mahidol University, Bangkok, Thailand

Malaria drug resistance is a major public health problem on a global scale. At present, the effectiveness of antimalarials is dwindling due to the spread of multidrug-resistant strains. However, the evolutionary process to change from drug-sensitive wild-type to drug-resistant mutants is under evolutionary constraints. One of the examples is the antifolate drug family. Antifolates inhibit the folate pathway enzymes that produce metabolites required for nucleotide synthesis. Antimalarial pyrimethamine inhibits dihydrofolate reductase (DHFR), a key folate enzyme. Four canonical mutations at the dhfr gene abrogate the effectiveness of pyrimethamine. Interestingly, the gains of these four dhfr mutations follow step-wise order, and, most important of all, there is trade-off between antifolate resistance and fitness in the evolutionary trajectory from wild-type to the quadruple mutant. Even though these mutations are highly beneficial under pyrimethamine, the mutants suffer from poor fitness when drug pressure is removed. To overcome this problem, malaria parasites accumulate multiple copies of the gene encoding rate-limiting folate enzyme GTP cyclohydrolase I (GCH1). Extra GCH1 from gene amplification was originally selected for slight improvement in antifolate resistance. The parasite co-opted the gain of extra GCH1 and used this mechanism to compensate for loss in fitness from dhfr mutations. In addition, extra GCH1 increases the overall robustness, which allows additional dhfr mutations and reduces the drug sensitivity level of other antifolates. A similar issue was also encountered in artemisinin resistance, an emerging problem in Southeast Asia. Parasite isolates with decreased sensitivity to artemisinin suffer from fitness loss. The parasites produce fewer progenies, corresponding to the loss of one round of mitosis. These parasites are metabolically impaired, resulting in growth arrest under stress. The loss in fitness might explain why the parasites cannot achieve higher level of artemisinin resistance like in the cases of chloroquine and antifolate.

1482

METABOLOMIC ANALYSIS OF *PLASMODIUM VIVAX* CHLOROQUINE RESISTANCE

Jorge L. Salinas[1], Karan Uppal[1], Fernando F. Val[2], Wuelton M. Monteiro[2], Gisely C. Melo[2], Andre M. Siqueira[2], Belisa Magalhães[2], Dean P. Jones[1], Mark P. Styczynski[3], Mary R. Galinski[1], Marcus V. Lacerda[2]

[1]Emory University, Atlanta, GA, United States, [2]Fundaçao de Medicina Tropical Doutor Heitor Vieira Dourado, Manaus, Brazil, [3]Georgia Institute of Technology, Atlanta, GA, United States

Chloroquine is the main drug used in the treatment of uncomplicated vivax malaria. Reports of chloroquine resistant (CQ-R) ***Plasmodium vivax*** malaria from the Western Pacific region followed by reports in the Americas and Asia have questioned its widespread use. However, the mechanisms associated with CQ-R malaria are not yet fully understood. We used plasma samples from individuals ≥18 years of age with ***P. vivax*** monoinfection treated at the Fundação de Medicina Tropical Heitor Vieira Dourado in Manaus, Brazil during 2011-2012. Chloroquine resistance was defined as recurrence of parasitemia with detectable plasma concentrations of CQ ≥100ng/dl. 33 individuals with CQ-sensitive

and 16 with CQ-R ***P. vivax*** malaria were included. Samples underwent randomization followed by Liquid Chromatography/Mass Spectrometry. We used xMSanalyzer for data extraction and obtained 21,360 ***m/z*** features. We then performed linear regression controlling for platelet and total bilirubin levels, as they were significantly associated with the outcome and for age and gender as they may have an impact in the metabolome. We adjusted for multiple hypothesis testing by the Benjamini-Hochberg false discovery rate (FDR) method. The linear regression model resulted in 18 ***m/z*** significantly different between both study groups (t-test, FDR<0.20). We then created a partial least squares discriminant analysis (PLS-DA) model without controlling for covariates in an effort to further explore our results. This model detected 354 ***m/z*** with a Variable Importance in Projection ≥2. Features detected by linear regression and PLS-DA had an overlap in 17 ***m/z***. We tested the 354 ***m/z*** from PLS-DA for pathway enrichment using ***mummichog***, an algorithm for pathway-level annotation of metabolomics data, and found alterations in steroid biosynthesis, glycerophospholipid and tryptophan metabolism (all p<0.05). Our analyses likely measure the net metabolic host-pathogen interaction rather than separating host or pathogen pathways. Although not evidence of causality, our effort yields potential biochemical pathways associated with chloroquine resistance in ***P. vivax*** from the Brazilian Amazon.

1483

INADEQUATE EFFICACY OF CLINDAMYCIN PLUS QUININE COMPARED TO ARTEMETHER-LUMEFANTRINE IN THE TREATMENT OF CHILDREN WITH UNCOMPLICATED FALCIPARUM MALARIA IN WESTERN KENYA

Charles O. Obonyo, Elizabeth Juma, Bernhards Oguto

Kenya Medical Research Institute, Kisumu, Kenya

Background: Clindamycin plus quinine is a non-artemisinin-based antimalarial drug combination. The evidence on the efficacy of clindamycin plus quinine compared with other antimalarial drugs is scanty, inconclusive and outdated. An open-label randomized controlled trial to evaluate the efficacy and safety of oral clindamycin plus quinine vs. artemether-lumefantrine in the treatment of children below 5 years of age with uncomplicated falciparum malaria was conducted in western Kenya. Methods: 384 children aged 6 to 59 months with uncomplicated malaria were enrolled at Homa Bay District and Ahero Sub-District Hospitals in western Kenya and randomized (1:1) to receive oral clindamycin plus quinine or dispersible artemether-lumefantrine tablets and followed for 28 days. The primary endpoint was parasitological cure rate after 28 days of follow up, unadjusted and adjusted by genotyping to distinguish recrudescence from new infections. Secondary endpoints included parasitological failure on days 3, 14, 21 and 28, parasite clearance rates, gametocyte carriage, recovery of haemoglobin concentration from baseline at day 28, and incidence of adverse events. Results: The unadjusted cure rate was 32.6% in the clindamycin plus quinine group and 78.9% in the artemether-lumefantrine group. The risk of treatment failure after adjusting by genotyping was significantly higher in the clindamycin plus quinine group (55.6%) compared to the artemether-lumefantrine (2.9%) group (risk difference 52.7, 95% confidence interval 43.0-62.4, p<0.0001). Parasitological clearance was significantly lower and the proportion of early treatment failures significantly higher in the clindamycin plus quinine group. Adverse events did not differ between the two groups. Three serious adverse events occurred in the clindamycin plus quinine group. Conclusion: The cure rate with clindamycin plus quinine in our study was significantly lower than artemether-lumefantrine. These findings question the recommendation of quinine-based combinations as second-line drugs for the treatment of malaria.

1484

IMPACT OF K13 MUTATIONS ON PARASITE FITNESS AND SUSCEPTIBILITY TO OZONIDES

Judith Straimer, Nina Gnadig, Michelle Ehrenberger, David Fidock

Columbia University, New York, NY, United States

Artemisinin (ART)-based combination therapies (ACTs) have contributed substantially to reducing the burden of malaria. Thus, alarms were sounded when efficacy studies in Western Cambodia documented the emergence of ART resistance in ***Plasmodium falciparum***. Recent reports have demonstrated that mutations in the K13 propeller domain associate strongly with slow parasite clearance rates in patients and confer elevated survival of drug-exposed ring-stage parasites ***in vitro***, as reported previously. Several K13 alleles have emerged in Southeast Asia and are now spreading across the Greater Mekong Subregion. In addition to the different levels of resistance that single K13 mutations may confer, we hypothesize that the impact of each mutation on parasite fitness is decisive in establishing the viability of a given haplotype in malaria-endemic settings. In this work we have determined the fitness cost imparted by several mutations in the K13 gene on parasite growth. We used genetically modified, otherwise isogenic, parasites with a selection of K13 propeller mutations and conducted direct growth competition experiments. We found that mutations in K13 exert a growth deficit on mutant parasites compared to their wild-type parental counterparts. We also assessed susceptibility of K13 mutant parasites to the next-generation long half-live ozonides OZ227 and OZ439, which are currently being evaluated as alternatives to ART. We identified cross-resistance between OZ277 and DHA (dihydroartemisinin), the active metabolite of all ARTs, whereas OZ439 demonstrated excellent potency against all mutant and wild-type K13 parasite lines tested. These data suggest that the major K13 mutations present in Cambodia do not protect parasites from OZ439 action, highlighting the potential benefit of replacing ARTs with ozonides.

1485

A COMPARISON OF NEW AND EXISTING *IN VITRO* METHODS FOR ASSESSMENT OF ARTEMISININ RESISTANCE BY *PLASMODIUM FALCIPARUM* RING SURVIVAL

Whitney A. Kite, Viviana Melendez-Muniz, Thomas E. Wellems, Juliana M. Sa

National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

As artemisinin (ART) resistance in ***Plasmodium falciparum*** spreads through Southeast Asia and threatens malaria control programs worldwide, assessment of phenotypes ***in vitro*** is necessary to survey parasite populations and study resistance mechanisms. A Ring Survival Assay (RSA) developed by Witkowski and colleagues in 2013 became instrumental to study ART response ***in vitro***. The method includes treatment of cultures with heparin, selection of late stage schizonts by Percoll gradient, and treatment of 0-3h ring stage parasites with sorbitol prior to a six hour drug pulse. These three chemical treatments, however, do not guarantee the exclusive drug exposure of 3h rings. We offer two alternative methods, one requiring less resources and one offering improved specificity for 3h rings. The first alternative acquires young rings through only sorbitol synchronization, lessening the list of needed chemicals from three to one. Additionally, this method uses only twenty microliters or less of parasite culture per assay. For instances where samples are scarce, this method provides an opportunity to assess phenotype ***in vitro*** that would otherwise not be possible. Our second alternative adapts the procedure of Boyle and colleagues, reported in 2010, involving filtration of late schizonts with a 1.2 µm filter to provide invasive merozoites to uninfected erythrocytes. In contrast to the original method, filtration provides a sharper synchronization of ring stage parasites without chemicals and allows drug incubation of exactly 3h-old rings. This enhanced specificity offers increased precision for determinations of

ring survival percentages. All three methods (the original, filtration, and sorbitol-only) tested on the same lines yielded comparable results of ring survival percentages: of a resistant line, percentages were 6.87%, 8.88%, and 6.92%, respectively; of a sensitive line, 0.55%, 0.68%, and 0.76%. A comparison of needed resources and procedural logistics for each method will be presented. The availability of three RSA methods provides flexibility in evaluating ART response in a variety of scenarios.

PREDICTIONS OF PIPERAQUINE SYSTEMIC EXPOSURE IN YOUNG CHILDREN UNDER DIFFERENT DOSING REGIMENS FOR CHEMOPREVENTION: A SIMULATION STUDY TO INFORM DOSING

Nancy Sambol[1], Jordan Tappero[2], Emmanuel Arinaitwe[3], **Sunil Parikh**[4]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Makerere University School of Medicine, Kampala, Uganda, [4]Yale School of Public Health, New Haven, CT, United States

Dihydroartemisinin-piperaquine, the first-line artemisinin combination therapy regimen, is under evaluation for intermittent preventive treatment (IPT). Dosing approaches in IPT have been inferred from treatment trials, and fail to adequately consider differences in PK/PD relationships, adherence, and safety concerns that exist with repeated dosing in chemoprevention. Further, we have recently demonstrated that young children are systematically underdosed in treatment settings. To better inform dosage selection of DP for IPT, we simulated PK profiles of candidate DP chemoprevention regimens based on a previously developed population model of piperaquine (PQ) in the setting of acute treatment of Ugandan children aged 6 months to 2 years. Regimens were simulated for children weighing over 10 kg (reference group), and included standard and 1.5x standard 3-day monthly regimens, bimonthly and weekly dosing, and use of a loading dose. The current approach (240 mg x 3 doses monthly) led to a predicted geometric mean steady-state trough capillary plasma level of 29 ng/mL, with 94%, and 47% of children maintaining levels ≥ 10 ng/mL and 30 ng/mL, respectively. Increasing doses by 50% lead to a predicted trough of 43 ng/mL, with 98% and 71% maintaining ≥ 10 ng/mL and 30 ng/mL. Notable improvement in exposure was seen with weekly 240 mg dosing, leading to a steady-state of 67 ng/mL, with 99.7% and 85% maintaining troughs ≥ 10 ng/mL and 30 ng/mL. Importantly, predicted maximum concentrations were 42% lower with weekly dosing compared to standard dosing. Previous studies have demonstrated that individuals have a higher risk of breakthrough malaria in the first few months of chemoprevention. The use of a loading dose with weekly dosing was associated with trough levels at the end of one month that are 94% of steady-state trough levels, compared to 70% without a loading dose. With corroborating clinical data, these alternate dosing approaches may prove favorable in terms of exposure, adherence and safety. This approach provides a systematic information-driven method to evaluate candidate antimalarial chemopreventive dosing regimens.

1487

ANALYSIS OF POLYMORPHISMS IN ARTEMISININ RESISTANCE ASSOCIATED GENES IN *PLASMODIUM FALCIPARUM* SAMPLES FROM SOUTH AMERICAN AND AFRICAN COUNTRIES

Juliana Inoue[1], Pedro Cravo[2], Camila M. Romano[1], Giselle F. Lima[1], Angélica D. Hristov[1], Marcos Boulos[1], Silvia M. Di Santi[1]

[1]Universidade de São Paulo, São Paulo, Brazil, [2]Universidade Federal de Goiás, Goiânia, Brazil

The emergence of ***Plasmodium falciparum*** resistance to artemisinin (ART) in Southeast Asia threats the disease control. ART resistance has been associated with mutations in some candidate genes and monitoring these events as well as its impact in treatment outcome may contribute to malaria control. This study aimed at analyzing ART-resistance associated genes ***pfATPase6***, ***pfAP2μ*** and ***pfK13*** in ***P. falciparum*** samples from South American and African countries collected in health facilities in Brazil, after informed consent. After sequencing with sense and antisense primers, sequences of 24 samples were aligned and compared to the reference ***P. falciparum*** 3D7 available in PlasmoDB. An empirical Bayesian method was applied using the M8 model to assess codons under selection. Datasets used for selection pressure analysis were built with sequences from this study and worldwide reference sequences retrieved from PlasmoDB and GenBank. The following mutations in ***pfATPase6*** gene were observed: R37K, L402V, E431K, N569K, A630S, G632E, G639D, H747Y and I898I. In ***pfAP2μ***, W250R and D3Y in one sample each, V127V in nine and S478S in one. Amino acid insertion was seen in three samples and deletion in other three. For ***pfK13*** gene, K189T was present in three samples, K189N in one. One sample harbored G112E and A578S. Overall, all genes are under negative selection, showing ω=0.4 for ***pfATPase6***, ω=0.12 for ***pfAP2μ*** and ω=0.5 for ***pfK13***. Several negatively selected codons were observed in all three genes, but few positive selected codons were seen within ***pfATPase6***, at positions 141, 402, 431, 569, 574 and 639 with significance level of 0.001. Interestingly, in the ***pfK13*** gene all codons under strong purifying selection were located within the Kelch motif. Mutation K189T was found in isolates from South America and Haiti in agreement with reports of this SNP in African countries. Despite the absence of C580Y mutation, it was found the A578S, whose structural analysis shows that could affect K13 gene function. These results generate a baseline data on three candidate genes associated with ART resistance that could be useful in view of the risk of ART resistance spread worldwide.

1488

GENETIC MODIFICATION VIA CRISPR/CAS9 IN *PLASMODIUM FALCIPARUM* MULTIDRUG RESISTANCE PROTEIN1 (PFMDR1) CONFER RESISTANCE TO A PIPERAZINE-CONTAINING ANTIMALARIAL AGENT IN BOTH ASEXUAL AND SEXUAL PARASITE STAGES

Caroline L. Ng[1], Giulia Siciliano[2], Mariana J. Almeida[1], Selina Bopp[3], Sergio Wittlin[4], Rachel Kasdin[1], David Plouffe[3], Christopher Binkert[5], Amelie LeBihan[5], Jasper Dingemanse[5], Elizabeth Winzeler[3], James McCarthy[6], Pietro Alano[2], David A. Fidock[1]

[1]Columbia University Medical Center, New York, NY, United States, [2]Istituto Superiore di Sanità, Rome, Italy, [3]University of California San Diego, San Diego, CA, United States, [4]Swiss Tropical and Public Health Institute, Basel, Switzerland, [5]Actelion Pharmaceuticals Ltd., Allschwil, Switzerland, [6]University of Queensland, Queensland, Australia

ACT451840 is a piperazine-containing antimalarial compound developed by Actelion Pharmaceuticals Ltd. with support from the Medicines for Malaria Venture. This compound is an exquisitely potent inhibitor of ***Plasmodium falciparum*** asexual blood stage parasites, with an IC_{50} value of <1 nM. Single-step drug-selection studies yielded resistant asexual blood stage parasites with 10 to 200-fold shifts in IC_{50} values compared to the sensitive parental line. Whole-genome tiling arrays and Illumina-based sequencing on resistant clones uncovered a host of novel point mutations in the ***P. falciparum*** multidrug resistance protein 1 (PfMDR1), resident on the parasite's digestive vacuole membrane. Using CRISPR/Cas9-based ***pfmdr1*** gene editing, we confirmed that the ***pfmdr1*** point mutations mediated resistance. Furthermore, when compared to wild-type isogenic parasites, ACT451840-resistant parasites became more susceptible to mefloquine, lumefantrine, halofantrine, and quinine, but not chloroquine or its active metabolite, and displayed a slight fitness cost ***in vitro***. We also observed potent activity of ACT451840 on mature ***P. falciparum*** gametocytes. Unexpectedly, stage V gametocytes harboring Cas9-introduced ***pfmdr1*** mutations acquired resistance to this compound, suggesting that PfMDR1 can also impart resistance to mature gametocytes. The potent asexual and gametocytocidal properties of this compound merit further investigation.

1489

DEVELOPMENT OF ANTIBODY-BASED IMMUNO-ASSAYS FOR QUALITY CONTROL OF ARTEMISININ-BASED COMBINATION THERAPIES

Insaf Khalil[1], **Xavier C. Ding**[2], Iveth J. González[2], Ib C. Bygbjerg[1], Facundo M. Fernandez[3], Paul N. Newton[4], Michael Alifrangis[1], Claus Koch[5]

[1]Centre for Medical Parasitology at Department of Immunology and Microbiology and Department of Public Health, University of Copenhagen, Copenhagen, Denmark, [2]Foundation for Innovative New Diagnostics, Geneva, Switzerland, [3]School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA, United States, [4]Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Microbiology Laboratory, Mahosot Hospital, Vientiane, Lao People's Democratic Republic, [5]Institute of Molecular Medicine, Department of Cancer and Inflammation, University of Southern Denmark, Odense, Denmark

Prompt treatment of uncomplicated ***Plasmodium falciparum*** malaria with artemisinin-based combination therapies (ACTs) is paramount to avoid clinical complications and deaths as well as to our ability to control this disease. Approximately 392 millions of ACT treatment courses have been procured to the public and private sectors in 2013, largely contributing to the globally decreasing malaria mortality rate. Yet, a significant fraction of antimalarial drugs are sold over-the-counter in poorly regulated settings, favoring the uncontrolled distribution of falsified or substandard antimalarial drugs in large quantities. Up to a third of antimalarial available in endemic countries can be of unacceptable quality, turning life-saving medicines into life-threatening substances. ACTs quality control (QC) is needed at all levels of the supply chain, and affordable analytical tools which can be easily deployed in settings with limited resources to perform routine quantitative analyses are currently missing. To address this issue, we have developed a set of monoclonal antibodies directed against key active pharmaceutical ingredients (APIs) of ACTs, such as artesunate, amodiaquine, and piperaquine, while work is ongoing to generate additional ones directed against dihydroartemisinin, artemether, lumefantrine and primaquine. We further developed and validated indirect competitive Enzyme-Linked Immunosorbent Assays (iELISAs) based on monoclonal antibodies against artesunate and amodiaquine for the rapid quantification of the corresponding molecules in pharmaceutical formulations. iELISAs are easy-to-handle as well as highly specific and sensitive, displaying a lower limit of detection between 1.0 and 3.9 ng/ml. Finally, proof-of-concept studies evaluating the performance of iELISAs as compared to high-performance liquid chromatography-mass spectrometry for the quantification of APIs in ACTs of varying quality are underway. iELSA could be used to instate or reinforce ACT QC at local levels and could be relatively easily deployed in simple laboratories to contribute ensuring the safety of key antimalarial drugs.

ARTEMISININ RESISTANCE AT THE CHINA-MYANMAR BORDER AND ASSOCIATION WITH MUTATIONS IN THE K13-PROPELLER GENE

Zenglei Wang[1], Mynthia Cabrera[1], Sony Shrestha[1], Awtum Brashear[1], Karen Kemirembe[1], Xiaoying Liang[1], Bhavna Gupta[1], Xiaolian Li[1], Jun Miao[1], Zhaoqing Yang[2], Liwang Cui[1]

[1]Pennsylvania State University, University Park, PA, United States, [2]Kunming Medical University, Kunming, China

The recent emergence and spread of artemisinin (ART) resistance in the Greater Mekong Subregion (GMS) of Southeast Asia greatly threatens malaria control and eradication. The K13-propeller gene (K13) has been lately identified as a promising maker to confer ART resistance. Investigation of K13 gene in parasites from the China-Myanmar border area, where ART use has the longest history, has revealed high prevalence of polymorphisms. Elucidation of their importance in ART resistance is highly needed. A total of >11,000 suspected malaria cases from three studies during 2008-2013 in this area were screened and 248 were recruited for clinical assessment. The day 3 positive rates in two studies with dihydrartemisinin-piperaquine treatment were below 10%, whereas in one study with artesunate monotherapy reached 23.1%. To validate the predictability of K13 mutations for potential ART resistance, we selected 24 day 3-positive cases and 33 day 3-negative cases from these three efficacy studies. The NN insertion at codon 137 and the predominant F446I mutation as well as the total mutations in the propeller domain were significantly associated with the day 3 parasite positivity ($P < 0.05$). To determine whether the suspected ART resistance in the study region could be further corroborated by ring-stage survival assay (RSA), we culture-adapted 19 isolates from day 3-positive cases and 25 from day 3 negative cases. The median percentage of viable parasites in isolates from the day 3 positive group was ~10 times greater than that of isolates from the day 3-negative group (0.5%) ($P < 0.0001$). Parasites with mutations in the propeller domain had a ~9 fold higher ring-stage survival rate ($P<0.05$). The NN insertion and F446I mutation also significantly associated with day 3 parasite positivity. From association studies between clinical data of day-3 positivity, ***in vitro*** ring-stage susceptibility, and K13 polymorphisms, we provide strong evidence indicating emergence of artemisinin resistance at the China-Myanmar border and K13 as a promising marker for artemisinin resistance.

1491

PRIMAQUINE: METABOLITE ACTIVITY AND SCHIZONTICIDE DRUG COMBINATION ACTIVITY ON ASEXUAL AND SEXUAL STAGES OF *PLASMODIUM FALCIPARUM*

Mynthia Cabrera, Jun Miao, Liwang Cui

Pennsylvania State University, University Park, PA, United States

Primaquine (PQ) used with Artemisinin Combination Therapies (ACTs) field studies in Southeast Asia and Africa has shown effective ***Plasmodium falciparum*** gametocyte clearance which is critically important for reducing the risk of malaria transmission and potentially mitigating the threat of drug resistant infections. Currently, the World Health Organization recommends adding a single 0.25 mg/kg dose of PQ on the first day of ACT treatment in areas under threat of ART resistance. PQ antimalarial activity ***in vivo*** has been historically attributed to the potential activity of its metabolites as well as perturbation of mitochondrial function. The former was investigated via 1) a PQ metabolite mixture generated ***in vitro***, 2) and synthesized PQ analogs from Walter Reed Army Institute of Research. The presence of potential PQ metabolites in the mixture was analyzed using LC-MS and gametocytocidal activity tested on transgenic male and female ***P. falciparum*** lines expressing green fluorescent protein in gametocytes using a flow-cytometry based drug sensitivity assay. The PQ analogs' activities on sexual and asexual stages were tested with the same gametocytocidal sensitivity assay and SYBR Green I drug assay, respectively. In addition, since PQ dosage is now a recommended addition to ACTs, we looked at the effect of PQ in combination with various antimalarials (chloroquine, mefloquine, piperaquine, lumefantrine, naphthoquine) on ***in vitro*** growth of asexual ***P. falciparum*** strains and gametocytocidal activity on ***P. falciparum*** gametocytes.

ATESUNATE/SULPHADOXINE/PYRIMETHAMINE COMBINATION SHOWS EQUAL ACTIVITY TO OTHER ACTS AGAINST *PLASMODIUM BERGHEI* IN MICE AFTER CO-TRMOXAZOLE PRETREATMENT

Akinwumi A. Akinyede[1], Oluwagbemiga Aina[2], Oluwafemi Kale[1], Olufunsho Awodele[1], Judith Nwadinigwe[1], Iyanu Olaniyonu[1], Sunday Olayemi[1]

[1]College of Medicine, University of Lagos, Lagos, Nigeria, [2]Nigeria Institute of Medical Research, Lagos, Nigeria

Co-trimoxazole(COT) therapy has been found to reduce the high early mortality rate in HIV-infected adults on ART in low- and middle-income countries hence the WHO recommended that the use of COT be scaled up in HIV-infected patients starting or receiving antiretroviral therapy. However, resistance due to drug pressure and subsequent cross- resistance between COT and sulphonamides such as sulphadoxine/pyrimethamine (S/P) which could otherwise be useful as part of ACTs is a concern. Knowledge of the effect of atesunate combination with S/P on malaria parasites previously exposed to COT would be instructive. COT pre-treatment was administered to 30 adult albino mice divided into 6 groups and weighing between 15-25g for 14 days after which the animals were inoculated with chloroquine sensitive ***Plasmodium berghei*** . Subsequently, the anti-malaria activities of curative doses of Artemether/Lumifantrine (AL), Atesunate/Sulphadoxine/Pyrimethamine (AS/SP), Atesunate/Amodiaquine (AS/AMQ) and Atesunate/Mefloquine (AS/MQ) combinations against ***Plasmodium berghei*** were investigated in each of 4 groups respectively. One of the two remaining groups serving as controls was administered chloroquine(CQ) and the other distilled water, respectively.The average parasite densities on day 0 were 28045.5 ± 26718.2, 36462.0 ± 7070.0, 65651.7 ± 27686.5, 78809.1 ± 6160.8 respectively for the groups administered AL, AS/SP, AS/AMQ and AS/MQ; On day 1, these values decreased to 11980.0 ± 11980.0**, 7838.4 ± 4038.7**, 7767.7 ± 4202.3**, 12677.0 ± 2893.1**respectively ($P < 0.01$, Vs Distilled water); there was complete parasite eradication by day 3. Total parasite eradication occurred in the CQ group by day 2 from an initial value of 76746.3 ± 28457.1, while there was an increase from 46459.4 ± 13949.2 to 130499.4 ± 936.2 between days 0 and 13 in the distilled water group with the mice in this group dying off by day 17. Atesunate combination with S/P was as active as other ACTs.Validation of this theory in humans may provide a wider range of ACTs useful even among patients on prior COT therapy.

1493

RESISTANCE ANALYSIS OF THE ANTIMALARIAL MK-4815: LOW FREQUENCY OF RESISTANCE AND CROSS-RESISTANCE PROFILE CONSISTENT WITH ROBUST CLINICAL CANDIDATE

Debora Casandra[1], Maryann Powles[2], Katherine Young[2], David B. Olsen[2], **Dennis E. Kyle**[1]

[1]University of South Florida, Tampa, FL, United States, [2]Merck Research Laboratories, Kenilworth, NJ, United States

Due to the emergence and increased prevalence of multi-drug resistant malaria, new drugs are urgently needed for combination therapy to effectively treat and eliminate malaria. Currently there are several new fast-acting antimalarial candidates in development, yet there is a dearth of long-acting compounds with good oral bioavailability, potency against multi-drug resistant strains, and low potential for resistance generation. One such candidate for combination therapy is MK-4815 (2-aminomethyl-3,5-di-***tert***-butylphenol), a Mannich base previously shown to be potent ***in vitro*** and ***in vivo*** and equally effective against wild-type and multi-drug resistant strains of ***Plasmodium falciparum***. We assessed the potential for MK-4815 to generate resistance and MK-4815's ***in vitro*** efficacy against multidrug resistant strains. First we examined the frequency of resistance after continuous drug pressure and were unable to select for resistant parasites, suggesting that the resistance frequency for MK4815 is less than 10^{-8} as found for atovaquone. Next the potential for drug resistance generation was assessed by step-wise pulse exposure to MK-4815 in the W2 clone of ***P. falciparum***. The base-line IC_{50} for MK-4815 in W2 is 7 ng/mL. We started with 5x IC_{50} concentration and applied four-day pulses of drug followed by wash out and a recovery period to allow parasites to grow. Once recovery was established, exposure continued with higher concentrations of MK-4815. Ultimately parasites recovered following 96 hr at 1,000x IC_{50}. Decreased susceptibility to MK-4815 was minimal and not stable. A three-week period without drug pressure was enough for the parasite response to return within 3-fold of baseline. In addition, we evaluated the IC_{50}'s of MK-4815 against multidrug resistant strains and found that MK-4815 has no discernable cross-resistance patterns with other anti-malarial drugs. The results of our studies suggest that MK-4815 has a low potential for selecting resistance in ***P. falciparum***; these data as well as its favorable pharmacokinetics, safety, and efficacy profiles, make MK-4815 an excellent drug combination candidate.

1494

TEMPORAL TRENDS IN SULPHADOXINE-PYRIMETHAMINE RESISTANCE MARKERS IN *PLASMODIUM FALCIPARUM* IN NIGERIA 2002 - 2014

Mary C. Oguike[1], Izehiuwa G. Enato[2], Elvis Shu[3], Daniel Chandramohan[4], Catherine O. Falade[5], Colin J. Sutherland[6]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Department of Child Health University of Benin Teaching Hospital, Benin City, Edo State Nigeria, Nigeria, [3]University of Nigeria Teaching Hospital, Ituku-Ozalla, Enugu, Nigeria, [4]Disease Control Department, London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]Department of Pharmacology and Therapeutics, University of Ibadan, Ibadan, Nigeria, [6]Immunology and Infection Department, London School of Hygiene & Tropical Medicine, London, United Kingdom

Intermittent preventive treatment of malaria during pregnancy (IPTp) and in infants (IPTi) with sulphadoxine-pyrimethamine (SP) is a major strategy for malaria control in African countries where malaria is endemic, including Nigeria. However, the implementation of this strategy is faced with challenges such as timing of SP administration and rising levels of parasite resistance to SP in the general population. SP resistance is associated with mutations in the genes of dihydropteroate synthetase (dhps) and dihydrofolate reductase (dhfr). Three Pfdhfr mutations N51I, C59R and S108N, known as the triple mutation, and the Pfdhps mutations A437G and G540E, known as the double mutation, collectively form the quintuple mutations. The quintuple mutation and an additional mutation on the dhps (A581G) are known to confer high level of SP resistance. The World Health Organization (WHO) has recommended that prior to implementation of IPT-SP in any region with moderate to high malaria transmission, the prevalence of these markers of resistance with special emphasis on K540E should be determined and IPT-SP commenced only in regions with a prevalence rate less than 50%. Recent data show growing concerns of SP resistance in Nigeria with emerging novel dhps haplotypes and the triple mutant (IRN) dhfr haplotypes but their effect on efficacy of IPT-SP is unknown. There is paucity of data on SP resistance markers in Nigeria. Therefore, there is need for continuous monitoring of these resistance markers over the years to provide comprehensive data that will guide implementation of IPT-SP in Nigeria. We identified molecular markers of SP resistance by direct PCR sequencing in 1200 malaria positive blood spots collected from pregnant women and children attending hospitals across Southwest, Southeast, South south and Northeast Nigeria. Prevalence of markers in each site, and temporal patterns in these markers from 2002 to 2014 will be presented.

1495

ASYMMETRICAL BIS-QUINOLINES AS CHEMOTHERAPEUTIC AGENTS FOR MALARIA

David H. Peyton, **Katherine M. Liebman**

Portland State University, Portland, OR, United States

Millions of people are afflicted by malaria each year, and hundreds of thousands die. Historically, the most successful synthetic antimalarial drug was chloroquine, as it was safe, inexpensive, and highly efficacious. However, plasmodial resistance to chloroquine now greatly limits its utility. Other 4-aminoquinoline drugs, such as the bis-quinoline antimalarial piperaquine, often exhibit activity against chloroquine-resistant malaria. A series of "asymmetrical bis-quinolines" are presented here that are highly active against chloroquine-resistant and chloroquine-sensitive ***P. falciparum*** malaria, with IC_{50} values that are in several cases remarkably potent. We also present an initial structure-activity relationship series for this new series of potentially useful chemotherapeutic agents for malaria.

1496

EFFICACY OF ARTEMETHER-LUMEFANTRINE IN DIORO, MALI: AN AREA WITH INTENSE TRANSMISSION

Lansana Sangare[1], Youssouf Diarra[1], Kotou Sangare[1], Sekou Traore[1], Trevor A. Thompson[2], Daouda Ndiaye[3], Davis Nwakanma[4], Sarah K. Volkman[5], Donald J. Krogstad[2], Ousmane A. Koita[1]

[1]University of Science, Technologies and Techniques, Bamako, Mali, [2]Tulane University, New Orleans, LA, United States, [3]University Cheikh Anta Diop, Dakar, Senegal, [4]Medical Research Council Unit, Fajara, Gambia, [5]Harvard T.H. Chan School of Public Health, Boston, MA, United States

Few studies have examined the efficacy of ACTs in Mali after the introduction of Artemether-Lumefantrine (AL) and the ban on monotherapy for treatment of uncomplicated malaria. In Dioro, Mali, we performed a prospective study to examine the efficacy of the AL combination for the treatment of uncomplicated ***P. falciparum*** malaria. Subjects enrolled in this study were between 2 and 15 years of age and had asexual parasitemias between 2,000 and 199,000 per µl. Giemsa-stained thick smears were used to examine asexual and sexual parasites before treatment and to estimate the asexual parasitemias on follow-up days 1, 2, 3, 7, 14, 21, 28, 35 and 42. Filter paper blots were used to collect parasite DNA for PCR to distinguish between recrudescence and re-infection. The Dapi assay was used to estimate the IC50s of ***P. falciparum*** isolates collected at the time of diagnosis. To estimate parasite clearance time, we considered only volunteers who were observed continuously during the 3 days of treatment. Two endpoints were considered for ACT efficacy: 1] parasite clearance on or before Day 7 and 2] lack of recrudescence between days 8 and 42. All 77 volunteers cleared their asexual parasitemias on or before Day 7 and 4 (5%) had late parasitologic failures between Days 28 and 42. In addition, 5 (9%) of the 53 patients examined for the PCT had persistent asexual parasites ≥ 48 hours after beginning treatment. There was a positive correlation between the initial parasitemia and the PCT with delayed clearance (≥ 48 hours after beginning treatment) more frequent in subjects with higher parasitemias (p=0.006). Molecular studies and IC50s are currently being performed to determine whether the 4 late parasitologic failures represent recrudescence of the original parasite(s) or new infections and to test for antimalarial resistance based on elevated IC50s.

1497

DYNAMICS OF DRUG RESISTANCE PATTERNS TO COARTEM USED IN SENEGAL

Ndiaye Daouda[1], Jules Gomis[1], Donald J. Krogstad[2]

[1]University Cheikh Anta Diop, Dakar, Senegal, [2]Tulane University, New Orleans, LA, United States

Artemether-lumefantrine (AL) was adopted as the recommended treatment for uncomplicated ***Plasmodium falciparum*** malaria for Senegal in 2006. Because the monitoring of drug efficacy is essential to ensure efficacy and recognize resistance when it appears, the efficacy of AL for the treatment of uncomplicated malaria in children aged 2 to 20 years has been evaluated in Thiès (Senegal). From September 2011 to November 2014, we have studied the treatment of uncomplicated malaria using AL in children with fever or a history of fever who have uncomplicated ***Plasmodium falciparum*** malaria. In this study, parasite samples have been examined using ***ex vivo*** testing to estimate IC50s for different antimalarials and followed for 6 weeks in accordance with World Health Organization (WHO) guidelines. Follow-up visits are performed on days 1, 2, 3, 7, 14, 21, 28, 35 and 42 to evaluate clinical and parasitological results. A total of 246 subjects have now been enrolled in Thiès and Dakar. There have been no early treatment failures and all patients have cleared asexual parasites from the blood on or before day 3. Polymerase chain reaction (PCR)-uncorrected adequate clinical and parasitological response rate (UACPR) was 98.8% at day 28 as well as at day 42. PCR-corrected ACPR at day 42 was 98.8%. We found no mutation at dhpsK540E in Senegal, high level of mutation in pfmdr1 - Y184F and decreased parasite sensitivity to artesunate and Lumefantrine. Coartem still show efficacy in Senegal. Anti-malarial being used in ACT except Lumefantrine, including artemisinin derivates, amodiaquine, mefloquine are ***ex vivo*** sensitive to falciparum.

1498

CONSEQUENCES OF RESTRICTING ANTIMALARIAL DRUGS TO RAPID DIAGNOSTIC TEST POSITIVE FEVER CASES AND CAUSES OF NON-MALARIAL FEBRILE ILLNESS

Catherine Olufunke Falade[1], Adebola E. Orimadegun[1], Obaro S. Michael[1], Hannah O. Dada-Adegbola[1], Joseph A. Badejo[1], Olusegun G. Ademowo[1], Ike Oluwapo O. Ajayi[1], Ayodele S. Jegede[1], James Ssekitooleko[2], Ebenezar Baba[2], Prudence Hamade[3], Jayne Webster[4], Daniel Chandramohan[4]

[1]University of Ibadan, Ibadan, Nigeria, [2]DFID-SUNMAP, Abuja, Nigeria, [3]Malaria Consortium, London, United Kingdom, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Current malaria treatment guidelines dictate that RDT-negative children do not receive ACT but should be evaluated for other causes of fever. This practice could lead to increased frequency of malaria and anemia in children who are denied ACT. 511 febrile children aged 3 to 59 months presenting with fever or history of fever within 48hours were enrolled in southwest Nigeria and followed up for 28 days. Malaria parasite was evaluated using SD-Bioline RDT (HRP-2 based) and microscopy of Giemsa stained blood film. Enrollees were investigated and treated for other causes of fever. RDT result was used to determine ACT treatment. RDT+ve children received artesunate-amodiaquine (ASAQ™) at standard dosage supervised. The mean age of enrollees was 26.41 ± 15.67 months. Malaria parasite was detected by RDT in 308 (60.3%) and by microscopy 227 (44.2%) enrollees. Parasite density ranged from 20 - 611,600/µL (Geomean = 7762/µL). 40/193 (20.7%) children with patent parasitemia on D0 had parasite recurrence on D28 while 18/232 (7.8%) of those who were free of patent parasitemia on D0 had parasitemia on D28 (ρ=<0.0001). The sensitivity and specificity of SD-Bioline RDT were 95.2% and 55.7% respectively while positive and negative predictive values were 70.19% and 94.6%. 12/493 (2.4%) blood cultures yielded bacterial growth while 84/392 (21.4%) mid-stream urine cultures yielded bacterial growth. 5/218 (2.3%) children had malaria-bacteremia co-infection while

22.5% (41/182) had malaria plus urinary tract infection. Other causes of fever among the children include measles, acute respiratory infection, diarrhea diseases and mumps. ASAQ cleared the malaria parasitemia promptly and was well tolerated. 78.8% of 189 parasitemic children who completed D28 follow up had adequate clinical and parasitological response. Two children who tested positive and receive ASAQ were referred to hospital because of severe anemia. The results of this study did not reveal any severe consequence sequel to the use of RDT result as basis for treatment.

1499

TERTIAN DURATION OF ARTEMISININS SELECTS FOR DELAYED PARASITE CLEARANCE WITH SINGLE 48 HOUR LIFECYCLE ARTEMISININ EXPOSURE

David J. Sullivan

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

In the 1990s many artemisinin combination dosing trials ranged from 2-7 days in duration. The three day or 48 hour dosing duration was just as effective as five or more days. The correct rationale at that time was that greater compliance would be achieved with tertian dosing rather than five or more days. This three day regimen was effective until the prolonged parasite phenotype was noted in Palin Cambodia. The three day or 'tertian' dosing equates to a single 48 hour ***Plasmodium falciparum*** lifecycle. The consequence of dosing most of the artemisinin component of an ACT within a single ***P. falciparum*** 48 hour lifecycle is selection for parasites with Kelch-13 gene mutations. Ring-stages of parasites in the peripheral blood at drug initiation only receive a single effective dose coincident with the sensitive trophozoite-stages, because two artemisinin doses (at initiation and the last dose) target the naturally more resistant ring-stages. Sequestered trophozoites in the tissues at drug initiation receive two effective trophozoite-stage drug doses at 0 and 40-48 hours resulting in greater reduction of these trophozoites in contrast to the rings. The parasite has been selected by the short pharmacodynamics of artemisinin behaviour within a single lifecycle to favour a mutant Kelch-13 gene to permit survival beyond a single cycle so that if the quinoline partner drug in an ACT is failing as well, then elimination of remaining parasites is compromised. Clinical drug failure measured at day 28 or 42 is failure for both ACT drugs, and should therefore be termed treatment failure. Importantly the tertian ACT 48 hour dosing regimens including the 60 hour every 12 hour artemether/lumefantrine dosing is presently selecting for additional ***foci*** of mutations outside Southeast Asia. Effective artemisinin combination therapy with present drugs now requires doubling the duration to six days. This allows initial ring-stage populations to encounter artemisinin drug exposure at least three times at the more sensititive trophozoite-stage rather than once. Incremental increase of an extra day of therapy is not sufficient.

NEXT-GENERATION SEQUENCING PLATFORM BASED ON MALARIA RAPID DIAGNOSTIC TESTS FOR SURVEILLANCE OF ANTIMALARIAL DRUG RESISTANCE

Sidsel Nag[1], Marlene Dalgaard[2], Magatte Ndiaye[3], Poul-Erik L. Kofoed[4], Amabelia Rodrigues[5], Johan Ursing[6], Reginald Kavishe[7], Michael Alifrangis[1], Ole Lund[2], Frank M. Aarestrup[2]

[1]University of Copenhagen, Copenhagen, Denmark, [2]Technical University of Denmark, Kgs Lyngby, Denmark, [3]University Cheikh Anta Diop, Dakar, Senegal, [4]Kolding Hospital, Kolding, Denmark, [5]Bandim Health Project, Bandim, Guinea-Bissau, [6]Karolinska Institute, Stockholm, Sweden, [7]Tumaini University, Moshi, United Republic of Tanzania

Antimalarial drug resistance is a constantly present threat towards one of the major tools necessary for rolling back malaria, namely efficient antimalarial drugs. It has occurred on several occasions and rendered the health systems close to helpless towards the malaria parasites, in particular towards ***Plasmodium falciparum*** malaria. For reasons that are not entirely understood by modern science, ***P. falciparum*** never ceases to be one step in front of the research community, repeatedly disarming the forces that try to combat the disease. The current global malaria situation situation involves ***P. falciparum*** parasites that are resistant towards artemisinin-based combination therapies in Asia, as well as global resistance towards sulphadoxine-pyrimethamine and chloroquine. With very limited antimalarial drugs remaining to effectively prevent malaria in children and pregnant women, as well as treat malaria-infected individuals, the local situation regarding antimalarial drug resistance needs to be monitored. With the help of molecular markers of resistance in terms of single nucleotide polymorphisms representative of tolerance or resistance of ***P. falciparum*** parasites towards specific antimalarial drugs, monitoring the antimalarial drug resistance situation becomes feasible. Furthermore, by applying used malaria rapid diagnostic tests, the source of ***P. falciparum*** DNA is acquired at very low costs and in plentiful numbers. Also, by applying a next-generation sequencing technology, the cost of sequence analysis is brought down 20-50 fold in comparison to commercial Sanger sequencing. Lastly, by applying indexing of the samples analysed, sequences can be traced back to a specific sample and a specific place of origin, allowing action to be taken in terms of fine-tuning policy guidance at the local level. This platform allows for real-time monitoring of antimalarial drug resistance in a cost-efficient and extremely high throughput manner.

1501

EVALUATION OF THE IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ADMINISTERED BY MASS CAMPAIGN IN SOUTHERN SENEGAL

Jean Louis A. Ndiaye[1], Babacar Faye[1], Magatte Ndiaye[1], Daouda Ndiaye[1], Medoune Ndiop[2], Isaac A. Manga[1], Roger Tine[1], Julie Thwing[3], Mady Ba[2], Paul Milligan[4], Oumar Gaye[1]

[1]Service de Parasitologie, Dakar, Senegal, [2]Ministry of Health and Social Action, Dakar, Senegal, [3]PMI, Dakar, Senegal, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Seasonal Malaria Chemoprevention (SMC) is a new strategy for the control of malaria in children involving monthly administration of sulfadoxine-pyrimethamine plus amodiaquine (SPAQ) to prevent malaria. In Senegal, the southern regions where malaria is highly seasonal, and transmission is intense are the most suited areas for SMC with 620,000 children under 10 years of age eligible for SMC. It is however important that scaling up of SMC by national Malaria Control Programmes is evaluated to document its coverage, the safety profile, the impact on malaria morbidity and drug resistance molecular markers. In 2014, to monitor malaria morbidity surveillance, 230 health structures were listed by district, with their catchment populations, (a total pop about 2 million) based on the 2012 census. A survey sample of 32 health post, 16 districts hospitals were selected with probability proportional per size, by systematic random sampling, checked with respect to geographical coverage, malaria cases and malaria incidence rates to ensure the sample was representative. One month after the 3 SMC rounds with an administrative coverage of more than 95%, 2000 children under 10 and 1750 adults into 45 villages selected by PPS were surveyed to document SMC coverage and drug resistance markers. A case - control study has been conducted in 2 districts to measure the efficacy of SMC treatments. 225 malaria cases and controls who do not have malaria have been recruited concurrently, and the dates of the doses of SMC they received noted by trained fieldworkers. The strengthened passive pharmacovigilance system detected only 80 mild adverse events and 2 serious adverse events (1 Lyell and 1 Steven - Johnson syndromes) after 1.843 million SMC treatments. The analysis is on going and efficacy results, impact on malaria morbidity and on drug resistance markers will be presented.

1502

THERAPEUTIC EFFICACY OF ATOVAQUONE-PROGUANIL AND ARTESUNATE ATOVAQUONE-PROGUANIL FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN AREAS OF MULTIDRUG RESISTANCE IN CAMBODIA

Chanthap Lon[1], Mali Ittiverakul[2], Sok Somethy[3], Soklyda Chann[1], Worachet Kuntawunginn[2], Nareth Kong[1], Jessica Manning[2], Jessica Lin[4], Dustin Harrison[5], Andrew Vaughn[5], Agus Ratchmat[5], Satharath Prom[3], Lek Dysoley[6], **David Saunders**[2]

[1]Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Royal Cambodian Armed Forces, Phnom Penh, Cambodia, [4]University of North Carolina, Chapel Hill, NC, United States, [5]Naval Medical Research Unit - 2, Phnom Penh, Cambodia, [6]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

We recently reported a clinical failure rate of greater than 54% for dihydroartemisinin-piperaquine, the last currently available artemisinin combination therapy (ACT) for the treatment of ***Plasmodium falciparum*** malaria in Cambodia. Few alternatives remain unfortunately. Atovaquone-proguanil (AP) is a safe, well-tolerated drug for the treatment of drug resistant ***P. falciparum***, and has recently been used in limited areas of Cambodia as part of public health interventions. There have been recent though unconfirmed reports of developing clinical AP resistance in Pailin province, as well as reports of mutations to the cytochrome bc-1 complex associated with atovaquone resistance. We are currently comparing two fixed-dose 3 day regimens of AP, with or without a 3 day course of co-administered artesunate (ASAP) for the treatment of uncomplicated malaria. This randomized, open label clinical trial will be conducted in up to 200 patients with ***P. falciparum*** or mixed ***P. falciparum/P. vivax*** infection at two sites in Cambodia. Enrollment began in Anlong Veng on the Thai-Cambodian border in December 2014, and will start in Kratie, on the Vietnamese border in May 2015. A single 15mg dose of primaquine is given on day 1, and subjects are followed for recurrence for 42 days. To date, 40 volunteers have been screened, 23 randomized to AP and 17 randomized to ASAP. Preliminary results indicate only 1 of 31 evaluable subjects (3.2%) completing 42 day follow up to date have had P.f. recurrence, while 8 (25.8%) have had a ***P. vivax*** recurrence. One subject in the ASAP group suffered a serious adverse event with suspected drug-induced liver injury. An interim report, including both efficacy, and safety results pertaining to the use of single low dose primaquine in subjects with G6PD deficiency, will be presented.

1503

MEASURING DIFFERENCES IN THE *IN VITRO* SUSCEPTIBILITY OF AFRICAN *PLASMODIUM FALCIPARUM* ISOLATES TO DIHYDROARTEMISININ USING A FLUORESCENT-READOUT PULSING ASSAY

Ifeyinwa Aniebo, Gisela Henriques, Colin Sutherland, Donelly van Schalkwyk

London School of Hygiene & Tropical Medicine, London, United Kingdom

Artemisinin-based combination therapy (ACT) is currently the most effective treatment strategy against ***Plasmodium falciparum*** malaria. There have been reports from Southeast Asia of parasite resistance to artemisinin and its derivatives, and there are fears that resistance to this class of drugs will spread to Africa. Artemisinin resistance is recognised by a relatively slow parasite clearance rate in patients receiving an ACT or artemisinin***. In-vitro*** or ***ex-vivo*** methods are conventionally used to determin the IC_{50} value - the drug concentration that inhibits parasite growth by 50%- for parasite lines in the laboratory. To date, there have been no consistent correlations between half lives of ***P. falciparum*** treated with artemisinin ***in-vivo*** and ***in-vitro*** IC_{50} estimates from standard 48-hour artemisinin susceptibility assays. This study investigates alternative methods of assaying artemisinin resistance by ***in vitro*** exposure to dihydroartemisin (DHA) - the major metabolite of all ACT. Artemisinins have short half lives (1-2h) ***in-vivo*** and so short drug pulses were applied to parasites in an effort to better mimic ***in-vivo*** conditions. A 6hr drug pulse assay and a standard 48hr assay were used to observe any differences that may exist in IC_{50} values between field isolates from Kenya (HL1204), Ghana (HL1210) and Nigeria (HL1212). In all three isolates tested, the mean DHA IC_{50} values for the 6hr pulse assays were higher than that of the standard 48hr assays. This trend was seen as a shift to the right in the dose response curve. This approach revealed differences in IC_{50} values for DHA among the isolates. Field isolates from Ghana (6 fold higher than 3D7 lab strain) and Nigeria (3.4 fold higher) showed elevated mean DHA IC_{50} value compared to that from Kenya (1.7 fold higher than 3D7). Results also showed that DHA IC_{50} values varied among experimental replicates, reflecting the polyclonal nature of the isolates used in this study. There is an urgent need to develop ***in-vitro*** assays that correlate with parasite artemisinin response ***in vivo,*** as this will be useful in elucidating the molecular basis of artemisinin resistance.

1504

CONTRIBUTION OF *PLASMODIUM FALCIPARUM*, *P. VIVAX* AND *P. MALARIAE* TO CLINICAL MALARIA CASES IN NORTH SUMATERA PROVINCE, INDONESIA

Inke Nadia D. Lubis[1,2], *Chairuddin P. Lubis[1], Munar Lubis[1], Hendri Wijaya[1] and Colin J. Sutherland[2]*

[1]Medical Faculty, University of Sumatera Utara, Medan, Indonesia, [2]Department of Immunology and Infection, London School of Hygiene & Tropical Medicine, London, United Kingdom

Indonesia, a country situated at the southeastern tip of Asia, has a total population of 245 million, of which 61% live in malaria endemic areas. Most of the endemic regions are in stable transmission zones although with low transmission risk. In 2012, WHO reported 2,051,425 malaria cases from Indonesia, comprising 22% of the malaria burden in Southeast Asia. All species of ***Plasmodium*** have been reported in the country with ***Plasmodium falciparum*** and ***P. vivax*** the predominant species. In order to carry out studies of ***in vivo*** efficacy of antimalarial treatment in North Sumatera, we conducted passive and active case screening by RDT and microscopy examination in Batubara regency, Langkat regency and South Nias regency. These semi-forested areas comprise dispersed small- to medium sized communities practising a mixture of permanent and shifting agriculture, as well as foraging in the forests. Two malaria parasite species, ***P. falciparum*** and ***P. vivax***, have previously been reported in these sites. Among febrile patients, ***P. vivax*** was the most common cause of malaria, followed by ***P. falciparum***. Demographic data and the features of clinical malaria in these communities will be presented, as well as the prevalence of each parasite species in febrile adults and children. We also describe the first PCR-confirmed clinical cases of ***P. malariae*** infection from this part of Indonesia.

1505

THE PREVALENCE OF MALARIA PARASITAEMIA IN SEVERELY MALNOURISHED AND WELL NOURISHED CHILDREN PRESENTED AT MULAGO HOSPITAL UGANDA

Moses Kiggundu[1], Sarah Kiguli[1], Ann Nanteza[1], Florence Nalubowa[2], Esther Sempa[2], Samuel Lubwama Nsobya[2]

[1]Infectious Diseases Research Collaboration/Makere University, Kampala, Uganda, [2]Mulago Hospital, Kampala, Uganda

Malnutrition and malaria remain the major causes of morbidity and mortality in young children mostly in sub-Saharan Africa. We hypothesized that the prevalence of ***Plasmodium falciparum*** will be higher in malnourished children compared to well nourished children. This study was case and control study whereby 100 samples of blood from severely

malnourished (cases) and 100 from well nourished (controls) children who presented to Mulago Hospital were examined for ***P. falciparum*** using light microscopy. The prevalence of Plamodium faciparum in malnourished children was 6% with mean geometric parasite density of 88/µl of blood, while that of well nourished children was 17% with average geometric parasite density of 1755/µl of blood caused by a mono-infection of ***P. falciparum***. Stratifying both groups with malaria and associating them with age, children between 2- 36 months had high prevalence of malaria in both the cases (66.8%) and control (88.2%). The findings showed that malnourished children are less likely to suffer from malaria as compared to well nourished ones (P- value = 0.0148). The low prevalence of ***P. falciparum*** in malnourished child may be due to lack of essential nutrients needed by malaria parasites to thrive in the red blood cells. In addition, the presence of parasites in both cases and controls may due to the fact that partial immunity for malarial infection is just developing.

1506

MALARIA IN DONATED BLOOD IN CHIPATA DISTRICT HOSPITAL, EASTERN ZAMBIA

Lungowe Sitali

University of Zambia, Lusaka, Zambia

Although malaria is preventable and treatable, it still claims 584,000 lives every year globally with children aged under five years having the highest burden. ***Plasmodium falciparum*** the parasite that cause malaria is one the most commonly encountered blood parasite. This parasite is transmitted by a female Anopheline mosquito, but can also be transmitted through blood transfusion and results in transfusion transmitted malaria (TTM). TTM poses a considerable risk of illness to the major recipients of blood. Unfortunately the blood collected is not routinely tested for malaria; hence the aim of this study was to determine the prevalence of malaria parasites in donated blood. A cross-sectional study where 600 donated blood samples from Chipata District Blood bank in Eastern Zambia were tested using rapid diagnostic tests (RDTs) for ***P.falciparum***. Out the 600 sample 74 were positive; hence the study showed 12.3% prevalence of malaria in donated blood. The study revealed prevalence 12.3%, therefore, it is important that there are preventive measures for all potential routes of transmission if the goal to eliminate it is to be achieved. Although the RDTs used have a 14 day antigen lag, hence is need to conduct a large study were microscopy and molecular methods are employed to detect parasites.

1507

TRENDS IN PROVIDER BEHAVIOR CAPTURED THROUGH ROUTINE MONITORING OF CASE MANAGEMENT OF FEVER AMONG ACCREDITED PROVIDERS IN UGANDA

Robert Mugerwa, John Baptist Bwanika, Tonny Kyagulanyi, Elizabeth Streat, Grace Nakanwagi

Malaria Consortium, Kampala, Uganda

Coverage of fever case management interventions remains low across sub-Saharan Africa, including Uganda. While many caregivers seek treatment for symptoms of fever in the private sector, private sector outlets may not have adequate diagnostics, training, waste management, and first line quality assured treatments to ensure appropriate case management. Malaria Consortium together with FIND, PSI and WHO are implementing a project creating a private sector market for quality assured RDTs in malaria endemic countries from April 2013 to date targeting private sector. Accredited outlet types including drug shops, pharmacies and clinics have been established, and participating members received training in integrated case management for febrile illnesses, supportive supervision, quality assured malaria rapid diagnostic test kits, and waste management services. Malaria Consortium UNITAID Private Sector RDT project implements a program monitoring system that collects routine data on a monthly basis. Data is captured by accredited private providers in a client register on phones and or patient slips, and which includes information on symptoms (e.g. fever), assessment (e.g. RDT results), and case management (i.e. referral, treatment). The register facilitates tracking numbers of patients, number of treatments administered, outcome of treatment and the extent to which providers are providing correct case management according to the treatment algorithm. Patient register data were entered into a database for calculation of indicators across the project. Trends in provider behavior over time will be presented. Implications for improving quality of care in the private sector, and approaches to effectively monitoring private providers will be discussed.

1508

POTENTIAL IMPACT OF RAPID DIAGNOSTIC TEST DIAGNOSTIC ERROR ON INCREASED MALARIA MORTALITY

Colin Ohrt[1], Awalludin Sutamardja[1], Maciej F. Boni[2], Andrew A. Lover[1]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]Nuffield Department of Medicine, University of Oxford, Oxford University Clinical Research Unit, Wellcome Trust Major Overseas Programme, Ho Chi Minh, Vietnam

It is crucial to investigate whether increased adoption of rapid diagnostic tests (RDTs) could have adverse effects on malaria mortality due to the high absolute number of initially untreated cases. Malaria rapid diagnostic tests (RDTs) have been recommended by the World Health Organization to obtain a specific malaria diagnosis before treatment of malaria. RDTs are now being used widely in malaria-endemic regions, including use by community health workers. Published estimates of RDT sensitivity for ***Plasmodium falciparum*** malaria typically range from 85-95% ((check)). In addition, real world sensitivity is often lower and treatment decisions may not be made correctly for both positive and negative RDT results due to limited education of many users, poor training for proper use and limited quality assurance. Globally, a 5% false negative rate in an RDT represents 25 million ((confirm)) untreated malaria cases. It is currently unknown what happens to these untreated cases. The mortality for delayed treatment in travelers is estimated to be ((confirm XX)), but is unknown in the developing world setting. The rationale for the use of RDTs will be presented along with methods to reduce the risk for mortality. Such methods include serial testing for a negative result, instructing of the patient about the possibility of a false negative result and for the patient to return promptly for persistent or worsening symptoms. In fact, presumptive treatment should be reconsidered in some situations. The myth of increasing artemisinin-resistance will be addressed and well as the potential real risk for resistance-induction with long half-life antimalarials. Lastly, methods to conduct quality assurance for RDTs, as well as to detect clinical relevant problems with RDTs will be described.

1509

COMPARISON OF BLOOD SMEAR WITH SERUM MOLECULAR TESTING FOR THE DIAGNOSIS OF MALARIA AMONG FEBRILE KENYAN CHILDREN

Jesse J. Waggoner[1], Julie Brichard[1], Francis Mutuku[2], Bryson Ndenga[3], John Vulule[3], Dunstan Mukoko[4], Benjamin A. Pinsky[1], A. Desiree LaBeaud[1]

[1]Stanford University, Palo Alto, CA, United States, [2]Technical University of Mombasa, Mombasa, Kenya, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Ministry of Health, Nairobi, Kenya

In endemic countries, accurate malaria diagnostics are needed to both correctly identify cases and exclude this as the etiology of nonspecific acute febrile illness in children. Molecular testing is the most sensitive diagnostic test for malaria, but this is typically performed using whole blood. Serum may provide a useful alternative; however, few data have been published on the performance of malaria molecular diagnostics using this specimen type. To compare the performance of blood smear with malaria molecular testing on serum, we randomly selected samples from 194 children who were enrolled in an ongoing, acute febrile illness surveillance study in coastal and western Kenya. Patients presented

within the first 3 days of fever. Blood smear was performed at the time of presentation. Serum samples were tested using a multiplex molecular test (referred to as the UFI assay), which detects all five ***Plasmodium*** species with the specific detection of ***Plasmodium falciparum***. Malaria was detected in 37 (19.1%) patients by blood smear and 59 (30.4%) patients using the UFI assay (p=0.01). Five patients with positive blood smears were negative for malaria in the UFI assay, whereas 27 patients only had malaria detected by molecular testing. Compared to the UFI assay, the sensitivity of blood smear was 54.2% and specificity was 96.3%. Among the 59 samples positive for malaria in the UFI assay, 48 were confirmed as ***P. falciparum*** (81.4%), 6 (10.2%) demonstrated evidence of a mixed infection with ***P. falciparum*** and another species, and 5 (8.5%) were positive only for non-falciparum malaria. Patients who tested positive for malaria by either method were significantly older than patients who tested negative (mean 5.7 yo (range 1-15.75) versus 4.4 yo (range 1-17.5), respectively; p<0.01). Using archived serum, the UFI assay detected malaria in significantly more febrile Kenyan children than peripheral blood smear performed at presentation. This study demonstrates the utility of serum for malaria molecular testing and suggests that malaria may be underdiagnosed if blood smear is relied upon.

1510

DEVELOPMENT OF A POINT OF CARE MOLECULAR TEST FOR *PLASMODIUM VIVAX*

Omar A. Saldarriaga[1], Alejandro Castellanos[1], Hayley Sparks[1], Gerald C. Baldeviano[2], Salomon Durand[2], Andres G. Lescano[2], Peter C. Melby[1], Bruno L. Travi[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]U.S. Naval Medical Research Unit - 6, Lima, Peru

Malaria is a major public health problem in tropical and subtropical countries with almost 200 million cases reported annually. In the American continent ***Plasmodium vivax*** extends from Mexico to northern Argentina and is responsible for the majority (>70%) of the ≈670,000 reported annual cases. In addition to its known high rate of post-treatment recurrence, recent reports indicated that ***P. vivax*** could be responsible for severe malaria cases. The elimination/eradication efforts include the development and implementation of specific and sensitive diagnostic tests. Several antigen-based Rapid Diagnostic Tests are currently being used in endemic areas with good results when parasite loads are high (≥2,000 parasites/μL), yet the sensitivity is poor when parasitemia is <200 parasites/μL. This is particularly evident with ***P. vivax***. Consequently, our objective was to develop a sensitive field-applicable molecular test for ***P. vivax*** capable of detecting low parasite burdens. We designed primers and probes targeting 18S rRNA of ***P. vivax*** for isothermal DNA amplification using Recombinase Polymerase Amplification coupled with a lateral flow immunochromatographic strip (RPA-LF). Blood DNA from infected patients from an endemic are in the Peruvian Amazon was extracted using the Qiagen® kit. Preliminary results in a small number of clinical samples (n=10) (30 min, 40 °C) showed that these primers specifically amplified ***P. vivax***. There was no cross reactivity with ***P. falciparum*** (n=6). We are currently evaluating the sensitivity of RPA-LF with the goal of detecting samples with low parasite burden. The utilization of lateral flow (LF) strips allowed detecting ***P. vivax*** infections with the naked eye, which makes this diagnostic test potentially applicable at the point of care.

1511

HIDDEN PREVALENCE OF SUB-MICROSCOPIC INFECTIONS: THE ROLE FOR MOLECULAR DIAGNOSTICS IN MADAGASCAR

Rosalind E. Howes[1], Thierry Franchard[2], Tovonahary A. Rakotomanga[2], Julie Rosenjack[3], Melinda Zikursh[3], Tiana Ramanatiaray[2], Brune Ramiranirina[2], Arsène Ratsimbasoa[2], Peter A. Zimmerman[3]

[1]Department of Zoology, University of Oxford, Oxford, United Kingdom, [2]National Malaria Control Programme of Madagascar, Antananarivo, Madagascar, [3]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States

Community prevalence of infection is a widely used, standardized metric for evaluating malaria endemicity status at the population level. Conventional methods for measuring prevalence include light microscopy (LM) and rapid diagnostic tests (RDT), but their detection thresholds leave them inadequate for assessing low density parasitaemias. The significance of sub-microscopic malaria infections is poorly understood in Madagascar, a country targeting pre-elimination status by 2017. The country's distinct epidemiological zones experience different patterns of endemic/epidemic transmission, and their underlying parasite reservoirs remain poorly quantified. A population prevalence survey of 2141 individuals was conducted across 25 villages in the western highland fringe region of Ampasimpotsy, Tsiroanomandidy district, in March 2014. LM and the SD Bioline Combo ***Pf/Pan*** RDT were used to screen for infection. PCR-based molecular evaluation by a ligase detection reaction-fluorescent microsphere assay (LDR-FMA) was subsequently conducted from filter-paper blood spots. Prevalence of ***Plasmodium*** infection diagnosed by LM, RDT, and PCR was 2%, 5% and 20%, respectively. This diagnostic discordance was greatest for ***Plasmodium vivax*** infection, which ranged from 0.2% prevalence by LM, to 11% by PCR. Diagnostic sensitivities and prevalence of sub-microscopic infections are examined in relation to patient age, fever, and history of fever. These observations of high prevalence of sub-microscopic infections in western Madagascar strongly call for wider assessment of the parasite reservoir in other regions of the country. The deadly epidemic during early 2015 highlights the threat that these reservoirs can present, particularly in apparently low endemic settings such as southern Madagascar. Pre-elimination will require a shift in focus towards attacking the parasite reservoir, including these sub-microscopic infections. The diagnostic disparities observed from this study corroborate calls globally for a transition towards higher-sensitivity diagnostics for epidemiological monitoring and assessing intervention impact.

1512

CLINICAL IMPACT OF MALARIA RAPID DIAGNOSTIC TESTING IN A NON-ENDEMIC SETTING

Leslie A. Enane, Kaede Ota-Sullivan, Kristen A. Feemster

The Children's Hospital of Philadelphia, Philadelphia, PA, United States

Children who develop malaria after returning to non-endemic settings are at high risk for critical delays in diagnosis and initiation of appropriate antimalarial therapy. Laboratory diagnosis traditionally depends on thick and thin Giemsa smears, requiring highly trained lab personnel. Rapid diagnostic testing (RDT) shows excellent sensitivity and negative predictive value, superior to blood smears, and does not require specific expertise. Yet RDT has not been adopted by most US clinical laboratories. An FDA-approved immunochromatographic assay for the rapid detection of ***Plasmodium*** antigens was introduced at the Children's Hospital of Philadelphia on August 1, 2007. RDT is performed on all samples tested for blood parasites, followed by routine blood smears. Use of RDT dramatically decreased time to report a positive result with any ***Plasmodium*** species (from 9.8 to 1.7 hours) and with ***P. falciparum*** (from 10.2 to 1.6 hours). The objective of this retrospective cohort study is to measure the impact of RDT on the management of children with malaria at an urban tertiary care children's hospital serving a large immigrant

population. Among 71 children admitted with laboratory-confirmed malaria from 2000 to 2014, we will compare clinical management and outcomes of malaria cases before and after RDT introduction while adjusting for disease severity and patient age. Primary outcome variables derived from electronic medical record abstraction include time to positive malaria result report, time to initiation of antimalarial therapy, time to clearance of parasitemia, need for exchange transfusion, ICU admission, and length of hospital stay. We hypothesize that implementation of RDT is associated with a significant reduction in time to initiation of antimalarial therapy, time to resolution of parasitemia, and length of hospital stay. The clinical impact of RDT has not previously been reported in a non-endemic setting. This research will emphasize the utility of RDT as a critical tool for the optimal management of patients with malaria in non-endemic settings. We anticipate completion of this ongoing study by August 2015.

1513

ASSESSING THE MARKET LANDSCAPE FOR AN INFECTION DETECTION TEST AIMED AT MALARIA ELIMINATION

Bhavya Gowda[1], Katherine Imus Misiuda[2], Paul LaBarre[2]

[1]PATH, Washington, DC, United States, [2]PATH, Seattle, WA, United States

PATH's Diagnostics for Malaria Elimination toward Eradication (DIAMETER) team is focused on bridging the gap between the rapidly evolving set of infection detection requirements that support elimination and the limitations of existing diagnostic tests. As the managing partner for Infection Detection Test (IDT) Development Initiative, the DIAMETER team is working to create a high quality, low cost, easy to use, and highly sensitive ***Plasmodium falciparum*** (Pf)-specific HRP2 IDT capable of identifying low density Pf infections that current rapid diagnostic tests (RDTs) cannot detect. In Phase 1, we worked with experts to draft a preliminary target product profile, landscaped potential pipeline technologies, and conducted field work to understand use scenarios for improved diagnostics. In Phase 2, we managed technical feasibility activities for next generation tests aimed at identifying individuals with low-density malaria infections. As a subset of this work, we sought to understand how the market will respond when such a test is available for use. Ultimately, the goal of our market research activities was to support the definition, commercialization, and implementation of the most promising, cost-effective, and impactful diagnostic technologies for malaria elimination while promoting investment and development of a healthy IDT market. First, we had to define the factors that could influence supply and demand of the proposed IDT. We assessed early market demand for the IDT by developing various demand scenarios. For instance, the IDT's intended use and whether the IDT would replace existing RDTs would impact product uptake by countries, donors, and implementing agencies as well as manufacturers' volumes. We modeled key factors, capturing project assumptions and develop these scenarios by engaging with subject matter experts and Ministry of Health malaria staff. Additionally, we conducted a comprehensive review in several focal countries to understand elimination strategy impact on the supply and demand issues associated with RDTs. We will present our methodology, findings, and implications related to IDT development decision.

1514

INCREASING USE OF AND ADHERENCE TO MALARIA DIAGNOSTIC TESTS THROUGH ENHANCED NATIONAL CASE MANAGEMENT TRAINING IN CAMEROON

Katelyn Woolheater, Kathleen Maloney, Justin Graves, Divine Nzuobontane, Andrew Atabe, Annold Vishi, Lyudmila Gorokhovich, Leslie Emebuonye, Lindsay Bryson, Justin M. Cohen, Arnaud Le Menach

Clinton Health Access Initiative, Boston, MA, United States

The national malaria strategy of Cameroon calls for at least 80% of suspected malaria patients (fever or history of fever) to receive a malaria test, and less than 20% of negative tests to receive anti-malarials. To improve testing and adherence rates towards these targets, the malaria program organized a two-day malaria case management training for providers and laboratory technicians in public health facilities between February and June 2014. As confirmatory diagnosis and adherence to negative tests were not routinely collected we placed consultation registers between October 2013 and September 2014 in 157 public health facilities across five of the ten regions in Cameroon. Patients of any age seeking care for any cause were recorded in the registers. Information was collected on demographics (age, gender), symptoms, malaria testing (microscopy or rapid diagnosis test), and any treatment received. A multivariable analysis was performed to assess whether patient symptoms and healthcare worker participation in the training were associated with test uptake and adherence to test results, adjusting for patient demographics, month of consultation, and health facility. During the study period, 126,462 patients were recorded across the 72 facilities that filled the register, of which 28% had suspected malaria. Overall, 69% of suspected malaria patients consulting before the training received a malaria test versus 76% after (p<0.001). However after adjusting for potential confounders, patient consulting after the training had reduced odds of being tested (OR=0.88, 95% CI=0.82-0.95) compared to those consulting before. Among patients who tested negative and reporting receiving a treatment, 22% received an anti-malarial before training compared to 17% after (p<0.01), consistent with increased adjusted odds of adhering to test results after training (OR=1.44, 95% CI=1.12-1.84). Over the course of the study, test uptake and adherence increased, however uptake remained below the national target. Further studies should explore whether additional efforts, such as mentorship, would be sufficient to improve test uptake to national targets.

1515

EVALUATION OF MALARIA RAPID DIAGNOSTIC TESTS AND GIEMSA LIGHT MICROSCOPY IN HIGHLY MALARIOUS DISTRICTS, AMHARA REGION, ETHIOPIA, 2014

Belay Bezabih Beyene[1], Woyneshet Gelaye[1], Ermias Demilew[2], Getnet Abie[1], Tsehay Tewabe[1], Peter Wassawa[3], Rick Steketee[4]

[1]Amhara Regional Health Bureau, Bahir Dar, Ethiopia, [2]World Vision, Addis Ababa, Ethiopia, [3]African Field Epidemiology Network, Kampala, Uganda, [4]PATH, Seattle, WA, United States

Malaria remains a leading health challenge in Ethiopia. A confirmatory diagnosis with a rapid diagnostic test (RDT) or microscopy is recommended for all suspected malaria cases, and understanding factors affecting the comparability of these diagnostics is important for good case management. We assessed factors related to RDT (SD BIOLINE) and microscopic diagnosis of malaria. A cross-sectional study was conducted in eight high malaria districts of Amhara Region from May 15 to June 15, 2014. All suspected cases presenting to health facilities were eligible for inclusion. With an estimated 9% malaria prevalence, sample size was calculated at 892 using Buderer's formula and 1,000 suspected cases were sought from ten health centers; 987 and 990 were tested for malaria by RDT and microscopy, respectively. The median age was 21 years old (range 1-88 years); 53% were male; 669 (67%) were over 15 years old, 172 (17%) were under 5 years old. The malaria positivity rate by RDT and microscopy was 17.1 % (169) and 16.5% (163), respectively. Compared to the microscopy standard, RDTs showed a sensitivity of 83.9%, specificity of 96.0%, positive predictive value (PV) of 80.4%, and negative PV of 96.8%. The level of agreement (Kappa value) between first and second microscopy reader was 0.74 (p-value < 0.001). In a multivariate logistic regression model, factors associated with higher infection included: male sex (OR=1.49, 95% CI=1.06-2.12), recent reported fever (OR=1.57, 95% CI=1.06-2.33), and having received malaria health education (OR=1.61, 95% CI=1.12-2.32). Children under 5 years old had a lower risk of malaria infection (OR=0.32, 95% CI=0.17-0.60). In this malarious area of Amhara Region, the specificity and negative-PV of the RDTs were excellent; however, the sensitivity and positive-PV were lower (83.9% and 80.4%, respectively). As malaria control improves and prevalence declines, the PV of a negative-RDT will be excellent, but the PV of a positive

test will become very low. Continued quality assurance and training of laboratory technicians on RDTs and microscopy will be critical to maintain comparability of these two important diagnostic methods.

1516

USE OF MALARIA RAPID DIAGNOSTIC TESTING AND ACCEPTABILITY OF RESULTS: AN ASSESSMENT AMONG MEDICAL LABORATORY SCIENTISTS IN NIGERIA

Adolor Aisiri[1], Abiodun Ojo[1], Bolatito Aiyenigba[2], Oluwole Adeusi[2], Halima Mwenesi[3]

[1]Malaria Consortium/Malaria Action Program for States, Abuja, Nigeria, [2]FHI360/MAPS, Abuja, Nigeria, [3]FHI 360, Washington, WA, United States

Confirming suspected cases of malaria through Rapid Diagnostic Tests (mRDT) is expected in secondary and tertiary health facilities when malaria microscopy is not feasible. Unavailability of trained microscopists, non-availability of functional microscope and quality reagents, and in some cases, high client load are challenges to quality malaria microscopy. Medical laboratory personnel sometimes question the validity of mRDT results leading to their low use and acceptance. This study assessed the perception of medical laboratory scientists on the validity and acceptance of mRDT results in secondary and tertiary health facilities in Nigeria. This cross sectional study purposively sampled 66 medical laboratory scientists attending a professional meeting. A pre-validated self-administered questionnaire was used to assess attitude towards validity and acceptability of results obtained through the use of mRDTs. The mean age of respondents was 43±8 years. The majority (98%) had heard of mRDT but only 67% use mRDT in their health facility. Sixty four percent (64%) agreed that mRDT results are valid and should be accepted by all health care providers, however only 49% agreed that mRDT has specificity and sensitivity levels comparable to microscopy. Although 83% of respondents agreed that mRDT results are useful for clinical decisions, 60% disagreed that mRDTs should be used in secondary and tertiary health facilities where microscopy is not feasible. Fifty percent claimed to have had challenges using mRDTs and 26% were related to the discordance with microscopy results. A large majority, 94% agreed that mRDT use skills should be incorporated in the school curriculum for medical laboratory scientists. Distrust of mRDT results persist among medical laboratory scientist and may exist among other health care professionals. Integration of mRDT training into medical professional curriculum should be advocated for, to increase use and acceptance of mRDT results. The current in-service training on mRDT for primary health care workers should be strengthened in secondary and tertiary health facilities in Nigeria.

1517

ASSESSMENT OF A STANDARD MALARIA MICROSCOPY TRAINING PROGRAM ON THE PERFORMANCE OF MEDICAL LABORATORY SCIENTIST IN NIGERIA

Abiodun Ojo[1], Bolatito Aiyenigba[2], Adolor A. Aisiri[1], Oluwole Adeusi[2], Halima Mwenesi[3]

[1]Malaria Consortium/Malaria Action Program for States, Abuja, Nigeria, [2]FHI360/MAPS, Abuja, Nigeria, [3]FHI 360, Washington, WA, United States

Rapid and precise diagnosis of malaria is an essential element in the effective case management and control of malaria. Malaria microscopy is used as the gold standard for malaria diagnosis, however results remain poor as positivity rate is consistently over 90%. The President's Malaria Initiative (PMI) through the Malaria Action Program for States in Nigeria supports 9 states to build capacity for malaria microscopy. This study demonstrates the effectiveness of in-service training on malaria microscopy amongst medical laboratory scientists. The training was based on WHO basic microscopy training manual. The training utilized a series of didactic lectures and examination of quality teaching slides using a CX 21 Olympus binocular microscope. Purposive sampling was used to enroll 109 medical laboratory scientists across 5 states in Nigeria. Evaluation of the training using a pre and post-test method was based on: written test questions; reading photographic slide images of malaria parasites; and prepared slides. There was a significant improvement in the mean post-test scores for the written test from 38±9% to 71±12%. Mean post-test score for computer based picture speciation test (63±16%) and picture detection test (89.2±10.0) were significantly higher than the mean post-test score for slide reading speciation test (38±20%) and slide reading detection test (70.7±15.3). The mean counting post-test score improved significantly from 4.2±8.0% to 27.9±14.0%. Parasite detection and speciation using enhanced visual imaging was significantly improved compared with using direct microscopy. Regular in-service training and provision of functional and high resolution microscopes are needed to ensure quality malaria microscopy.

1518

REAL-TIME QUANTITATIVE PCR AS THE GOLD STANDARD FOR MALARIA DIAGNOSIS: EVIDENCE FROM THE PERUVIAN AMAZON, A MALARIA HYPOENDEMIC REGION

Roberson Ramirez[1], Lindsay Prado[1], Mitchel Guzman[1], Freddy Gutierrez[1], Jorge Sangama[1], Dionicia Gamboa[2], Joseph Vinetz[3], Alejandro Llanos-Cuentas[2]

[1]Laboratorio Satelite Iquitos, Universidad Peruana Cayetano Heredia and University of California San Diego, Iquitos, Peru, [2]Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]University of California San Diego, San Diego, CA, United States

The diagnosis of malaria requires the identification of malaria parasites or ***Plasmodium*** antigens/products in patient samples. While conventional microscopy remains the gold standard, quantitative real time PCR (qPCR) despite technological and cost challenges remains an important tool for quantification and confirmation of low density parasitemia and mixed infections. With the goal of finding potential human reservoirs of malaria transmission asymptomatic, clinically immune, ***Plasmodium***-parasitemic individuals_we compared qPCR (***Plasmodium*** 18S rDNA target) to light microscopy on blood samples obtained from a longitudinal cohort of six communities in the Peruvian Amazon. Of 7,494 samples 868 (11.6%) were positive by qPCR; of these, 73% were ***P. vivax***, 27% ***P. falciparum***. By microscopy, only 320 (4.3%) were positive; 95% were ***P. vivax***, 5%. ***P. falciparum***. Sensitivity and specificity of microscopy were 24% and 17%, respectively, compared to qPCR. No mixed infections were detected by either method. The 526 asymptomatic infections had very low parasite density (16/µl; SD ± 18.47) detected only by qPCR. Most asymptomatic subjects (40%) were 30-50 years old. Compared to the light microscopy, qPCR or any other molecular tool, with appropriate quality controls, should be implemented at the public health level for monitoring programs and control of malaria. Further work to determine if treatment of qPCR-positive/light microscopy-negative individuals has an impact on malaria is important to carry out.

1519

DIAGNOSTIC TESTING AND ADHERENCE TO ANTIMALARIAL MEDICATION: EVIDENCE FROM A RANDOMIZED CONTROLLED TRIAL IN UGANDA

Jessica L. Cohen, **Indrani Saran**

Harvard T.H. Chan School of Public Health, Boston, MA, United States

Artemisinin-combination therapies (ACTs), currently the only effective treatment for malaria, have contributed to large declines in the morbidity and mortality burden of the disease over the past decade. Though it is a short 3-day treatment for malaria, 34 percent of patients do not complete the full course of ACTs. This is not only harmful for the individual, but also increases the risk of widespread pathogen resistance to the drugs. Adherence to ACTs is complicated by the fact that, historically, both health workers and patients have relied primarily on the patients' symptoms to diagnose malaria. Since the symptoms of malaria overlap with several other common diseases, patients are likely to be uncertain about whether

they are actually suffering from malaria, which reduces the expected benefit of completing the treatment. We conducted a randomized controlled trial in Central Uganda to examine whether patients who received a confirmed diagnosis of malaria, using a rapid diagnostic test (RDT), are more likely to finish their medications. Among a sample of 1,525 patients purchasing ACTs at private drug shops, we randomly offered 573 (37%) a free malaria rapid diagnostic test and then visited all patients at their households three days later to assess whether they had completed the treatment. Of those who were offered and consented to testing, 68% tested positive for malaria while, overall, 66% of patients finished the full course of drugs. Compared to those who were not offered the test, a positive malaria test did not increase the odds of completing the treatment, not even among young children for whom the risk of malaria mortality is highest. However, patients who received a positive malaria test had 25% fewer tablets remaining at the follow-up survey than those not offered the test, indicating that a confirmed diagnosis encouraged some patients to complete a few additional doses of the drug. We also show that patients who still felt unwell on the second day of treatment had approximately twice the odds of completing the treatment which suggests that many people may stop taking the medicines because they feel better and believe that they are cured of malaria.

1520

STRUCTURAL CHARACTERIZATION OF *PLASMODIUM FALCIPARUM* HRP2: ANALYTICAL CHALLENGES IN *PLASMODIUM FALCIPARUM* HRP2-BASED IDT DEVELOPMENT

Ihn Kyung Jang[1], David Sullivan[2], Maria Kahn[1], Robert Burton[1], Paul LaBarre[1]

[1]PATH, Seattle, WA, United States, [2]Johns Hopkins Malaria Research Institute, Baltimore, MD, United States

With improved performance over rapid diagnostic tests (RDTs), infection detection tests (IDTs) currently under development will provide improved diagnostic support for global ***Plasmodium falciparum*** (Pf) elimination campaigns. By targeting Pf-specific histidine rich protein 2 (PfHRP2), which persists several weeks in peripheral blood, prototype IDTs are designed to detect low-level and episodic Pf infections. Commercially available PfHRP2-based RDTs have a high degree of variability in their clinical and analytical sensitivity. The naturally-occurring sequence variations of PfHRP2, especially the frequency and types of tandem amino acid repeats found in various isolates, may affect the performance of these tests, especially at low levels of parasitemia. As we begin to characterize the performance of IDT prototypes in the product development pipeline, we recognize that evaluation of these tests using available PfHRP2 reference standards that are not equivalent to endogenous PfHRP2 may provide a relative, but not truly definitive, quantitative measure of PfHRP2 test performance. The aim of the present study is to investigate the effects of the sequence and repeat number variation of PfHRP2 proteins on the binding of PfHRP2-specific antibodies, and to examine potential shortcomings of current reference standards used for IDT test development. Recombinant PfHRP2 proteins that possess or lack an affinity purification tag were evaluated for binding to PfHRP2-specific antibodies in an in-house developed sandwich enzyme linked immunosorbent assay. Our preliminary data show that the detection limit of PfHRP2 proteins lacking an affinity purification tag is much lower than for those carrying an affinity purification tag, indicating that the extra unnatural amino sequence might hinder the access of antibodies to their epitopes. Evaluating the effect of PfHRP2 sequence variations on the binding of PfHRP2-specific antibodies used for IDTs is currently ongoing. The present study will provide new evidence to enable rationale selection of reference standards in support of IDT development for detecting low level Pf infections.

1521

A SEMI-QUANTITATIVE PAPER-BASED TEST FOR PREDICTING PROGRESSION TO SEVERE MALARIA

Chelsey Smith[1], Karl Seydel[2], Terrie Taylor[2], Rebecca Richards-Kortum[1]

[1]Rice University, Houston, TX, United States, [2]Michigan State University, East Lansing, MI, United States

Severe malaria affects thousands of children in sub-Saharan Africa annually, with the majority of these children under the age of five. Parasites sequester in microcapillaries and cause hypoxia that may lead to dysfunction of vital organs. Unless treatment is given quickly, severe malaria can lead to mortality or permanent complications for the child. Retinopathy and other suitable methods to predict progression to severe malaria are not feasible for low-resource settings due to cost and infrastructure requirements. Additionally, the gold standard for malaria diagnosis, blood smear microscopy, is not indicative of disease progression. Recent studies have shown that plasma concentration of ***Plasmodium falciparum*** histidine-rich protein 2 (pHPR2), a protein secreted by parasite-infected erythrocytes, can identify children with uncomplicated malaria that might progress to severe malaria. We have developed a low-cost 2D paper network which semi-quantitatively reports the concentration of pHRP2. The device works with one drop of whole blood, costs about 1 USD, and has a limit of detection of 10 ng/mL, which is lower than current RDTs on the market. It involves minimal user input and runs within 30 minutes. Pilot tests have assessed the ability of the device to semi-quantitatively differentiate levels of pHRP2 using spiked human blood from various donors. Once validated, our device could potentially allow for simultaneous diagnosis of malaria and prediction of progression to severe malaria. Therefore, we believe the test could provide clinicians with a low-cost tool to make informed decisions for parasitemic children.

IMPACT OF MALARIA RAPID DIAGNOSTIC TESTS ON PATIENT CARE: RESULTS FROM THE ACT CONSORTIUM

Katia Bruxvoort, Baptiste Leurent, Heidi Hopkins, ACT Consortium RDTs in Context Working Group

London School of Hygiene & Tropical Medicine, London, United Kingdom

Malaria rapid diagnostic tests (RDTs) are intended to have a beneficial impact on management of suspected malaria, including that patients with confirmed malaria receive artemisinin-based combination therapy (ACT) and patients without malaria receive non-antimalarial treatment. The ACT Consortium includes several studies designed to test operational strategies for ACT and RDT implementation in various settings, providing an opportunity to draw on data from multiple projects that have introduced RDTs across a range of clinical, social, and epidemiological contexts, and in public, private retail, and community health service sectors. To assess the impact of RDTs on patient treatment and satisfaction at the consultation, data were examined from nine studies comparing scenarios where RDTs were made available to control scenarios where RDTs were not made available. Where RDTs were introduced, the proportion of patients tested ranged from 39% to 99%; figures were similar for children under 5 years and for older patients. Prescription of ACT was lower in nearly all RDT scenarios (range 8-64% versus 15-99% in scenarios without RDTs), driven mostly by reduced prescription for RDT-negative patients (range 3-45% versus 18-98% for RDT-positive patients). An exception to this pattern was seen in public facilities in a high-transmission setting where RDTs were irregularly available in the control arm. The impact of RDTs on prescription of systemic antibiotics varied, ranging from 15-73% in scenarios without RDTs and 21-75% in scenarios with RDTs available, and was slightly higher for RDT-negative patients (range 29-78% versus 13-65% for RDT-positive patients). There was no clear pattern observed for prescription of other treatments, polypharmacy, or patient satisfaction. This ongoing analysis

aims to understand factors associated with variation in case management outcomes in order to offer more tailored guidance for RDT introduction in other areas.

1523

MODELLING THE COST-EFFECTIVENESS OF INTRODUCING MALARIA RAPID DIAGNOSTIC TESTS IN THE PRIVATE FOR-PROFIT SECTOR

David Bath, Catherine Goodman, Clare Chandler, Shunmay Yeung

London School of Hygiene & Tropical Medicine, London, United Kingdom

During the last five to ten years, major changes have occurred in the diagnosis of malaria in primary level public health facilities in endemic countries, as malaria rapid diagnostic tests (mRDTs) have been widely deployed. There are now increasing calls for mRDTs to be made available outside formal public health facilities - and in particular through the private for-profit sector, where a high proportion of people with suspected malaria seek care. Private sector antimalarial providers include private hospitals and clinics, though in most settings the majority of antimalarials are distributed through drug retailers, primarily drug stores and small pharmacies, which very rarely provide blood tests. It is common to find that a high proportion of patients sold antimalarials at such outlets are not parasite positive, while many other clients who are parasite positive do not receive appropriate antimalarial treatment. Private sector mRDT introduction on a large scale has already begun in several African countries, though robust evidence on the impact and value for money of these strategies is not yet available. Fundamental questions remain as to where and how mRDTs should be introduced, and what the impact will be on costs, individual health outcomes and public health. We have developed a cost-effectiveness decision tree model of management of non-severe febrile illness, adapting and expanding previous models to cover the private sector, and updating them by drawing on parameters from recent published and unpublished data. The model documents care-seeking pathways, test accuracy, and the effect of test results on treatment choice and adherence to treatment. Results will be presented on the impact on treatment outcomes, costs, and cost effectiveness of different mRDT roll-out packages, for those with malaria and those with other febrile illnesses. Cost-effectiveness will be reported in terms of cost per disability adjusted life year (DALY) averted and cost per death averted. The overall cost implications for implementing agencies, across a range of malaria transmission and health system settings, will also be discussed.

1524

MALARIA RAPID DIAGNOSTIC TEST MARKET TRENDS IN SUB-SAHARAN AFRICA, 2009-2014

Megan Littrell, The ACTwatch Group

Population Services International, Washington, DC, United States

In 2012, the WHO launched the Test, Treat, Track initiative recommending confirmatory testing prior to antimalarial treatment. National malaria control programs (NMCP) across sub-Saharan Africa (SSA) subsequently aligned national guidelines with this recommendation. Strategies to scale up testing using malaria rapid diagnostic tests (mRDT) were introduced by NMCPs. We use multi-country outlet survey data collected between 2009-2014 by ACTwatch to describe mRDT markets in Benin, the DRC, Kenya, Madagascar, Nigeria, Tanzania, Uganda and Zambia. A census of outlets with potential to distribute antimalarials was conducted among a representative sample of administrative units. In addition to an antimalarial audit, information was captured for malaria microscopy and all mRDTs in stock including retail price and amount distributed in the past week. The private sector distributes the majority of antimalarials in all project countries except Zambia. Although modest improvements in mRDT availability have occurred, testing availability among antimalarial-stocking private sector outlets remains low, ranging from 4% in Madagascar to 25% in Uganda. Subsequently, while majority of antimalarials are distributed by the private sector, the public sector provides the majority of testing. The price of an mRDT among private sector outlets is generally higher than the price of a pediatric pre-packaged quality-assured artemisinin combination therapy (QAACT). However, the private sector price of an mRDT is generally lower than the price for one QAACT adult equivalent treatment dose. Confirmatory testing prior to antimalarial treatment is currently limited across high burden countries in SSA due to limited availability at the private sector outlets where most antimalarials are distributed. Where mRDTs are available, financial incentive to test before treating with QAACT is apparent with respect to adult testing and treatment. There is generally no such incentive to test young children before QAACT treatment. Implications for policies and strategies to implement WHO and national guidelines on confirmatory malaria testing will be discussed.

1525

SUSCEPTIBILITY OF DIFFERENT STRAINS OF MICE TO LIVER-STAGE INFECTION WITH *PLASMODIUM BERGHEI* SPOROZOITES BY USING *IN VIVO* IMAGING SYSTEM

Qigui Li, Lisa Xie, Diana Caridha, Qiang Zeng, Norma Roncal, Jing Zhang, Ping Zhang, Lisa T. Read

Walter Reed Army Institute of Research, Silver Spring, MD, United States

The liver stages of ***Plasmodium*** parasites are important targets for the discovery and development of prophylactic drugs. A sensitive and useful mouse model with an ***in vivo*** imaging system (IVIS) to monitor the liver stage was established. The transgenic ***P. berghei*** parasite expressing the bioluminescent reporter protein luciferase was utilized to visualize and quantify parasite development in BALB/c, C57BL/6, C57BL/6 albino, C3H, and ICR mice. These inbred strains of mice were tested to study the differences in susceptibility to ***P. berghei*** hepatic infections previously monitored with the liver resection methods. As an additional endpoint, blood stage parasitemia was monitored by flow cytometry. A real-time IVIS instrument determined the exposure level of luminescence measured from luciferase expressing of sporozoites through development in the hepatocyte and assessed through liver, peritoneum, skin, and hair coat. The luminescence values (photon counts/min) measured from the anatomical liver location in untreated mice infected with 10,000 ***P. berghei*** sporozoites at 24 hours post inoculation were 8.15×10^5 for C57BL/6 albino, 2.12×10^5 for C3H, 0.91×10^5 for C57BL/6 WT, 0.58×10^5 for BALB/c, and 0.08×10^5 for ICR. The high grow-up rate of sporozoites in hepatocytes was also found in C57BL/6 albino, C57BL/6 WT, and C3H mice, and low rate was shown in BALB/c and ICR mice. In addition, similar to previous studies, the susceptibility of female mice to liver-stage infection is higher than that of male mice. In summary, this data supported the use of highly susceptible mouse strains (C57BL/6 albino, C57BL/6 WT, and C3H) at the WRAIR to study ***Plasmodium*** hepatic infection by IVIS monitoring. The study indicates that by using IVIS, the C57BL/6 albino, C57BL/6 WT, and C3H mice infected with ***P. berghei*** sporozoites are preferable for investigating the discovery and development of prophylactic antimalarial drugs.

1526

NICOTINAMIDE ENHANCES ANTIMALARIAL EFFECTS OF CHLOROQUINE, PYRIMETHAMINE AND ARTEMISININ *IN VITRO*

Sergey O. Tcherniuk*, Olga Chesnokov*, Irina V. Oleinikov, **Andrew V. Oleinikov**

Charles E. Schmidt College of Medicine, Department of Biomedical Science, Florida Atlantic University, Boca Raton, FL, United States

Malaria is a dangerous infectious disease of humans and other animals caused by protozoan microorganisms belonging to the genus ***Plasmodium***. The malarial parasite causes different symptoms including fever, fatigue, vomiting, headaches, yellow skin, seizures and even death. ***Plasmodium falciparum*** represents the most virulent form of human

malaria, causing about a half million deaths per year. Despite the attempts to develop various antimalarial vaccines, chemotherapy is still a major approach of malaria prevention and treatment. Systematic use of common antimalarial drugs together with the high genetic variability of the malaria parasite leads to the appearance of resistant ***Plasmodium*** strains. Therefore, identification and development of new antimalarial compounds and treatments remains an important problem of malarial parasitology. Nicotinamide (vitamin B3) is a water soluble amide derivative of nicotinic acid, which has been used at high doses for a variety of therapeutic applications. It has been demonstrated earlier that nicotinamide inhibits ***P. falciparum*** growth. However, its antimalarial effect, in combination with other antimarial drugs, has not been described to our knowledge. In this work, we analysed the antimalarial effects of nicotinamide in combinations with chloroquine, pyrimethamine and artemisinin on the blood stages of ***P. falciparum***. Our results demonstrate that combinations of nicotinamide with chloroquine, pyrimethamine or artemisinin lead to synergetic antimalarial effects ***in vitro*** and significantly enhance the anti-parasite potential of these drugs. Moreover, treatment of uninfected red blood cells with high dose of nicotinamide (20 mM) does not provoke LDH release, demonstrating its non-toxicity for erythrocytes. These results suggest that nicotinamide might be useful not only as a vitamin supplement but also as a strong enhancer of the anti-parasitic effect of common antimalarial drugs, including chloroquine, pyrimethamine and artemisinin. *Equal contributions

1527

DEVELOPMENT OF ANTIMALARIALS WITH SERCAP PROFILE FROM DOS DERIVED COMPOUNDS

Eamon Comer[1], Nobutaka Kato[1], Jessica Bastien[1], Timothy Lewis[1], Morgane Sayes[1], Tomoyo Sakata-Kato[2], Amanda Lukens[2], Sean Eckley[3], Fabian Gusovsky[3], Jeremy Duvall[1], Marshall Morningstar[1], Dyann Wirth[2], Christina Scherer[1], Stuart Schreiber[1]

[1]The Broad Institute, Cambridge, MA, United States, [2]Harvard School of Public Health, Boston, MA, United States, [3]Eisai Inc., Andover, MA, United States

Despite increased efforts in the last decade, the antimalarial drug discovery and development pipeline still lacks compounds with non-erythrocyte stage activity and target diversity. We previously performed a high throughput screen (HTS) on approximately 100,000 diverse small molecules from the Broad Institute's Diversity Oriented Synthesis compound collection which contains unique core structures more likely to have novel antimalarial mechanisms of action. The present study describes the discovery and optimization of a novel series from our HTS study displaying potent activity against a panel of clinical strains harboring resistance to known antimalarial drugs as well as agents in clinical development. The compound series inhibits phenylalanine t-RNA synthetase activity, a novel molecular target, and shows robust ***in vivo*** efficacy in erythrocytic, hepatic and sexual stages with a single dose. We also present extensive pharmacokinetic and preclinical safety data that supports the progression of this novel antimalarial agent towards clinical development to treat malaria.

1528

DIFFERENTIAL KINETIC PROFILES AND METABOLISM OF PRIMAQUINE ENANTIOMERS BY HUMAN HEPATOCYTES

Pius S. Fasinu[1], Bharathi Avula[1], Babu L. Tekwani[2], Dhammika Nanayakkara[1], Yan-Hong Wang[1], Bandera Herath[1], Narayan Chaurasiya[1], Ikhlas Khan[2], Mahmoud ElSohly[3], Shabana Khan[2], Larry Walker[2]

[1]National Center for Natural Products Research, School of Pharmacy, University of Mississippi, University, MS, United States, [2]National Center for Natural Products Research; and Department of Biomolecular Sciences, School of Pharmacy, University of Mississippi, University, MS, United States, [3]National Center for Natural Products Research; and Department of Pharmaceutical Sciences and Drug Delivery, School of Pharmacy, University of Mississippi, University MS; and ElSohly Laboratories, Oxford, MS, United States

The clinical utility of primaquine (PQ), which is used as a racemic mixture of two enantiomers, is limited due to metabolism-linked hemolytic toxicity in G6PD deficient individuals. The current study aimed to investigate differential metabolism of the enantiomers in light of the suggestions that toxicity and efficacy might be largely enantioselective. Using cryopreserved human hepatocytes, ^{13}C-labeled (+)-, (-)- and (±)-PQ were separately incubated. Substrate depletion and metabolite production were monitored via UHPLC-MS/MS. The initial half-life was 217 and 65 min for (+)- and (-)-PQ; with an elimination rate constants (λ) of 0.19 and 0.64 h^{-1} respectively. The ***in vitro*** intrinsic clearance was 2.55 and 8.49 (µL/min)/million cells which when upscaled ***in vivo*** yielded 6.49 and 21.6 (mL/min)/kg body mass respectively for (+)- and (-)-PQ. Extrapolation to ***in vivo*** human hepatic clearance was performed using the well-stirred liver model. The rate of hepatic clearance of (+)-PQ was only 45% that of (-)-PQ. Two major primary routes of metabolism were observed as earlier reported: oxidative deamination of the side chain terminal amine; and hydroxylations on the quinoline moiety. The major deaminated metabolite, carboxyprimaquine (cPQ), a putative PQ terminal alcohol (***m/z*** 261), a cyclized side chain derivative from the aldehyde (***m/z*** 241), cyclized carboxylic acid derivative (***m/z*** 257), a quinone-imine product of hydroxylated cPQ (***m/z*** 289), cPQ glucuronide (***m/z*** 451), and the glucuronide of PQ alcohol (***m/z*** 437) were preferentially generated from the (-)-PQ. The major quinoline oxidation product (***m/z*** 274) was preferentially generated from (+)-PQ. A prominent conjugate (***m/z*** 422) (seemingly a glycosylated PQ, but still under investigation) was preferentially generated by (+)-PQ. An accumulating metabolite (***m/z*** 480) thought to be a carbamoyl glucuronide of PQ was exclusively generated from (+)-PQ. In the light of the desire to establish clinical differences in PQ enantiomers, these current findings may provide important information that may lead to clearer understanding of PQ-induced hemolysis and possible enantioselective safety.

1529

NITRIC OXIDE DONOR DIHYDROARTEMISININ DERIVATIVES AS MULTITARGET AGENTS FOR THE TREATMENT OF CEREBRAL MALARIA

Massimo Bertinaria[1], Pamela Orjuela-Sanchez[2], Elisabetta Marini[1], Anthony Hofer[2], Stefano Guglielmo[1], Graziela M. Zanini[3], John Frangos[2], Roberta Fruttero[1], Alberto Gasco[1], **Leonardo J. Carvalho**[3]

[1]Universita di Torino, Torino, Italy, [2]La Jolla Bioengineering Institute, La Jolla, CA, United States, [3]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil

A series of hybrid products in which the dihydroartemisinin scaffold is combined with NO-donor furoxan and NONOate moieties were designed, synthesized and studied as potential tools for the treatment of experimental cerebral malaria (ECM) in C57BL/6 mice infected with ***Plasmodium berghei*** ANKA. Five synthesized products were able to dilate rat aorta strips precontracted with phenylephrine with a NO-dependent mechanism. All hybrid compounds showed preserved antiplasmodial activity ***in vitro*** and ***in vivo*** against ***Plasmodium berghei*** ANKA,

comparable to artesunate. Compound 8, selected for additional studies, was capable of increasing survival of mice with late-stage ECM from 33.3% to 63.6% compared with artemether. Artemisinin-NO-donor hybrid compounds show promise as potential new drugs for treating cerebral malaria.

1530

DIFFERENTIAL DECAY OF ANTIMALARIAL ACTIVITY OF ARTEMISININ AND ITS DERIVATIVES WHEN INCUBATED IN PHYSIOLOGICALLY RELEVANT CONDITIONS

Silvia Parapini[1], Donatella Taramelli[1], **Piero Olliaro**[2], Nicoletta Basilico[1]

[1]University of Milan, Milan, Italy, [2]UNICEF/UNDP/World Bank/World Health Organization Special Programme on Research and Training in Tropical Diseases, World Health Organization, Geneva, Switzerland

Artemisinins are peroxidic antimalarial drugs which are known to be very potent, yet chemically highly unstable: they degrade quickly in the presence of ferrous iron, Fe(II)-heme or biological reductans. Less known is how their chemical decay relates to antimalarial activity. We incubated dihydroartemisinin (DHA) and artemisinin (ART) in a range of conditions relevant to both treated patients and in-vitro assays (PBS, plasma or erythrocytes lysate for different durations and pHs) and measured their residual activity on ***P. falciparum in vitro*** using the pLDH method. Chloroquine was also used to verify if drug instability was related to the presence of the endoperoxide. A significant reduction of the antimalarial activity of DHA was observed after incubation in plasma or serum, and to a lesser extent in erythrocytes lysate or PBS. ART showed a different behavior: its antimalarial activity was significantly reduced by incubation with erythrocytes lysate but was minimally affected by PBS, plasma or serum. Moreover, the serum-enriched medium (10% human serum or 10% albumax) customarily used for ***in vitro*** cultures also affected DHA, and to a lesser extent, ART efficacy. Decreasing pH from 7.6 to 7.2 led to a decrease in artemisinins degradation and this increased activity. The presence of reductans such as ascorbic acid or N-acetylcysteine in the erythrocytes lysate strongly reduced artemisinins activity and CO binding to Fe(II)-heme conferred partial protection. Adding ascorbic acid to plasma had no effect on artemisinins activity. Chloroquine was unaffected in any of the tested ***in vitro*** conditions. Biological results correlated well with chemical degradation quantified as degradation rate constant. These results suggest that instability is likely due to the endoperoxide, but C10 substitutions can further modulate the stability of the molecules. Particular care should to be taken in conducting and interpreting ***in vitro*** studies, and in storing these compounds. Moreover, conditions such as hemolysis or acidosis associated with malaria severity may contribute to artemisinins instability and reduce its effectiveness.

1531

LEAD CANDIDATE SELECTION OF BROAD-SPECTRUM ANTIMALARIAL ACRIDONES

Jane X. Kelly[1], Rosie Dodean[1], Christina Nolan[2], Yuexin Li[1], Qiqui Li[2], Sean Marcsisin[2], Paul Olmeda[2], Thulan Long[2], Heather Gaona[2], Diana Caridha[2], Lisa Xie[2], Norma Roncal[2], Brittney Potter[2], Isaac Forquer[1], Rolf Winter[1], Dave Hinrichs[1], Stephanie Huezo[3], Roland Cooper[3], Mike Riscoe[1], Lisa Read[2]

[1]Portland Veterans Affairs Medical Center, Portland, OR, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]Dominican University of California, San Rafael, CA, United States

We have previously reported the discovery of a novel antimalarial acridone chemotype that displays efficacy against sporozoite-induced ***Plasmodium*** infection in addition to efficacy against blood stage parasites. We have been successful in producing extremely potent new lead candidates with pico molar IC50 values against MDR resistant parasites, as well as full protection of liver stage infection at comparable dosage with primaquine. Details of the design, chemistry, structure-activity relationships (SAR), safety, metabolic studies, and mechanism of action will be presented.

1532

PROVEBLUE (METHYLENE BLUE): A PROMISING ANTIMALARIAL DRUG

Bruno Pradines[1], Jérôme Dormoi[1], Marylin Madamet[1], Bécaye Fall[2], Rémy Amalvict[1]

[1]Institut de Recherche Biomédicale des Armées, Brétigny sur Orge, France, [2]Hôpital Principal de Dakar, Dakar, Senegal

In 2011, the World Health Organization recommended artesunate as the first-line treatment for severe malaria. In recent years, several studies have reported clinical failures or at least extended parasite clearance times in Asia. There is an urgent need to discover partners for combination with artemisinin derivatives. Proveblue (PVB) (international patent no. PCT/FR/2007/001193), which is a methylene blue preparation that complies with the European Pharmacopoeia and contains limited organic impurities and heavy metals of recognized toxicity, was demonstrated to possess ***in vitro*** antimalarial activity (at a geometric mean 50% inhibitory concentration [IC50] of 3.62 nM) against 23 ***Plasmodium falciparum*** strains that were resistant to various other antimalarials. The IC50 for PVB ranged from 0.88 nM to 40.2 nM with a mean of 5.3 nM in Senegalese isolates collected from November 2013 to January 2014 at the Hôpital Principal de Dakar. PVB exhibited noticeable ***in vitro*** synergistic effects in combination with mefloquine and quinine and high synergistic effects associated with dihydroartemisinin, the active metabolite of artemisinin derivatives. Treatment with 1 to 10 mg/kg of weight of PVB for five days significantly reduced or prevented cerebral malaria in mice. PVB demonstrated high efficacy in cerebral malaria in comparison with dihydroartemisinin or quinine. These results confirm the therapeutic potential of Proveblue, which could be integrated into the pipeline of new antimalarial combination therapies.

1533

RESISTANCE SELECTION APPROACH TO IDENTIFY AND VALIDATE TARGETS FOR ANTIMALARIAL DRUG DISCOVERY

Pamela Magistrado[1], Tomoyo Sakata-Kato[1], **Amanda K. Lukens**[2], Victoria C. Corey[3], Maria Linares Gomez[4], Francisco-Javier Gamo[4], Elizabeth A. Winzeler[3], Dyann F. Wirth[1]

[1]Harvard T. H. Chan School of Public Health, Boston, MA, United States, [2]The Broad Institute, Cambridge, MA, United States, [3]University of California San Diego School of Medicine, La Jolla, CA, United States, [4]GlaxoSmithKline, Tres Cantos, Spain

The emergence and spread of drug resistance to current antimalarial therapies remains a pressing concern, escalating the need for compounds that demonstrate novel modes of action and prevent the development of drug-resistance. As part of the Malaria Drug Target Identification Project efforts, we have adopted a chemogenomic approach to identify the targets of the most prominent compounds from chemically diverse libraries. Study compounds were selected based on availability, purity, potency in a multi-drug resistant isolate, and lack of known mechanism of action towards the mitochondrion or folate biosynthesis. To further eliminate overlap with known targets, we performed cross-resistance testing against a panel of drug resistant parasite lines with well-characterized mutations in diverse targets. Here we present studies of two molecules: a drug-like compound from the Malaria Box, MMV007564, and a probe-like molecule from a Diversity Oriented Synthesis library, BRD3842. ***In vitro*** resistant lines were generated by single-step selection and whole genome sequencing employed to identify genetic variants contributing to the resistance phenotype. Novel variants were identified in the Pf cyclic-amine resistance locus (PfCARL) (MMV007564), and the phosphatidylinositol-4-OH kinase (PI(4)K) (BRD3842), both of which have been previously implicated in the mechanism of action for compounds

chemically distinct from those in this study. These results demonstrate that multiple chemical classes are able to inhibit common parasite targets and suggest that there are a limited number of pathways in the parasite susceptible to inhibition and/or that contribute to drug-resistance. Drug-development strategies that counteract these common escape mechanisms may therefore become invaluable in extending the usable lifetime of future therapies.

1534

TARGETING FREP1 TO BLOCK MALARIA TRANSMISSION THROUGH SMALL MOLECULES

Guodong Niu, Genwei Zhang, Jarrod B. King, Robert H. Cichewicz, Jun Li

The University of Oklahoma, Norman, OK, United States

Inhibiting ***Plasmodium*** development in mosquitoes will block malaria transmission. Fibrinogen-related protein 1 (FREP1) has been demonstrated to be critical for parasite infection in mosquitoes. Here, we further determined that FREP1 protein binds ***P. falciparum***-infected red blood cells (iRBCs) and ookinetes. We propose that small molecules disrupting the interaction between FREP1 and ***Plasmodium*** will prevent parasites from infecting mosquitoes. To test this hypothesis, we developed an ELISA-based method to screen a fungal extract library, and obtained one candidate fungal extract (Chapel SA-3) that inhibited about 98% of the FREP1-***Plasmodium*** interaction. The inhibition was further confirmed by indirect immunofluorescence assays (IFA). We also verified the inhibition specificity between FREP1 and ***Plasmodium***. Notably, feeding Chapel SA-3 to mosquitoes significantly inhibits ***P. falciparum*** infection in midgut. The candidate fungal extract does not affect the development of ***P. falciparum*** gametocytes or ookinetes. Therefore, we conclude that disruption of the interaction between FRPE1 and ***Plasmodium*** effectively reduces malaria infection in mosquitoes. Targeting FREP1 with fungal small molecules is thus an effective novel approach to block malaria transmission.

1535

HUMAN PATHWAYS FOR METABOLISM OF PRIMAQUINE: IMPLICATIONS IN TOXICITY AND EFFICACY OF 8-AMINOQUINOLINE ANTIMALARIALS

Babu L. Tekwani[1], Bharathi Avula[1], NP. Dhammika Nanayakkara[1], Narayan D. Chaurasiya[1], Pius Fasinu[1], HMT Bandara Herath[1], Shabana I. Khan[1], Ikhlas A. Khan[1], Mahmoud A. ElSohly[1], Brandon S. Pybus[2], Jason C. Sousa[2], Sean R. Marcsisin[2], Gregory A. Reichard[2], James D. McChesney[3], Larry A. Walker[1]

[1]University of Mississippi, University, MS, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]Ironstone Separations, Inc, Eta, MS, United States

Primaquine (PQ), an 8-aminoquinoline, is the drug of choice for the radical cure of ***Plasmodium vivax*** malaria and utility for prevention of malaria transmission. Efficacy and hemolytic toxicity of PQ have been attributed to the metabolites. Reactive nature and low quantities pose major challenge for identification and quantification of these metabolites in clinical and experimental studies. We have recently addressed this challenge with application of PQ labeled with ^{13}C-stable isotope and analysis of the metabolites with UPLC integrated with QTOF-MS. Chemical synthesis of key metabolites have provided necessary standards for confirmation of structures and quantification. Comprehensive experimental and clinical studies with primary human hepatocytes, the recombinant human enzymes (CYPs and amine oxidases) and healthy human volunteers along with use of specific enzyme inhibitors have been useful in phenotyping of key PQ metabolites and their relative quantification. The results have been utilized for prediction of pathways for metabolism of PQ. Human metabolism of PQ follows two distinct pathways. The major pathway is initiated by oxidative deamination of PQ by monoamine oxidase B to carboxy PQ. Carboxy PQ is further metabolized through CYP mediated pathways and phase II metabolism generating reactive quinoneimine metabolites and glucuronide conjugates. This pathway determines characteristic pharmacokinetic and pharmacodynamic properties of PQ. Another pathway mediated through CYPs (predominantly CYP2D6) generates multiple mono hydroxylated metabolites. CYP2D6 mediated oxidation of PQ occurs at different positions on the quinoline ring. An orthoquinone product of a hydroxyl product 5-OH-PQ was identified as the major CYP2D6 metabolite, a likely marker for the 5-hydroxylation pathway. Pharmacological studies suggest 5-OHPQ as highly reactive and may be responsible for the efficacy/toxicity of PQ. Direct metabolism of PQ through phase II glucuronide conjugation and excretion in urine was also observed. Critical analyses of these pathways have helped in understanding the mechanism of efficacy and toxicity of PQ

1536

A PROTOCOL TO EVALUATE THE EFFECTIVENESS AND FEASIBILITY OF REACTIVE TARGETED PARASITE ELIMINATION (TPE) TO REACTIVE CASE DETECTION (RACD) AS A COMMUNITY LEVEL INTERVENTION IN SWAZILAND

Bongani A. Dlamini[1], Mi-suk Dufour[2], Nomcebo Mkhonta[3], Calisile Malambe[3], Gugu Mphalala[4], Nyasatu Ntshalintshali[1], Danica Helb[5], Bryan Greenhouse[6], Kimberly Batzell[7], Hugh Starrock[5], Grant Dorsey[7], Deepika Kandula[8], Justine M. Cohen[8], Arnaud LeMenach[8], Roly Gosling[5], Simon Kunene[3], Michelle Hsiang[5]

[1]Clinton Health Access Initiative, Mbabane, Swaziland, [2]University of California San Francisco, San Francisco, CA, United States, [3]National Malaria Control Programme, Manzini, Swaziland, [4]Swaziland National Clinical Laboratory Services, Mbabane, Swaziland, [5]Malaria Elimination Initiative, Global Health Group, University of California San Francisco, San Francisco, CA, United States, [6]Department of Medicine, University of California San Francisco, San Francisco, CA, United States, [7]Department of Family Health Care Nursing, University of California San Francisco, San Francisco, CA, United States, [8]Clinton Health Access Initiative, Boston, MA, United States

Reactive case detection (RACD), which is testing and treatment of individuals residing near passively detected index cases, is recommended for malaria elimination yet some available diagnostics have limited sensitivity and there are logistical challenges including cost. Treatment without testing or targeted parasite elimination (TPE) may be a more effective and feasible approach for reducing and interrupting transmission. As an operational research study embedded into malaria program activities, we plan a cluster-randomised control study design trial to evaluate reactive-TPE in the low transmission setting of Swaziland. The primary aim is to compare the impact of reactive TPE versus RACD on malaria incidence, with a hypothesis that TPE will result in lower cumulative malaria incidence. A total of 58 high risk localities or clusters will be included in the trial (population 124,737) and randomized to either TPE or RACD. Over 2 years, individuals residing within a radius of 200 m from an index case will be targeted for either RACD or TPE within 1 week of index case presentation. Incidence will be measured using passive surveillance with subsequent household follow up to identify which cluster the index case resides in. The study is powered to detect a difference in cumulative incidence of 1.1/1000 in the TPE arm versus 2.2/1000 in the RACD arm observed in 3 previous malaria seasons in RACD study area. Secondary outcome measures of effectiveness will include: seroprevalence and prevalence (in a cross sectional survey at the end of the study), proportion of imported incident cases, and transmission potential (utilizing genotypes). Secondary outcome measures of feasibility will include: coverage, adherence, serious adverse events, acceptability, and cost-effectiveness. Findings will inform malaria elimination strategies for Swaziland and other countries pursuing malaria elimination.

1537

SEASONAL VARIATION IN ACCESSING BIOMEDICAL HEALTHCARE FACILITIES IN AN AREA OF LOW MALARIA TRANSMISSION IN RURAL ZAMBIA: POTENTIAL IMPACT ON MALARIA ELIMINATION PROGRAMS THAT USE REACTIVE CASE FINDING

Lynne Lohfeld[1], Jailos Lubinda[2], Timothy Shields[3], Southern Africa ICEMR Group

[1]McMaster University, Hamilton, ON, Canada, [2]Macha Research Trust, Macha, Zambia, [3]Johns Hopkins University, Baltimore, MD, United States

Many malaria elimination programs use reactive case finding or diagnose and treat malaria in symptomatic patients presenting at a biomedical healthcare facility and then track asymptomatic cases living in the vicinity of an index case. The premise behind these programs is they are less expensive than communitywide mass diagnosis and treatment campaigns. However, if symptomatic patients are unwilling or unable to travel to a biomedical facility for the initial diagnosis, the program cannot effectively cut transmission due to missed pockets of asymptomatic carriers. Anecdotal evidence indicates that in the low-transmission area of Macha, Choma District, Southern Province, Zambia, people are less able to reach a government health center or regional hospital during the heavy rainy season, which coincides with the period of highest malaria transmission. We tested this hypothesis through transforming interview data on all pathways and routes used in the dry and rainy seasons to reach local healthcare providers (biomedical and traditional) in four villages into GPS coordinates and maps. Additional information on the highest level of use (footpath, bicycle, motorcycle, oxcart or car/truck), and average time needed to reach providers was used to calculate signficant differences in access to biomedical resources providing malaria diagnosis and treatment. Results can help identify communities where environmental factors serve as barriers to accessing a government-run malaria elimination program in an area of very low transmission.

1538

NEW INFECTION DETECTION TESTS TO ENABLE IDENTIFICATION OF LOW DENSITY INFECTIONS: THE ACCESS FRAMEWORK

Jenny Richards[1], Robert Burton[1], Katherine Imus Misiuda[1], Kendall Magnuson[1], Smita Das[1], Ihn Kyung Jang[1], Bhavya Gowda[2], Rebecca Barney[1], Paul LaBarre[1]

[1]PATH, Seattle, WA, United States, [2]PATH, Washington, DC, United States

As malaria prevalence declines due to successful malaria control programs, more sensitive diagnostic tests are need to identify an increasing number of low-density infections that contribute to the infectious reservoir. PATH's Diagnostics for Malaria Elimination towards Eradication (DIAMETER) team is committed to enabling access to the most appropriate diagnostic tools to support malaria elimination, bridging the gap between rapidly evolving elimination tactics and diagnostic capabilities. As the managing partner for the Bill & Melinda Gates Foundation-funded Infection Detection Test (IDT) Development Initiative, the DIAMETER team is working to create a high quality, low cost, easy to use, and highly sensitive ***Plasmodium falciparum*** (Pf)-specific HRP2 IDT capable of identifying low density Pf infections that current rapid diagnostic test cannot detect. In this poster, we will review progress on the IDT's development and outline next stages in the product development value chain, focusing on the transition from technical feasibility phase to operational feasibility and product development. We will identify remaining questions and propose a plan to resolve these while advancing the IDT toward commercialization and impact. Finally, we will review remaining challenges and outline key elements of the access framework including manufacturing, forecasting, procurement, distribution, delivery, and governance. Included in this review are: results from prototype IDT evaluation; an update on regulatory pathways; an assessment of HRP2 issues that impact standard selection; a revised market assessment; and an updated target product profile.

1539

PRIVATE SECTOR SURVEILLANCE AND RESPONSE: LESSONS FROM WESTERN CAMBODIA

Soy Ty Kheang

University Research Co., LLC, Bethesda, MD, United States

Tracking data on malaria cases treated by Cambodian public health facilities (HFs) and village malaria workers (VMWs) is part of routine surveillance. However, patients who first present to private providers remain largely untracked and unreported, limiting effective planning and monitoring of national malaria control efforts. Data from a national health survey suggests 75% of recipients prefer seeking treatment from the private sector due to perceptions of prompter service and constant availability. The National Strategy for Public and Private Mix (PPM) directs private providers in endemic areas where no drug resistance has been documented (zone 2) to provide early diagnosis and treatment. However, private providers in areas where drug resistance has been documented (zone 1) can test, but must refer cases to a public HF or VMW. Private providers must report all suspected malaria cases (diagnosed, treated or referred) to the national malaria information system. Private providers taking part in PPM gain access to supplies available at local HFs. The Control and Prevention of Malaria (CAP-Malaria) Project strengthens linkages between public and private providers and improves the quality of care provided by the private sector. The project works with 167 registered private providers in 3 operational districts (ODs) in Western Cambodia, engaging them in public sector response. In 2014, 114 suspected malaria patients in zone 1 were referred from 56 private providers to HFs and VMWs. 102, (89%) reached the designated service points; of those, 93 patients (91%) were diagnosed with malaria. In Sampov Meas (zone 2), 2,733 suspected patients were tested and 1,574 were found malaria positive and treated by private providers while 2,852 were tested and 1,112 found positive at public HFs. In comparison, 39%, 27% and 34% of malaria cases in Sampov Meas were managed by private providers, public HFs and VMWs, respectively. Recognizing the strong role of the private sector, CAP-Malaria, with the provincial health department and ODs, engaged private sector partners in a campaign for intensive health education, net distribution, and active case detection.

1540

INCREASING ACCESSIBILITY OF MALARIA SERVICES AMONG CROSS-BORDER POPULATIONS IN THE GREATER MEKONG SUB-REGION

Soy Ty Kheang

University Research Co., LLC, Bethesda, MD, United States

While malaria morbidity and mortality have declined significantly in the Greater Mekong Sub-region countries, the emergence and spread of artemisinin-resistant malaria (ARM) in border areas has raised alarm. A potential source of transmission and a cause of the spread of resistant parasites in the region is population mobility. Cross-border workers often have limited knowledge of malaria risk, making them highly vulnerable to malaria. Because many are unfamiliar with the local health services, they may not seek services and thus remain untreated and unknown by health authorities, inadvertently carrying the parasite from one country to another. To improve accessibility of malaria services by cross-border populations in the GMS countries, the Control and Prevention of Malaria Project (CAP-Malaria) is engaging local authorities along the borders between Cambodia, Thailand, and Myanmar through a Twin-Cities approach that aims to increase coordination of activities and contain the spread of ARM. With the project's support, Twin-Cities working groups were established in four pairs of cities located across a border, engaging representatives from the district level, from health facilities, and from

among community-based malaria workers. The working groups meet on a quarterly basis to share data on malaria, discuss and develop joint work plans, and monitor implementation of activities. The groups also conduct exchange visits and maintain a map of health service delivery points along the border areas to facilitate access to services. Health providers in the area take advantage of bilingual malaria control materials developed by the CAP-Malaria Project. Preliminary observations suggest that the Twin-cities approach improves awareness of malaria among mobile and migrant populations, facilitates their access to malaria services, and promotes a supportive environment for quality services. It also holds the potential for improved coordination at the local level, coordination that is critical should the spread of ARM be contained.

1541

ENGAGING THE PRIVATE SECTOR IN MALARIA SURVEILLANCE: A REVIEW OF STRATEGIES AND RECOMMENDATIONS FOR ELIMINATION SETTINGS

Anton Lorenzo Villacorte Avancena

University of California San Francisco, San Francisco, CA, United States

In malaria elimination settings, all malaria cases must be identified, documented, and investigated. To facilitate complete and timely reporting of all malaria cases and effective case management, engagement with private providers is essential, particularly in settings where the private sector is a major source of healthcare. Research on the role and performance of the private sector in malaria case management and reporting is limited. Moreover, effective strategies for private sector engagement in malaria diagnosis, treatment, and reporting in elimination settings remain unclear. A purposive sample of 21 key informant experts in malaria elimination, surveillance, and private sector engagement were interviewed. An extensive review of grey and published literature on malaria surveillance and private sector engagement in malaria testing, treatment, and reporting was also conducted. Additional literature research was conducted for six country case studies on eliminating (Swaziland and Vietnam) and neighboring, non-eliminating settings (Cambodia, Mozambique, Myanmar, and Zambia). The private sector is a diverse and often unaffiliated group of providers that can be categorized based on their profit or business model (for-profit vs. nonprofit) and their regulation status within a country (formal vs. informal). Because the private sector varies from country to country, conducting a baseline assessment of the private sector is critical to understanding its composition, size, geographical distribution and quality of services provided. Facilitating reporting, referral, and training linkages between the public and private sectors and making malaria a notifiable disease are effective strategies to improve private sector involvement in malaria surveillance. The private sector can also be organized and better engaged through social franchising, effective regulation, professional organizations, and government outreach. This review highlights the importance of engaging private sector stakeholders early and often in the development of malaria elimination strategies.

1542

PREDICTIVE MALARIA RISK MODELING USING AGGREGATE CASE DATA FOR IMPROVED INTERVENTION TARGETING IN HONDURAS

Darlene Bhavnani[1], Bricia Trejo[1], Luis M. Perez[1], Justin M. Cohen[1], Arnaud Le Menach[1], Engels Banegas[2]

[1]Clinton Health Access Initiative, Boston, MA, United States, [2]National Malaria Control Program Ministry of Health, Tegucigalpa, Honduras

Countries in Central America recently committed to eliminate malaria by 2020. Honduras, a low endemic country in the region, plans to reach elimination by strengthening surveillance, improving case management, and targeting interventions. To help target elimination efforts in Honduras, we used national surveillance data reported in aggregate to predict spatial patterns of malaria transmission. The numbers of confirmed malaria cases, reported by 294 of 298 municipalities between 2003 and 2013, were combined with social, demographic, and ecological variables in a Bayesian hierarchical model to predict incidence by municipality and year. Incidence was predicted because of the potential for underreporting. Predicted incidence in 2013 was compared with reported incidence, used to estimate the population at risk, and used to evaluate the spatial distribution of malaria interventions. Highest risk of malaria was concentrated in the Northeast along the border with Nicaragua. In 2013, predicted incidence was highest in two of the 294 municipalities, Wampusirpi (32 cases/1000 persons) and Puerto Lempira (18 cases/1000 persons), in which predicted incidence was higher and lower than reported incidence, respectively. These two municipalities were expected to account for a third of all malaria cases and 0.5% of the total population in Honduras. Higher incidence was associated with lower elevation, greater distance to roads and rivers, and distribution of long-lasting insecticide treated nets (LLINs). In 2013, LLINs were targeted to high-risk municipalities in the Northeast, while indoor residual spraying was targeted to low and medium risk municipalities in other regions of the country. Focusing interventions, improving case management, and implementing active surveillance in municipalities at highest risk, may help reduce the burden of malaria in Honduras. Predictions based on aggregate case data can be used to direct malaria resources. However, these predictions are still coarse in resolution. Georeferenced case reports from a strong passive surveillance system could be used to target malaria elimination activities even further.

1543

PRELIMINARY RESULTS FROM THE BIOMARKERS FOR MALARIA ELIMINATION (BIOME) STUDY

Paul LaBarre, Smita Das, Robert Burton, Ihn Kyung Jang, Katherine Imus Misiuda

PATH, Seattle, WA, United States

The Bill & Melinda Gates Foundation Accelerate to Zero strategy aims to eradicate malaria swiftly to minimize the negative effects and setbacks caused by malaria resurgence and the spread of drug resistance. Acceleration will require identifying individuals who harbor and transmit low density infections. The proportion of low density infections varies inversely with transmission intensity; when a high transmission region has a rapid decrease in prevalence, it can become more difficult to detect and treat infected individuals. Active infection detection (ID) tactics such as mass test and treat, focal test and treat, and reactive ID following an index case aim to find and treat low density infections. However, existing tools used for detecting clinical malaria lack the sensitivity to detect low density infections. Other tools lack the ease of use, affordability, rapid time to results, and portability required for large scale field use. To improve the efficiency of active ID tactics, new, low cost, portable tools with improved limits of detection (LOD) are being developed and are called malaria infection detection tests (IDTs). Very limited data exist regarding the concentration of target biomarkers and their kinetics over the course of a ***Plasmodium falciparum*** (Pf) infection. Thus, informed IDT product development requires a greater understanding of the fraction of PCR positives we can detect with a new IDT at 10x improved LOD, and of the relevance of the undetected population to transmission at this LOD. The BIOME study is generating clinical data to better characterize the extent and relevance of the human Pf reservoir stratified by individual biomarker concentrations. This study builds evidence for validation of key target product profile performance criteria for an HRP2-based IDT. The focus of the study is to generate data to select a LOD for the IDT sufficient to interrupt transmission. The study is a comparative evaluation of the concentration of DNA, HRP2, total NA, and asexual stage parasites in the peripheral blood of individuals with low density infections. Here, we present the preliminary results from our Thailand and Uganda cohorts.

1544

ASSESSING READINESS TO ACCELERATE TOWARDS MALARIA ELIMINATION: A COMPARATIVE ANALYSIS OF THE DECISION-MAKING ENVIRONMENT IN KENYA, ETHIOPIA, SENEGAL AND ZAMBIA

Geoffrey Kirkwood[1], Adem Agmas[2], Ashley Bennett[3], Jeff Bernson[1], Yakou Dieye[4], Duncan Earle[5], Asefaw Getachew[2], Philippe Guinot[4], Angela Hartley[1], Michael Hainsworth[1], Todd Jennings[5], John Miller[5], Abdi Mohamed[2], Kammerle Schneider[1], Kammerle Schneider[1], Hailemariam Reda[2], Sarah Hamm Rush[6], Melkamu Tiruneh[2]

[1]PATH, Seattle, WA, United States, [2]PATH, Addis Ababa, Ethiopia, [3]PATH, Washington, DC, United States, [4]PATH, Dakar, Senegal, [5]PATH, Lusaka, Zambia, [6]Independent Consultant, Seattle, WA, United States

Optimizing national malaria control activities and accelerating towards malaria elimination will require a unified critical pathway in which robust evidence generation and national policy guidance are complemented by appropriate financing, planning and operations, and governance. The opinions of national decision makers and implementers in four sub-Saharan African countries with varying malaria epidemiology, health and regulatory systems, and national malaria targets were collected and analyzed in order to assess opportunities and barriers to accelerating progress along this critical pathway. Attitudes towards the feasibility and desirability of national malaria elimination targets were also assessed. In each country, Ethiopia, Kenya, Senegal and Zambia, interviewers conducted on average 35 semi-structured interviews with stakeholders including policymakers, regulators, donors, procurement officials, academic researchers, NGO representatives, health care workers, and community advocates. Stakeholder responses were qualitatively coded and ranked using quantitative indicators including formal power, informal influence, knowledge of national malaria targets and support for malaria elimination as a national target. Thematic content analysis revealed new information about what stakeholders in each country perceive to be the strengths and challenges of their national malaria control programs and what adjustments are needed along the critical pathway to accelerate towards malaria elimination. The need to address population mobility, increase private sector engagement and strengthen and expand human resources for case management emerged as major themes. Attitudes towards the feasibility and desirability of national malaria elimination targets, and levels of knowledge and approval of new tools and approaches for elimination, varied by country and by organizational and individual perspective. In addition, interview responses yielded numerous proposals for improving malaria implementation efforts that may merit additional consideration by policymakers.

1545

SO YOU SAY YOU WANT ELIMINATION? USING COMMUNICATION AND ADVOCACY TO ADVANCE MALARIA ELIMINATION IN THE AMERICAS

Marisabel Sanchez, Julie de Carvalho, Ricardo Echalar

Links Media, Rockville, MD, United States

A qualitative assessment of the communication component of National Malaria Control Programs (NMCPs) in 11 countries in Latin America and the Caribbean was conducted from 2013-2014. The assessment surveyed the overall programmatic objectives, existing resources for communication, malaria stakeholders, target audiences, ongoing communication activities, and gaps. Among the main findings of the assessment showed challenges in providing information to decision-makers to support and sustain efforts, expanding and strengthening partnerships beyond the health sector, and reaching special populations that have a higher burden of disease including indigenous communities and migrant workers. Overall, communication activities were found to be focused at the community level with less attention paid to decentralized health system professionals, and very few if any activities directed at the policy-level. Two examples of the role of effective communication at the policy-level include Suriname, which made significant strides against malaria from 1995-2015 and is now on the path to elimination with help from a National Malaria Board that brings together technical advisors, civil society actors, and other government ministries to help guide the policy making process. In Brazil, new legislation was passed in 2014 to require companies completing infrastructure projects in the Amazon region to engage in a series of activities, including social mobilization, to assess the impact and mitigate the risk of greater malaria transmission in the surrounding area. As more countries in the Americas transition towards elimination, malaria communication will have a sizable role to create a shared understanding among key decision-makers and malaria partners of what it means for countries to be working towards elimination and beyond, in terms of funding levels, technical interventions, multi-sectoral engagement, and sustained surveillance and reporting requirements. Channels and mechanisms that have worked in some countries should be explored for use in others, especially at the policy-level to ensure long-term commitment.

1546

MASS TESTING AND TREATMENT FOR MALARIA IN MODERATE TRANSMISSION AREAS IN AMHARA REGION, ETHIOPIA

Callie Scott[1], Caterina Guinovart[1], Belendia Serda[2], Berhane Tesfay[2], Asnakew Yeshiwondim[2], Adem Agmas[2], Melkamu Zeleke[2], Girma Guesses[2], Asmamaw Ayenew[2], Worku Workie[2], Elias Zegeye[2], Michael Kalnoky[1], Ruben Conner[1], Rick Steketee[1], Belay Bezabih[3], Asefaw Getachew[2]

[1]PATH, Seattle, WA, United States, [2]PATH, Addis Ababa, Ethiopia, [3]PATH, Amhara National Regional State Health Bureau, Ethiopia

In moderate malaria transmission areas, strategies to clear parasites from populations are a means to reduce infection and transmission. A malaria mass testing and treatment (MTAT) intervention was implemented in six intervention villages in Amhara Region, Ethiopia, at the beginning of the 2014 malaria transmission season. Intervention villages were purposively selected and matched with control villages based on the incidence of passively detected ***Plasmodium falciparum*** (***Pf***) and mixed malaria during the 2013 malaria transmission season. All households in the intervention villages were targeted. Participants received a rapid diagnostic test (RDT) and RDT-positive individuals received artemether-lumefantrine (***Pf***, mixed) or chloroquine (***Plasmodium vivax*** [***Pv***]). Of 9,130 households in the intervention villages, 7,974 households (87.3%) were visited by 93 field teams over a period of three weeks. The average household had 4.4 individuals and the average number of households visited per day per team ranged from 3.7 to 8.5. Of the 35,389 individuals living in the households, 30,712 (86.8%) received an RDT. Of these, 47% were <20 years of age, 67% slept under a mosquito net last night, 52% resided in a household that received indoor residual spraying (IRS) in the last 12 months, and 1% spent ≥1 night away from home in the last month. Among tested individuals, 421 (1.4%) were RDT-positive. The prevalence of ***Pf*** or mixed RDT-positivity was 1.0% (0.7% ***Pf***, 0.3% mixed), ranging from 0.1% to 4.6% by village; 58% of ***Pf*** or mixed infections had no fever or history of fever in the preceding 24 hours. Of individuals with a ***Pf*** or mixed RDT result, 61% were <20 years of age, 64% slept under a mosquito net last night, 44% resided in a household that had received IRS in the last 12 months, and 8% spent ≥1 night away from home in the last month. Spatial clustering of RDT-positives varied by village. The incidence of passively detected, RDT-confirmed malaria cases at the health post in each village will be compared before and after the intervention and between intervention and control villages to evaluate the impact of the MTAT intervention and implementation costs will be estimated.

1547

EVALUATING THE ANNUAL COSTS OF IMPLEMENTING CASE INVESTIGATION TO SUPPORT MALARIA ELIMINATION IN SOUTHERN PROVINCE, ZAMBIA: A MICRO-COSTING ANALYSIS

Bruce Larson[1], Thandiwe Ngoma[2], Kafula Silumbe[2], Marie-Reine Rutagwera[2], Busiku Hamainza[3], Anna Winters[4], John Miller[2], Callie Scott[5]

[1]Center for Global Health and Development, Boston University School of Public Health, Boston, MA, United States, [2]PATH, Lusaka, Zambia, [3]National Malaria Control Programme, Lusaka, Zambia, [4]Akros, Lusaka, Zambia, [5]PATH, Seattle, WA, United States

The Zambian Ministry of Health and partners are implementing a package of interventions and surveillance systems in Southern Province to support the national malaria control and elimination agenda. Case investigation (CI) is part of this package. With CI, if a malaria case is detected at a health facility or in the community, a community health worker (CHW) then visits the household of the malaria case and other nearby households, tests all individuals using a rapid diagnostic test (RDT), and treats all RDT-positives with artemether-lumefantrine. We estimated the cost of implementing CI in 173 health facility catchment areas (HFCAs) in ten districts in Southern Province during the 2014 calendar year. Primary data on unit costs and quantities of various resources used during implementation (e.g. drugs, RDTs, other supplies, labor) and key programmatic outputs (number tested, number testing positive, number treated) were obtained from programmatic records and the health management information system. At the HFCA level, average annual costs were estimated at US$2,142. Main cost categories include: labor at the HFCA (33%), mobile phone talk time for CHWs (15%), equipment (15%), RDTs (13%), artemether-lumefantrine (5%), and other supplies (19%). On average, 6.7 CHWs conducted CI activities in each HFCA (average population 7,432). On average, 127 households were visited per HFCA in 2014, 560 individuals were tested, and 86 (15%) were RDT-positive and treated. The average cost per household visited was $46, per individual tested was $11, and per individual testing positive and treated was $232. The estimates reported here are preliminary and do not yet include additional costs associated with training CHWs on CI implementation and supervision. Costs of surveillance and interventions implemented to support malaria control and elimination are useful for budgeting, identifying opportunities to improve program efficiency, and informing additional analyses on the cost-effectiveness and budget impact of different approaches to malaria elimination.

1548

DESIGNING A SUFFICIENT SURVEILLANCE SYSTEM AGAINST RE-ESTABLISHMENT OF MALARIA IN A SPATIALLY CONNECTED MODEL

Philip A. Eckhoff, Caitlin A. Bever, Jaline Gerardin, Milen Nikolov, Andre Lin Ouedraogo, Edward A. Wenger

Institute for Disease Modeling, Bellevue, WA, United States

Malaria transmission is spatially heterogeneous, and movement of individuals connects locations over local, regional, and global scales. Elimination planning must therefore account for this interconnectivity and its ability to reintroduce parasites to previously-cleared areas or to stall progress at low prevalence. One important component of elimination efforts is surveillance systems in areas of low-prevalence and sub-regions which have at least temporarily achieved elimination. Robust and timely surveillance may allow sufficiently vigorous and rapid response to the reintroduction of parasites to prevent re-establishment of malaria in cleared areas. Options for this surveillance may include clinic-based surveillance, active and passive case detection, mass screening, parasite genetics, and immune serology. We implement a spatial simulation model for malaria transmission in the EMOD framework across varying spatial scales and in varied transmission settings, with interconnectivity through human movement and spatially heterogeneous baseline transmission. This spatial simulation is then used to demonstrate the operational impact of surveillance systems once a sub-region has at least temporarily achieved elimination. Areas with different baseline transmission rates, potential for transmission following re-introduction, population densities, local mosquito populations and feeding behaviors, and primary health care coverage require different levels of investment in surveillance systems to ensure robust maintenance of elimination.

1549

THE IMPACT OF CLIMATE VARIABILITY ON MALARIA INCIDENCE RATES IN LORETO, PERU

Aneela Mousam[1], Antonio M. Quispe[2], Viviana Maggioni[1]

[1]George Mason University, Fairfax, VA, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Despite a decade of reduction (2001-2010), data shows that during 2011-2014, malaria has increased about 5 folds in Loreto. Past studies indicate that climate variables can play a crucial role in malaria transmission. The purpose of this work is to understand why certain populated centers report a higher parasite incidence rate compared to other ones, and which specific climate variable is the most associated with a higher malaria incidence. Annual parasite incidence (API) and weekly NASA climate data of the 2000-2014 period from the 315 populated centers that serve as surveillance reporting units within Peru were analyzed using a generalized linear model with a Poisson distribution and a link log. The analysis focused on comparing the top 10 percentile in terms of API from the whole period as compared to the rest. During the years 2000-2014 Loreto reported 539,315 malaria cases, which were mostly due to ***Plasmodium vivax*** (81%). The average API at the district-level was 51 cases per 1,000 inhabitants (95% Confidence Interval [95% CI], 41-61). The reporting units were located on average at -4.5 degrees of latitude from the Equator (range, -8.4– -0.14). The average microclimate was significantly different across reporting units ($p<0.01$) regarding surface temperature (range, 294.9– 300.8 K), 2 meter above ground temperature (294.9- 300.8 K), specific humidity (range, 0.012– 0.019 kg vapor * kg^-1 air), and surface pressure (range, 91965-100065 Pa). The API rates are the log odds of ranking among the top 10th percentile malaria endemic populated centers in Loreto during the years 2000-2014. The API increased with latitude (OR, 1.11; 95% CI 1.10-1.12) and decreased with surface pressure (OR, 0.99; 95% CI 0.99-0.99), 2 meter above ground humidity (OR, 2.59*10^-10; 95% CI, 2.51*10^-13-2.66*10^-7), surface temperature (OR, 0.98; 95% CI, 0.97-0.99), and soil moisture (OR, 0.77; 95% interval, 0.59-0.99). The observed and regression-estimated API were poorly correlated (Pseudo R^2: 5%, $p<0.001$). Further studies will be conducted on weekly malaria incidence rates at each populated center to understand the potential impact of microclimate variability.

1550

ACTIVE SURVEILLANCE THROUGH PEER REFERRAL TO IDENTIFY POPULATIONS AT HIGHER RISK FOR MALARIA IN ZAMBEZI REGION, NAMIBIA

Carmen Cueto, Jerry Jacobson, Jenny Smith, Davis Mumbengegwi, Hugh Sturrock, Roly Gosling, **Adam Bennett**

University of California San Francisco, San Francisco, CA, United States

As malaria transmission declines, infection risk is increasingly clustered in individuals or groups of individuals with specific occupations or behaviors. Often these individuals will remain uncaptured through passive surveillance due to poor health care access or asymptomatic infections. With the goal to eliminate malaria by 2020, Namibia faces the challenge of identifying these higher risk populations in order to better target interventions. Motivated by the novel patient-initiated peer referral approach to identify undiagnosed HIV cases, we designed a strategy to screen and interview individuals connected through their social networks to malaria cases

from February to May of 2015. RDT positive index cases, which served as "seeds" to begin the peer referral recruitment chains, were identified at 6 randomly selected health facilities within Zambezi Region in northern Namibia; recruitment was embedded within a concurrent case-control study at these health facilities to identify and refine risk factors. All eligible cases (15 years and older) were randomly assigned to distribute referral coupons within either their social network or their household. Each referral in the social network group had to fit the risk criteria of regularly sleeping or working outdoors during evening and morning mosquito biting hours. Individuals receiving coupons from either group were asked to visit the health facility to participate in an interview- assisted survey and provide a blood sample for malaria testing via RDT and DBS. Participation was tracked to assess the linkage to his or her recruiter. Recruitment and return were incentivized with LLINs, travel reimbursement, or mobile phone airtime. In this presentation, we discuss the feasibility of this study design in a rural setting characterized by transportation barriers as well as the challenges of peer centered recruitment during a season with low case numbers. We also evaluate the ability of active surveillance through peer referral to identify individuals with specific high risk behaviors and current infections diagnosed by PCR, through comparison to a concurrent household survey.

1551

MODELING THE OPTIMAL INTERVENTION MIX FOR MALARIA ELIMINATION IN DIFFERENT SPATIALLY CONNECTED TOPOLOGIES

Caitlin A. Bever, Jaline Gerardin, Milen Nikolov, André Lin Ouédraogo, Philip A. Eckhoff, Edward A. Wenger

Institute for Disease Modeling, Bellevue, WA, United States

Elimination of malaria is not complicated, in principle, if we have unlimited resources at our disposal. In practice, logistical, political, and financial constraints couple with the complex etiology of the disease to cloud the path forward. While there are many means at our disposal to address the issue, it is not clear how to combine them for optimal efficacy, especially when we account for the fact that local variation in the characteristics of endemic settings may significantly impact the best choice of intervention mix. To address this question, we used the EMOD malaria model as the basis for a prioritization tool that recommends intervention mixes as a function of a region's current attributes. The results are based on simulations of the impact of combining interventions, such as vaccines, insecticide treated nets, drug campaigns, and case management, analyzed through a context of feasibility: grounded by data and experience, what are achievable levels of coverage, what does administration cost, and are there implementation synergies that could favor certain combinations? Spatial heterogeneity is another important factor in planning for elimination, particularly in environments that are susceptible to reimportation, and was accounted for by running the simulations across spatially connected regions, each of which may be distinct in terms of transmission intensity and access to care. While the primary results were calculated using simulations of existing intervention standards, e.g., RTS,S in the case of vaccines, hypothetical scenarios provide insight into what might be achievable if new products become available and suggest how elimination strategies might be adapted in response.

1552

SCALE-UP OF CASE INVESTIGATION AND REACTIVE CASE DETECTION EVALUATIONS IN THAILAND: RESULTS FROM FIVE PROVINCES

Prayuth Sudathip[1], Chris Cotter[2], Alex Luo[3], Adam Bennett[2], Roly D. Gosling[2]

[1]Bureau of Vector Borne Diseases, Ministry of Public Health, Nonthaburi, Thailand, [2]Global Health Group, University of California San Francisco, San Francisco, CA, United States, [3]Global Health Sciences, University of California San Francisco, San Francisco, CA, United States

Case investigation and reactive case detection (RACD) activities are implemented in many low transmission settings and recommended by the World Health Organization as a key strategy for malaria elimination. Determining the origin of infection, known as case investigation, and screening household members and neighbors of passively detected malaria cases for infection, known as RACD, requires substantial programmatic and human resources. By evaluating the program performance of case investigation and RACD activities, gaps in reporting completeness and timeliness can be identified to determine if improvements are required. Thailand is implementing case investigation and RACD and aims to eliminate malaria by 2024. Based on the findings from a pilot evaluation conducted, the Thailand Bureau of Vector-Borne Diseases (BVBD) scaled-up the use of a standardized monitoring and evaluation (M&E) tool to identify best practices and gaps in case investigation and RACD to inform active screening efforts in Thailand. Data will be presented on the five evaluation provinces covering a range of transmission endemicities. Routine surveillance data on case investigation and RACD reporting completeness, timeliness and coverage from 2013 and 2014 are analyzed from the national malaria information system as well as from district-level malaria clinics, malaria posts and border malaria posts. Questionnaires were administered to surveillance program personnel regarding RACD operations and procedures to understand their knowledge, practices and the challenges to conduct RACD. Costing data for personnel, commodities, and other services related to case investigation and RACD expenditures were collected and analyzed to determine the primary cost drivers and operating costs for RACD. Preliminary findings from the evaluation provinces have informed the BVBD on where program efficiencies can be achieved, including the need for additional RACD-specific trainings. M&E of case investigation and RACD will assist the BVBD in improving RACD program effectiveness and help Thailand achieve its goal of malaria elimination.

DEVELOPMENT OF A PREGNANCY-SPECIFIC SEROLOGY TEST: A PATH TOWARDS A NEW TOOL TO MEASURE MALARIA TRANSMISSION IN THE CONTEXT OF ELIMINATION

Ana Maria Fonseca[1], Eusebio Macete[2], Raquel González[1], Chenjerai Jairoce[2], Chenjerai Jairoce[2], Jennifer Hegewisch[1], María Rupérez[1], Llorenç Quintó[1], Pau Cisteró[1], Pau Cisteró[1], Anifa Vala[2], Arsenio Nhacolo[2], Chetan Chitnis[3], Esperanza Sevene[2], Clara Menéndez[1], **Alfredo Mayor**[1]

[1]ISGlobal, Barcelona Ctr. Int. Health Res. (CRESIB), Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, Barcelona, Spain, [2]Manhiça Health Research Center (CISM), Manhiça, Mozambique, [3]International Center for Genetic Engineering and Biotechnology, New Delhi, India

New metrics for malaria transmission are needed for malaria elimination. ***P. falciparum*** infection during pregnancy is associated with a strong antibody response against VAR2CSA (pregnancy-specific antigen expressed by the parasite on the erythrocyte membrane that binds to placental Chondroitin Sulphate A), suggesting that detection of these antibodies in pregnant women at antenatal clinics could be used for surveillance of malaria. To select antigens with the highest potential for a VAR2CSA-based serological test, we measured IgGs in Mozambican pregnant women, as

well as in non-exposed individuals, using a quantitative suspension array technology that included 46 peptides from both conserved and semi-conserved regions of VAR2CSA, 3 recombinant proteins (DBL3x, DBL5ε, DBL6ε) and non-pregnancy specific antigens. Dynamics of antibody responses during pregnancy were also determined to assess acquisition and longevity of antibody responses. We first excluded those antigens that were a) poorly recognized by plasmas from pregnant women with high antibody levels against a VAR2CSA-expressing parasite line (CS2) (n=106); b) recognized by Mozambican men (n=102) and Spanish individuals (n=100) and c) not associated with antibody acquisition in women infected with ***P. falciparum*** during pregnancy (n=252, longitudinal cohort with 3 time-points per women). Among the 25 antigens selected, antibodies against 17 peptides, DBL3X and DBL5ε mirrored falls and rises in malaria prevalence in Manhiça during 2003-2012 (n=654). Finally, 9 out of the 17 peptides, DBL3X and DBL5ε were selected based on high boosting of antibody by malaria infection, low time to double the levels when infection occur (rapid generation of antibodies) and short half-life (detectable during one pregnancy). We are currently exploring the value of VAR2CSA serology to detect recent changes in ***P. falciparum*** exposure associated with the use of intermittent preventive treatment with different antimalarials. This pregnancy-specific serological test could be placed into action to provide information for malaria surveillance in elimination campaigns.

1554

OVERVIEW OF MALARIA SURVEILLANCE SYSTEMS IN ELIMINATION SETTINGS: LESSONS FROM THE PAST, AND ASSESSING CRITICAL PROGRAM NEEDS

Christopher Lourenco[1], Andrew J. Tatem[2], Deepika Kandula[1], Justin M. Cohen[1], Arnaud Le Menach[1]

[1]Clinton Health Access Initiative, Boston, MA, United States, [2]University of Southampton, Southampton, United Kingdom

Achieving malaria elimination requires a well-designed surveillance system which can guide targeted efforts and selection of impactful strategies. However, challenges remain to design systems to fit countries' needs and constraints. A systematic literature review of surveillance systems from countries that have eliminated malaria or have a national elimination policy in place was conducted to build a stronger evidence-base on what technical elements are essential to efficiently support elimination. The review evaluated the system structure and surveillance activities in each country while focusing on what data were collected, what output was generated to direct programmatic response, and what technical components are required. We reviewed 10 countries worldwide that eliminated malaria between 1965 and 2014, and 9 countries that are in the process of eliminating. According to the review, every country that successfully eliminated malaria described a system that had strong passive case detection as its backbone. The passive systems included individual case reporting and detailed investigations, parasitological confirmation of cases, ***foci*** identification, staff at district or village level specifically assigned to assist in surveillance activities, and entomological data collection. 7 out of the 10 countries that have eliminated also described conducting reactive case detection with responses varying depending on country context, and 8 out of 10 had a response mechanism incorporated into their surveillance systems that triggered programs to target interventions based on current data (i.e. implementation of indoor residual spraying dependent on ***foci*** investigation). In comparison, not all of the 9 eliminating countries had individualized reporting or thorough case investigations directing their interventions. However, those countries have begun to adopt technologies such as web-based or mobile tools that might enable a quicker response. As countries work to strengthen surveillance for elimination, lessons learned from historical experience should be used to highlight and prioritize components critical for success.

1555

THE PROBABILITY OF ACUTE ILLNESS FOLLOWING *PLASMODIUM VIVAX* PRIMARY INFECTION AND RELAPSE IN A COHORT OF CHILDREN FROM PAPUA NEW GUINEA

Amanda Ross[1], Cristian Koepfli[2], Peter Siba[3], Ingrid Felger[1], Ivo Mueller[2], Marcel Tanner[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [3]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea

The probabilities of clinical illness following ***Plasmodium vivax*** primary infection and relapse are unclear in people living in endemic areas. A major difficulty lies in the inability to distinguish primary infections and relapses. We previously analysed genotyping data to show that the seasonal pattern of the incidence of primary infections and relapses differed in a cohort of children in Ilaita, Papua New Guinea. The differential seasonality can be used to gain leverage to estimate the probability of clinical illness following primary infection and relapse in the same cohort. The children, aged one to three years at enrolment, were followed up over 16 months. Illness was detected during active case detection every two weeks and carers were encouraged to visit the study clinic if the child was ill at other times. ***P. vivax*** illness was defined as fever or reported fever in the last 48 hours with a parasite density of 500/µl or greater. We relate the number of observed ***P. vivax*** cases in each age-group and each two month time period to the expected numbers of primary infections and relapses, and use the expected cumulative number of lifetime genotypes seen as a proxy for clinical immunity. The expected numbers of primary infections and relapses are derived from a simulation model, parameterized by previous analyses of the same cohort and including the seasonal pattern of primary infections, differential biting by age by weighting by body surface area, the durations of blood-stage infections, the number and timing of relapses, and treatment. We assume relapses occurring when a blood-stage infection by the same genotype is present do not cause illness and are not counted. The estimated probability of acute illness declined with the cumulative number of genotypes seen. For the ages in this cohort, the probability following primary infection ranged from 0.3 to 0.05, following the first relapse, 0.07 to 0.0006, and for the second or later relapse, the probability was low. These results can inform estimates of the burden of ***P. vivax*** disease and provide building blocks for mathematical models for predicting the impact of interventions against ***P. vivax***.

1556

ABSENCE OF EFFECT OF HETEROZYGOUS HEMOGLOBIN S ON THE PREVALENCE OF PLACENTAL MALARIA AND LOW BIRTH WEIGHT

Jaymin C. Patel[1], Victor Mwapasa[2], Linda Kalilani[2], Feiko O. ter Kuile[3], Carole Khairallah[3], Kyaw L. Thwai[1], Steven R. Meshnick[1], Steve M. Taylor[4]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]College of Medicine, Blantyre, Malawi, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]Duke University Medical Center, Durham, NC, United States

Heterozygous hemoglobin S (HbAS), or sickle trait, protects children from life-threatening falciparum malaria. The mechanism of this protection is unclear, and evidence suggests that HbAS reduces expression of, ***Plasmodium falciparum*** erythrocyte membrane protein 1 (PfEMP1) and thereby attenuates adherence of infected erythrocytes (IEs) to extracellular ligands. Such binding of IEs to ligands is central to the pathogenesis of placental malaria, wherein the expression of the PfEMP1 variant VAR2CSA mediates IE binding to chondroitin sulfate in the placenta; thus, placental malaria serves as an ***in vivo*** model of PfEMP1-mediated sequestration of IEs. We hypothesized that HbAS would be associated with reduced risks of placental malaria and its sequelae, including low birth weight (LBW). We tested this hypothesis in a cross-sectional study of 850 delivering

women in Southern Malawi. Demographic, clinical, and antenatal records were collected from enrolled women along with infant birth weight. Placental histology was scored for markers of malaria, and parasites were detected in peripheral and placental blood by real-time PCR. The overall prevalence of HbAS was 3.7%. The prevalence of ***P. falciparum*** was 8.5% in peripheral blood and 12.7% in placenta by PCR and 24.4% by any histological evidence. The prevalence of LBW (<2500g) was 11.2%. There were no significant associations between HbAS and placental ***P. falciparum*** (OR: 1.29, 95% CI: 0.48, 3.41) or any histological evidence of placental malaria (OR: 0.98, 95% CI: 0.40, 2.34). ***P. falciparum*** densities, as estimated by PCR, were also similar between groups. Furthermore, mean (standard deviation) birth weights of infants born to HbAS (2947g [563g]) and HbAA (2991g [465g]) mothers were similar, as was prevalence of LBW (OR: 0.82, 95% CI: 0.24, 2.73). Across a range of parasitologic, clinical, and histologic outcomes, HbAS did not confer protection from placental malaria or its adverse effects. Although HbAS reduces cytoadherence of IEs to endothelium, the absence of protective effects in this study suggest that HbAS does not attenuate the ability of IEs to sequester in the placenta.

1557

DISTRIBUTION AND PREVALENCE OF MALARIA IN CHILDREN UNDER THE AGE OF FIVE IN THE DEMOCRATIC REPUBLIC OF THE CONGO, 2013-2014

Lauren Levitz[1], Mark Janko[2], Corinna Keeler[2], Melchior Kashamuka Mwandagalirwa[3], Stephanie Doctor[1], Olivia Anderson[1], Amy Whitesell[1], Kyaw Thwai[1], Henry Ntuku[3], Michael Emch[2], Joris Losimba Likwela[4], Antoinette K. Tshefu[3], Steven Meshnick[1]

[1]Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, United States, [2]Department of Geography, Carolina Population Center, University of North Carolina, Chapel Hill, NC, United States, [3]Ecole de Santé Publique, Faculté de Médecine, Université de Kinshasa, Kinshasa, Democratic Republic of the Congo, [4]Programme National de Lutte contre le Paludisme, Kinshasa, Democratic Republic of the Congo

The Democratic Republic of the Congo has one of the highest malaria burdens in the world. Over 8,000 children under the age of 5 in 540 population-representative clusters were tested for malaria in the 2013-4 Demographic and Health Survey. Infection was ascertained by microscopy, rapid diagnostic tests (RDT), and PCR for the ***Plasmodium falciparum*** lactate dehydrogenase gene. Weighting for populations, 34.1% of children were PCR-positive for ***P. falciparum*** malaria. In contrast, 22.7% and 30.9% were positive by microscopy and RDT, respectively. The prevalence of microscopic gametocytemia was 1.4%. Malaria was common in all 26 national health divisions. PCR prevalence, like microscopy, increased with age and was higher in those living in rural areas compared to urban areas. PCR prevalences ranged from 10 to 68%. We estimate that prevalence of mono-infections with P. malaria or P. ovale was approximately 1%. Of the RDT-positive samples, 18% were both PCR- and microscopy-negative, probably due to persistence of HRP-2 in the circulation. This high burden of malaria was found despite the fact that insecticide-treated net (ITN) ownership increased from 7% of households in 2007 to 70% in 2013.

1558

ESTIMATING THE MALARIA ATTACK RATE IN TANZANIAN MILITARY CAMP: RISK FACTORS ASSOCIATED WITH MALARIA EPIDEMIOLOGY IN MILITARY CAMPS IN TANZANIA

Charles E. Mwanziva[1], Mercy Chiduo[2], Lucky Temu[3], Francis Filbert[2], Humphrey Mkali[2], Sarah Chiduo[3], David Schnabel[4], George Amoo[5], Lalaine Anova[6], Colin Ohrt[4], Eyako Wurapa[4], Akili Kalinga[7], Christopher Mswanya[1], Deus Ishengoma[2], Yadon M. Kohi[1], Dennis Janga[1]

[1]Tanzania Peoples Defence Forces, Dar es Salaam, United Republic of Tanzania, [2]National Institute for Medical Research, Tanga Research Centre, Tanga, United Republic of Tanzania, [3]Walter Reed Malaria Programme-Tanzania, Dar es Salaam, United Republic of Tanzania, [4]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [5]Amethyst Technologies LLC, Baltimore, MD, United States, [6]ClinicalRM Inc., Hinckley, OH, United States, [7]National Institute for Medical Research, Tukuyu Research Centre, Tukuyu, United Republic of Tanzania

In Tanzania, malaria ranks number one cause of morbidity and mortality, accounts for over 32% of the National disease burden. There is high heterogeneity of malaria transmission. Imported cases by travellers to and from different areas in Tanzania poses a great challenge in malaria epidemiology. The aim of this study was to identify risk factors associated with malaria attack rate among individuals when entering a training camp in a highly endemic area. Tanzania People's Defence Forces (TPDF) Recruits eligible to study in Mgambo National Service camp -Tanga, were randomly selected by multistage sampling; consented and followed for six months. Fortnightly malaria smear was collected. Blood samples for serological tests were collected. Microscopy was a gold standard method for malaria diagnosis. Data was subjected to univariate and multivariate analysis, logistic regression model was used to identify the risk factors. Among 549 recruits who were involved in this study, 31.7% (174) were malaria positive, of which 80.5% (442) were male recruits. Female recruits had 54% significantly reduced chances of being malaria positive [OR: 0.46; 95% CI: 0.28 - 0.77; P=0.003]. Among positive cases, those who didn't sleep under treated net previous night were found to have significantly increased odds of being malaria positive [OR: 7.71; 95% CI: 1.01-58.61; P=0.048]. Travelling outside the camps in the past one month had increased odds of being malaria positive [OR: 1.25; 95% CI: 0.87-1.79; P=0.232]. There was significant difference between malaria positivity and place of travel [X^2=40.1; P=0.015]. This study revealed failure to use bed nets and travel are major drivers of malaria. Identification of gaps in net use, knowledge, relevant types of human movement and development of strategies addressing travel is highly recommended. Mgambo NS being a high malarial endemic area is ideal site for malaria drug prophylaxis or vaccine studies, where TPDF recruits from various transmission intensity areas train under similar exposure environment.

1559

A COMPARISON OF HOUSEHOLD SURVEY SCREENING FOR MALARIA AMONG OLDER CHILDREN (5-14YRS) AND ADULTS VERSUS YOUNG CHILDREN TO DETERMINE FINE-SCALE HETEROGENEITY IN AN AREA OF HIGH TRANSMISSION

Mark Sherlock[1], Emanuele Giorgi[2], Arantxa Roca-Feltrer[1], Clemens Masesa[1], Kamija Phiri[3], David Lalloo[4], Peter Diggle[2], Dianne Terlouw[1]

[1]Malawi-Liverpool Wellcome Trust Research Centre, Blantyre, Malawi, [2]University of Lancaster, Lancaster, United Kingdom, [3]College of Medicine, Blantyre, Malawi, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

There are increasing calls for more targeted malaria control interventions that take into account transmission heterogeneity. Capturing such heterogeneity and identifying hotspots accurately at the sub-district and district level however remains a challenge. Current parasitaemia indicators

for household surveys are based on children aged 6 to 59 months. While there is an increasing interest to expand parasitaemia screening in household surveys to older children or adults, its added value remains unclear. We investigated whether screening older age groups in addition to young children within households could improve precision in mapping heterogeneity and malaria hotspots. We conducted a monthly continuous ('rolling') population based household-level malaria indicator survey (rMIS) in an area of ~400km2 in Chikwawa district, southern Malawi. Malaria parasitaemia screening was conducted in three age groups: 6-59 months, 5-14 years, and ≥15 years, and based on a pLDH/HRP2 rapid diagnostic test (First Response® Malaria Ag. pLDH/HRP2 Combo Card Test, Premier Medical Corporation Ltd., India). Further collected household information included socioeconomic status, long-lasting insecticide-treated net and indoor residual spraying coverage. A total of 1,197 children aged 6-59 months, 1,506 aged 5-14 years, and 1,1881 aged ≥15 years were sampled. Parasite prevalence was 16.7% (95%CI 14.5, 19.2) in the youngest age group, 11.8% (95%CI 10.1, 13.7) in the 5 to 14 years age group and 5.4% (95%CI 4.5, 6.3) in the ≥15 year group. This data was used to create geospatial maps of parasite prevalence for both individual age groups and combined groups, using generalized linear geostatistical models. Comparative analyses of these maps suggest that the older age groups do not increase the accuracy or precision in mapping malaria hotspots. These findings thus suggest that in settings of high but varying malaria transmission the screening of older children and adults in addition to children under the age of 5 in household surveys will not contribute to a more accurate picture of heterogeneity and identification of malaria hotspots.

1560

CLINICAL SPECTRUM OF DISEASE IN ADULTS AND CHILDREN WITH *PLASMODIUM KNOWLESI* MALARIA IN A DISTRICT SETTING IN SABAH, MALAYSIA

Matthew J. Grigg[1], Timothy William[2], Prabakaran Dhanaraj[3], Jayaram Menon[2], Giri Rajahram[2], Bridget Barber[1], Chris Wilkes[1], Arjun Chandna[1], Kaajal Patel[1], Jonathan Cox[4], Chris Drakeley[4], Tsin Yeo[1], Nicholas Anstey[1]

[1]Menzies School of Health Research, Darwin, Australia, [2]Queen Elizabeth Hospital, Kota Kinabalu, Sabah, Malaysia, [3]Kudat District Hospital, Kudat, Sabah, Malaysia, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Plasmodium knowlesi is now the most common cause of malaria in Malaysia, but prospective studies describing the clinical spectrum have only detailed adult disease. In our prospective study (2012-ongoing) at 3 district hospitals in Sabah, Malaysia, previously untreated, non-pregnant patients of any age hospitalised with PCR-confirmed malaria includes: 368 ***P. knowlesi*** (32 [8.7%] children ≤ 12 yrs), 152 ***P. vivax*** (63 [41.5%] children), 56 ***P. falciparum*** (11 [19.6%] children), 14 ***P. malariae***, and 1 mixed ***Pk/Pf***. Preliminary data include a lower baseline parasite count for ***P. knowlesi*** malaria patients (median 2274/μL, IQR 537-9252) than ***P. falciparum*** (9762/μL, IQR 2030-24010, ***P***<0.001), and ***P. vivax*** (4319/μL, IQR 1588-9608, ***P***=0.011). Parasite counts were higher in adults with ***P. knowlesi*** compared to children (2427 vs. 890/μL, ***P***=0.013). In ***P. knowlesi*** (WHO criteria) anaemia was present in 37% of adults vs. 86% in children (***P***<0.001), however was less prevalent than in ***P. vivax*** overall (60%, ***P***<0.001). Acute kidney injury (AKIN criteria and/or creatinine >132mmol/L) was found in 42/285 (14.7%) with ***P. knowlesi*** including 42/263 (16%) adults and 14/27 (52%) of those with severe disease, compared to ***P. vivax*** overall (12/140, 8.6%, ***P***=0.073). In those with ***P. knowlesi*** 28/366 (7.7%) had severe malaria (modified WHO 2010 criteria): 28/334 (8.4%) in adults but none in children. In comparison, severe disease was seen in 5/152 (3.2%, ***P***=0.062) with ***P. vivax*** and 4/56 (7.1%, ***P***=0.839) with ***P. falciparum***. 207/359 ***P. knowlesi*** patients were treated with artemisinin combination therapy, including 39 with prior intravenous artesunate, and the remainder with oral chloroquine. There were no treatment failures in knowlesi malaria patients seen at 28 days. There was one ***P. knowlesi*** malaria death, with delayed parenteral artesunate due to misreported hyperparasitaemia. Overall ***P. knowlesi*** malaria predominantly affected adults, with AKI (16%) and severe malaria (8.4%) commonly developing in this age-group. Although anaemia was more common in children than adults with ***P. knowlesi***, parasitemia was lower and severe anaemia, AKI or other severe disease was not seen.

1561

PROGRESS TOWARDS ACHIEVING MILLENNIUM DEVELOPMENT GOAL AND ROLL BACK MALARIA TARGETS IN GHANA

Wahjib Mohammed, Keziah L. Malm, Constance Bart-Plange

National Malaria Control Programme, Accra, Ghana

Ghana has been implementing the Roll Back Malaria Strategy since 2003, and is currently operating with the 2008- 2015 strategic plan. The overall goal of the 2008 - 2015 malaria strategic plan is to reduce both malaria deaths and malaria burden by 75% by 2015 using 2000 as baseline. In line with the MDG Goal 6, the programme is aimed at halting malaria deaths by 2015. This study aimed to assess progress towards attainment of 2015 MDG/RBM malaria targets in Ghana. This study employed desk review of annual reports, policy and operational guidelines, reports of health facility and community based surveys including Multiple Indicator Survey (MICS), Demographic and Health Surveys (DHS) and Malaria Indicator Surveys between 2000 -2014. All cause under-five years mortality rate was reduced from 111/1000 in 2003 to 60/1000 in 2014. Malaria case fatality rate in under-five children reduced from 14.4% in 2001 to 0.51% in 2014. Ghana also achieved up to 50% reduction in parasite prevalence between 2002 and 2014 from a national average of over 50% to 26.7%. There was an increase in the use of ITNs among children under five and pregnant women, from 3.5% and 2.7% in 2003 to 58.8% and 56.3% in 2014 respectively. Proportion of pregnant women receiving at least 2 doses of IPT was 64.4% in 2011 against the target of 80% by 2015. Proportion of malaria cases treated with Artemisinin-based Combination Therapy (ACT) increase from 39% in 2011 to 82.5% in 2014. Ghana has made significant progress towards attainment of the MDGs goals of halting malaria deaths. There is however the need to sustain the gains and improve in areas such the coverage of IPTp and ITN use.

1562

ESTIMATING THE MOST RESOURCE-EFFICIENT MALARIA INTERVENTION PACKAGES AND SPATIAL SCALES TO ACHIEVE ELIMINATION ACROSS AFRICA

Patrick G. Walker, Jamie T. Griffin, Neil M. Ferguson, Azra C. Ghani

MRC Centre for Outbreak Analysis and Modelling, London, United Kingdom

Resource constraints mean that the elimination of malaria in much of Africa, if achievable, is likely to require available resources to be allocated carefully. Here we use a dynamical model of malaria transmission, capturing the heterogeneity in transmission of malaria which exists across sub-Saharan Africa, to identify the most efficient combination of interventions and spatial scale of implementation to achieve different elimination milestones. Our results demonstrate that, while bed-nets are a cost-effective step towards any control target, the choice of further interventions to deploy within a setting depends on the time scale over which a given target is to be achieved and whether disease reduction or elimination of infection is the priority. We found that while chemoprevention within risk groups such as children are the most cost-effective means by which to achieve rapid reductions in malaria burden, the changing age-distribution of disease as transmission falls and large asymptomatic reservoir means that sustaining low burden or other more ambitious elimination milestones requires interventions which target the general population such as indoor residual spraying or mass drug administration (MDA). At 90% population coverage, we estimate that packages including one, two or three annual rounds of

MDA would achieve pre-elimination levels of transmission (<0.001 case per person year) in 75%, 82% and 91% of the population at risk in mainland Africa respectively, with the latter achieving pre-elimination in 25 of the 42 countries with ongoing transmission. We then investigated how the resources needed to achieve this target depend upon whether interventions are deployed at the country or provincial (first administrative unit) level. We found that on average provincial level policies reduced the resources necessary to achieve pre-elimination by 40%, with countries with high levels of heterogeneity in transmission such as Tanzania, Senegal, and Angola benefiting most. In other countries such as Zambia, high within-province variation may suggest the need for even higher resolution local-level policies.

1563

SPATIAL AND TEMPORAL DYNAMICS OF MALARIA INCIDENCE FROM 2009-2013 IN BANDIAGARA, MALI

Drissa Coulibaly[1], Mark A. Travassos[2], Jean Gaudard[3], Youssouf Tolo[1], Abdoulaye K. Kone[1], Matthew B. Laurens[2], Karim Traore[1], Issa Diarra[1], Amadou Niangaly[1], Modibou Daou[1], Mody Cissoko[1], Boureima Guindo[1], Stanislas Rebaudet[3], Bourema Kouriba[1], Mahamadou A. Thera[1], Renaud Piarroux[3], Christopher V. Plowe[4], Ogobara K. Doumbo[1]

[1]Malaria Research & Training Center, University of Science, Techniques & Technology, Faculty of Medicine and Dentistry, Bamako, Mali, [2]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Aix-Marseille University, Marseille, France, [4]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Despite recent progress in reducing malaria morbidity and mortality in many places, empirical and theoretical evidence suggests that the current suite of interventions will not be sufficient to eliminate malaria from many areas in sub-Saharan Africa with historically high levels of malaria transmission. Careful description of the micro-epidemiology of malaria is essential for an accurate assessment of local transmission risk and hotspot localization in order to support malaria control programs, particularly in countries with limited resources. Our study aimed to measure malaria incidence and to investigate spatial and temporal dynamics of malaria in a single town in Mali from June 2009 to July 2013. Malaria incidence was measured in a cohort of 400 children through active and passive surveillance. Households were georeferenced using a handheld Global Position System (Garmin: Personal Navigator) with an accuracy goal of <15m and assigned to blocks of houses. A GIS map of Bandiagara was established from satellite photography and field surveys. Malaria cases were mapped using PHILCARTO (TM). SaTScan® software was used to look for intra-annual and inter-annual clusters of high or low risk. The incidence was stable from 2009-2013. The annual cumulative incidence varied from 1.3 to 2.0 clinical episodes per child from 2009-2013. The weekly clinical malaria episodes and rainfall were plotted. Three month phase shifts were detected between the beginning of seasonal rains and the peaks of clinical malaria episodes. During high malaria transmission periods, hotspots were stable and localized to the southwest part of the town, as well as in the northeast section near the Yamé river. The central and eastern parts of the town were relatively protected. No significant clustering was found during the low transmission period. Overall, there was a marked spatial heterogeneity of malaria cases with stable hotspots and stable incidence in Bandiagara from 2009 to 2013. This analysis of malaria microepidemiology may inform local malaria control and elimination strategies.

1564

COST-EFFECTIVE SCALE-UP OF CURRENT INTERVENTIONS AND RTS,S IN SUB-SAHARAN AFRICAN SETTINGS

Peter Winskill, Patrick G. Walker, Jamie T. Griffin, Azra C. Ghani

Imperial College London, London, United Kingdom

Despite continuing progress in the control of malaria, in many countries, especially in sub-Saharan Africa, the burden of disease remains high and the availability of interventions remains sub-optimal and subject to resource constraints. In light of this, the setting-specific cost-effectiveness of new tools to control malaria, such as the RTS,S vaccine, must be evaluated alongside other control options, including investing more resources in further scaling-up existing interventions already in place. We used an existing mathematical model of malaria to describe the effectiveness of LLINS, RTS,S and chemoprevention in children across the highly heterogeneous range of transmission settings that exist across Africa. Costs were estimated using a production function framework for a range of interventions, including LLINs and the RTS,S vaccine. The most efficient, step-wise approach to scaling up a combination of interventions was determined by comparing the incremental cost-effectiveness ratios (ICERs) associated with increasing the coverage of each intervention and choosing the most favourable option. This process was repeated until the coverage or usage of all interventions was maximised. Outcomes considered include the reduction over ten years of clinical incidence in infants (6 months to 5 years old) and clinical incidence in all age groups. LLINs are generally considered the most cost-effective malaria control method currently available. We found that, when including RTS,S with an assumed unit cost of production of $5 per dose as an option, providing LLINs to the majority of the population remains the most cost-effective control strategy across a wide range of transmission settings. However, under the realistic assumption that reaching individuals without a net becomes increasingly difficult as coverage increases, if there are sufficient remaining resources, strategies such as chemoprevention or RTS,S may be a more cost-effective alternative to achieving very high levels of LLIN coverage.

1565

COMPARING THE EPIDEMIOLOGY OF MALARIA INFECTION AND ILLNESS IN PNG CHILDREN BEFORE, DURING AND AFTER THE INTENSIFICATION OF CONTROL MEASURES

Maria Ome-Kaius[1], Johanna H. Kattenberg[1], Matthew Siba[1], Shadrach Jally[1], Daisy Mantila[1], Jason Ginny[1], Peter M. Siba[1], Christopher L. King[2], Ingrid Felger[3], James W. Kazura[2], Ivo Mueller[4], Leanne J. Robinson[4]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]Case Western Reserve University, Cleveland, OH, United States, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]Walter and Eliza Hall Institute of Medical Research, Parkville, Victoria, Australia

In Papua New Guinea (PNG), children less than 5 years of age typically experience high levels of clinical illness with ***Plasmodium falciparum*** and ***P. vivax***. Children appear to acquire clinical immunity to ***P. vivax*** rapidly and clinical episodes are rare after 5 years of age, whilst clinical episodes of ***P. falciparum*** remain common. Perennial exposure as well as the high rates of relapses and clinical disease due to ***P. vivax*** in early childhood may contribute to the rapid acquisition of clinical immunity early in life. The incidence of clinical malaria with both species is comparable in children less than 5 years. However, the prevalence and incidence of ***P. falciparum*** infection and illness increases with age, with minimal signs of any acquisition of clinical immunity to ***P. falciparum*** in this age group. In the last decade, there has been a renewed focus on the implementation of an effective National Malaria Control Program and this is successfully reducing malaria transmission in the country. However, a detailed understanding of the impact on the burden of infection and clinical malaria, as well as the acquisition of clinical immunity in the most vulnerable age group, 1-5 year olds, is lacking. To assess this, a longitudinal cohort study of 1-5 year

olds was conducted in the same area of East Sepik Province as previous studies that were conducted prior to (Lin et al) and during (Betuela et al) the introduction of sustained control measures. Preliminary analysis shows a marked reduction in the prevalence of ***P. vivax*** infection at enrolment (by PCR) from 53.0% in 2006 to 14.0% in 2013 and ***P. falciparum*** infection from 49.6% to 14.0%. Similarly, prevalence of clinical malarial episodes has significantly declined from 20.5% to 4.8%. Detailed analysis of the incidence and risk of malaria in the 10 month follow-up period will be presented. In conclusion, preliminary data confirms a profound decline in the prevalence of malaria infection and episodes achieved through sustained control measures.

1566

EXPLORING THE RELATIONSHIP BETWEEN CLIMATIC FACTORS AND ITN USE IN 17 AFRICAN COUNTRIES

Emily E. Ricotta[1], Hannah Koenker[1], Joshua Yukich[2], Olivier Briët[3]

[1]Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland

While there is much anecdotal evidence of climatic factors such as rainfall and temperature affecting insecticide-treated net (ITN) use, there is little actual data demonstrating this association. Qualitative research has reported decreased ITN use during the dry season due to perceptions of being too hot, and increased use during the rains due to increases in perceived nuisance biting. This analysis uses data from national household surveys, as well as remotely-sensed climate data, to assess how factors such as ITN use is influenced in different ecological environments at different times of the year. The most recent national survey with available geographic location data was obtained for 17 African countries. Monthly rainfall estimates (mm) at a roughly 4 km resolution were acquired, and the mean rainfall estimate at each survey cluster location for the month in which the survey was conducted was merged with the national survey dataset. Logistic regression was run to assess whether there was a significant relationship between estimated rainfall quantile and ITN use in each of the study countries. Preliminary results suggest that in 10 of the 17 countries surveyed in this analysis, there is a significant association between estimated rainfall and ITN use. In some countries, higher quantiles of estimated rainfall increased the odds of net use significantly (Benin – OR: 1.45, p=0.001). However, in a few countries, higher quantiles were associated with decreased odds of using an ITN when controlling for access to an ITN in the household (Senegal – OR: 0.75, p=0.024). Further studies are necessary in order to understand what additional climatic factors, such as land surface temperature, nocturnal dew point, and relative humidity, play a role in ITN use, as well as the reasoning behind these associations and what they mean for in-country malaria prevention programs.

1567

THE EFFECTIVENESS OF A TARGETED INDOOR RESIDUAL SPRAY CAMPAIGN WITH PIRIMIPHOS-METHYL IN NCHELENGE DISTRICT, NORTHERN ZAMBIA

Marisa A. Hast[1], Mike Chaponda[2], Daniel J. Bridges[3], David Larsen[3], Kelly M. Searle[1], James Lupiya[2], Tamaki Kobayashi[1], Timothy M. Shields[1], Modest Mulenga[2], Frank C. Curriero[1], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Tropical Disease Research Centre, Ndola, Zambia, [3]Akros, Lusaka, Zambia

The WHO has identified vector control as a key priority in reducing community malaria burden. In Nchelenge District, Luapula Province, Zambia, the main malaria vectors are An. gambiae s.s. and An. funestus, both of which are highly anthropophilic and endophilic, making indoor residual spraying (IRS) a potentially effective strategy. Nchelenge District has hyperendemic malaria, with greater than 50% parasite prevalence by rapid diagnostic test (RDT). Malaria vectors in Nchelenge District are susceptibile to the organophosphate insecticide pirimiphos-methyl, and this compound was used for the first time in Zambia in a large-scale IRS campaign in Nchelenge District conducted by the Ministry of Health, the President's Malaria Initiative (PMI), and NGO partners over 6 weeks in October-December 2014. Sub-district areas were targeted for spraying based on population density and health center case reports. This is the first use of a targeted IRS strategy in Zambia. Approximately 30 months of data from 425 households in active surveillance cohorts was used to establish baseline seasonal malaria prevalence in Nchelenge District. After the IRS campaign, six months of enhanced surveillance from 250 households will be used to evaluate the impact of this IRS strategy, both in targeted areas and district-wide. Parasite prevalence as measured by rapid tests and PCR in serial bimonthly cross-sectional data collections are compared pre- and post-intervention, and changes in time to reinfection in longitudinal cohorts and vector abundance using CDC light traps are quantified.

1568

SHIFTING EPIDEMIOLOGICAL PATTERN OF MALARIA IN NORTH CENTRAL AND SOUTHWESTERN NIGERIA

Adeola Y. Olukosi, Chimere Agomo, Oluwagbemiga Aina, Samuel Akindele, Hilary Okoh, Bartholomew Brai, Olusola Ajibaye, Bassey Orok, Bamidele Iwalokun, Adeniyi Adeneye, Adedapo Adeogun, Olajumoke Akinyele, Nkechi Oparaugo, Grace Akintunde, Veronica Enya, Maureen Aniedobe, Olatoun Fesobi, Abiodun Olakiigbe, Samson Awolola

Nigerian Institute of Medical Research, Lagos, Nigeria

Characterization of malariometric indices is a necessary precursor for planning malaria control activities. Resulting baseline values of these epidemiological parameters provide evidence basis for intervention purposes. A survey of four villages in Borgu, Niger State representing a Sudan savannah vegetation of North Central Nigeria and Ijede a semi urban town, in a forest vegetation belt of South West was conducted. Consenting participants were screened for malaria using mRDT and microscopy. Temperature, PCV, height and weight were measured. Of a total of 1648, 813 from Borgu and 835 from Ijede, malaria positivity by RDT was 19.4%, 95% CI = 17.42-21.53 (Ijede 9.6% and Borgu 32.5%) and 11.9 %, 95% CI = 10.33-13.67 by microscopy (Ijede 11.5% and Borgu 17.1%). Fever was significantly associated with malaria positivity [OR = 2.1417 (1.3554-3.3842), P=0.001] overall but not at individual sites [Ijede: OR=1.361 (0.4647 - 3.9865), P=0.573; Borgu: OR= 1.6869 (0.9812 - 2.90), P=0.057]. Malaria positivity rate was significantly lower in under 5 year than in 5-15 year (P = 0.043) in both study sites. Children under five years of age had significantly lower malaria positivity rate (16.3%) as well as a lower parasitemia level(382p/µl) when compared to 5-15 years age group with 41.3% and 490p/µl corresponding values (P<0.001). Overall anemia rate was 21.6%; 95% CI 19.46%-23.74%. Anemia rate and distribution was similar at both sites with children under the age of 5years 17.7% recording lower rates, compared to the rest of the population 22.3 %(P<0.001). This preliminary investigation revealed a lower malaria prevalence rate and parasitemia in under fives compared to children 5-10years. There should be a high index of suspicion for alternative causes of fever, other than malaria in children under the age of 5years in Nigeria.

1569

MULTIPLICITY OF INFECTION AND DISEASE SEVERITY IN *PLASMODIUM FALCIPARUM* AND *P. VIVAX* IN AREAS WITH SEASONAL TRANSMISSION OF COLOMBIA

M. Andreina Pacheco[1], Mary Lopez-Perez[2], Andres Vallejo[2], Socrates Herrera[2], Myriam Arevalo-Herrera[3], Ananias A. Escalante[1]

[1]Temple University, iGEM, Philadelphia, PA, United States, [2]Caucaseco Scientific Research Center and Centro Internacional de Vacunas, Cali, Colombia, [3]Faculty of Health, Universidad del Valle, Cali, Colombia

A common observation in malaria endemic areas is that there could be multiple lineages of the parasite concurrently infecting a patient; this is referred to as multiplicity of infection (MOI). MOI is the result of the co-transmission of parasite variants (co-infections) or the overlap of variants due to multiple infectious contacts (superinfections). Distinguishing between the two processes is laborious so MOI usually refers to a sample with multiple parasite genotypes. Previous studies have postulated a link between MOI and disease severity; association that has been tested in *Plasmodium falciparum* mostly in Africa with limited information on *P. vivax*. In this study, the association between MOI and disease severity is explored in seasonal malaria areas from Colombia where *P. vivax* and *P. falciparum* can be compared. Overall 422 *P. vivax* and 282 *P. falciparum* samples were collected between 2011 and 2013 from three distinct malaria endemic areas of Colombia. A total of 41 *P. vivax* and 27 *P. falciparum* cases were classified as clinically complicated cases. Samples were genotyped by using 8 microsatellite loci, any infection with two or more alleles at any locus was considered a multiple infection. *P. vivax* displayed more MOI (50.9%) than *P. falciparum* (21.6%). Uncomplicated cases were sampled in an interval of 5 to 8 days around each complicated case so both complicated/uncomplicated cases where matched in time as closely as possible. An analysis using a Fisher exact test yield a significant association ($p<<0.05$) between MOI and disease severity in *P. vivax*. In contrast, no association was observed in *P. falciparum*. Similar analyses were performed on all the samples regardless time of collection and the association observed in *P. vivax* remained whereas no association was still observed in *P. falciparum*. We observed that multiple infections with *P. falciparum* usually involved genetically related lineages whereas in *P. vivax* there were distinct genotypes circulating. However, the low number of complicated malaria cases did not allow to proper exploring the effect that this factor may have in the differences observed between the two parasites species.

1570

DECLINE IN THE BURDEN OF MALARIA IN PREGNANCY IN SOUTHERN MOZAMBIQUE: EVIDENCE FROM A 14-YEAR PERIOD AND IMPLICATIONS FOR MALARIA ELIMINATION

Raquel Gonzalez[1], Francisco Saúte[2], Azucena Bardaji[1], Sonia Maculuve[2], María Rupérez[1], Caterina Guinovart[1], Anifa Vala[2], Ruth Aguilar[1], Esperança Sevene[2], John Aponte[1], Eusebio Macete[2], Pedro L. Alonso[1], Clara Menendez[1], Alfredo Mayor[1]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]Manhiça Health Research Center (CISM), Maputo, Mozambique

Knowledge of the trends in malaria transmission is essential to evaluate the impact of elimination campaigns. Pregnant women are especially vulnerable to malaria and have been suggested as a potential reservoir of *Plasmodium falciparum* parasites. The objective of this study was to describe changes in the burden of malaria in pregnancy and its maternal and infant adverse consequences over a 14-year period in southern Mozambique. The study was designed as a retrospective pooled analysis of data collected in five studies that enrolled pregnant women of all gravidities between 1998 and 2012. Temporal changes of maternal *P. falciparum* infection and pregnancy outcomes, as well as the effect of gravidity and HIV infection on the changes on malaria burden were assessed over the period. 4973 pregnant women contributed to this analysis; 27.2% of them were primigravidae and 29.3% were HIV-infected. A significant drop in peripheral parasitemia prevalence was found between 1998 and 2010 (from 15.3 % to 0.5% $p<0.001$) with a slight but significant rebound in 2012 (to 3.5%, $p=0.003$). The mean parasite density in peripheral blood was higher in 2010 compared with that in 1998 (66683 versus 4667.9 parasites/μL, $p<0.001$). The prevalence of placental infection also significantly drop during the study years (from 50.7% in 2003 to 3.5% in 2012, $p<0.001$).Primigravidae had higher prevalence of *P. falciparum* infection than multigravidae across all studied periods ($p<0.001$). No significant differences were found in the prevalence of peripheral parasitemia between HIV- infected and uninfected pregnant women. Maternal anemia ranged between 57.4% and 37.4% with no specific pattern over the study years. The prevalence of low birth weight decreased during the study period (from 19.8% in 2003 to 6.1% in 2012, $p<0.001$).A significant decrease in the malaria burden in pregnancy was observed in this area of southern Mozambique over the period. Importantly, the increase in P falciparum infection found at the end of the period calls for the need of continuous monitoring and surveillance of malaria transmission in pregnant women.

1571

MALARIA EPIDEMIOLOGY IN LOW ENDEMICITY AREAS OF THE NORTHERN COAST OF ECUADOR

Fabián E. Sáenz[1], Andrea Arévalo[1], Andrés F. Vallejo[2], Gabriela Valenzuela[1], Andrea Poveda[1], Angélica Castellanos[2], Enrique Castro[3], Julio Valencia[4], Amanda Pereira[5], Myriam Arévalo[2], Sócrates Herrera[2]

[1]Pontificia Universidad Católica del Ecuador, Quito, Ecuador, [2]Centro de Investigación Científica Caucaseco, Cali, Colombia, [3]Ministerio de Salud Pública, Guayaquil, Ecuador, [4]Ministerio de Salud Pública, Esmeraldas, Ecuador, [5]Ministerio de Salud Pública, San Lorenzo, Ecuador

The recent scale up in malaria control measures in Latin America has resulted in an impressive decrease in the number of reported cases in most countries of the region. In Ecuador the incidence decreased from more than 100 thousand cases in 2001 to 377 cases in 2013) with occasional outbreaks of both falciparum and vivax malaria particularly in the coastal and Amazonian regions. The success in control measures in recent years has led Ecuador to change its malaria policy from control to elimination, nevertheless, there is no evidence that current interventions alone particularly the passive case detection could lead to malaria elimination in the country as it has been reported that a large proportion of human malaria infections could be asymptomatic. We have studied the malaria prevalence in four communities of an endemic area in northwest Ecuador. A total of 650 blood samples were analyzed by microscopy, real time PCR as well as serology using ELISA and immunofluorescence. The total prevalence of malaria infections in the study area was 8% (98% asymptomatics). This number is comparable to the reported prevalence in a neighbor endemic area of Colombia (Tumaco) and it implies a much higher prevalence of malaria in the area than expected according to the official records. Our results infer that the transition from control to elimination strategies in a country like Ecuador will demand an improvement in malaria diagnostics to detect parasites in asymptomatic carriers and in infections with low parasite densities as well as a change in the treatment policy.

1572

CHANGING MALARIA EPIDEMIOLOGY IN UGANDA BETWEEN 2011 AND 2014: RETROSPECTIVE ANALYSIS OF KEY MALARIA INDICATORS AND SURVEILLANCE DATA

Bosco B. Agaba[1], Peter Okui[1], Ann Gasasira[2], Humprey Wanzira[3], Henry Katamba[1], Mathias Kasule[1], Belay Kassahun[4], Bryan Kapella[4], Emmanuella Baguma[5], Lucia Baguma[1], Denis Rubahika[1], Denis Walusimbi[5], Myers Lugemwa[1], Anthony Nuwa[6], Charles Katureebe[7]

[1]Department of Disease Control, Malaria Program, Kampala, Uganda, [2]Uganda Malaria Surveillance Project, Kampala, Uganda, [3]Department of Disease Control, Malaria Control, Kampala, Uganda, [4]U.S. President's Malaria Initiative, Kampala, Uganda, [5]Clinton Health Access Initiative, Kampala, Uganda, [6]Malaria Consortium Uganda, Kampala, Uganda, [7]World Health Organization, Kampala, Uganda

The National Malaria Program has been implementing the malaria 2011-2015 strategic plan (MSP) since January 2011. A mid-term review was conducted to examine progress against the targets outlined in the MSP, identify key challenges and provide evidence to inform the next 2016-2020 strategic planning period. This paper summarizes key findings from the review and their implications on future malaria control plan. The Review was conducted between November 2013 and April 2014. Data to assess changes in intervention coverage, malaria burden and compliance to Uganda's malaria "testing guidelines" were primarily from the HMIS (DHIS2). Where available, sentinel surveillance data were used to validate HMIS findings and additional data were got from surveys and program reports. We used descriptive statistics to assess changes in intervention coverage and generate trends for key malaria indicators. To assess the changes in malaria burden, we analyzed the difference between the Test Positivity Rate in the baseline year (2011) and 2014. The proportion of households with 1 LLIN per 2 persons increased from 28% in 2011 to 59.6 % by end of 2013 while outpatient visits attributed to malaria in under-5s was recorded to have declined from 52% to 13.7% in the same period. In ten districts where IRS has been consistently deployed for 5 years, the test positivity rate declined by 25%. Malaria Case fatality rate dropped from 2% in 2010 to 0.72% in 2013. Proportion of cases receiving a parasitological test before treatment improved from 25% in 2010 to 59% in 2013.The MTR was used as an opportunity to identify,collate and analyze data from different sources to evaluate progress in malaria control. Although our results should be interpreted with caution because of the inherent data quality problems of routine surveillance systems and low malaria testing during the review period, the compilation of data from different sources suggests that Uganda has made progress in malaria control and is on track to achieve most of its 2015 intervention targets. Strategies contributing to these successes were evaluated and informed the next strategic planning period

1573

MALARIA PREVALENCE IN REPUBLIC DEMOCRATIC OF THE CONGO: PRELIMINARY RESULTS IN 13 HEALTH ZONES

Thierry L. Bobanga[1], Dieudonné N. Mumba[1], Solange E. Umesumbu[2], Zimbombe Vulu[1], Celestin Manianga[1], Celestin N. Nsibu[1]

[1]University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [2]National Malaria Control Program, Kinshasa, Democratic Republic of the Congo

Malaria remains a health problem in the DRC despite interventions today conducted a large scale. Few evaluations were conducted in the DRC on malaria, the country has very little information on the basic indices of malaria. This makes it difficult to evaluate the interventions and monitor their impact. A community survey was conducted in 13 health zones in different regions with different epidemiological characteristics The prevalence ranged from 0.4% to 42% respectively at Musienene in North Kivu Province and Kapolowe in Katanga Province. The average prevalence was 12.5%. With a mean parasitaemia of 356 trophozoites per microliterd with the highest parasitemia at 27300 trophozoites per microliter These results show that the malaria profil in DRC is vaery varoius and the control effort must be considered differently.

1574

HOW INFECTIOUS IS THE ASYMPTOMATIC RESERVOIR?

Hannah C. Slater[1], Chris Drakeley[2], Teun Bousema[3], Azra Ghani[1]

[1]Imperial College, London, United Kingdom, [2]Malaria Centre, London School of Tropical Medicine and Hygiene, London, United Kingdom, [3]Radboud University, Medical Center, Nijmegen, Netherlands

In a malaria endemic population, many individuals will have asymptomatic infections. These individuals do not seek treatment, so continue to infect mosquitoes and continue transmission. In a time where malaria elimination is back on the agenda, identifying and treating these asymptomatic individuals is likely to be a key part of any elimination strategy. An important question yet to be answered is: how infectious is the asymptomatic reservoir, and how much of this reservoir do we need to target to drive the reproductive number of malaria below one? In this study we use a range of data sources from the published literature to estimate how infectivity varies across different age groups, different transmission settings, and across the transmission season. We also consider how parasite densities of asymptomatic populations vary, and, for a given time, how many of these infections are detectable using a diagnostic such as microscopy or RDT. A study from Burkina Faso estimates that 53% of infected individuals in a population have sub-microscopic parasite densities, and that these individuals contribute 24% to the infectious reservoir. We also find that in areas with high transmission, children are more infectious to mosquitoes than adults, therefore identifying and treating children could be a relatively more impactful way to reduce the infectious reservoir. Finally, we use the available information to validate an existing mathematical model of malaria transmission and to explore the implications of age- and location-specific infection and infectivity profiles on malaria control interventions.

1575

DECLINING PARASITE PREVALENCE AND IDENTIFICATION OF NON-*PLASMODIUM FALCIPARUM* INFECTIONS IN MALARIA-ENDEMIC SOUTHWESTERN UGANDA

Michelle Roh[1], Caesar Oyet[2], Gertrude Kiwanuka[2], Juliet Mwanga-Amumpaire[3], Sunil Parikh[1], Yap Boum II[3]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Mbarara University of Science and Technology, Mbarara, Uganda, [3]Epicentre Mbarara Research Centre, Mbarara, Uganda

Malaria transmission in Uganda is remarkably heterogeneous, and declines in prevalence have not been uniform. Previous surveys in southwestern Uganda have shown declines in parasite prevalence from 2004 to 2010. In order to assess the current status of malaria control, we conducted a multi-stage cluster sampling cross sectional survey for malaria infection using rapid diagnostic tests and microscopy. 631 children under five years of age were sampled from three districts, previously characterized as low (Mbarara), intermediate (Bushenyi), and high (Isingiro) transmission intensities. Blood samples were collected to determine the presence of parasitemia using the following: (1) a combined ***Plasmodium*** HRP-2/LDH rapid diagnostic test (RDT) (SD Bioline Malaria Ag P.f/Pan), (2) microscopy, and (3) PCR testing for species confirmation. Prevalence of parasitemia was higher by RDT compared to microscopy (6.2% (95% CI: 4.3-8.1) vs. 3.2% (95% CI: 1.8-4.5)). By district, parasitemia prevalence was 1.2% (3/242) in Mbarara, 3.2% (5/157) in Bushenyi, and 5.2% (12/232) in Isingiro. All 20 microscopy positive cases were detected by RDT. Of the 19 cases detected only by RDT, 7 (36.8%) reported having been treated for malaria within the past month. Notably, of the 20 microscopy positive children, 50% (10/20) were infected with ***P. falciparum***, 40% (8/20) with ***P. malariae***, and the remaining 2 children were ***P. vivax*** and ***P. ovale*** mono-infections.

Knowledge, attitudes, and practice regarding malaria prevention were also assessed, revealing a high proportion of households reporting bednet use (91.6%), but only a small fraction of households participating in indoor residual spraying (0.8%). Our preliminary findings indicate continued significant strides in malaria control over the past 10 years in southwestern Uganda. Combined HRP-2/LDH correctly identified all microscopy positive cases. Most notably, our survey reveals a striking shift in species prevalence in this region of Uganda, with nearly 50% of asymptomatic children infected with non-falciparum species. PCR confirmation of screening results is currently underway and will be presented.

1576

MALARIA INFECTION AND GAMETOCYTE CARRIAGE RATE, ASSESSED IN A COHORT OF ADULTS DURING MALARIA TRANSMISSION BLOCKING ASSAY DEVELOPMENT IN BANCOUMANA, MALI

Issaka Sagara[1], Mahamadoun H. Assadou[1], Yimin Wu[2], Merepen A. Guindo[1], Mamady Kone[1], Kourane Sissoko[1], Moussa L. Diakite[1], Sintry Sanogo[1], M'Bouye Doucoure[1], Sekouba Keita[1], Ruth Ellis[3], Erin Gabriel[4], Sara A. Healy[5], Patrick E. Duffy[5], Ogobara Doumbo[1]

[1]University of Bamako, Bamako, Mali, [2]Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health and MVI, Rockville, MD, United States, [3]Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, [4]Biostatistical Research Branch, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [5]Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

For malaria elimination/eradication, transmission blocking tools are key interventions to be integrated into existing control strategies. Epidemiological characterization of the transmission reservoirs in endemic countries are being evaluated in targeted populations prior to the start of phase 1 or 2 transmission blocking vaccine clinical trials in order to support study designs and analysis plans. From 2011 to 2014, we have followed a dynamic cohort of adults aged from 18 to 50 years, in Bancoumana, Mali, in order to improve assays that support trials of transmission blocking vaccines. After community permission, individual informed consent was obtained for each volunteer. Both National Institute of Allergy and Infectious Diseases/NIH in USA and FMPOS IRB in Mali approved the study protocol and informed consent documents. Volunteers were screened monthly for malaria parasites and gametocytes carriage. Passive surveillance and care were also provided to volunteers in cases of illness throughout the duration of the study. Malaria smears were stained using Giemsa and assessed by two different readers for the presence of malaria parasites. In November, a peak month for parasite carriage, the ***Plasmodium falciparum*** infection rates were: 22.58 (14/62), 25.79 (57/221), 32.94 (28/85), respectively in 2011, 2012 and 2014. Likewise, October, a peak month for gametocytes carriage, the gametocyte carriage rates were: 8.57 (6/70), 10.07 (30/298), 6.82 (6/88), respectively in 2011, 2012 and 2014. There were no statistically significant differences seen, in the ***Plasmodium falciparum*** infection rate or the gametocyte carriage rate between the different years of the study during the peak months of carriage. Malaria infection and gametocytes carriage are sufficiently prevalent in the adult population at the study area to conduct trials that assess the activity of transmission blocking vaccines.

1577

EPIDEMIOLOGICAL AND ENTOMOLOGICAL CHARACTERIZATION OF URBAN MALARIA TRANSMISSION IN QUIBDÓ-COLOMBIA

Karen Molina-Gómez[1], Julio Padilla[2], Pablo Chaparro[3], Martha L. Quiñones[4], Martha Ahumada[5], Myriam Arévalo-Herrera[6], Sócrates Herrera[7]

[1]Malaria Vaccine on Drug Development Center, Cali, Colombia, [2]Ministerio de Salud y Protección Social de Colombia de Colombia, Bogotá, Colombia, [3]Instituto Nacional de Salud de Colombia, Bogotá, Colombia, [4]Universidad Nacional de Colombia, Bogotá, Colombia, [5]Universidad Nacional de Colombia, Cali, Colombia, [6]School of Health-Universidad del Valle, Asoclinic Inmunología LTDA, Cali, Colombia, [7]Malaria Vaccine on Drug Development Center; Caucaseco Scientific Research Center, Cali, Colombia

It is suspected that anarchical urbanization, presence of mosquito vector with high adaptability to urban environments, arrival of infected individuals to communities with low levels of immunity and deficiency of sanity and infrastructure contributes to establishment of malaria transmission in urban and peri-urban areas. A number of malaria endemic municipalities in Colombia (n=17) have been reported by the National Surveillance System as having urban malaria transmission, although there is poor evidence for the presence of autochthonous urban cases. A pilot study is being conducted in Quibdó the municipality with highest amount of reported cases in order to ascertain urban malaria transmission. The study includes malaria active case detection (ACD) and passive case detection (PCD) both followed by a reactive case detection (RCD), to assess epidemiological and entomological dynamics in selected urban and peri-urban settings. Adult Anopheles mosquitos collected by human landing catches and larval habitats are being searched neighborhood of malaric houses in urban, peri-urban settings. Preliminary data has been collected from a total of 68 houses with 390 inhabitants in the peri-urban (Cabi and Casablanca) and urban neighborhoods by ACD. Two positive cases were detected by thick blood smear (1Pv, 1 Pf) whereas qPCR detected eight (3Pf 5Pv). So far only 1 case (Pv) has been recorded among urban patients who reported not having visited endemic areas. RCD of this urban case indicated that neither the family nor neighbors had malaria, in contrast, the RCD of the other seven positive cases confirmed by qPCR as index cases indicated that: In peri-urban areas, Casablanca none of the family members of one of the cases was infected, whereas a neighbor of a second case was positive (Pf). In Cabi, a total of 13 additional cases were found in index case homes and 11 more in neighbors' houses. Of 298 adult mosquitos collected 75% were from rural area, 23% peri-urban area and only 1 specimen (0.3%) urban area where no larvae habitats were found. This data clearly indicate that transmission in Quibdó is mainly peri-urban with so far no evidence for urban transmission.

1578

MALARIA CASES TRENDS IN RWANDA 2001-2014

Corine K. Karema[1], Alphonse Rukundo[1], Allan Kabayiza[1], Kaendi Munguti[2], Agnes Binagwaho[3], Abdisalan M. Noor[4]

[1]Malaria and Other Parasitic Diseases Division, Kigali, Rwanda, [2]President's Malaria Initiative-United States Agency for International Development, Kigali, Rwanda, [3]Ministry of Health, Kigali, Rwanda, [4]INFORM, Spatial Health Metrics Group, Department of Public Health Research, KEMRI/University of Oxford-Wellcome Trust Research Programme, Nairobi, Kenya

Rwanda has achieved signficant progress in scaling up malaria control interventions with reductions of more than 50% of malaria prevalence and incidence countrywide. Rwanda is now considered to be on target to achieve malaria pre-elimination by 2018. However, recently the NMCP Rwanda reported rise of malaria cases for the past 3 years which threatens to undermine these gains. The aim of our study was to investigate the trends in malaria over a 13-year period (2001-2014) and to evaluate the impact of malaria control interventions on malaria burden in Rwanda. Monthly health facility data on countrywide confirmed malaria cases from

the Rwanda Health information system were assembled for the period 2001-2014. Data were aggregated by district, province and national levels. Time series analaysis was undertaken to describe the trends in malaria cases, slide positivity rate, crude case incidence and the proportion of outpatients attendances that were due to malaria. These were matched with a timeline of changes in climate indices, policy and malaria control interventions to contextualise the observed trends. From 2001 there was a generally declining trend in malaria slide positivity rate while cases numbers were lower compared to the peak of 2005. However, compared to 2011, when the lowest case numbers and slide positivity rates were recorded, there was an increase in the malaria burden. The highest increase for the last 3 years was in the districts of Eastern and Southern provinces located in high malaria transmission zones bordering the high transmission countries . Some of the peaks appear to correspond to lagged rainfall and temperature changes as well as low malaria control interventions effective coverage. In conclusion, malaria cases have steadily increase in Rwanda in the last three years in Rwanda despite substantial scale up in malaria control. The increase in malaria control interventions coverage appear to result in a declining trend as was observed between 2005-2008 and 2010-2011. A detailed empirical analysis is required to determine the key drivers of the rising trend.

TOOLS FOR IDENTIFYING MALARIA HIGH RISK POPULATIONS: PILOT OF A CASE-CONTROL METHODOLOGY IN ZAMBEZI REGION, NAMIBIA

Jenny Smith[1], Erastus Haindongo[2], Carmen Cueto[1], Roly Gosling[1], Adam Bennett[1], Davis Mumbengegwi[2], Hugh Sturrock[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]University of Namibia, Windhoek, Namibia

Targeting interventions to populations at high-risk for malaria infection remains a challenge in meeting Namibia's elimination target for 2020. To effectively target infections, it is crucial to better understand the demographic, occupational and geographic risk factors for malaria. A case-control methodology, termed the Malaria Elimination Risk Factor Assessment Tool (MERFAT), was piloted between February and May 2015 in Zambezi Region, in order to locally characterize high risk groups and inform intervention strategies. All malaria cases confirmed by RDT at six randomly selected health facilities were included in the study. Controls were age and gender-matched to cases using frequency matching within broad categories and allocated to health facilities based on probability proportional to size of the health facility catchment population. Following an incident case, the first eligible patient who (i) tested negative for malaria by RDT or microscopy and (ii) matched a site-specific control profile was recruited into the study, with an aim of matching all cases within a two-week period. Multivariate logistic regression was used to evaluate potential environmental, socio-demographic, intervention, behavioral and travel-related risk factors. Spatial patterns of malaria risk were also analyzed. We will present descriptive statistics of the case and control study populations and evaluate spatial clustering of infection over the study area. We will also present results from the risk factor analysis, including assessment of environmental, sociodemographic, intervention, behavioral and travel-related risk factors. Implications for targeting local intervention strategies by geographical location and to profiled high-risk characteristics will be discussed, as well as the use of these methods as a programmatic tool in elimination settings.

1580

THE ROLE OF MATERNALLY DERIVED ANTIBODIES TO *PLASMODIUM FALCIPARUM* SCHIZONT EGRESS ANTIGEN-1 (PFSEA-1) AND NATURAL EXPOSURE IN THE DEVELOPMENT OF INFANTS' ANTIBODIES TO PFSEA-1

Sangshin Park[1], Sunthorn Pond-Tor[1], Edward R. Kabyemela[2], Michal Fried[3], Patrick E. Duffy[3], Jonathan D. Kurtis[1], Jennifer F. Friedman[1]

[1]Center for International Health Research, Rhode Island Hospital, Brown University Medical School, Providence, RI, United States, [2]Tumaini University, Moshi, United Republic of Tanzania, [3]Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Recently, we demonstrated that antibodies (Abs) to a novel malarial vaccine candidate, ***Plasmodium falciparum*** schizont egress antigen-1 (PfSEA-1), are associated with protection from severe malaria in children. Few studies have evaluated the impact of passively transferred cord blood anti-malarial Abs on the development of antimalarial Abs following natural exposure in early childhood. The objectives of this study were to a) longitudinally assess the relationship between parasite densities and subsequent anti-PfSEA-1 Ab levels among young children and b) evaluate whether higher levels of maternal Abs modified the relationship between natural exposure and development of infant anti-PfSEA-1 Ab. A total of 646 Tanzanian infants born between 2002 and 2005 were monitored every 6 months for anti-PfSEA-1 Ab levels until 30 months of age. We used two-way repeated measures analysis of variance to evaluate the changes in anti-PfSEA-1 Ab levels across three levels of both cord blood anti-PfSEA-1 Ab and cumulative parasite density in the preceding six months. Anti-PfSEA-1 Ab levels decreased up to 6 months of age and then began to increase until 24 months. Parasitemia within 6 months after birth induced significantly higher anti-PfSEA-1 Abs at 6 and 12 months compared to the group without parasitemia ($P < 0.05$). At 6, 12, and 24 months of age, infants with the highest tertile of average parasite densities for 6 months prior had significantly higher anti-PfSEA-1 level than the non-parasitemic group ($P < 0.05$). Cord blood Ab level did not modify the relationship between parasite density in preceding six months and infant anti-PfSEA-1 Ab level, ($P < 0.05$) suggesting cord blood Ab endowment does not interfere with Ab development during natural exposure. Malaria exposure influenced anti-PfSEA-1 Ab levels in infants longitudinally, and cord blood anti-PfSEA-1 Ab levels did not dampen acquisition of anti-PfSEA-1 Abs during natural exposure, suggesting that vaccinating pregnant women is unlikely to interfere with naturally acquired immune responses to PfSEA-1.

As plans develop to eliminate malaria from Greater Mekong Subregion in hopes of stopping the dissemination of artemisinin-resistant ***Plasmodium falciparum***, malaria infection without clinically recognizable illness is being targeted for drug treatment. It has long been recognized that asymptomatic malaria is common in semi-immune people in parts of sub-

Saharan Africa where malaria transmission is moderate or high, and that asymptomatic malaria during pregnancy in these regions is associated with adverse pregnancy outcomes. However, studies of asymptomatic malaria are very limited in areas of low malaria transmission such as Myanmar, particularly in pregnant women. We conducted a prospective longitudinal cohort study of pregnant women in 12 villages in Shwe Kyin and Madaya, two rural townships in Bago and Mandalay Regions, respectively, in Myanmar, to estimate the prevalence of asymptomatic malaria over time. Co-infections including HIV and intestinal helminths were also diagnosed. A total of 699 pregnant women making their first antenatal visit to a rural health center were enrolled between August 2013 and October 2014, and followed monthly for clinical and laboratory evaluations. Blood was collected for hemoglobin measurement, microscopic and PCR analysis of ***P. falciparum*** and ***P. vivax*** malaria, and rapid diagnostic testing of HIV. Stool was collected for microscopic examination of ova and parasites and speciation of intestinal helminths. In preliminary analyses, the prevalence of falciparum malaria at enrollment ranged from 3-15% and the prevalence of vivax malaria was less than 1%, and only one participant tested positive for HIV. Results from laboratory analyses, including the sequence analysis of K13 molecular marker associated with artemisinin resistance, and longitudinal dynamics of falciparum and vivax malaria will be presented. Preliminary data suggest that the burden of asymptomatic malaria in pregnancy in Myanmar is higher than expected at some sites, and heterogeneous across the study sites.

1582

SEASONAL CHANGES IN THE EPIDEMIOLOGY OF MALARIA IN THE GAMBIA

Abdullahi Ahmad, Serign J. Ceesay, Musa Jawara, Alfred Ngwa, Muna Affara, Fatou Joof, Ismaela Abubakar, Umberto D'Alessandro, Davis Nwakanma

Medical Research Council, The Gambia Unit, Banjul, Gambia

Recent reductions in the burden of malaria observed in many malaria endemic areas have mainly been due to improved coverage of malaria control interventions. To track the progress from these interventions and assess their impact, changes in malaria transmission and in the disease and immunity patterns needs to be monitored regularly in areas where these interventions are deployed. In a prospective cohort study, we enrolled 1402 individuals of all ages and of both genders from 168 households in Gambissara(GMB), Sare Bondo(SBND), Fula Morie Boche(FMB) and Sare Jawbe(SJWB) villages located within distance of 3 to 11 kilometres from each other in the upper river region (URR) of The Gambia. Over malaria transmission seasons of 2012, 2013 and 2014, we followed up the cohort via cross sectional surveys at beginning and at the end of each transmission season to determine parasite prevalence by microscopy. In addition, filter paper blood spots for later polymerase chain reaction analysis and blood samples for later haemoglobin typing and determination of prevalence of antibodies to selected malaria parasite antigens were collected at each survey. Results of 2012 surveys showed malaria prevalence was 1.6%(19/1147),10.9%(7/65), 18.1%(21/116) and 29.4%(20/68) at the beginning of transmission season and 10.7%(97/907), 14.3%(8/56), 35.2%(38/108), and 60.3%(35/58) at the end of the transmission season in GMB, SBND, FMB and SJWB villages respectively. In 2013, malaria prevalence was 2.6%(25/969), 8.1%(5/62), 20.0%(19/95) and 26.2%(16/61) at the beginning of transmission season and 4.6%(42/896), 5.4%(3/55), 20.3%(21/103), and 40.0%(21/53) at the end of the transmission season in GMB, SBND, FMB and SJWB villages respectively. In 2014, malaria prevalence was 3.4%(31/906), 6.4%(4/62), 14.0%(14/102) and 42.2%(21/54) at the beginning of transmission season in GMB, SBND, FMB and SJWB villages respectively. The wide differences in malaria prevalence consistently observed between our study villages over three transmission seasons suggests heterogeneity in malaria transmission in the URR of The Gambia.

1583

FOCAL TRANSMISSION OF MALARIA: PREVALENCE AND INCIDENCE OF MALARIA IN DANGASSA VS. BAMOGOLA IN MALI FROM 2012 TO 2014

Mahamoudou Toure[1], Sory I. Diawara[1], Daouda Sanogo[1], Nafomon Sogoba[1], Sekou F. Traore[1], Seydou Doumbia[1], Donald J. Krogstad[2]

[1]University of Science, Technologies and Techniques, Bamako, Mali, [2]Tulane University, New Orleans, LA, United States

During the past decade, the Government of Mali has launched a number of interventions to improve the prevention and treatment of ***Plasmodium falciparum*** malaria among the most vulnerable subgroups within the population. The purpose of this study was to examine the prevalence and incidence of ***P. falciparum*** malaria in Dangassa, a village located in an area of Mali with intense seasonal transmission. In 2011 we performed a census to select a representative sample of 1412 persons from the general population. Because we used a household-based sampling approach, once a household was selected, all the members of the household were invited to participate in the study. We then performed five serial (longitudinal) surveys to estimate the prevalence of parasitemia (infection) in the study population at the beginning and the end of the transmission season and during the dry season. A clinician based in Dangassa throughout the year was responsible for passive case detection (PCD) during those two and a half years in order to assess the incidence of malarial disease. Standard methods such as rapid diagnostic tests and positive thick smears were used to identify ***P. falciparum*** infection and thus to estimate the prevalence of infection and the incidence of disease (based on PCD). The prevalence of parasitemia (infection) varied with the season from 10% in June (at the beginning of the transmission season) to 39% in October (at the peak of the transmission season). A similarly low prevalence of 9% was observed during the dry season in February. These variations in the prevalence of infection are consistent with the PCD data which indicate that 55% of malaria cases occurred during the four month period from August to November. In addition, 60% of the severe malaria cases occurred during October and November. Despite the use of multiple interventions such as insecticide-treated bed nets for malaria prevention, the prevalence of infection (parasitemia) remains high in Dangassa among all age groups during the transmission season. Interventions such larviciding and seasonal malaria chemoprevention may be required to further reduce the burdens of infection and disease in such communities.

1584

MALARIA IN GOLD-MINING AREAS IN COLOMBIA

Angélica M. Castellanos[1], Cristhian Morales[2], Cindy Alegría[2], Pablo Chaparro[3], Julio Padilla[4], Myriam Arévalo-Herrera[5], Sócrates Herrera[2]

[1]Malaria Vaccine and Drug Development Center, Cali, Colombia, [2]Caucaseco Scientific Research Center, Cali, Colombia, [3]National Institute of Health of Colombia, Bogotá, Colombia, [4]Ministerio de Salud y Protección Social, Bogotá, Colombia, [5]Facultad de Salud, Universidad del Valle, Cali, Colombia

Despite significant decrease in recent years, malaria remains a major public health problem in Colombia. Among the multiple factors contributing to malaria maintenance, gold mining appears to play a major role. During the last decades, gold mining mostly illegal and associated to the military conflict, has significantly expanded in Colombia in areas with limited health care and disease prevention for the National Malaria Control Program, as well as their efficacy and generate a great negative impact on the socio-economic structure of the mining communities. In order to set up the bases for more effective malaria control strategies a descriptive study has been carried out to characterize the epidemiology and transmission of malaria in gold mining areas. The study focused on determining the prevalence of malaria cases in mining districts of Colombia. Approximately 31.6% of malaria cases from gold mining

district were reported from Nordeste Antioqueño (Antioquia), Montelibano (Córdoba) and from Buenaventura (Valle del Cauca) in the Pacific Coast. In Itsmina mining district (Chocó), it was found that 58.5% of malaria cases (165/282) displayed clinical symptoms some of them with (52/165) warning signs, and 52.8% in adolescents (< 18 years old). While on the study in Buenaventura was detected that 33% (162/492) of the cases occurred in miner worker specifically from Zaragoza, a rural site near the city which contributed 89% of total cases of the region; most of them (34%) asymptomatic only detectable by PCR. In conclusion, gold mining represents a specific epidemiological scenario of high risk for malaria transmission in communities engaged in this activity. The constant generation of small and temporary mines creates mosquito breeding sites which make it difficult to establish a profile of the vector species involved in transmission. Intervention strategies in the mining population have not been evaluated but are potentially useful to reduce the disease burden. The impact on the socio-economic structure of the mining communities help to maintain or increase malaria when mining populations migrate from or to malaria naïve communities.

1585

PARALLEL DECLINES IN MALARIAL AND NON-MALARIAL CHILDHOOD FEBRILE ILLNESS IN WESTERN KENYA

Alastair I. Matheson[1], Ondari Mogeni[2], Allan Audi[3], Godfrey Bigogo[3], Jennifer R. Verani[4], Jon Wakefield[1], Judd L. Walson[1], Joel M. Montgomery[4]

[1]University of Washington, Seattle, WA, United States, [2]Kenya Medical Research Institute/Centers for Disease Control and Prevention Public Health and Research Collaboration, Nairobi, Kenya, [3]Kenya Medical Research Institute/Centers for Disease Control and Prevention Public Health and Research Collaboration, Kisumu, Kenya, [4]Centers for Disease Control and Prevention, Nairobi, Kenya

Much of sub-Saharan Africa has recently seen substantial declines in malaria-related childhood morbidity due, in part, to effective control interventions. This has implications both for the etiologies of acute febrile illness (AFI) and demand for healthcare services. Overall childhood AFI may decline in parallel with malaria or, alternatively, non-malarial AFI may increase due to a reduction in asymptomatic parasitemia that was previously misclassified as malarial AFI. Current research has only described changes in rates of malaria rather than AFI overall. We used data from an area of high malaria transmission to examine this issue. We included 11,560 records of visits of children (<5 years) to an outpatient clinic in western Kenya from Jan. 1, 2009-Dec. 31, 2014. AFI was defined as temperature of ≥38.0°C from any cause and malaria by a positive smear result. We used quasi-Poisson regression to explore changes in counts of total, malarial, and non-malarial AFI, and quasi-binomial regression to examine the change in proportion of AFI that was malaria positive. We compared outpatient data with rates of self-reported AFI during regular household visits over the same period. There was marked seasonal variation in numbers of clinic visits for both malarial and non-malarial AFI, with some commonality to the patterns. We found similar rates of decline for numbers of total, malarial, and non-malarial AFI visits (0.76%, 0.79%, and 0.72% per month, respectively, P<0.01 for all three rates). The probability of a febrile child having malaria varied seasonally but remained constant across each year (P<0.748). Self-reported AFI from household surveillance declined at a slightly greater rate (0.94% per month, P<0.001). We found no evidence of change in the ratio of malarial to non-malarial AFI; both decreased at similar rates and may reflect a general improvement in the population's health. Non-malarial AFI declines may also stem from introduction of the pneumococcal conjugate vaccine or a link between malaria and risk of other AFI etiologies. Long-term reductions in outpatient AFI morbidity may be driven by factors other than malaria control programs.

1586

GENOME-WIDE ANALYSIS AND DIVERSITY OF *PLASMODIUM FALCIPARUM* IN SOUTHWESTERN NIGERIA

Muyiwa K. Oyebola[1], Emmanuel Idowu[2], Adeola Olukosi[1], Olusola Ajibaye[1], Olubunmi Otubanjo[2], Samson Awolola[1], Alfred Amambua-Ngwa[3]

[1]Nigerian Institute of Medical Research, Lagos, Nigeria, [2]University of Lagos, Lagos, Nigeria, [3]Medical Research Council, Banjul, Gambia

The burden of malaria is especially high in sub-Saharan Africa. Varying selection caused by differences in host immunity and antimalarial drug pressure leads to evolutionary changes responsible for high level of genetic variations in the parasite. Effective control methods require population-specific genetic studies to survey for genes under polymorphisms as a result of the influence of drug pressure or host immunity. We performed a genome-wide analysis of Nigerian isolates of ***Plasmodium falciparum*** and used frequency based neutrality test (Tajima's D) and integrated haplotype score (iHS) to identify genes under selection. Fourteen shared iHS regions that had at least 2 SNPs with a score > 2.5 were identified. These regions contained genes that were likely to have been under strong directional selection. Two of such genes were chloroquine resistance transporter (CRT) located in chromosome 7 and multidrug resistance 1 (MDR1) located in chromosome 5. There was a weak signature of selection in dihydrofolate reductase (DHFR) in chromosome 4 and MDR5 genes in chromosome 13 with only 2 and 3 SNPs respectively identified within the iHS window. Although there was no evidence of recent directional selection in dihydropteroate synthase (DHPS) gene in chromosome 8, there exists strong selection pressure attributable to continued chloroquine and sulfadoxine-pyrimethamine use despite the official proscription; hence the re-introduction of the drug as was done in other endemic countries after a period of withdrawal may yet be inappropriate. There was also a major selective sweep on chromosome 6 which had 32 SNPs within the shared iHS region. Tajimas's D values were mostly negative with a mean value of -0.86. One hundred and twelve genes (3.59%) had positive values. Tajima's D values of Circumsporozoite Protein (CSP), Erythrocyte-Binding Antigen (EBA-175), Merozoite Surface Proteins - MSP3 and MSP7, Merozoite Surface Protein Duffy Binding-Like (MSPDBL2) and Serine Repeat Antigen (SERA-5) were 1.38, 1.29, 0.73, 0.84 and 0.21 respectively. These positive values suggest their candidacy as target antigens of host immunity.

1587

COMPLEXITY OF INFECTION, DIVERSITY AND DRUG RESISTANCE IN CAMBODIAN *PLASMODIUM VIVAX*

Lindsey R. Friedrich[1], Jean Popovici[2], Didier Menard[2], David Serre[1]

[1]Genomic Medicine Institute, Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, OH, United States, [2]Institute Pasteur in Cambodia, Phnom Penh, Cambodia

In Cambodia, malaria is one of the foremost public health problems, with 2.5 of the estimated 13 million inhabitants living at risk of contracting the disease. Despite the implementation of extensive control efforts, the number of reported malaria cases attributed specifically to ***Plasmodium vivax*** has significantly increased since 1997 and treatment failure to chloroquine (CQ) has been reported. In absence of reliable long-term ***in vitro*** cultures, measures of genetic diversity by using neutral single nucleotide polymorphisms (SNPs) are useful to characterize ***P. vivax*** population structure, assess impacts of control efforts, and identify and track parasites lineages through space and time. We developed a genotyping technique to amplify and sequence 130 selected SNPs distributed throughout the ***P. vivax*** genome that are highly variable among Cambodian ***P. vivax*** isolates. We first applied this assay to 401 ***P. vivax***-infected patients recruited from nine study sites throughout Cambodia between 2004 and 2013. Our analyses revealed that most ***P. vivax*** infections in Cambodia (92%) are polyclonal and confirmed the

high genetic diversity of this population. Interestingly, our analyses showed that the proportion of monoclonal infections significantly increased between 2004 and 2013 suggesting that the control strategies against vivax malaria in Cambodia may be successfully affecting the parasite population. We then analyzed with the same method, blood samples from 23 ***P. vivax*** infected patients collected before treatment and every eight hours after CQ treatment to evaluate the relative susceptibility of each clone to CQ compared to the original infection. Combined with on-going whole genome sequencing of the parasites before treatment, these data will enable us to conduct a genome wide association study to hopefully identify polymorphisms underlying CQ susceptibility in ***P. vivax***.

1588

A SPATIAL GENETIC-EPIDEMIOLOGICAL MODEL OF MALARIA PARASITE TRANSMISSION

Edward A. Wenger

Institute for Disease Modeling, Bellevue, WA, United States

A model of malaria transmission dynamics is presented that tracks the full genomes of individual ***Plasmodium falciparum*** infections including outcrossing of strains both within and between infections. We explore quantitatively the relationship between transmission intensity and genetic observations, for example the repeated observations of identical and closely related strains and their persistence across successive transmission seasons. Extending to a spatially connected network of human and parasite populations, we model the sensitivity of genetic sequencing to identify the relative contributions of local hotspots versus re-importation in sustaining transmission in pre-elimination settings. Finally, we model the effects of local transmission intensity and anti-malarial drug pressure on the population-level genetic signatures of emerging drug resistance.

1589

ROBUST SCORING OF MICROSATELLITE MARKERS FROM NEXT GENERATION SEQUENCING IN *PLASMODIUM FALCIPARUM*

Ian H. Cheeseman[1], Shalini Nair[1], Standwell Nkhoma[2], Marina McDew-White[1], Ashley M. Vaughn[3], Richard Pinapati[4], Aung P. Phyo[5], Kanlaya Sriprawat[5], Francois Nosten[5], Stefan H. Kappe[3], Mike T` Ferdig[4], Timothy J. Anderson[1]

[1]Texas Biomedical Research Institute, San Antonio, TX, United States, [2]Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [3]Seattle Biomedical Research Institute, Seattle, WA, United States, [4]Notre Dame University, South Bend, IN, United States, [5]Shoklo Malaria Research Unit, Mae Sot, Thailand

There are enormous numbers of microsatellites repeats (~1 microsatellite every 650bp) in the genome of the malaria parasite, ***Plasmodium falciparum***. These markers are multiallelic and therefore more informative than SNPs for many research questions, yet they are problematic to score using next generation sequence data, and remain an untapped source of genetic variation for population genomic analyses. We used three approaches to validate scoring of microsatellite loci from next generation sequence data: (1) we sequenced the progeny of a genetic cross (n=14), and examined microsatellite calling in genome regions inherited from each parent; (2) we sequenced (in duplicate) parasites from a mutation accumulation experiment (n=38), and measured reproducibility and accuracy of scoring in >36K microsatellite loci throughout the parasite genome. (3) We compared microsatellite genotypes in genome sequence data from 6 single clone patient samples that had previously been scored for 335 microsatellites using traditional capillary electrophoresis. These analyses define the robustness with which microsatellites bearing different sequence motifs can be scored, and provide a map of callable microsatellites for large scale analysis of malaria parasite populations. To examine the utility of these markers for population genomic analyses, we determined genome-wide patterns of microsatellite variation in sequence data from 50 isolates obtained from a focus of emerging drug resistance in South-East Asia. We identify loci under strong, recent, positive selection in these samples, including known drug resistance loci, and we recapture the kelch locus underpinning artemisinin resistance.

1590

PATTERNS OF *PLASMODIUM FALCIPARUM* GENOTYPES IN AN AREA OF LOW MALARIA TRANSMISSION IN SOUTHERN ZAMBIA

Kelly M. Searle[1], Ben Katowa[2], Tamaki Kobayashi[1], Mwiche Siame[2], Sungano Mharakurwa[3], William J. Moss[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Macha, Zambia, [3]Biomedical Research Training Institute, Harare, Zimbabwe

Understanding the epidemiologic patterns of local malaria transmission and importation is crucial to achieving elimination and preventing re-introduction. A 24 single nucleotide polymorphism (SNP) ***Plasmodium falciparum*** molecular barcode has been used to identify and track circulating parasite populations. This molecular barcode was used to determine the genetic diversity and complexity of the circulating parasite population among malaria infected participants enrolled in a population-based, serial cross-sectional cohort study in Choma District, southern Zambia from 2008-2013. In this region the prevalence of malaria by rapid diagnostic test decreased from 8% in 2008 to <1% in 2013. Parasite DNA was extracted from dried blood spots from approximately 100 infected participants using the Chelex method. DNA pre-amplification specific to the target sites of each of the 24 SNPs was performed because of the low level of parasitemia. The molecular barcoding was performed using TaqMan genotyping assays on the Applied Biosystems StepOne and the Roche Lightcycler. Genotype results were assigned using each system's software. When the software was not able to identify the allele, the call was made manually. A subsample of duplicates was analyzed using both the Applied Biosystems and Roche platforms to validate the results. Analyses were conducted to determine the number of identical molecular barcodes within each year and persistent molecular barcodes between years. The proportions of mixed infections and polygenomic molecular barcodes were calculated for each year and compared across all years. No identical barcodes were identified within any year or between years. The proportion of samples with mixed infections was high for all years with an increasing trend as prevalence declined (90% in 2008, 94% in 2009, and 100% in years 2010-2013). The proportion of samples with polygenomic molecular barcodes decreased from 85% in 2008 to 73% in 2010, then increased to 92% in 2011 and 100% in 2012 and 2013. The results suggest that as malaria prevalence declined, local transmission ceased, and all infections were imported.

1591

COMBINATION OF HEMOGLOBIN-A2 PROMOTER VARIANTS AND THALASSEMIA-$A^{3.7}$ DELETION IS ASSOCIATED WITH *PLASMODIUM FALCIPARUM* ANEMIA

Zachary S. Karim[1], Prakasha Kempaiah[1], Samuel B. Anyona[2], John M. Ong'echa[3], Douglas J. Perkins[1]

[1]Center for Global Health, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, [2]Maseno University, Maseno, Kenya, [3]University of New Mexico Laboratories of Parasitic and Viral Diseases, Kenya Medical Research Institute, Kisumu, Kenya

Alpha (α)$^+$ thalassemia (α-thal) is a hemoglobinopathy induced by defective α-globin production which can be characterized by deletions in either or both hemoglobin (***HBA1*** and ***HBA2***) genes. Amongst populations in sub-Saharan Africa, a 3.7kb ($-\alpha^{3.7}$) deletion of the region between ***HBA1*** and ***HBA2*** results in phenotypes of heterozygous ($-\alpha^{3.7}/\alpha\alpha$) and homozygous ($-\alpha^{3.7}/-\alpha^{3.7}$) carriers. Within sub-Saharan African populations, severe malarial anemia [SMA, hemoglobin (Hb)<5.0g/dL with ***Plasmodium falciparum*** infection], is a leading cause of morbidity and mortality,

particularly in children. In the present study, we utilized our findings from high-throughput genotyping [Human BeadChip' (>2.45x10^6 markers)] and global gene expression arrays [HumanHT-12 v4 BeadChip (47,231 probes)] to identify novel genetic variants. Among the list of significant novel genes, ***HBA2*** emerged as an important gene associated with susceptibility to severe malaria in Kenya children (3-36mos). To validate the whole genome findings, we genotyped two functional promoter SNPs (rs1203833 and rs2974771) in ***HBA2*** (n=1,668 study participants). To examine the influence of the $\alpha^{3.7}$ deletion on SMA, this genotype was also generated. Binary logistic regression analysis, controlling for covariates (age, gender, G6PD, HIV-1, bacteremia, and HbAS status) revealed that carriage of the TA haplotype (-1789T/-4314A) together with the homozygous α-thalassemia deletion ($-\alpha^{3.7}/-\alpha^{3.7}$) increased susceptibility to SMA (OR: 3.2, 95%CI: 1.2-8.4, ***P***<0.05). These results demonstrate that variation in ***HBA2*** in combination with α-thalassemia variants influence susceptibility to SMA.

1592

HAPLOTYPES WITHIN THE NFKB1 PROMOTER ARE ASSOCIATED WITH RISK OF SEVERE MALARIAL ANEMIA

Elly O. Munde[1], Zachary S. Karim[2], Frank G. Onyambu[3], Evans O. Raballah[3], John M. Ong'echa[3], Collins Ouma[4], Prakasha Kempaiah[2], Douglas J. Perkins[2]

Understanding the molecular mechanisms involved in pathogenesis of severe malaria anaemia [SMA, hemoglobin (Hb)<5.0g/dL and any density parasitemia)] in children is a crucial step in the design of therapeutics interventions. Transcription factors are important in modulating cellular processes, such as immunity, since they are the primary regulators of gene expression. For example, nuclear factor of kappa light enhancer in B-cells (NF-κB) plays an important role in infectious and autoimmune disease pathogenesis through regulation of molecular pathways that generate soluble immune modulators (e.g. cytokines). Imbalances in immune modulators, such as IL-17, are central to the pathogenesis of childhood SMA. As such, we examined if genetic variation within the ***NFKB1*** promoter affected susceptibility to SMA. Functional association between ***NFKB1*** variants (-3297 T>C, rs980455 and -8079A>G, rs747559), SMA, and production of IL-17 was, therefore, determined in children (n=1,065, aged 6-36 months) presenting with ***P. falciparum*** malaria in Siaya County, a holoendemic transmission area of Kenya. Bivariate regression analyses controlling for covariates revealed that carriage of the ***NFKB1*** -8079A/-3297C (AC) haplotype was associated with increased risk of SMA (OR 1.60, 95%CI 1.10-2.40, ***P***=0.012). The AC haplotype was also associated with reduced Hb levels (***P***=0.001) and low circulating IL-17 levels (***P***=0.018) determined by the Human Cytokine 25-plex Array (Invitrogen). Spearman correlation revealed that Hb and IL-17 levels were positively associated (ρ=0.151, ***P***=0.027). Taken together, these results demonstrate that variation in the promoter of ***NFKB1*** is associated with susceptibility to pediatric SMA, potentially through altering the downstream expression of inflammatory mediators, such as IL-17.

1593

ASSOCIATION BETWEEN INTERFERON GAMMA (IFN-Γ) PROMOTER HAPLOTYPES AND ERYTHROPOIESIS IN KENYAN CHILDREN WITH *PLASMODIUM FALCIPARUM* MALARIA

Evans Raballah[1], Prakasha Kempaiah[2], Zachary S. Karim[2], Elly Munde[3], Douglas J. Perkins[4], John M. Ong'echa[3]

[1]Department of Medical Laboratory Sciences, Masinde Muliro University of Science and Technology, Kakamega, Kenya, [2]Center for Global Health, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, [3]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [4]Center for Global Health, University of New Mexico, Albuquerque, NM, United States

Plasmodium falciparum malaria is among the leading causes of morbidity and mortality among African children. In ***P. falciparum*** holoendemic transmission areas of western Kenya, severe malaria commonly manifests as severe malarial anemia [SMA; hemoglobin (Hb) <5.0 g/dL, any density parasitemia] in pediatric populations. Interferon-gamma (IFN-γ) is a pleotrophic cytokine associated susceptibility to severe malaria. Since the functional role of IFN-γ genetic variants in conditioning susceptibility to SMA remains largely unexplored, the association between single nucleotide polymorphisms (IFN-γ; -183 G/T, rs2069709 and -1616 A/G, rs2069705), their haplotypic structures, and SMA were investigated in parasitemic children (n=744, aged 3-36 mos.) presenting at a rural hospital in Siaya, western Kenya. Bivariate logistic regression analysis, controlling for age, gender, sickle-cell trait, bacteremia, and HIV-1 status, demonstrated that relative to homozygous -1616 A (wild-type) individuals, carriage of GG genotype was associated with protection against reduced erythropoiesis [reticulocyte production index (RPI)<2] (OR, 0.564; 95% CI, 0.323-0.983; ***P***=0.043). Additionally, carriage of the GA haplotype was associated with protection against reduced erythropoiesis (OR, 0.500; 95% CI, 0.393-0.637; ***P***<0.001). Conversely, GG (OR, 1.910; 95% CI, 1.504-2.427; ***P***<0.001) and TG (OR, 6.551; 95% CI, 1.399-30.679; ***P***=0.017) haplotypes were associated with increased risk of reduced erythropoiesis. Taken together, these results suggest the association between variation in ***IFNG*** and SMA may be mediated through the impact of the variants on erythropoiesis

AUTOMATED METHODS FOR HIGH-THROUGHPUT ANALYSIS OF *PLASMODIUM* MICROSATELLITE GENOTYPING DATA

Max Murphy[1], Alanna Schwartz[1], Yaobao Liu[2], Jordan Kemere[3], Michelle Hsiang[4], Bryan Greenhouse[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Jiangsu Institute of Parasitic Diseases, Jiangsu, China, [3]Baylor College of Medicine, Houston, TX, United States, [4]University of Texas Southwestern Medical Center, Dallas, TX, United States

Microsatellite genotyping of ***Plasmodium*** infections offers some advantages, in particular the relatively large diversity present at each locus and the resultant ability to obtain information from mixed infections. However, manual classification of electropherogram peaks as true alleles versus artifact can make this process subjective and time-consuming. To overcome these barriers, we have developed software to analyze microsatellite data in a high throughput and automated manner. These processes include automated processing of raw data files to carry out basic quality control and identify spectral pull-up, storage of run data in a centralized database, robust automated peak detection, contextual algorithms exploiting patterns identified in artifactual peak stutter on a per microsatellite basis that allow for true peak classification, and a web-based interface for manual curation of data. Using lab-cultured strains of ***Plasmodium falciparum*** (Pf) with known genotypes, we quantified segmental linear relationships between allele length and surrounding artifactual "stutter" peaks. With these relationships, we classified peaks as true alleles or artifact. Using 9 lab-cultured strains of Pf in 16 distinct double strain mixtures with relative parasite concentrations ranging from

2% to 98%, for a total 181 combinations, we identified true alleles for 9 microsatellite loci. Of these 9 loci, 2 were found to have complex artifact patterns, such as interactions between alleles, not well handled by a linear model and requiring manual curation. For the remaining 7, we identified true alleles with 94% specificity and 85% sensitivity. On a per microsatellite basis, specificity ranged from 83% to 98% and sensitivity ranged from 76% to 97%. Automated peak classification shortens time from experiment to results and reduces bias incurred by manual analysis and makes possible high-resolution genotyping.

PRELIMINARY STUDY: DIFFERENT POPULATION STRUCTURE OF *PLASMODIUM VIVAX* BETWEEN SYMPTOMATIC AND ASYMPTOMATIC PATIENTS FROM PERUVIAN AMAZON

Henry Herrera[1], Julio Miranda[1], Paulo Manrique[1], Oscar Nolasco[1], Ananias Escalante[2], Alejandro Llanos-Cuentas[3], Joseph Vinetz[4], Dionicia Gamboa[1]

[1]Departamento de Ciencias Celulares y Moleculares, FCF, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Institute for Genomics and Evolutionary Medicine, Temple University, Philadelphia, PA, United States, [3]Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, [4]University of California San Diego, San Diego, CA, United States

Different diagnostic methods have revealed a high frequency of ***Plasmodium vivax*** infections that occur without clinical symptoms. Furthermore little is known about its implications in the transmission dynamics of these infections and their relationship with the parasite population structure. The aim of this study was to explore the parasite population structure of symptomatic and asymptomatic patients from Cahuide, a rural community located 60 km away from Iquitos city. To achieve our goal, 20 microsatellites were amplified (a new set of 11 markers and 9 previously reported) in a selected group of samples. In this way, 113 ***P. vivax*** positive field samples were collected in March (55 samples) and June 2013 (58 samples) by active case detection. 25 Samples were excluded due to low parasitemia levels and the 88 remaining samples were used for microsatellite analysis. Microsatellite PCRs were performed and subsequently analyzed using an ABI PRISM 3100 avant genetic analyzer. Out of 88 samples, 24 were polyclonal whereas 64 were monoclonal, but just 50 had an almost-complete allele profile (75% or higher). Our results showed an average genetic diversity of 0.47 and 39 haplotypes were found. Interestingly, the diversity found in June was greater than in March (0.58 and 0.38 respectively). Using Structure ver2.3, 2 sub-populations (A and B) were found arranging by month (March 2013 and June 2013) and by symptomatology (symptomatic and asymptomatic patients). In March sub-population A was mainly found in asymptomatic patients while sub-population B was predominant in the symptomatic ones. In contrast, in June sub-population A was predominant in the symptomatic patients and both sub-populations were equally distributed in the asymptomatic ones. This data suggests that the asymptomatic patients carrying sub-population A might have served as a reservoir for further infections of the symptomatic patients. This study provides a first approach of the role of asymptomatic patients in malaria transmission which should be considered within the malaria control strategies.

A NEW ASSESSMENT OF THE TRANSCRIPTOMES OF PFSPZ AND THREE DAY LIVER STAGES

Malcolm J. Gardner[1], **Liliana Losada**[2], Yun Wu[3], Sumana Chakravarty[4], William Nierman[2], B. Kim Lee Sim[3], Stephen L. Hoffman[4]

[1]Global BioConsulting, Shoreline, WA, United States, [2]J. Craig Venter Institute, Rockville, MD, United States, [3]Protein Potential, Rockville, MD, United States, [4]Sanaria, Rockville, MD, United States

Over the last 20 years, genomics, transcriptomics, and proteomics have provided fascinating insights into ***Plasmodium*** biology and pathogenesis, contributing to basic research and development of new diagnostics, drugs, and vaccines against malaria. The opportunity to understand the biology of sporozoites and exoerythrocytic stages has arisen due to the ability to produce large quantities of these stages for analysis. We assessed aseptic, purified, and viable ***P. falciparum*** salivary gland sporozoites, and sporozoites that were axenically transformed, morphologically similar to 3-day 'liver stage' parasites expressing new proteins. We used next generation sequencing to profile transcripts expressed in sporozoites, axenic 72-hr liver stages, and asexual stages in order to uncover the molecular, biochemical, and cell biological processes that occur across the parasite's life cycle.

In malaria endemic areas, the fetus may be exposed to malarial antigens ***in utero*** and produce sensitized B and T lymphocytes. Most of our knowledge of ***in utero*** responses to malaria comes from studies of full term newborns. Little is known about the timing of malaria-specific immune responses ***in utero***. This study investigated the timing of ***in utero*** antibody (Ab) responses to ***P. falciparum*** (Pf) antigens. Since B1-cells are functional during prenatal life, the possibility of innate B1-derived Ab to Pf was also explored. Plasma samples from 600 Cameroonian neonates were studied: 373 full-term deliveries (FTD, ≥37weeks) and 227 pre-term deliveries (PTD, <28 weeks [n=33], 28-33 weeks [n=100] and 34-36 weeks [n=94]). Since IgM does not cross the placenta, fetal IgM in cord plasma was quantified to a panel of 8 Pf antigens (PfAg) and to known B1 antigens phosphorylcholine (PC) and pneumococcal polysaccharides (PP). IgG to PfAg was also measured in culture supernatants of cord blood mononuclear cells (CB-MNC) (n=70). Placental malaria (PM) was assessed from placental impression smears. IgM to one or more PfAg was detected in 10.6% of the neonates, with similar prevalence and titers in PTD and FTD. IgM to PfAg was detected at 22 weeks of gestation and throughout the 2nd and 3rd trimesters. PfAg IgM was significantly associated with PM in PTD and FTD (p=0.01). The proportion of PC IgM responders was not influenced by PM (p=0.83) and 51% of PC IgM-positive newborns were Pf IgM negative, suggesting that ***in utero*** "innate" Ab were not directly induced by malaria. Overall, 65% of culture supernatants from 70 CB-MNC cultures had IgG to one or more PfAg. In summary, the data show that fetal B cells made Pf-specific IgM Ab from as early as 22weeks of pregnancy through birth. Many of the newborns also had Pf-specific IgG-producing cells at delivery. B1-derived Ab were not associated with malaria. Studies are in progress to determine if ***in utero*** exposure to Pf leads to the production of short-lived antibody secreting cells or memory B cells.

The complex nature of the ***Plasmodium falciparum*** life cycle coupled with the further complexities of antigenic polymorphism presents a significant challenge for the design of an effective vaccine against malaria. There is a strong body of evidence that supports antigens expressed by ***P. falciparum*** merozoites as important targets of human immunity and therefore promising vaccine candidates. However, the specific targets of protective immunity remain elusive. Therefore identifying candidate antigens that correlate with a protective immune response remains a priority. We have developed an antigen production pipeline based on E. coli for the expression of purified recombinant antigens. By applying a number of in silico tools intended to aid the design of each antigen construct, we have focused on key regions, where appropriate, of each target gene avoiding the wholesale expression of candidate open reading frames. Using this approach we have been able to avoid difficult to express regions (e.g. transmembrane domains) and achieve expression of soluble constructs with a >90% success rate. Each antigen is then screened by ELISA and validated for reactivity to a subset of positive and negative control sera. Using protein microarrays we have screened approximately 94 validated antigens, many of which represent new, previously undescribed targets across a range of lifecycle stages. So far this panel largely focusses on the merozoite stage (81%) but also includes proteins associated with the infected erythrocyte (18%) and sporozoite (1%) stages. Work is currently ongoing to address this unintended bias. Comparison of data between the protein microarray and ELISA platforms using key validatory antigens, PfMSP1-19 and PfAMA, showed a strong correlation between the platforms (r2=0.78 and 0.73, respectively). Antibody reactivities from 350 individuals assayed at three time points (1050 sera total) from a region of high endemicity in Northern Uganda were used to determine reactivity profiles for each antigen. Preliminary analysis has identified a number of novel immune-reactive targets for prioritisation as putative vaccine candidates.

IMPACT OF MALARIA, HYPERGAMMAGLOBULINEMIA, AND IMMUNE COMPLEXES ON TRANSPLACENTAL TRANSFER OF MALARIA-SPECIFIC AND ANTI-TETANUS TOXOID ANTIBODIES IN PAPUA NEW GUINEA

Fernanda L. Alvarado[1], Indu Malhotra[1], Phantica Yambo[2], Jessica Atwell[3], Célia Dechavanne[1], Maria Ome-Kaius[2], Peter Siba[2], Stephen Rogerson[4], Leanne J. Robinson[2], Christopher L. King[1]

[1]Case Western Reserve University and Veterans Affairs Medical Center, Cleveland, OH, United States, [2]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [3]Johns Hopkins School of Public Health, Baltimore, MD, United States, [4]University of Melbourne, Melbourne, Australia

Malaria in pregnancy (MIP) can induce placental alterations (PM), malaria-specific immune complexes (IC), and/or maternal hypergammaglobulinemia (MHG) that may interfere with transplacental transfer of immunoglobulin G (IgG). To determine the relative roles of these factors in IgG transfer, 300 paired maternal and cord serum specimens were collected from two geographically similar cohorts in Papua New Guinea in 2005-08 (AXH) and after malaria control interventions 2011-13 (FIS). We measured IgG levels detected by bead array recognizing 20 ***P. falciparum*** (Pf) antigens and 14 ***P. vivax*** (Pv) antigens. ICs were measured using a C1q-based ELISA. Tetanus toxoid (TT) IgG levels served as controls. Placental malaria (PM) prevalence was 59%, MHG (≥1700mg/dL) was 54%, and high IC (≥0.85 mg/ml) was 30% in the AXH cohort; compared to 10%, 7% and 10% respectively in the FIS cohort. Differences were statistically significant with p values of <0.0001, 0.0034, and 0.0004. The cord to maternal transfer ratio (CMTR) was significantly lower in the AXH cohort for almost all anti-malaria antibodies (Ab), compared to the FIS cohort (P <0.001). Impaired transport of malaria-specific IgG (CMTR <1) ranged from 66% to 92% in AXH compared to 48% to 84% in FIS. By contrast, transplacental transport of TT-specific IgG was the same between the two cohorts and averaged of 35% impaired transport. A multivariate model showed a strong negative effect of MHG (P=0.0013), but no association of PM or IC, on transplacental transfer of TT Ab. By contrast, impaired transplacental transfer of Pf and Pv antibodies was associated with MHG, PM and IC with p values of <0.01, <0.001, and <0.001 respectively. There was an interaction between MHG, PM and IC for some antigens, but those factors were also independently associated with impaired transplacental transfer of malaria-specific IgG.The negative correlation of PM and IC only with Pf and Pv Ab but not with TT suggest receptor saturation and/or trapping of Abs rather than impaired placental function are the primary factors reducing transplacental Ab transfer.

THE TIMING OF MALARIA INFECTION DURING PREGNANCY INFLUENCES THE TYPE OF FETAL IMMUNE RESPONSE

Celia Dechavanne[1], Roslyn Tobby[2], Phantica Yambo[2], Daisy Mantilla[2], Alice Sato[1], Maria Ome-Kaius[2], Indu Malhotra[1], Stephen Rogerson[3], Peter Siba[4], Leanne Robinson[2], Christopher Lee King[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [3]University of Melbourne, Parkville, Australia, [4]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea

Epidemiological studies show that infants born to mothers with ***Plasmodium falciparum*** (Pf) malaria during pregnancy have a higher risk of malaria infection in early childhood. This increased risk is associated with whether the fetus has been exposed to malaria ***in utero*** and the generation of an immunoregulatory phenotype characterized by high IL-10 and low IFNg/IL-13 production that persists into early childhood. Why some fetuses acquire this immunoregulatory phenotype and others do not may relate to when the fetus is exposed to malaria during gestation. To examine this hypothesis, mothers were randomly assigned to receive intensive or limited malaria chemoprophylaxis during pregnancy. Depending on the gestational age at the time of enrolment and study arm, mothers were protected from malaria during defined times during pregnancy. Cytokine levels in cord plasma and/or cord blood mononuclear cells from 407 newborns defined the type of immune response. Cytokine responses were measured in culture supernatants, by flow cytometry of lymphocyte subsets and transcript levels by quantitative PCR following stimulation with Pf schizont extract and/or recombinant PfMSP1. Preliminary results indicate malaria exposure during the second trimester compared to the third trimester is associated with elevated IFNg and low IL-10 levels. By contrast the offspring of women exposed to malaria during the third trimester was associated with higher IL-10 levels relative to IFNg levels. More complete results will be available by the time of the meeting. These results suggest that the timing of malaria infection during pregnancy differently affects the newborns' lymphocyte responses and thus implications for the timing and frequency of malaria chemoprophylaxis during pregnancy.

[1]Malaria Research & Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Sciences Techniques and Technologies of Bamako, Bamako, Mali, [2]BRB, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, [3]Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

In areas of high malaria transmission, immunity to disease develops more rapidly than immunity to infection. Proteins expressed on the surface of infected erythrocytes (IE) have been described as the targets of immunity to malaria. Chan et al 2012, reported that the presence of antibodies to 3D7 parasite line is associated with a reduced risk of developing symptomatic malaria. Here, in the context of a longitudinal birth cohort we examined prospectively the association between antibodies to surface IE of parasites circulating among the children and protection from clinical malaria and reduction in parasite density. The study was conducted in Ouelessebougou Mali, where malaria transmission is highly seasonal. Antibodies to IE surface proteins in plasma were measured by flow cytometry. The analysis included samples from 125 children at the end of the transmission season and at the end of the dry season. Median (range) age of the children at the two time points were 17.9 (6-32) and 21 (9.3-39) months. IgG levels were defined as geometric MFI after subtracting MFI with uninfected erythrocytes and reactivity with plasma from naïve donors. On average children included in this analysis experienced 2.2 malaria infections (range 0-12) and 1.4 clinical malaria episodes (range 0-5). The proportion of parasite isolates recognized by the plasma samples and the level of reactivity did not predict protection from clinical malaria. Similarly, antibody reactivity with surface IE proteins was not associated with reduced parasite burden. Here, the children were younger than subjects included in previous studies that reported increased IE recognition with age that could account for the different results. Alternatively, we hypothesize that functional antibodies such as those that inhibit parasite adhesion may be more strongly associated with reduced risk of clinical malaria and parasite density, and these studies are ongoing. We will present data relating anti-adhesion antibodies with surface IE recognition, and the association between anti-adhesion antibodies to multiple receptors and the risk of malaria disease and parasite density.

1602

MALAWIAN NEWBORNS SHARE A VARIANT SURFACE ANTIGEN ANTIBODY REPERTOIRE WITH THEIR MOTHERS THAT IS AFFECTED BY MATERNAL MALARIA INFECTION IN PREGNANCY

In malaria-endemic regions, severe malaria in infants is rare. Protection may be attributable to maternal antibody transfer during pregnancy. Parasite antigens expressed on the surface of infected erythrocytes are associated with severe malaria pathogenesis. We hypothesized that the repertoire of antibodies to these variant surface antigens (VSAs), particularly ***Plasmodium falciparum*** erythrocyte membrane protein-1 (PfEMP1) antigens, is transferred to newborns, potentially providing protection against severe malaria. A protein microarray was printed with 176 fragments of PfEMP1s based on the 3D7 reference genome, including both extracellular and intracellular fragments, along with three repetitive interspersed family proteins (RIFINs), and six sub-telomeric variable open reading frame proteins (STEVORs). Seroreactivity to these fragments was measured in the second trimester for 36 Malawian mothers in their first or second pregnancy and compared to seroreactivity at delivery and in cord blood samples of their newborns. Eleven mothers had evidence of malaria infection in the placental or peripheral blood during pregnancy. Reactivity to VSAs was higher in sera from women with evidence of malaria infection versus women who did not have malaria during pregnancy at both enrollment and delivery and extended to the cord blood of newborns. Overall, seroreactivity intensity to VSAs was similar in cord blood compared to mothers at delivery. However, for mothers who did not have malaria during pregnancy, seroreactivity for several VSAs was higher in the infant than in the mother. These findings indicate that malaria infection during pregnancy may interfere with antibody transfer and may lead to increased risk of malaria disease during infancy. Future work will examine malaria infection and disease vis-à-vis the rate of decline of VSA antibodies in this infant cohort over time.

CYTOKINE PROFILE IN HELMINTH AND MALARIA INFECTIONS AMONG AFEBRILE AND FEBRILE CHILDREN IN IBADAN, SOUTHWEST NIGERIA

George O. Ademowo, Ayokulehin M. Kosoko, Olawunmi R. Rabiu, Hannah A. Dada-Adegbola, Ganiyu O. Arinola, Catherine O. Falade

College of Medicine, University of Ibadan, Ibadan, Nigeria

Intestinal helminths and malaria are among the most prevalent infectious diseases in the tropics. The effect of coinfections on immune response is not clearly understood. We therefore investigated the immune response profile in children with and without symptoms. A total of 78 afebrile school children (20 helminth-malaria co-infected, 17 helminth infected, 19

malaria infected and 22 uninfected) and 75 febrile children (14 helminth-malaria co-infected, 16 helminth infected, 20 malaria infected and 25 uninfected) were recruited into the study. Helminths were screened using Kato Katz method while malaria parasite screening was done using Giemsa-stained thick blood films. Circulating TNF-α, IFN-γ, IL-1, IL-10 and IL-6 concentrations were assessed by ELISA from serum samples. Data were analysed using analysis of variance. Among the afebrile school children, IL-10 was significantly increased in helminth infected children compared with helminth-malaria co-infected, malaria infected and uninfected groups ($p<0.05$). IFN-γ was significantly elevated in malaria and malaria-helminth coinfection relative to helminth alone ($p<0.05$). IL-1 level was significantly higher in single infection of helminth and malaria relative to coinfection and the uninfected groups ($p<0.05$). An insignificant difference was observed for IL-6 and TNF-α concentrations across all the four groups while among febrile children, IL-6 was significantly increased among helminth alone and helminth-malaria coinfection relative to malaria infected group ($p<0.05$). IL-10 was significantly elevated in co-infected group compared with helminth or malaria infected group while TNF-α was significantly increased in helminth and helminth-malaria coinfection compared with uninfected or malaria infected group ($p<0.05$). IFN-γ level was insignificant in the infection groups relative to uninfected group ($p<0.05$). IL-1 level similar across the groups. Helminth infection seem to upregulate Th2 immune response among children with symptomatic uncomplicated malaria while there was no significant changes in Th immune response among afebrile children.

1604

BIOSIGNATURES OF NATURALLY ACQUIRED IMMUNITY UNDER CHANGING MALARIA TRANSMISSION IN MALARIA ENDEMIC AREA OF PAPUA NEW GUINEA

Gabriel Frato[1], Leanne Robinson[2], Maria Orme[2], Robert Fort[1], Ivo Mueller[3], James Kazura[1], Peter Siba[2], Christopher L. King[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [3]Walter and Eliza Hall Institute of Medical Research, Parkville, Australia

A simple blood test that assesses levels of naturally acquired immunity (NAI) would provide a critical tool to monitor the impact of interventions to reduce malaria transmission and broaden our understanding of how NAI develops around the world as a function of age and exposure. Since antibodies (Abs) are important in mediating malaria immunity, we postulate when an individual acquires a certain threshold of Abs to panel of malaria antigens (Ags), they become clinically immune to malaria. To examine this hypothesis, we measured immunoglobulin G (IgG) Abs to a panel of 32 ***Plasmodium falciparum*** (Pf) and ***P. vivax*** (Pv) antigens, using a multiplex bead array assay. Samples were collected from two geographically similar cohorts of children aged 5-14 years. The first cohort was completed before malaria control measures (Mugil I, 2004, N=206) and the second cohort was completed following malaria control measures (Mugil II, 2012/13, N=433). Children who were treated with antimalarials at enrollment were observed prospectively for malaria reinfection. High IgG levels to Pf microneme, rhoptry and EBA proteins, which are involved in merozoite invasion of erythrocytes, were strongly associated with protection against clinical malaria, similar to previously published studies from the same cohort. High IgG levels to Pv microneme, rhoptry and some merozoite proteins were significantly associated with protection against Pv infection. IgG levels to almost all the proteins were significantly lower in subjects from the Mugil II versus Mugil I cohorts although some individuals retained high malaria-specific IgG levels associated with protection in the Mugil I cohort. Analysis is currently underway to assess whether individuals that sustained high Ab levels corresponding to the protective threshold found in the Mugil I cohort also confer protection in the Mugil II cohort. These analyses will be completed by the time of the meeting. This study identifies Ags that are possible targets of protective immunity and/or biosignatures of immunity in malaria surveillance and control.

1605

CHARACTERIZATION OF NATURALLY ACQUIRED BINDING-INHIBITORY ANTIBODIES AGAINST *PLASMODIUM VIVAX* DUFFY BINDING PROTEIN IN RURAL AMAZONIA

Sarah Frischmann[1], Vanessa Nicolete[2], Michael Razavi[1], Marcelo Ferreira[2], Christopher King[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]University of Sao Paulo, Sao Paulo, Brazil

Plasmodium vivax (Pv) invades human reticulocytes requiring an interaction of the parasite ligand, Duffy Binding Protein (PvDBPII), with an erythrocyte membrane protein known as the Duffy antigen/receptor for chemokines or DARC. Some Pv exposed subjects acquire functional antibodies that block binding of PvDBPII to DARC (Fy), partially inhibit Pv invasion of reticulocytes ***in vitro***, and correlate with protection against Pv malaria. PvDBPII is highly polymorphic and DARC has a polymorphism which influences PvDBPII binding to DARC. The frequency, persistence, and strain-specificity of these naturally acquired binding-inhibitory antibodies (BIAb) under changing malaria transmission conditions have been poorly characterized. We measured BIAbs from 587 samples from 271 individuals seen 1-8 times in serial cross-sectional surveys, conducted in the Brazilian Amazon between 2010 and 2014, when malaria transmission dropped significantly. 82% of malaria infections were Pv**.** Binding inhibition was measured using an ELISA-based format to look at binding between DARC and multiple PvDBPII variants. Samples with greater than 80% binding inhibition relative to a North American control were defined as high blockers. We found 17% of unique individuals tested had high blocking activity and the proportion of individuals with high blocking activity increased with age. Once high levels of BIAb were obtained, the majority of individuals with repeated sampling retained high blocking activity even in the presence of declining Pv transmission. Some individuals retained high blocking activity with titers as high as 1:640. For most individuals, blocking activity was strain-specific - apparent when samples were titered. The presence of DARC polymorphisms affected acquisition of high BIAbs; 4% of the FyA/Fy- (reduced binding) compared to 16% of all other DARC phenotypes associated with higher binding ($p=0.065$). The presence of high BIAbs may represent a biomarker of naturally acquired immunity in some individuals and may suggest induction of high blocking activity following vaccination with rDBPII, predicting strain-specific protection against Pv.

ANTIBODY SEROREACTIVITY TO *PLASMODIUM FALCIPARUM* ERYTHROCYTE MEMBRANE PROTEIN 1 DOMAINS AND CLINICAL PRESENTATION OF MALARIA IN MALIAN CHILDREN

Jason A. Bailey[1], Amed Ouattara[1], Drissa Coulibaly[2], Matthew B. Laurens[1], Matthew Adams[1], Shannon T. Harrison[1], Kirsten E. Lyke[1], Christopher G. Jacob[1], Jozelyn Pablo[3], Rie Nakajima[3], Aldis Jasinskas[3], Amadou Niangaly[2], Mahamadou A. Thera[2], Ogobara K. Doumbo[2], Philip L. Felgner[3], Christopher V. Plowe[1], Mark A. Travassos[1]

[1]University of Maryland, Baltimore, Baltimore, MD, United States, [2]University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, [3]University of California Irvine, Irvine, CA, United States

A strong correlate for protection from malaria disease has been largely elusive. ***Plasmodium falciparum*** erythrocyte membrane protein-1 (PfEMP1) is a parasite surface adhesion protein implicated in malaria pathogenesis, particularly for placental and cerebral malaria. We probed a diversity-reflecting protein microarray with pre-rainy season sera collected from 75 children one to six years of age enrolled in a malaria vaccine trial in Bandiagara, Mali. The array was populated with protein fragments representing coupled domains of all PfEMP1 proteins in the laboratory reference strain 3D7. Clinical malaria outcome was defined as parasitemia (>2500 parasites per ul) and presence of fever (>37.5C) during

unscheduled clinic visits during 240 days of follow up. Using a Kaplan-Meier survival analysis, children with above-mean PfEMP1 seroreactivity at baseline had a delayed time until first clinical malaria episode versus those with below-mean PfEMP1 seroreactivity. Lower pre-season seroreactivity to PfEMP1 domains was associated with an increased odds of having at least one clinical malaria episode, controlling for covariates. Pre-season PfEMP1 seroreactivity was significantly associated with time to clinical malaria episode in a multivariable Cox proportional hazards model; suggesting that antibodies directed at PfEMP1 may have an association with protection distinct from other malaria antigens. In addition, pre-season seroreactivity to CD36 binding PfEMP1 domains correlated with increased time until clinical malaria episode compared to non-CD36 binding domains. These results suggest the importance of PfEMP1 antibodies in the prevention or delay in the progression of more severe instances of symptomatic malaria, particularly when compared to antibodies directed at other malaria candidate vaccine antigens. Multivariable regression models are particularly powerful in using protein microarray results to identify antigens associated with natural protection against malaria.

INTERFERON GAMMA AND INTERLEUKIN-10 PROFILE IN PATIENTS WITH *PLASMODIUM FALCIPARUM* MALARIA INFECTION IN LAGOS, NIGERIA

Uche T. Igbasi, Wellington A. Oyibo

ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine University of Lagos, Idi-Araba, Lagos, Nigeria

Malaria is the world's most prevalent parasitic disease and is a top public health concern although currently, its control and interventions has been scaled up in Nigeria. Challenges encountered in the design of a successful vaccine against ***Plasmodium*** are our dearth knowledge of protective immunity and how it can be induced. The immune response to ***Plasmodium falciparum*** infection involves interplay between different cell types and cytokines. Therefore, a greater appreciation of the mechanisms of protective immunity and of immunopathology would provide crucial clues as to how manipulation of the immune system may best be achieved. The study aimed to determine the plasma profile of IFN-γ and IL-10 in malaria patient drawn from a ***P. falciparum***-endemic area in Ikorodu LGA of Lagos State, Nigeria. A cross sectional study of 1650 participants who assessed malaria diagnostic services at our study sites (four health facilities at Ikorodu LGA, Lagos State) were screened for malaria by microscopic method using Giemsa stained thick and thin blood films. The plasma level of IL-10 and IFN- γ was assessed among 140 patients who were diagnosed as having ***P. falciparum*** infection and 8 malaria negative subjects, using indirect enzyme-linked immunosorbent assays (ELISA) (MABTECH AB, Sweden). The mean plasma concentration of IL-10 was found to be elevated (6966.8 ±5028.2 pg/ml) in malaria infected individuals compared to the aparasitemic control group 5747.6 ± 3861.7 pg/ml and this was statistically significant ($p<0.01$). In contrast IFN-γ levels were found to be lower in malaria patients (17277.6 ± 12055.8 pg/ml) compared to non-malaria patients tested (23362.4 ± 11341.3pg/ml). There was however a significant relationship between IL-10 and parasite density ($r=0.213$; p value= 0.009); negative correlation between age and parasite density ($r=-0.163$; $p=0.048$). In conclusion, levels of IFN- γ and IL-10 and the relative balance between the pro- and anti-inflammatory cytokines response, illustrates how populations residing in areas of varying disease endemicity may respond to ***P. falciparum***-induced immune challenge.

1608

LIVER STAGE MALARIA INDUCES INTERFERON-DEPENDENT GENE EXPRESSION IN HEPATOCYTES

Jessica Brownell, Alyse Douglass, Nadia Arang, Brandon Sack, Alexis Kaushansky, Stefan Kappe

Seattle BioMed, Seattle, WA, United States

Malaria is a serious global health problem that causes substantial morbidity and mortality in developing countries. Infection is caused by ***Plasmodium*** sporozoites, which are transmitted to a mammalian host through a bite from an infected female ***Anopheles*** mosquito. Sporozoites then travel from the skin to the liver, invade hepatocytes, and quickly replicate to produce tens of thousands of first generation infectious merozoites. These merozoites initiate the blood stage infection that is responsible for symptomatic illness. Live-attenuated sporozoite vaccination can prevent the onset of disease by inducing sterile, adaptive immunity against liver stage infection. However, few studies have explored whether parasite liver infection engenders localized innate immune responses as well. Recent studies in our laboratory have shown that ***Plasmodium*** induces type I interferon (IFN) responses in the liver, and that these responses can protect from a secondary liver stage infection. We show here that these type I IFNs are produced by infected hepatocytes and coincide with the induction of pro-inflammatory Interferon Stimulated Genes (ISGs) such as the chemokine CXCL10 and the anti-viral protein Viperin. Furthermore, we demonstrate that ***Plasmodium*** infection of hepatocytes impacts expression of the JNK signaling pathway in a type I IFN-dependent manner. Future work will help uncover how these initial responses impact inflammatory gene expression, liver stage parasite growth, and the progression to blood stage infection. This knowledge will have significant impact on the selection and use of adjuvants in the future development of vaccines targeting the liver stage of malaria infection.

1609

ANALYSIS OF ANTIBODIES IN LYMPHOCYTE SECRETIONS (ALS) OF MALIAN CHILDREN WITH ACUTE MALARIA REVEALS PLASMABLASTS AND MEMORY B-CELL SUB-POPULATIONS OF DIVERSE ANTIGEN SPECIFICITY

Emmanuel Y. Dotsey[1], Silva Portugal[2], Huw D. Davies[1], Ogobara K. Doumbo[3], Aissata Ongoiba[3], Boubacar Traore[3], Peter Crompton[2], Philip L. Felgner[1]

[1]University of California Irvine, Irvine, CA, United States, [2]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, [3]Mali International Center of Excellence in Research, University of Sciences, Techniques, and Technology of Bamako, Bamako, Mali

During a primary response to an acute infection, naïve B cells are activated in the presence of Follicular Helper T cells within the follicles of secondary lymphoid tissue leading to clonal expansion and affinity maturation to produce antigen-specific memory B cells and plasma cells in the germinal center (GC). Prior to homing into secondary lymphoid tissue, immature plasma cells (plasmablasts) circulate in the blood producing the initial protective antibodies against invading pathogens. After several days, plasmablasts die or differentiate into mature plasma cells which migrate to the bone marrow to become long lived plasma cells. Affinity-matured plasma cells and memory B cells provide the antibody response to subsequent infection by the same pathogen. To evaluate the plasmablast and memory B cell/plasma cell compartments generated after infection in the context of malaria, we employed the ALS assay and proteome microarray. PBMCs and serum samples were collected from Malian children with malaria at day 14 post infection and from malaria-naïve US adults. PBMCs were cultured in media containing stimulatory factors and after 3 days the culture media was removed and replaced with fresh media. PBMCs were then cultured for 3 additional days and final culture supernatants were collected at day 6. Sera and culture supernatants

containing lymphocyte secretions were probed on Pf1000 microarray containing 1000 proteins from ***Plasmodium falciparum*** strain 3D7. Our results show that the antibody profile of 3-day (plasmablast) cultures is a subset of the 6-day (memory B cell/plasma cell) cultures and serum antibody profiles. The results also reveal a sub-population of antibodies present only in the memory B cell/plasma cell compartment and in serum. Our approach successfully illustrates how combining ALS assay and proteome arrays can be used to rapidly profile serum antibody and antibodies in the plasmablast and memory B cell/plasma cell compartments after an acute infection.

SERO-EPIDEMIOLOGICAL EVALUATION OF *PLASMODIUM FALCIPARUM* MALARIA IN SENEGAL

Khadime Sylla[1], Roger Clément Kouly Tine[1], Magatte NDiaye[1], Doudou Sow[1], Aïssatou Sarr[1], Marie Louise Tshibola Mbuyi[2], Ibrahima Diouf[1], Amy Colé Lô[1], Annie Abiola[1], Mame Cheikh Seck[1], Mouhamadou NDiaye[1], Aïda Sadikh Badiane[1], Jean Louis Abdourahim NDiaye[1], Daouda NDiaye[1], Oumar Faye[1], Thérèse Dieng[1], Yémou Dieng[1], Oumar Ndir[1], Oumar Gaye[1], Babacar Faye[1]

[1]University Cheikh Anta Diop, Dakar, Senegal, [2]Département de Parasitologie-Mycologie, Université des Sciences de la Santé, Libreville, Gabon

In Senegal, significance decrease of malaria transmission intensity has been noted the last years. In such a context parasitaemia has become lower and therefore more difficult to be detected by microscopy. In the context of submicroscopic parasitaemia, it has become relevant to rely on relevant malaria surveillance tools to better document malaria epidemiology in such settings. Serological markers have been proposed as an essential tool for malaria surveillance. This study aimed to evaluate the sero-epidemiological situation of ***Plasmodium falciparum*** malaria in two sentinels sites in Senegal. Cross sectional surveys were carried out in Velingara (South of Senegal) and Keur Soce (Center of Senegal) between September and October 2010. Children less than 10 years living in these areas were enrolled using two level random sampling methods. ***P. falciparum*** infection was diagnosed using microscopy. Pf antibodies against Circum Sporozoït Protein (CSP), Apical Membrane Protein (AMA1) and Merozoït Surface Protein 1_19 (MSP1_42) were measured by ELISA method. A stepwise logistic regression analysis was done to asses factors associated with Pf antibodies carriage. A total of 1865 children less than 10 years were enrolled. The overall Pf malaria prevalence was 4.99% with high prevalence in Velingara 10.03% compared to Keur Soce 0.03%. Symptomatic malaria cases (fever associated with parasitaemia) represented 17.37%. Sero-prevalence of anti-AMA1, anti-MSP1 and anti-CSP antibody was 38.12%, 41.55% and 40.38% respectively. The sero-prevalence was more important in Velingara and increased with age, active malaria infection and area of residence. Conclusion: The use of serological markers can contribute to improve malaria surveillance in areas with declining malaria transmission. This study provided useful baseline information about the sero-epidemiological situation of malaria in Senegal and can contribute to the identification of malaria hot spots in order to concentrate intervention efforts.

1611

DEVELOPMENT OF A MICROSCALE INHIBITION OF LIVER STAGE DEVELOPMENT ASSAY FOR *PLASMODIUM FALCIPARUM* AND *P. VIVAX*

Alison E. Roth[1], Steven P. Maher[1], Naresh Singh[1], Jetsumon Sattabongkot[2], Dennis E. Kyle[1], Wajeeh Saadi[3], PATH Malaria Vaccine Initiative, John H. Adams[1]

[1]University of South Florida, Tampa, FL, United States, [2]Mahidol Vivax Research Unit, Mahidol University, Bangkok, Thailand, [3]Draper Laboratory, Tampa, FL, United States

Vaccine development targeting sporozoite and pre-erythrocytic stages of the ***Plasmodium*** parasite is one of most challenging areas in malaria research because biological complexities, such as inadequate methods for ***in vitro*** culture, result in the lack of a functional assay capable of visualizing and quantifying antibody inhibition. This study describes the development of a new type of Inhibition of Liver Stage Development Assay (ILSDA) utilizing cryopreserved sporozoites paired with an ***in vitro*** human liver model based on a microscale platform. Proof of concept is demonstrated in experiments targeting the ***P. vivax*** and ***P. falciparum*** circumsporozoite (CSP) protein with inhibitory concentrations of species-specific anti-CSP monoclonal antibodies. The bioassay was found to be sensitive and efficient, showing the blocking of pre-erythrocytic stages of both ***P. vivax*** and ***P. falciparum*** in a concentration dependent fashion. Additionally, the assay allows for further functional validation as immunofluorescence imaging revealed a potential anti-CSP mechanism involved in the post-invasion inhibition of sporozoite and liver stage development. This study provides an improved ILSDA that can be used to evaluate future drug and vaccine candidates targeting the pre-erythrocytic stages of ***P. falciparum*** and ***P. vivax***.

IDENTIFYING CRITICAL BIOLOGICAL AND IMMUNOLOGICAL ROLES OF GLYCOSAMINOGLYCANS IN THE DEVELOPMENT OF PLACENTAL MALARIA

Louise Randall, Stephen Rogerson, Wina Hasang

Department of Medicine, Melbourne Academic Centre at the Doherty Institute, The University of Melbourne, Australia

During pregnancy, the developing fetus must be protected from the maternal immune system. The maternal immune system is considered to be in an altered or compromised state during pregnancy and this is achieved by factors released by the placenta, including hormones and cytokines. Placental malaria is characterised by the accumulation of ***Plasmodium falciparum***-infected erythrocytes (IE) in the placenta, and results in poor outcomes for both the mother and the fetus, including anaemia, low birth weight and miscarriage. Pregnancy-specific IE bind to the glycosaminoglycan chondroitin sulphate A within the placenta. We hypothesise that chondroitin sulphate containing proteoglycans act as immune system modulators during pregnancy and that the binding of IE to chondroitin sulphate A in the placenta allows the establishment of the initial parasite niche. Here, we show that bovine-derived chondroitin sulphate A dampens the immune response of human peripheral blood mononuclear cells (PBMCs) to IE and bacterial products. In the presence of chondroitin sulphate A, monocytes produced less tumour necrosis factor, had differential expression of pattern recognition receptors and were skewed towards a classical phenotype. We show that proteoglycans derived from human placental tissue also modulate the monocyte response to pathogen products and discuss the implications of the parasite interacting with the placental barrier.

1613

MEASURING ANTIBODY-MEDIATED PROTECTION AGAINST *PLASMODIUM FALCIPARUM* CHALLENGE IN LIVER CHIMERIC-HUMANIZED MICE

Brandon K. Sack[1], Sebastian Mikolajczack[1], Matthew Fishbaugher[1], Ashley Vaughan[1], Judith Epstein[2], Bradley Hickey[2], Eileen Villasante[2], Joanne Lumsden[2], Sharina Reyes[2], Robert Sauerwein[3], Robert Hermsen[3], Stephen Hoffmann[4], Robert Seder[5], Andrew Ishizuka[5], Stefan H. Kappe[1]

[1]Seattle Biomedical Research Institute, Seattle, WA, United States, [2]Naval Medical Research Center, Silver Spring, MD, United States, [3]Radboud University Medical Center, Nijmegan, Netherlands, [4]Sanaria, Inc., Rockville, MD, United States, [5]National Institutes of Health, Bethesda, MD, United States

Immunization with live-attenuated sporozoites has proven to be the most efficacious means of vaccination against malaria parasite infection, yielding complete sterilizing protection in controlled human malaria challenge trials. These encouraging clinical results not only provide a strong rational for development of a live-attenuated parasite vaccine, but enable exploration of immune correlates of protection which further accelerate malaria vaccine development and will inform the design of subunit malaria vaccine candidates. However, there are limited tools available to directly assess contribution of cellular and humoral immune responses to protection. Currently, functional analysis of anti-***Plasmodium falciparum*** sporozoite antibodies is largely limited to ***in vitro*** invasion assays using hepatoma cells, an environment which does not accurately mimic the complex journey of sporozoites from the dermis to the liver parenchyma. Here, we have optimized ***in vivo P. falciparum*** infection in a humanized liver-chimeric mouse model where sporozoite challenge is delivered by mosquito bite and liver stage parasite burden quantified by bioluminescent imaging. This model supports measurement of protection by passive transfer of polyclonal antibodies from individuals immunized with whole sporozoites as well as monoclonal antibodies to individual sporozoite proteins such as CSP. We found this method to be sensitive and reliable in directly detecting varying degrees of antibody efficacy against sporozoite liver infection while allowing for animal survival and simultaneous analysis of parasite progression to blood stage infection. We will present data on the inhibitory activity of serum and IgG elicited by different types of attenuated sporozoite immunizations as well as data for antibodies to specific parasite proteins. The liver-chimeric humanized mouse/challenge model thus constitutes the most physiologically relevant system for analysis of antibody-mediated protection against malaria infection. As such it will accelerate the identification of new antibody targets and the establishment of immune-correlates of protection.

1614

NOVEL SEROLOGIC BIOMARKERS PROVIDE ACCURATE ESTIMATES OF RECENT *PLASMODIUM FALCIPARUM* EXPOSURE FOR INDIVIDUALS AND COMMUNITIES

Danica A. Helb[1], Kevin K. Tetteh[2], Philip L. Felgner[3], Jeff Skinner[4], Alan E. Hubbard[5], Emmanuel Arinaitwe[6], Harriet Mayanja-Kizza[7], Isaac Ssewanyana[6], Moses R. Kamya[7], James G. Beeson[8], Jordan Tappero[9], David L. Smith[10], Peter D. Crompton[4], Peter D. Crompton[4], Philip J. Rosenthal[11], Grant Dorsey[11], Chris Drakeley[2], Bryan Greenhouse[11]

[1]University of California Berkeley/University of California San Francisco, San Francisco, CA, United States, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]University of California Irvine, Irvine, CA, United States, [4]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States, [5]University of California Berkeley, Berkeley, CA, United States, [6]Infectious Disease Research Collaboration, Kampala, Uganda, [7]Makerere University, Kampala, Uganda, [8]Burnet Institute for Medical Research and Public Health, Melbourne, Australia, [9]Centers for Disease Control and Prevention, Atlanta, GA, United States, [10]Sanaria Institute for Global Health and Tropical Medicine/University of Oxford, Rockville, MD, United States, [11]University of California San Francisco, San Francisco, CA, United States

Tools to reliably measure ***Plasmodium falciparum*** (Pf) exposure in populations are needed to guide and evaluate malaria control interventions. Serologic assays can potentially produce precise exposure estimates at low cost; however current approaches, based on responses to a few established antigens, are not designed to detect recent changes or estimate exposure in individuals. Pf-specific antibody responses differ by antigen, suggesting that selection of antigens with defined kinetic profiles will improve estimates of Pf exposure. We tested this hypothesis by evaluating responses to 856 Pf antigens via protein microarray in 186 Ugandan children, for whom detailed Pf exposure data in the prior year were available. Using data-adaptive statistical methods, we identified combinations of antibody responses which maximized information on exposure. Considering individual exposure, responses to three novel Pf antigens accurately classified whether an individual had been infected within the last 30, 90, or 365 days (cross-validated AUC: 0.86-0.93), while responses to another three antigens accurately estimated malaria incidence in the prior year. Considering community exposure, cross-validated incidence predictions provided accurate stratification of exposure between communities and suggest that precise estimates can be obtained from analysis of a single plasma sample from a small subset of the population. In addition, serologic incidence predictions accurately characterized heterogeneity within a community, performing nearly as well as one year of incidence data. Development of simple, ELISA-based assays derived from the successful selection strategy outlined here offers the potential to generate rich epidemiologic surveillance data that will be widely accessible to malaria control programs.

1615

HOUSE STRUCTURE AND SLEEPING ARRANGEMENT AFFECTS BED NET USE IN THE GAMBIA

Susan Dierickx[1], Charlotte Gryseels[1], Julia Mwesigwa[2], Fatou Jaiteh[2], Sarah O'Neill[1], Melanie Bannister-Tyrrell[1], Julia Irani[1], Maya Ronse[1], Jane Achan[2], Umberto D'Alessandro[2], Koen G. Peeters[1]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Medical Research Council Unit, Fajara, Gambia

Although coverage of Long-Lasting Insecticide-treated Nets (LLIN) has steadily increased, a growing number of studies report gaps between net ownership and use. In order to achieve universal coverage and use of LLIN, there is a need to identify those population sub-groups that are least protected. Certain types of housing structures and inside-outside sleeping arrangements may make the attempt to use bed nets difficult. This study aimed to identify risk groups by understanding the relationship between

bed net use, housing structure and inside-outside sleeping patterns in the Gambia. An ethnographic study was carried out in the Gambia between April 2013 and November 2014 in two phases: a first explorative phase in 12 rural villages representing a variety of ethnic groups, and a second phase in which two villages with different traditional housing styles were selected as cases for in-depth analysis. In addition to net availability, net use is affected by housing structure and sleeping patterns inside and outside the house. Children, women and men often rest and sleep unprotected outside their houses during the early evenings. Boys leave the bed of their mother at a younger age compared to girls, and as such are less likely to sleep under LLIN. Boys and adolescent men are particularly at risk because they are not prioritized when allocating nets, are more likely to rest and sleep outdoor in public spaces, and often move between different sleeping spaces. In addition, particular subgroups are unlikely to use their bed nets due to late night activities such as the protection of farms, the herding of cattle, charcoal burning, fishing and hunting. Malaria risk varies substantially between different regions in the Gambia, which could partially be explained by the variable uptake of malaria control interventions such as LLINs. Designing bed nets adapted to the local context and taking into account people's net preference may increase the uptake of LLINs in particular risk groups.

1616

SUPPLY CHAIN MANAGEMENT CONSIDERATIONS FOR LONG-LASTING INSECTICIDE-TREATED BED NETS CONTINUOUS DISTRIBUTION SYSTEMS

Naomi Printz[1], Hannah Koenker[2]

[1]United States Agency for International Development | DELIVER PROJECT, John Snow, Inc., Arlington, VA, United States, [2]Johns Hopkins Bloomberg School of Public Health, Bethesda, MD, United States

Many countries, as part of their national malaria strategy, use a combination of mass distribution of free long-lasting insecticide-treated bed nets (LLINs) and continuous distribution of LLINs through health facilities as a proven intervention to reduce malaria-related morbidity and mortality. LLINs have unique supply chain characteristics that must be considered when implementing continuous distribution systems. Generally, LLINs have long procurement lead times. Because they contain pesticides, their logistics management is often outside malaria medicines and tests. They are extremely bulky, which has implications for attendant storage and inventory management. Expert coordination is required because they may be managed at different points within a facility, and by different cadres of staff. LLINs can be a target for theft, underscoring the need for accountability; as they need to be replaced periodically, their demand is ongoing. The demand for LLINs for campaigns may take priority over LLINs earmarked for routine distribution. Program managers should conduct a logistics system design activity by describing how commodities and information moves through the different levels of the health system. As part of this design, a logistics management information system (LMIS) is included_managers should collect consumption data on LLINs and days out of stock. Reporting and resupply should be linked. To calculate resupply, consumption data and stock on hand data should be used. Accountability of LLINs throughout the supply chain is critical, and information detailing the movement and use of LLINs must be tracked and verified. To accommodate the bulkiness of LLINs, minimal buffer stock should be used to reduce the required storage space; if possible, smaller bale sizes should be procured. System designers should consider the advantages and disadvantages of longer review periods; they must also ensure sufficient and secure storage. The quantification of LLINs for continuous distribution and campaigns should be coordinated; program managers should routinely compare LMIS data and health management information systems data.

1617

INSECTICIDE-TREATED NET DISTRIBUTIONS IN SUB-SAHARAN AFRICA: AN ASSESSMENT OF MASS CAMPAIGNS FROM 2006-2014

Cristin A. Fergus[1], Sadaf Milani[2], Michael Lynch[3], Richard Cibulskis[1], n. Global Malaria Programme, World Health Organization

[1]World Health Organization, Grand-Saconnex, Switzerland, [2]University of Florida, Gainesville, FL, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States

Insecticide-treated mosquito nets (ITNs) are one of the most cost-effective malaria interventions. This aim of this project is to compile and analyze data from ITN distribution campaigns in Sub-Saharan Africa from 2006-2014. A database of ITN distribution campaigns occurring from 2006-2014 was assembled by extracting data from weekly conference calls organized by the Alliance for Malaria Prevention, and supplementing campaign data through a systematic review of published literature. We identified 95 ITN campaigns occurring from 2006 to 2014. The defining characteristics of ITN distribution campaigns were determined to be geographic location, length, targeting, integration, allocation, and delivery system. There were campaigns across all geographic regions of Africa, with the majority in West Africa. The lengths of campaigns were found to be highly varied from a couple days to a few years. Several other common characteristics were noted: campaigns tended to target the general population rather than solely focusing on pregnant women and children under five years old; among campaigns aiming to achieve universal coverage, the most commonly used net allocation formula was one net per two people, although there were several other formulas utilized; and the majority of campaigns directly delivered the ITNs, while few campaigns used voucher schemes. Of the campaigns that reported integrating the distribution with other public health interventions, a majority were integrated with immunization campaigns. The most widely cited problems in planning and implementing campaigns were financial and availability of nets at the time of the campaign. The results of this analysis have highlighted a number of needs pertaining to the surveillance and monitoring of insecticide-treated net distribution for the prevention of malaria. With such a large amount of resources being invested in ITNs as a malaria intervention, there is a need for systematic tracking of campaigns. Assessments of ITN distribution mechanisms should continue, and the results should be incorporated into campaign planning processes.

1618

DEVELOPING NOVEL *IN VITRO* MODELS OF HEME-INDUCED DISRUPTION OF BLOOD-BRAIN BARRIER

Mingli Liu, Carmen Dickinson-Copeland, Hassana Salifu, Jonathan K. Stiles

Morehouse School of Medicine, Atlanta, GA, United States

Background: The blood-brain barrier (BBB) breakdown is the major pathological change of cerebral malaria. The BBB is an active interface which contains cerebral endothelial cells sealed together by tight junctions (TJ), the basement membrane, and pericytes as well as astrocytes. In this study, we tried to develop an ***in vitro*** BBB model based on the culture of human brain endothelial cells (HBVEC) and C6 glioma cells to test the effects of heme on the TJs.Methods: Co-culture (Trans-well): C6 glioma cells were grown in the bottom of the lower chamber which possibly influence the other cells by secreted factors into the media. 24 h later, HBVECs were grown on a filter insert coated with attachment factor for 24 h. After starvation with serum-free medium for 24 h, HBVECs were then treated with 60μM heme for another 24 h. Staining by anti- occluding, claudin and ZO-1 antibodies were visualized using the Alexa-488 fluorescence system. Results: In mono-culture systems, phase contrast images show the spindle shaped morphology o HBVECs in culture. Proteins occludin, claudin-5 are located in the cell membrane, while ZO-1 is located in cytoplasmic region. However the cells are not

capable of forming a continuous line of tight junctions at the cell borders as detected by staining with antibodies against the TJ proteins occludin, ZO-1 and claudin-5. In co-culture systems, transmembrane protein occludin and cytoplasmic protein ZO-1 show a clear and continuous membrane staining, which reveals a line of tight junctions at the cell borders. However, the normal structure of tight junctions is significantly lost after heme treatment. In addition, heme also decreases expression of occludin, ZO-1 and claudin-5, and induces an irregular cell border staining.Conclusions: Data regarding baseline expression of TJ proteins and changes in expression of these proteins in response to heme stimuli can be obtained by using ***in vitro*** co-culture BBB models. These co-culture conditions provide a BBB model that is easy to use to perform histological analysis and permeability test induced by heme.

1619

COMPARISON OF MALARIA DIAGNOSTIC TESTING AND TREATMENT OUTCOMES AT OUTLETS PARTICIPATING IN A PROJECT TO SUPPORT PRIVATE SECTOR RDT ADOPTION IN MBEYA, MOROGORO AND TANGA, TANZANIA: RESULTS FROM CLIENT EXIT INTERVIEWS

Stephen Poyer[1], Emily Gloekler[2], Daniel Michael[2], Stephanie Dolan[1], Nikki Charman[1]

[1]Population Services International, Nairobi, Kenya, [2]Population Services International, Dar es Salaam, United Republic of Tanzania

Tanzania's malaria treatment guidelines state that all suspected cases should be confirmed prior to treatment. By late 2012 RDTs had been rolled out to public facilities nationwide, supported by a comprehensive training plan. As part of an intervention to support increased RDT availability and correct use in the private sector in Tanzania, we conducted client exit interviews at 26 project (intervention) and 26 matched non-project (control) facilities 8 months into the project. The aim was to describe differences in testing and treatment outcomes between the two groups. Eligible outlets were those that offered any diagnostic testing services at the time of interview and eligible clients were adults seeking treatment for fever for themselves or on behalf of someone else. In total, 2,383 clients were screened and interviews were conducted with 1,118 eligible clients. Clients at intervention clinics were slightly less likely to be tested than those at control clinics (89.4% compared to 94.8%, p=0.08), and intervention clinics presented greater clinic-level variation in testing levels (min: 45.1%, max: 100%) than did control clinics (min: 73.3%, max: 100%). Overall, 46.1% of tested clients reported testing positive for malaria, with no significant difference between the groups. 86.8% of test-positive clients received ACT at intervention clinics, compared with 77.2% at control clinics (p=0.3), and less than 5% of test-negative clients received any antimalarial in both groups. The study provides some evidence that when both microscopy and RDTs were available RDT use was more common in intervention clinics (44.0%) than control clinics (25.4%, p=0.09), while microscopy was more common in the control clinics (65.4% compared to 41.5%, p=0.06). Preliminary modelling suggests clients tested by microscopy were twice as likely to receive a positive test result, and that treatment outcomes depended on both test result and type of test. Understanding variations between and within study groups is important to ensure efficient and cost-effective performance improvement steps are taken to improve malaria case management in these private facilities.

QUINAZOLINDIONE SERIES IDENTIFIED FROM TCAMS: A NEW ANTIMALARIAL SERIES WITH POTENTIAL FOR BLOCKING TRANSMISSION OF THE DISEASE

Esther Fernandez-Velando, Malaria DPU, Diseases of the Developing World

GlaxoSmithKline, Tres Cantos, Spain

Nowadays, Malaria is still one of the major global health problems. ***Plasmodium*** has been able to adapt to the different treatments developed by humans along history. However there has not been such a wide knowledge of the illness as we currently have. This fact, joined to the urgent need for novel antimalarial drugs that can replace ACTs and the awareness of governments/health systems/funding agencies, makes the current time a unique opportunity to change the course of this disease and achieve the control and finally the eradication. Using a Phenotypic screening approach, in 2010 GSK published the Tres Cantos antimalarial set (TCAMS) which comprises over 13,533 hits derived from whole cell screening of 2M compounds from the GSK corporate collection against ***P. falciparum***. A clear strategy was required to rapidly identify those molecules that have both the best chance of being converted into differentiated antimalarial drugs and that are also likely to have the lowest risk of attrition in development. Identification of a new class of anti-malarial agents that possess dual activity and are able to inhibit the asexual blood-stage (schizonticidal, responsible of disease symptoms) as well as block transmission was initiated in our group. As a result, a new assay to screen compounds for their potential to inhibit late stage gametocytes was developed and used successfully to screen the output from TCAMS. Quinazolindione series was identified as a very promising family with dual activity (both schizonticidal and gametocytocidal). Initial weaknesses of the series were modest ***in vitro*** and ***in vivo*** potency as well as poor pharmacokinetic profile. After a Lead Optimisation program, Late Leads have been identified having excellent ***in vitro*** and ***in vivo*** potency, a very good developability profile and potential for targeting two different TCPs (Target Compound Profiles). Medicinal Chemistry strategy followed during the Lead Optimisation program was focused on improving the physicochemical and developability properties.

"THERE IS NO FREE HERE, YOU HAVE TO PAY": ACTUAL AND PERCEIVED COSTS AS BARRIERS TO INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY IN MALI

Meredith C. Klein, Emily Hurley, Namratha Rao, Steve Harvey

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

"There is no free here," the words of a Malian husband, illustrate how perceptions of cost can deter uptake of intermittent preventive treatment of malaria in pregnancy (IPTp). Following WHO recommendations, the Malian Ministry of Health (MOH) recommends three doses of IPTp at monthly intervals. However, despite a national policy that IPTp be provided free of charge, only 35% of pregnant women receive at least one dose and less than 20% receive two or more doses. We explored perceptions and experiences of IPTp cost in Mali, and their impact on uptake, using qualitative interviews and focus groups with pregnant women, husbands and mothers-in-law. We also interviewed and observed health workers at four health centers two in Sikasso Region and two in Koulikoro. Despite national-level policies, actual IPTp costs varied widely at our study sites - between regions, facilities, and visits. Pregnant women may pay for IPTp, receive it free, or both at different times. Health centers often charge a lump sum for ANC visits that include both some free and some fee-based drugs and services. This makes it difficult for women and families to decipher which services are free and which require payments. As a result, some forego even free care that, because it is not itemized, appears not

to be free. Varying costs also complicate household budgeting for health care, particularly as women often rely on their husbands or husbands' families for money. While health facilities operating under the cost-recovery model strive to provide free IPTp, their own financial constraints often make this impossible. Preventing malaria in pregnancy depends upon women receiving the recommended doses of IPTp. However, it is clear that both actual and perceived costs are currently barriers to IPTp uptake. Given the confusion around cost of services in the two study regions, more detailed national-level studies of both perceived and actual costs could help inform policy and program decisions promoting IPTp. These studies should evaluate both quantitatively and qualitatively the cost information provided by health facilities and pharmacies to pregnant women and their families.

1622

BENEFICIARY SATISFACTION ASSESSMENT TO GUIDE HEALTH PROGRAM COMMUNICATION AND INCREASE ACCEPTANCE OF INDOOR RESIDUAL SPRAYING

Beth Brennan[1], Allison Belemvire[2], Shadreck Sande[3], Tendayi Muchenje[3], Ben Johns[1]

[1]Abt Associates, Bethesda, MD, United States, [2]United States Agency for International Development, Washington, DC, United States, [3]Abt Associates, Zimbabwe, Zimbabwe

Indoor Residual Spraying (IRS) is considered effective when 85 percent of a community's homes are sprayed. However, there are logistical and educational barriers that affect residents' decisions to accept IRS and a program's ability to fully protect a targeted area from malaria infection. Current behavioral change communication (BCC) efforts for an IRS campaign primarily require paying hundreds of mobilizers to walk long distances to reach residents during work hours, when people are typically not home. BCC efforts seek to highlight the dangers of malaria, the benefits of IRS, and how and when people can prepare their homes for spraying; but, these messages are not universally received. After the 2014 IRS campaign in Zimbabwe, the President's Malaria Initiative-supported (PMI) Africa Indoor Residual Spraying (AIRS) project randomly surveyed 485 households in four IRS districts to assess beneficiary IRS knowledge and satisfaction, and identify locally-preferred methods of IRS messaging. Two thirds of the respondents were females, roughly 43 years old, reporting a high level of IRS and malaria knowledge. However, preliminary findings show that the BCC campaign did not reach all target areas or publicize clearly the IRS schedule. It is crucial to finish an IRS campaign in the fewest number of days possible, since each additional day needed to revisit an unprepared village adds significant costs to the program budget. AIRS Zimbabwe is using the beneficiary feedback to reshape their BCC messaging and improve operational efficiency in 2015. I will present the full findings of the assessment and explain how this activity, a first for the project, can also improve spray coverage in the other AIRS countries.

1623

THE MASS DISTRIBUTION OF LONG-LASTING INSECTICIDE-TREATED NETS IN SOUTHERN PROVINCE, ZAMBIA: HOW MUCH DOES IT COST?

Thandiwe Ngoma[1], Bruce Larson[1], Kafula Silumbe[1], Busiku Hamainza[2], Ketty Ndhlovu[3], Mukumbuta Nawa[4], John Miller[1], Callie Scott[5]

[1]PATH, Lusaka, Zambia, [2]National Malaria Control Programme, Lusaka, Zambia, [3]Zambia Ministry of Health, Lusaka, Zambia, [4]United Nations Development Programme, Lusaka, Zambia, [5]PATH, Seattle, WA, United States

The Zambian Ministry of Health and partners are implementing a package of interventions and surveillance systems in Southern Province in support of the national malaria control and elimination agenda. As part of this package, mass distribution of long-lasting, insecticide-treated nets (LLINs) was implemented in 2014 with the aim of achieving universal coverage of all household sleeping spaces and a net utilization rate of 80%. We estimated the cost of this mass distribution of LLINs in 183 health facility catchment areas (HFCAs) in ten districts in Southern Province. Various partners were engaged at different stages of implementation, which included importing LLINs with delivery to Lusaka, delivery from Lusaka to multiple staging locations in Southern Province, delivery from staging locations to specific HFCAs, and then delivery by community health workers (CHWs) to households in their catchment area. Primary data on unit costs of various resources used during implementation, quantities of resources used, and key programmatic outputs were obtained from programmatic records. The average implementation cost per HFCA in 2014 was US$28,892. Procurement of LLINs and delivery to Lusaka accounted for 54% of the total cost. Other costs included storage, loading, offloading (43%), and labor for CHWs, health facility, and district-based staff (3%). On average, 1,800 households_representing approximately 5,300 sleeping spaces_received LLINs in each HFCA during the distribution. A coverage rate of 80% was achieved. The average cost per sleeping space reached was US$5.45 (US$15 per household reached). These results are preliminary and do not yet include costs associated with training and supervision of implementation. Costs of LLIN distribution and other malaria interventions are useful for budgeting and planning, identifying opportunities to improve program efficiency, and informing additional analyses on the cost-effectiveness and budget impact of different approaches to malaria elimination.

1624

DETERMINING THE OPTIMAL MODE FOR DELIVERY OF SEASONAL MALARIA CHEMOPREVENTION IN MALI

Djirilla Issiaka[1], Amadou Barry[1], Moctar Tounkara[1], Tiangoua Traore[1], Ibrahim Diarra[1], Diakalia Kone[2], Mohamed Keita[2], Issaka Sagara[1], Ogobara Doumbo[1], Erin Gabriel[3], Patrick Duffy[4], Michal Fried[4], Alassane Dicko[1]

[1]Malaria Research and Training Center, University of Bamako, Bamako, Mali, [2]National Malaria Control Program, Bamako, Mali, [3]BRB/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, [4]Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States

Seasonal malaria chemoprevention (SMC), the administration of complete therapeutic courses of antimalarials to children aged 3-59 months during the malaria transmission season, is a new strategy recommended by WHO for malaria control in Sahelian countries with seasonal transmission such as Mali. The strategy is a highly cost-effective approach to reduce malaria burden in these areas. Despite the huge benefit of SMC on malaria infection and disease, the optimal approach to deliver SMC remains to be determined. While fixed-point delivery (FPD) combined with non-directly observed treatment (NDOT) by community health workers is attractive for the SMC implementation, it needs to be evaluated and compared to other modes of delivery. To determine the optimal mode (fixed-point (FPD) vs door-to-door delivery (DDD); directly observed treatment (DOT) vs. non-DOT (NDOT)), 32 villages in four health sub-districts were randomized to receive three rounds of SMC with SP+AQ at monthly intervals using one of the following methods: FPD+DOT; FPD+NDOT; DDD+DOT; DDD+NDOT. The primary endpoint was SMC coverage assessed by cross-sectional survey in 2,132 children at the end of intervention period. Coverage was defined as the proportion of children who received all three days of SMC treatment during the three monthly rounds (primary endpoint). Coverage was significantly higher in children who received SMC using DDD compared to FPD (76.1% versus 62.2%), p = 0.0028). It was similar in children who received SMC using DOT or NDOT (68.2% versus 68.6%; p = 0.95). When the four arms are compared, coverage was highest in DDD+NDOT (77.7%), followed by DDD+DOT (74.5%), FPD+DOT (64.2%) and FPD+NDOT (60.0%), p =0.038. In summary, door-to-door delivery of SMC provides better coverage than FPD. Directly observed therapy, which requires more time and resources, did not improve coverage with SMC.

1625

MDA-A: AN ANDROID-BASED ODK TOOL TO SUPPORT FIELD DATA COLLECTION AND MANAGEMENT FOR A MALARIA MASS DRUG ADMINISTRATION TRIAL IN ZAMBIA

Chris Lungu[1], Benjamin Kayungwa[1], Timothy Finn[2], Thom Eisele[2], John M. Miller[1]

[1]PATH MACEPA, Lusaka, Zambia, [2]Department of Global Health Systems and Development, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

Since 2011, the Zambia Ministry of Health (MoH) has developed time-limited antimalarial treatment campaigns conducted by trained community health workers (CHWs) to reduce the malaria parasite reservoir in an area of Southern Province with current high levels of malaria prevention coverage. These operational research activities focused on mass drug administration (MDA) or focal MDA (fMDA) targeting 60 health facility catchment areas (HFCAs) randomized for participation. Key to monitoring uptake of treatment interventions is collection of intervention data on a large scale across all HFCAs. Data collection tools were developed and have been used by CHWs and enumerators that visit households as part of a cross-sectional campaign or longitudinal cohort study. An application, MDA-a, was developed on an Android platform using ODK survey software. It is used to document data of all eligible household participants including their existing coverage and use of prevention interventions, travel histories, and results from malaria parasite tests. Adherence monitoring to taking DHAp (anti-malaria drug dihydroartemisinin-piperaquine) for mass and focal treatment administration is also done by in-field data exchange among adherence officers accompanying testing pairs. The application monitors the campaign process by the CHW-enumerator pair team and adherence to treatment administered by the testing pair team matched to individuals from a household. We will describe the development of MDA-a, using android-based smart phones at catchment level for large volume data handling, to effectively plan, implement, and monitor MDA activities. The implementation of MDA-a, its functionality, and field use experience during the two rounds of the MDA trial in Zambia will be discussed. Results show that in the first round a total of 35,996 households were involved in the MDA and fMDA arms, with 81% of household members tested for malaria in the fMDA arm, and 89% in the MDA arm. Malaria incidence in these areas was low to modest, with a rapid diagnostic test prevalence of 8.3%.

1626

MASS TESTING AND TREATMENT FOR MALARIA FOLLOWED BY WEEKLY VISITS TO SCREEN FOR FEVER CASES IN LOW TRANSMISSION AREAS IN MATAM AND LOUGA REGIONS, SENEGAL: A PILOT STUDY

Farba Faye[1], Caterina Guinovart[2], Yakou Dieye[1], Badara Cisse[1], Adama Tall[1], Michael Hainsworth[2], Callie Scott[2], Ruben Conner[2], Mame Demba Sy[3], Doudou Sene[3], Souleymane Ba[3], Elhadji Doucoure[3], Tidiane Thiam[3], Ritu Kumar[2], Michael Kalnoky[2], Moustapha Cisse[3], Fatou Ba Fall[3], Mady Ba[3], Duncan Earle[4], Philippe Guinot[1], Richard Steketee[2]

[1]PATH, Dakar, Senegal, [2]PATH, Seattle, WA, United States, [3]Ministry of Health, Dakar, Senegal, [4]PATH, Lusaka, Zambia

Population-wide interventions using antimalarial drugs to decrease the reservoir of ***Plasmodium falciparum*** infection are malaria elimination tools that need further evaluation in different transmission settings. A pilot quasi-experimental study of a malaria mass testing and treatment (MTAT) followed by weekly screening of fever cases was conducted in six health post catchment areas in the districts of Kanel, Linguère, and Ranérou (Senegal). Seven adjacent health posts with similar characteristics and malaria incidences were selected as controls. Villages within the catchment areas were stratified according to the 2013 incidences of passively detected malaria cases, and those with an incidence ≥15 cases/1000/year were targeted for an MTAT early in the 2014 malaria transmission season (September). All households were visited, all consenting individuals were tested with a rapid diagnostic test (RDT), and, if positive, treated with dihydroartemisinin-piperaquine. Following the MTAT, a weekly screening of fever cases, testing (only fever cases were tested), and treatment was conducted in all households throughout the transmission season until end of January 2015. To evaluate the impact of the interventions, the incidence of passively detected, RDT-confirmed malaria cases at the health posts will be compared before and after the intervention and between intervention and control villages. During the MTAT, 1954 (83%) of 2361 total households were visited, 16,583 (86%) out of 19,389 individuals were tested, and of those 1.5% had a positive RDT (ranging from 0.5% to 5.2% by health post). Overall, 44% of infections occurred in households with at least one other infection and 94% of households did not have any RDT positives; 82% of RDT-positive individuals were younger than 20 years old, 72% were asymptomatic (no fever or history of fever in the last 24 hours), and 85% completed treatment. All reported adverse events (9.5% vomited, 3.5% had fever and 0.4% had itching) were mild and tolerable. Results of the impact evaluation, assessment of geographical clustering of infections, and estimates of implementation costs will be available in mid-2015.

1627

REVIEW OF DATA STRENGTHENING PROCESS FOR MALARIA SURVEILLANCE SYSTEM, ZAMBIA

Marie-Reine Rutagwera[1], John Miller[1], Michael Hainsworth[1], Chris Lungu[1], Prudence Malama[1], Kalenga Kakompe[1], Mercy Mwanza[2], Mulakwa Kamuliwo[2]

[1]PATH, Lusaka, Zambia, [2]Ministry of Health, Lusaka, Zambia

A robust, high-quality surveillance system is crucial for the Zambia Ministry of Health to achieve its goal of at least five malaria free zones by 2015. Effective malaria control depends on timely acquisition of high-quality data to efficiently deploy supplies, plan interventions, and focus attention where most needed. To inform action and monitor progress towards this goal, MACEPA supported the Zambia National Malaria Control Program to establish a scalable Rapid Reporting system at health facility and community levels in 2011. This system is currently active in 36 districts and was designed to track malaria outpatient trends, malaria diagnostics, and treatment commodities at health facility and community levels using the DHIS2 mobile reporting platform with low cost mobile phones. Data quality standards to strengthen malaria surveillance are enforced at two levels. Within DHIS2, dashboard charts are used to identify outliers, data validation rules are checked to identify logical errors, and summary reports are run to review completeness and timeliness. At the facility and community levels, routine data quality audits (RDQA) compare data in source documents with reported data on DHIS2. The RDQA approach includes monitoring and technical support (MTS) to discuss key findings, develop data quality improvement action plans, and provide necessary field-level support. The RDQA and MTS approach identifies data to be corrected and reporting procedures to strengthen, provides feedback to community and health facility staff, and promotes capacity building and collaboration across multiple levels of the health system. Factors identified in 2015 that affect reporting completeness and timeliness include staff turnover with poor hand-over procedures, poor network coverage, and damaged or lost phones. Sources of most data quality problems included entering data incorrectly on mobile phones and incomplete aggregation of data from registers. Thus, integration of monitoring and technical support with data audits can provide instant on-site capacity building and promote collaboration between health facility staff and the local health teams.

1628

CASE INVESTIGATION WITH REACTIVE FOCAL TESTING AND TREATMENT FOR MALARIA IN A LOW-TRANSMISSION AREA IN AMHARA REGION, ETHIOPIA

Asnakew Kebede Yeshiwondim[1], Callie Scott[2], Caterina Guinovart[2], Belendia Serda[1], Berhane Tesfay[1], Adem Agmas[1], Belay Bezabih[3], Melkamu Zeleke[1], Girma Guesses[1], Asmamaw Ayenew[1], Worku Workie[1], Elias Asefaw Zageye[1], Pooja Bansil[2], Rick Steketee[2], Asefaw Getachew[1]

[1]PATH, Addis Ababa, Ethiopia, [2]PATH, Seattle, WA, United States, [3]Amhara National Regional State Health Bureau, Bahir Dar, Ethiopia

When malaria transmission is low, investigation of individual cases and neighboring households is a means of identifying and containing the source and spread of infections. Case investigation with testing and treatment for malaria in the case and neighboring households was implemented in ten intervention villages in Amhara Region, Ethiopia during the 2014 transmission season. Intervention villages were purposively selected and matched with control villages based on the incidence of passively detected ***Plasmodium falciparum*** (***Pf***) and mixed malaria cases during the 2013 malaria transmission season. In intervention villages, a passively detected ***Pf*** or mixed index case triggered an investigation that targeted the index case household and up to ten neighboring households in a 100-meter radius. All available household members received a rapid diagnostic test (RDT) and RDT-positive individuals received artemether-lumefantrine (***Pf***, mixed) or chloroquine (***P. vivax*** [***Pv***]). From October to November, 2014, 353 ***Pf*** or mixed index cases were passively detected in the intervention villages. Of these, 209 (59.2%) were investigated; 88.9% were male; 63.5% were aged 20-39 years; and 61.5% spent ≥1 night away from home in the last month, ranging from 0.0% to 96.6% by village. Among the 3,711 residents in the 838 households investigated, 2,923 (78.8%) received an RDT and 121 (4.1%) were RDT-positive (2.4% ***Pf***, 0.6% ***Pv***, and 1.2% mixed). Comparisons between intervention and control villages and estimates of implementation costs will be available in October 2015. In six of ten villages, few index cases and secondary cases were identified, suggesting little local transmission. In three of ten villages, many index cases were identified, most had a history of travel, and few secondary cases were identified, suggesting importation with little local transmission. In one of ten villages, no cases had a history of travel and many secondary cases were identified, suggesting substantial local transmission. To achieve malaria elimination in Amhara Region, intervention strategies targeting these patterns of transmission and population movement are required.

1629

MULTI-COUNTRY ROUTINE DATA QUALITY ASSESSMENT (RDQA) FOR MALARIA INFORMATION

Jeff Bernson[1], Michael Hainsworth[1], Marie-Reine Rutagwera[2], John Miller[2], Chris Lunga[2], Adem Ahmed[3], Melkamu Zeleke[4], Girma Guesses[4], Asmamaw Ayenew[4], Worku Workie[4], Prudence Malama[5], Kalenga Kakompe[5], Mercy Mwanza[5], Mulakwa Kamuliwo[5]

[1]PATH, Seattle, WA, United States, [2]PATH, Lusaka, Zambia, [3]PATH, Addis Ababa, Ethiopia, [4]PATH, Addis Ababa, Zambia, [5]Ministry of Health, Lusaka, Zambia

As National Malaria Control Programs increasingly focus on malaria elimination, real time, accurate, and actionable data are critical to target geographies and populations and to optimize the allocation of resources. The MACEPA project assessed the quality of weekly data captured through a mobile phone application built on DHIS2 in Ethiopia and Zambia over a 24-month period to understand how data quality improvement practices can be strengthened to support system needs for rapid and more focal data. Data was captured from 209 health facility catchment areas across four health zones in Amhara Region, Ethiopia, covering an estimated population of 1.6 million in Ethiopia and 220 facility catchments in Southern Province, Zambia, covering a population of nearly 2 million in Zambia. We used two methods for assessing data quality: applying data validation rules on reported data elements directly in DHIS2 to check for logical inconsistencies and produce performance indicators around reporting, completeness, timeliness, and validity; and applying a routine data quality assessment tool to describe the strengths and gaps in the data management and reporting systems, comparing source data from health facility registries with data reported through the mobile phone-based rapid reporting system. This multi-country approach has produced well documented, promising quality assessment practices and lessons learned along with an opportunity to compare the quality of data from rapid reporting systems in different contexts: varying malaria incidence profiles, different mobile technology, role of data reporters, and levels of support by partners and national health systems, providing insights into factors to strengthen and normalize data quality.

1630

SAIMIRI BOLIVIENSIS AS A MODEL TO STUDY MOSQUITO TRANSMISSION OF *PLASMODIUM VIVAX*

Jennifer S. Armistead[1], Juliana M. Sá[2], Roberto R. Moraes Barros[2], Thomas E. Wellems[2], John H. Adams[1]

[1]Department of Global Health, University of South Florida, Tampa, FL, United States, [2]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Despite the global burden of malaria disease caused by ***Plasmodium vivax***, little advancement has been made to enable the study of this parasite's unique biology. Lack of an ***in vitro*** continuous culture system has made non-human primates (NHPs) a critical model to study ***P. vivax*** asexual and sexual stages, and mosquito transmission. It has also become the main source of intraerythrocytic stages and sporozoites to investigate drug efficacy, liver stage biology, dormant hypnozoite forms, and relapse. Despite the suitability of NHPs for ***P. vivax*** infection, efforts to produce a robust, reliable model of the complete life cycle have been limited, and this invaluable tool remains elusive. Using recombinant progeny from a genetic cross between subpopulations of a ***P. vivax*** line with chloroquine sensitive (VK210) and resistant (VK247) parasites (NIH-1993-S×NIH-1993-R) we are evaluating conditions to maximize production of sporozoites and select an adapted line to complete the parasite life cycle using ***Saimiri boliviensis*** monkeys. Infections initiated via intravenous inoculation of infected erythrocytes varied widely in time to patency and intensity, but parasitemias reaching ~1% were obtained. ***Anopheles freeborni*** and ***An. albimanus*** were found to be the most competent vectors among those tested. Oocyst and sporozoite counts indicated that artificial membrane feeding following serum replacement with human AB^+ serum produced the most intense infections. No correlation was found between the intensity of mosquito infection and parasitemia or gametocytemia. A more sensitive molecular assay to retrospectively correlate gametocytemia and the male:female sex ratio with transmission success is under development. Our findings will provide important information regarding the utility of this New World monkey as a model to study ***P. vivax*** biology, and to facilitate development of novel diagnostics, effective antimalarial drugs and vaccines, which will be indispensible for malaria eradication.

1631

PHASE 1, DOSE ESCALATION, RANDOMIZED CONTROLLED TRIAL TO EVALUATE THE SAFETY, IMMUNOGENICITY AND EFFICACY OF INTRAVENOUSLY ADMINISTERED ATTENUATED *PLASMODIUM FALCIPARUM* SPOROZOITE VACCINE IN TANZANIAN ADULTS: PRELIMINARY RESULTS

Said A. Jongo

Ifakara Health Institute, Bagamoyo, United Republic of Tanzania

A Phase 1 study of PfSPZ Vaccine administered IV at doses ranging from 2,000 to 135,000 PfSPZ in USA showed the vaccine is safe, well-tolerated and immunogenic in malaria naïve population in the U.S. It is important to know early on if there are differences with endemic population. The present double blind placebo controlled trial was conducted at the Bagamoyo Clinical Trials Unit of the Ifakara Health Institute in Tanzania and aimed at demonstrating that doses of 135,000 and 270,000 PfSPZ are safe, immunogenic and effective in African population as in USA. A total of 73 healthy adult male subjects were enrolled according to pre-defined inclusion and exclusion criteria into five groups. The 1st group of 3 volunteers were given 3 ascending doses of 30,000, 135,000 and 270,000 PfSPZ each, at 4 weeks interval for demonstration of safety. The 2nd and 3rd groups had 20 out of 24 subjects per group given 5 vaccinations of 135,000 and 270,000 PfSPZ respectively while 4 out of 24 subjects in each group were blinded normal saline controls. After the 5th vaccination, all subjects in the 2nd and 3rd groups were challenged with controlled human malaria infection (CHMI) at 3 weeks and at 24 weeks. The 4th group had 6 subjects receiving 5 vaccinations of 270,000 PfSPZ and were challenged with CHMI at 24 weeks after the 5th vaccination. The fifth group had 16 subjects who were used as unblinded normal saline controls for 2nd and 3rd groups during the CHMI at 3 weeks (2 subjects per group) and at 24 (6 subjects per group) after the 5th vaccination. The primary outcomes were safety and tolerability after each vaccination as well as protective efficacy after CHMI with PfSPZ homologous Challenge (NF54). Other important outcomes were immune responses after PfSPZ vaccine. Preliminary results suggest that the vaccine given at 135,000 PfSPZ and 270,000 PfSPZ is as safe and well tolerated in Tanzanian adults as in naïve US population. The assessment of efficacy using controlled human malaria infection for the second, third and fourth groups is underway and will be presented. Potential future trials to establish effective dose in different age groups will be also be discussed.

1632

PROTECTIVE EFFICACY OF *PLASMODIUM VIVAX* RADIATION ATTENUATED SPOROZOITES IN HUMAN VOLUNTEERS

Myriam Arévalo-Herrera[1], **Juan M. Vásquez-Jiménez**[2], Andrés B. Amado-Garavito[2], Mary López-Pérez[2], Andres F. Vallejo[2], Angélica Castellanos[2], Nora Cespedes[2], Sergio A. Ochoa-Orozco[2], Michelle Larmat-Delgado[2], Nora Martínez[2], Juliana Henao-Giraldo[2], Karen Molina-Gómez[2], David A. [1]Malaria Vaccine and Drug Development Center and Faculty of Health, Universidad del Valle, Cali, Colombia, [2]Malaria Vaccine and Drug Development Center, Cali, Colombia, [3]Asoclinic Inmunnologia, Cali, Colombia, [4]Centro Médico Imbanaco, Cali, Colombia, [5]Hospital Universitario del Valle, Cali, Colombia, [6]Meridional R&D, São Paulo, Brazil, [7]Malaria Vaccine and Drug Development Center and Caucaseco Scientific Research Center, Cali, Colombia

Immunization of human volunteers with radiation-attenuated sporozoites (RAS) of ***Plasmodium falciparum*** has shown to be highly protective against infectious challenge with live sporozoites. Due to the lack of P.vivax ***in vitro*** cultures, development of a vaccine based on RAS to this species has lagged behind. A phase 1/2, controlled clinical trial was conducted with the aim of assessing the safety, protective efficacy, and immune correlates of protection of immunization with Pv RAS which may guide future vaccine development. Healthy adult volunteers were immunized with Pv RAS (150 ± 10 cGy) through mosquito bites. Duffy positive (Fy+) individuals (n=21) were randomly assigned to either experimental (Exp, n=14) or control group (Ctr, n=7), and received bites from irradiated ***P. vivax***-infected and non-infected mosquitoes, respectively. Additionally, Duffy negative (Fy-) volunteers (n=7) were assigned to a third group and received bites of infected non-irradiated mosquitoes in order to assess the response to non-attenuated parasites. After each immunization, patients were followed-up with clinical assessments and safety laboratory tests. After completing a total of seven immunizations, volunteers were subjected to a ***P. vivax*** sporozoite infectious challenge. A total of 20 volunteers completed the infectious challenge phase (12 Exp, 3 Ctr and 5 Fy-). Exp volunteers received a mean of 430 (362-497) infective Pv-irrad-spz mosquito bites, Ctr, 934 (895-963) non-infective bites and Fy- 442 (358-487) infected non-irradiated bites. All infected volunteers developed symptoms except for one, with a mean incubation period of 9.9 days (range 8-13), and a mean pre patent period 12.6 days (range 11-14). The immunization model with Pv RAS was safe and sterile immunity was achieved in five experimental volunteers (42%) with an average dose of 418 infectious bites and Fy- volunteers remained negative. The overall protection was lower than expected, probably because the planed minimal dose was not achieved in all the volunteers (1000 infective bites). High throughput immune analyses and correlates of protection will be presented.

The oral, intramuscular, subcutaneous (SC) and intradermal (ID) routes are often selected to inoculate humans with antigenic material for the purpose of inducing long term, protective immunity. The intravenous (IV) route, while standard for cellular or humoral immunotherapies and immunoprophylaxis (e.g., hepatitis B immune globulin), has not generally been used. Sanaria and collaborators are now testing the IV route for a vaccine immunogen – whole ***Plasmodium falciparum*** (Pf) sporozoites (SPZ) – to facilitate targeting the liver. Clinical grade vaccine product

was first manufactured in 2008, consisting of aseptic, purified, radiation attenuated cryopreserved PfSPZ meeting FDA standards for parenteral injection (PfSPZ Vaccine). Initial trials showed high-grade (100%) protection against Pf with IV injection through an indwelling catheter (IV line), as previously published, but not when injected by the ID or SC routes (Epstein et al ***Science***, 2011). Because it is impractical to consider immunizing large numbers of individuals by placing an IV line and then injecting through it, and to improve operability for mass administration campaigns to eliminate malaria, direct venous inoculation (DVI) has been developed. A small-bore (25 gauge) needle is inserted, blood "flashback" is documented, and the PfSPZ are injected rapidly. This often painless procedure has been performed 913 times to inject PfSPZ into 305 adults in the US, Germany, Spain, Mali, Tanzania, Gabon and Equatorial Guinea. When used for PfSPZ Vaccine, DVI induces high-grade protection after 3 doses. The injections cause limited local and essentially no systemic reactogenicity, and there have been no allergic reactions or disenrollments due to adverse events. Moreover, injection of infectious PfSPZ (PfSPZ Challenge) by DVI induces Pf infection consistently, and when study subjects receive concurrent oral chloroquine, PfSPZ Challenge given by DVI induces high levels of protective immunity. Based on the excellent safety, tolerability, infectivity and potency record in adults, the first trials of PfSPZ administered to infants and children by DVI will be initiated in 2015.

1634

USE OF FLUOROSPOT ASSAY TO ASSESS IFNG, IL2, AND IFNG PLUS IL2 RESPONSES AGAINST WHOLE *PLASMODIUM FALCIPARUM* SPOROZOITES AND SELECTED ANTIGENS AFTER IMMUNIZATION WITH RADIATION-ATTENUATED SPOROZOITES ADMINISTERED BY MOSQUITO BITES

Harini Ganeshan, Jun Huang, Maria Belmonte, Steve Abot, Arnel Belmonte, Joanne Lumsden, Sharina Reyes, Jo Glenna Banania, Charlotte Fedders, Anatalio Reyes, Yolanda Alcorta, Alicia Simmons, Carlos Vasquez, Santina Maiolatesi, Alexandra Singer, Bradley Hickey, Eileen Villasante, Judith Epstein, Martha Sedegah

Naval Medical Research Center, Silver Spring, MD, United States

In vivo depletion experiments in animals have shown that protective immunity induced by radiation-attenuated sporozoites (RAS) is dependent on CD8+ T cells (mice and non-human primates) and IFNg (mice). Based on results from our previous clinical trial where 50% (5 of 10) of subjects immunized with RAS were protected after controlled human malaria infection (CHMI), the number of bites required to achieve the same level of 50% protection was calculated and used for the current study. Among the 11 subjects who received an average of 1,027 bites over 5 immunization-sessions, 6 were protected after CHMI (55%), allowing for the study of protective immune effector mechanisms and/or surrogate markers of protective immunity. Of the possible 5000 antigens predicted to be present in ***Plasmodium falciparum (Pf)***, the specific antigens involved in protective immunity induced by RAS vaccine is unknown. Using the highly robust FluoroSpot assay that assesses single cells simultaneously secreting two cytokines, IFNg and IL2, we measured T cell responses to purified aseptic sporozoites (SPZ) using freshly isolated peripheral blood mononuclear cells (PBMC) from subjects prior to each of the 5 immunizations, and before and after CHMI. We also assessed T cell responses against overlapping 15-mer peptide pools of four standard ***Pf*** proteins that have been evaluated in clinical trials, including CSP, AMA1, SSP2/TRAP, and CelTOS. All true immunized subjects, but none of the mock immunized, developed IFNg and IL2 T cell responses to SPZ. The highest magnitude and frequency of responses was detected at 28 days post first immunization. At pre-CHMI, there was a trend towards higher magnitude of responses and percent responders in protected subjects vs. non-protected subjects, but this did not reach statistical significance. As expected, responses against the four antigens tested were of lower magnitude and prevalence than the responses against whole SPZ. Interestingly, all pre-CHMI responses decreased in protected and increased in non-protected subjects post-CHMI. A possible hypothesis to explain this finding will be discussed.

1635

CHEMOPROPHYLAXIS VACCINATION (CVAC) OF RHESUS MACAQUES USING *PLASMODIUM KNOWLESI* SPOROZOITES AND THE ANTIMALARIAL DRUG PYRIMETHAMINE: ESTABLISHING A REGIMEN THAT COMPLETELY PREVENTS DEVELOPMENT OF BLOOD STAGES

Agnes Mwakingwe[1], Sara A. Healy[1], Erin Gabriel[2], Irfan Zaidi[1], Lynn Lambert[1], Sachy Orr-Gonzalez[1], Junhui Duan[1], Dariyen Carter[1], Brandi Butler[1], Jen C. Hume[1], Charles Anderson[1], Sumana Chakravarty[3], Stephen L. Hoffman[3], Patrick E. Duffy[1]

Chemoprophylaxis Vaccination (CVac) involves inoculation of ***Plasmodium*** sporozoites under antimalarial drug coverage, and CVac using chloroquine (CQ) has been shown to induce potent and long-lasting immunity in humans and animals. The contribution of blood stage immunity versus liver stage immunity to protection has been a point of controversy. We seek to induce highly effective immunity in humans with CVac regimens that kill parasites during liver stage development thus completely inhibiting exposure to blood stages. We have conducted a study of a CVac drug schedule in Rhesus monkeys. Rhesus macaques were inoculated with 12,500 purified, cryopreserved, ***P. knowlesi*** sporozoites (PkSPZ) by direct venous injection (DVI). Monkeys subsequently received oral pyrimethamine (PYR; 1 mg/kg) treatment, in an attempt to kill liver stage parasites and prevent emergence of blood stage infection. An Up/Down study design was implemented to evaluate the appropriate timing of PYR following PkSPZ DVI. Groups of macaques were dosed with PYR on either days 1, 2 (Group 2, n=4) or on days 2, 3 (Group 3, n=7) post PkSPZ. qRT-PCR and blood smears were performed from day 5 to day 27 post PkSPZ inoculation, to detect subpatent and patent parasitemia respectively. All macaques (n=11) in Groups 2 and 3 were blood smear and qRT-PCR negative at all time points after PkSPZ inoculation. All control macaques that did not receive PYR were qRT-PCR and blood smears positive by day 6 and day 8, respectively. Upon second and third vaccinations, administered 4 weeks apart, all macaques in Groups 2 and 3 remained negative for subpatent and patent parasitemia. Results from homologous challenge (2,500 PkSPZ DVI) to evaluate development of protective immunity will be presented. This study provides evidence that PYR following PkSPZ CVac can prevent blood stage infection in non-human primates, thus guiding the design for an upcoming human trial of CVac with PYR.

1636

SAFETY AND EFFICACY OF DIRECT VENOUS INOCULATION WITH RADIATION ATTENUATED *PLASMODIUM FALCIPARUM* NF54 SPOROZOITES (PFSPZ VACCINE) IN HEALTHY MALIAN ADULTS

Richie[4], Michael Walther[2], Stephen L. Hoffman[4], Patrick E. Duffy[2], Ogobara Doumbo[1]

[1]Malaria Research and Training Center, Mali-NIAID ICER, University of Science, Techniques and Technologies of Bamako, Bamako, Mali, [2]Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, [3]Biostatistical Research Branch, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [4]Sanaria Inc, Rockville, MD, United States

A double blind, randomized Phase 1/2 clinical trial was conducted in Mali, West Africa to assess the safety, immunogenicity and protective efficacy of Sanaria® PfSPZ Vaccine administered via direct venous inoculation (DVI) against natural malaria exposure in healthy 18-35 year old adults. Twelve volunteers (safety group) received 2 doses of PfSPZ Vaccine (Day 0: $1.35x10^5$ and Day 14: $2.7x10^5$) and 88 volunteers received 5 doses of $2.7x10^5$ PfSPZ Vaccine or normal saline (Day 0, 28, 56, 84, 140; total dose of 13.5×10^5). The incidence and severity of local and systemic adverse events occurring within 7 days after each dose were solicited. During the malaria transmission season, volunteers were examined and blood smears obtained every 2 weeks for 20 weeks in total, with the primary efficacy endpoint being time to first positive blood smear. Injection site pain, headache, fatigue, myalgia, and pyrexia were the most frequent solicited adverse events in both vaccine groups. There was no significant difference in local site reactogenicity, solicited systemic adverse events, or laboratory abnormalities between PfSPZ Vaccine and control volunteers. In this adult population, malaria transmission was intense with 93% (41/44) of the control group having at least one positive blood smear. Vaccine efficacy beginning 28 days after the last dose of PfSPZ Vaccine and through the next 20 weeks by estimated by cox proportional hazard 48% (15 , 69) P-value: 0.01 and by proportional analysis was 29% [8, 47], p = 0.006. Immunogenicity, measured by PfCSP antibody responses by ELISA, was not predictive of individuals who remained blood smear negative throughout the transmission season. The study demonstrates that repeated DVI administration of the PfSPZ Vaccine in a healthy adult African population was easy to administer, safe, well tolerated and efficacious in an intense seasonal malaria transmission area of Mali. To our knowledge, this is the highest estimated protective efficacy against Pf parasitemia for 6 month follow-up vaccination of African adults. We are now working on altering the immunization regimen to increase immune responses and protective efficacy.

A MODEL FOR DEPLOYMENT OF CRYOPRESERVED PFSPZ VACCINE FOR FOCAL ELIMINATION OF MALARIA ON BIOKO ISLAND

Eric R. James[1], Adam J. Ruben[1], Aderonke O. Awe[1], Henry Huang[1], José Raso[2], Peter F. Billingsley[1], Thomas L. Richie[1], Ally Olotu[3], Alli Hamad[3], Chris Schwabe[4], Dianna Hergott[4], Carl Maas[5], Marcel Tanner[6], Anita Manoj[1], Betty K. Sim[1], Salim Abdulla[3], Stephen L. Hoffman[1]

[1]Sanaria, Rockville, MD, United States, [2]Ministerio de Sanidad y Bienstar Social, Malabo, Equatorial Guinea, [3]Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, [4]Medical Care Development International, Silver Spring, MD, United States, [5]Marathon Oil Corporation, Houston, TX, United States, [6]Swiss Tropical Public Health Institute, Basel, Switzerland

PfSPZ Vaccine, composed of aseptic, purified, radiation-attenuated, cryopreserved, ***P. falciparum*** (Pf) sporozoites (SPZ) is being assessed in multiple clinical trials in the USA, Europe and Africa. The goal is to finalize a 3-dose regimen that induces high level (>80%), durable (>6 months) protection against controlled human malaria infection and natural exposure by heterologous/heterogeneous Pf parasites. The PfSPZ, being eukaryotic organisms, are cryopreserved and stored and distributed through a liquid nitrogen vapor phase (LNVP) cold chain. The clinical development plan has a goal of licensure by mid to late 2018 for non-immune travelers and early 2019 for use in targeted focal elimination campaigns, for which it will serve as an ideal tool alone or in combination with other control measures. The first campaign is planned for Bioko Island, Equatorial Guinea. Bioko is ~2,000 km^2 and has a population estimated for 2018 of ~300,000, concentrated in the capital, Malabo. The island is accessible by automobile, 95% of houses are currently mapped, and 85% of residents enumerated using a tablet-based Campaign Management Information System. Vaccine will be airfreighted to Malabo in large LNVP dry shippers each containing 5×10^4 cryovials and transferred at a central store to a LNVP cryobank or directly into small LNVP dry shippers for transport to the immunization clinics. Options for vaccinating Bioko's population include fixed clinics, mobile clinics, and door-to-door vaccination. Each will be tested in a trial of 3,000 subjects in 2017. The LNVP dry shippers (free-standing, independent of electricity) will serve both for delivery and for temporary storage on a rotating schedule to fixed or mobile clinics. Each dry shipper will hold up to 1,000 single dose vaccine vials. Plans include immunizing 15,000 people per day and completing each immunization round in 4 weeks. The assumptions and challenges of this and other approaches will be discussed. As the first such focal elimination campaign, Bioko Island will serve as a crucial test of the distribution logistics for PfSPZ Vaccine and as a model for subsequent campaigns.

1638

ASSESSING AND INCREASING THE POTENCY OF *PLASMODIUM FALCIPARUM* SPOROZOITES FOLLOWING CRYOPRESERVATION

Adam J. Ruben[1], Eric R. James[1], Aderonke O. Awe[1], Henry Huang[1], Sumana Chakravarty[1], Michelle Laskowski[1], Enni Fomumbod[1], Soundarapandian Velmurugan[1], Patricia De La Vega[1], Maria Orozco[1], Anita Manoj[1], Sandra M. Riera[2], Sangeeta M. Bhatia[2], B. Kim Lee Sim[1], Stephen L. Hoffman[1]

[1]Sanaria Inc., Rockville, MD, United States, [2]Massachusetts Institute of Technology, Cambridge, MA, United States

Sanaria has a unique capability to manufacture aseptic, purified ***Plasmodium falciparum*** (Pf) sporozoites (SPZ), which are stored in liquid nitrogen vapor phase until clinical use. The effectiveness of thermostabilization is shown by 100% protection of volunteers against controlled human malaria infection (CHMI) after immunization with radiation-attenuated PfSPZ (PfSPZ Vaccine); 100% infection following

injection of infectious PfSPZ (PfSPZ Challenge); and 100% protection against CHMI when chloroquine is given concurrently with PfSPZ Challenge (PfSPZ-CVac approach). These results using cryopreserved PfSPZ, unprecedented in clinical vaccinology, indicate that Sanaria's PfSPZ are potent and infective. They are also concordant with the results of 4 ***in vitro*** assays we use to monitor PfSPZ viability and potency: a membrane integrity assay, 3- and 6-day hepatocyte assays that assess PfSPZ infectivity in hepatocytes, and an axenic culture assay that measures PfSPZ transformation in cell-free culture. By these assays, cryopreservation leads to losses of ~10%, 5%, 5% and 40%, respectively, compared to freshly dissected PfSPZ, while the micropatterned cellular co-culture (MPCC) assay integrates multiple aspects of viability and shows cryopreservation losses of 85% to 90%. These reductions compare very favorably with those of other live vaccine agents after thermostabilization but also indicate that process improvements could enable more efficient manufacturing and lower cost of goods. To this aim, Sanaria has focused on improving 3 areas using Pf, ***P. vivax*** (Pv) and ***P. yoelii*** (Py) SPZ: cryoprotectant additive mixtures, freezing protocols, and thawing methods. Combining several approaches, we have doubled the infectivity and potency of cryopreserved PySPZ ***in vivo***. In the MPCC assay infectivity has been increased by 2- to 3-fold for both PfSPZ and PvSPZ. When integrated into manufacturing processes in the future, these improvements are expected to reduce by 2- to 3-fold the numbers of PfSPZ required to achieve high-level protective efficacy or infectivity after administration of PfSPZ Vaccine, PfSPZ-CVac, or PfSPZ Challenge, respectively.

1639

THEY SAID IT COULD NOT BE DONE: MANUFACTURING PFSPZ VACCINES AT SCALE FOR MALARIA ELIMINATION

B. Kim Lee Sim[1], Anita Manoj[1], Tao Li[1], Abraham Eappen[1], Eric R. James[1], Sumana Chakravarty[1], Adam M. Richman[1], MingLin Li[2], Richard E. Stafford[1], Adam J. Ruben[1], Yun Wu[2], Peter F. Billingsley[1], Stephen L. Hoffman[1]

[1]Sanaria Inc., Rockville, MD, United States, [2]Protein Potential LLC, Rockville, MD, United States

Sanaria® PfSPZ Vaccine and PfSPZ-CVac are highly protective vaccines targeting ***Plasmodium falciparum*** (Pf) that are currently in clinical trials in the US, Europe and multiple countries in Africa. The immunogen comprises aseptic, purified, cryopreserved, metabolically active whole Pf sporozoites (SPZ) attenuated by irradiation or an antimalarial drug. The PfSPZ consortium of international investigators met on March 11-12, 2015 in Germany to develop plans to urgently move these promising PfSPZ vaccines forward. Evidence that such radiation attenuated PfSPZ administered to humans by mosquito bite could confer sterile protection has been available since the 1970s. Why then was this approach not developed as a vaccine? In large part this was due to the misconception that such a vaccine that met regulatory and cost of good standards could not be manufactured. The idea that aseptic mosquitoes, highly infected with PfSPZ, could be reared and the PfSPZs harvested was considered an impossible dream. Compounding this notion was the thought that purifying these PfSPZs and stabilizing them for pharmaceutical use was not possible. Sanaria's manufacturing team has optimized the Pf life cycle in compliance with current Good Manufacturing Practices to obtain >1.5x10^5 infectious PfSPZ/ aseptic mosquito. Nonetheless, there continues to be disbelief that a mosquito can ever be raised as an aseptic organism. Sanaria's aseptic mosquitoes are quality controlled to pass USP<71> sterility tests that are mandated for aseptic manufacture. But how can PfSPZs be harvested from each mosquito salivary gland in a manner that is compatible with GMP at scale? Our operators harvest at average rates of 3 mosquitoes/minute. Thus a single lot of 1x10^3 vials of PfSPZ vialed at 1.5x10^5 PfSPZ per vial requires a team of 6 dissectors working for 2 hours; a yield of 3x10^3doses of PfSPZ-CVac. Our automated dissection intends on harvesting 1 mosquito/sec. Our cryopreservation methodology stabilizes PfSPZ for >4 years. This presentation will de-mystify our manufacturing process and explain the specifics of how we intend to manufacture for Phase 3 clinical trials and product launch.

1640

THE NF54-BASED WHOLE-ORGANISM PFSPZ VACCINE IN THE CONTEXT OF GLOBAL GENETIC DIVERSITY OF *PLASMODIUM FALCIPARUM*: IMPLICATIONS FOR SELECTION OF VACCINE AND CHALLENGE STRAINS

Kara A. Moser[1], Elliott F. Drábek[1], Amed Ouattara[2], Cesar Arze[1], B. Kim Lee Sim[3], Stephen L. Hoffman[3], Judith E. Epstein[4], Christopher V. Plowe[2], Joana C. Silva[1]

[1]Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Sanaria Inc., Rockville, MD, United States, [4]U.S. Military Malaria Vaccine Program, Malaria Department, Naval Medical Research Center, Silver Spring, MD, United States

Genetic diversity in ***Plasmodium falciparum*** (Pf) is an obstacle to broadly efficacious malaria vaccines. The attenuated whole-organism malaria vaccine PfSPZ Vaccine is based on the African strain NF54, the parental stock of the reference Pf isolate 3D7. Controlled human malaria infection (CHMI) trials are underway to replicate initial promising results from homologous CHMI, and to assess heterologous protection using the South American strain 7G8. The degree of genetic dissimilarity between NF54 and strains used in CHMI, as well as to circulating strains in natural populations, can assist in the interpretation of protective efficacy, in the identification of additional challenge strains, and in the determination of whether regional-based or multivalent whole-organism vaccines are needed. To this end, we utilized whole-genome sequencing data from 32 clinical isolates from Africa and southeast Asia (SEA), which we compared with NF54, 7G8, and NF135 (the latter an isolate from SEA and potential vaccine component). We generated SNP calls relative to 3D7 for a panel consisting of ~1 million validated variable positions in protein-coding genes. We identified an average of 4,200, 4,500 and 5,300 SNPs in samples from East and West Africa and SEA, respectively. Similarly to clinical samples from SEA, NF135 differs from 3D7 in 5,280 SNPs, while the difference between 7G8 and 3D7, at 4,722 SNPs, is intermediate between that of African and of SEA samples. With no SNPs called, NF54 is identical to 3D7 in all nucleotide positions in the panel. Principal coordinate analysis using genetic distances between samples showed a clear separation of strains from Asia and Africa according to the first two coordinates, with NF135 clustering with the former. NF54 clustered more closely with strains from West Africa, and 7G8 appears in the periphery of the African clade according to the first four components, suggesting clear differences but close ancestry between them. These results suggest that heterologous challenge studies demonstrating efficacy of PfSPZ in preventing infection against 7G8 would be very encouraging for the prospect of its efficacy in Africa.

MECHANISTIC CHARACTERIZATION OF THE COMPLEMENT RECEPTOR 2 DERIVED PEPTIDE P28 AS A POTENT ADJUVANT FOR VACCINES

Elke S. Bergmann-Leitner, Casey Storme, Heather Hosie, Elizabeth Duncan, Tatyana Savransky, Evelina Angov

Walter Reed Army Institute, Silver Spring, MD, United States

Second generation malaria vaccines are currently being identified with the help of reverse vaccinology, which takes advantage of genome- and proteome-based antigen discovery. Targeting immune responses to antigens expressed on sporozoites ideally impacts the ability of parasites to migrate to the liver and/or infect hepatocytes. The ***Plasmodium*** Cell-Traversal protein for Ookinetes and Sporozoites (CelTOS) plays an essential role in parasite movement in both, mosquitoes and vertebrates, and is required for successful infection. We previously characterized the ability of a CelTOS-based protein vaccine to induce protective immunity in preclinical models using conventional adjuvants. To overcome the

shortcomings plaguing malaria vaccines, ***i.e.***, requirement for large antigen doses and short duration of protection, we employed a peptide adjuvant that has been shown to greatly enhance the immunogenicity of circumsporozoite protein (CSP). The peptide is based on the minimal binding site for complement receptor 2 (CD21) of complement factor C3d. Antigen uptake and activation studies with bone marrow derived dendritic cells revealed superiority of the PfCelTOS-p28 chimeric protein over the wildtype PfCelTOS. Mice were immunized with different doses, containing or lacking extraneous adjuvant (Montanide) to determine the optimal dose of the vaccine for a subsequent challenge with heterologous ***P. berghei*** sporozoites. The cellular analysis revealed a) that significant IFN-γ and IL-4 responses were induced even in the absence of extraneous adjuvant, and b) superiority in the magnitude of the responses compared to the wildtype PfCelTOS. Immunization with 100 fold lower dose of the chimeric protein (0.1 µg PfCelTOS-p28) had a higher efficacy (80%) than immunization with adjuvanted wildtype protein (10 µg). Studies are underway to determine the longevity of the protective response. In conclusion, targeting a protein vaccine to CD21 using this peptide adjuvant can greatly enhance immunity and can also bypass the need for extraneous adjuvant.

THE COMBINED IMPACT OF TRANSMISSION-BLOCKING DRUGS AND RTS,S VACCINES IS SYNERGISTIC?

Ellie Sherrard-Smith, Leanna Upton, Sara Zakutansky, Katarzyna Sala, Azra Ghani, Thomas S. Churcher, Andrew Blagborough

Imperial College London, London, United Kingdom

The Malaria Vaccine Roadmap aims to develop a vaccine that provides 80% protective efficacy against ***Plasmodium falciparum*** by 2020. The most advanced malarial vaccine is currently the pre-erythrocytic vaccine RTS,S which targets the circumsporozoite protein (CSP) and has been shown in clinical trials to reduce the clinical incidence of malaria in children by 46% (range 40 - 77%). It is thought to be most efficacious in regions of low transmission. Methods to reduce mosquito-to-human transmission within a given region prior to vaccine application could enhance the vaccine's overall effectiveness. One approach could be the use of partially effective transmission blocking interventions (TBIs) which aim to reduce human-mosquito transmission. Using mosquito-vertebrate systems we estimate the combined impact of a TBI candidate (atovaquone) and a pre-erythrocytic vaccine (which targets CSP in a similar manner to RTS,S and has an estimated efficacy of approximately 50%) to determine whether the different interventions are antagonistic, additive or synergistic. A mathematical model is developed which captures the population dynamics of the parasite in the mosquito and mouse population and is used to estimate the mosquito-to-vertebrate and vertebrate-to-mosquito transmission probabilities and how they change following the introduction of vaccine. The functional relationship between the probability of blood-stage infection and quantity of oocysts in the mosquito mid-gut does not change with TBI treatment but the number of oocysts is reduced at lower biting rates (and eliminated at 1 or 2 bites after 4 successive generations). The estimated probability of transmission to the vertebrate is therefore lower with TBIs compared to control estimates. We present and discuss the potential benefits of using TBIs with RTS,S-like vaccines to reduce malarial transmission.

1643

A NEWLY ENGINEERED MUTANT OF THE *PLASMODIUM VIVAX* DUFFY BINDING PROTEIN ENHANCES INDUCTION OF BROADLY NEUTRALIZING ANTIBODIES

Francis B. Ntumngia[1], Miriam T. George[1], Edwin Chen[2], Niraj H. Tolia[2], John H. Adams[1]

[1]University of South Florida, Tampa, FL, United States, [2]Washington University School of Medicine, St. Louis, MO, United States

The vital role ***Plasmodium vivax*** Duffy binding protein (DBP) in blood-stage development justifies its consideration as a vaccine candidate. However, similar to other microbial vaccine candidates the polymorphic nature of this ligand represents a serious problem that may compromise efficacy of a DBP vaccine. In particular there is the tendency for immunity to be strain specific. Our hypothesis is that polymorphic dominant B cell epitopes of DBP represent an evasion mechanism to misdirect immune responses away from functional, conserved epitopes. Consistent with this interpretation, the dominant B cell epitopes in DBP are polymorphic surface-exposed motifs adjacent to the dimer interface but these variable residues are generally not important for binding the erythrocyte receptor DARC. To overcome the inherent bias towards strain immunity, we previously evaluated an engineered DBP mutant DEKnull that partially overcame strain-specific immunity. In the current study we have evaluated three additional novel engineered DBP immunogens that altered (1) variant epitopes, (2) functional residues, and (3) residues for dimerization. Each strategy altered the nature of functional antibodies elicited and importantly design #1 induced more broadly neutralizing antibodies against a range of diverse allelic variants. The successful results indicate a potential approach that can be used generally to improve efficacy of other malaria vaccine candidates. Structural studies into these novel antigens are currently underway.

1644

IDENTIFICATION AND CHARACTERIZATION OF NEW *PLASMODIUM VIVAX* ANTIGENS AS POTENTIAL TARGETS FOR PRE-ERYTHROCYTIC VACCINES AGAINST VIVAX MALARIA

Mindy Leelawong[1], Julio A. Ventocilla[1], Karina P. Leiva[1], Emily Smith[2], Kimberly A. Edgel[2], Gissella Vasquez[1], Robert Gerbasi[1], Eileen Villasante[2], Andres G. Lescano[1], Joao Aguiar[2], Geral Christian Baldeviano[1]

[1]U.S. Naval Medical Research Unit - 6, Callao, Peru, [2]Naval Medical Research Center, Silver Spring, MD, United States

Despite the large global burden of ***Plasmodium vivax*** (Pv) infection, there is a dearth of promising vaccine candidates against vivax malaria. Four vaccines have progressed to clinical trials, three of which are based on the abundant sporozoite surface protein, the circumsporozoite protein. To identify additional promising pre-erythrocytic vaccine antigens, data from a high-throughput ***P. falciparum*** (Pf) antigen screening project was used. The most immunogenic proteins were selected based of their ability to induce antibodies and cytokine production in T cells from volunteers immunized with radiation attenuated Pf sporozoites. Two of the Pf proteins, falstatin, a cysteine protease inhibitor, and the gamete egress and sporozoite traversal protein (GEST) are expressed in the sporozoite and liver stages and are capable of inducing protection in a ***P. yoelii*** rodent model. We expressed full-length PvFalstatin and PvGEST using an optimized wheat germ cell-free expression system protocol. Antibodies to both falstatin and GEST were measured by ELISA in individuals naturally infected with ***P. vivax***. Additionally, we assessed the capacity of these proteins to induce cytokine production in T cells from ***P. vivax***-infected individuals living in endemic areas in the Peruvian Amazon. We will present data that indicate that lessons from ***P. falciparum*** antigen discovery may provide a promising and valid platform for identifying potential vivax vaccine candidates.

IMPORTANCE OF CHOOSING THE RIGHT ANIMAL MODEL FOR THE DOWN-SELECTION OF SECOND GENERATION CSP BASED VACCINES

Anthony May[1], Mike Porter[1], Farhat Khan[1], Margot Debot[1], Aziz Qabar[1], Norman Waters[1], Phillipe Saudan[2], **Sheetij Dutta**[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Cytos Biotechnology, Schlieren, Switzerland

Plasmodium falciparum Circumsporozoite protein (CSP) remains the most promising malaria vaccine candidate. We have expressed a near

full-length soluble recombinant CSP in ***E. coli***. The protein contains the conserved N-terminal region, NANP repeats and the C-terminal region of PfCSP. It is widely believed that adjuvanted soluble CSP would not be sufficiently immunogenic to confer protection against parasite challenge and that particulate delivery platforms are a way to overcome this hurdle. We investigated whether conjugating the soluble CSP to a nanoparticle would substantially augment its immunogenicity as compared to adjuvanted soluble CSP. A recombinant capsid protein of bacteriophage Qb that assembles into a 25 nm particle was used as a carrier. CSP was chemically conjugated to the Qb virus-like particle (VLP) and the immunogenicity of the resulting VLP vaccine was tested in C57Bl/6 mice. Alum adjuvanted Qb -CSP induced higher antibody titersthan soluble CSP. Upon challenge with a transgenic ***P. berghei*** parasite that expresses the full-length ***P. falciparum*** gene, the CSP and Qb-CSP vaccines showed high level of sterile protection. The differences between soluble and particulate CSP was most pronounced after the 1st vaccination and particulate presentation most strongly influenced the titers of the repeat region. Since immunogenicity in mice does not always translate to humans we also tested the Qb-CSP and soluble CSP vaccine in the Rhesus monkey model. Unlike mouse data, no significant difference in the immunogenicity of Alum adjuvanted CSP and Qb-CSP was observed in Rhesus. While potent immunogenicity and protection was observed in mice, Alum adjuvanted CSP and Qb-CSP were not highly immunogenic in the Rhesus model. The availability of transgenic parasite challenge strains allows us to use mice as a go-no-go model for vaccine progression, however our data shows that mice may be much more sensitive to Alum based formulations and particulate vaccines than higher primates. Hence Rhesus immunogenicity should remain as the final go-no-go criteria for down-selecting second generation CSP based vaccines for human trials.

1646

BREADTH OF MALARIA VACCINE TARGET ANTIGEN SEROREACTIVITY AND PLACENTAL TRANSFER AMONG MOTHER-NEWBORN PAIRS IN MALAWI

Jenny A. Walldorf[1], Jason A. Bailey[1], Sarah Boudová[1], Titus Divala[1], Randy Mungwira[2], Patricia Mawindo[2], Jozelyn Pablo[3], Algis Jasinskas[3], Rie Nakajima[3], Amed Ouattara[1], Matthew Adams[1], Terrie Taylor[2], Philip L. Felgner[3], Christopher V. Plowe[1], Mark A. Travassos[1], Miriam K. Laufer[1]

[1]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Blantyre Malaria Project, University of Malawi College of Medicine, Blantyre, Malawi, [3]Division of Infectious Diseases, Department of Medicine, University of California, Irvine, CA, United States

In young infants, malaria vaccine efficacy may be inhibited by maternal antibody interference with potential vaccine targets. Little is known about the comparative efficiency of transplacental transfer of antibodies targeting different ***Plasmodium falciparum*** antigen variants and the effect of placental malaria (PM) infection. PM is one of several factors thought to inhibit antibody transfer. We used a protein microarray to assess breadth of seroreactivity to 314 target malaria vaccine antigens in 32 mother-newborn pairs in Malawi. The array included 264 apical membrane antigen 1 (AMA1), 20 merozoite surface proteins (MSP) 1 and 2, and 30 reticulocyte-binding protein homologue 5 (RH5) protein variants. At delivery, maternal peripheral and cord blood samples were obtained. Placentas were inspected for histological and molecular evidence of PM. The categorical definition of seroreactivity was median fluorescent intensity (MFI) 2 standard errors above the mean for 10 malaria-naïve controls for each antigen variant. Of all mothers, 80% (95%CI: 78-81) were seroreactive across AMA1 variants, 75% (95%CI: 70-81) to MSP, and 33% (95%CI: 26-40) to RH5 variants. Breadth of seroreactivity was greater among mothers with evidence of PM than without. Categorical mother-newborn outcomes were concordant in all three antigen groups by McNemar's test while Spearman correlation of continuous MFIs was 0.74, 0.83, and 0.35 for AMA1, MSP, and RH5 respectively. Maternal-newborn correlation results for each antigen group were similar stratifying by PM status. In this pilot study, seroreactivity to RH5 was less prevalent among mothers and less correlated between mothers and newborns than for AMA1 or MSP variants. PM may alter breadth of seroreactivity in mothers and their newborns. Protein microarrays may be a userful tool that will allow us to determine the influence of PM and maternal antibody transfer to the fetus on potential vaccine candidates.

1647

INDUCING BOTH PROTECTIVE ANTIBODIES AND CD8 T CELLS BY PRIME-BOOST WITH LIVE ATTENUATED VACCINE

Sumana Chakravarty[1], Yun Wu[2], Minglin Li[2], Richard E. Stafford[2], Meredith L. Leong[3], Peter Lauer[3], Dirk G. Brockstedt[3], Thomas W. Dubensky[3], Steven G. Reed[4], Chris Fox[4], Shahid M. Khan[5], Chris Janse[5], Ahmed M. Salman[5], Patrick E. Duffy[6], David Jones[6], Stephen L. Hoffman[1], B. Kim Lee Sim[2]

[1]Sanaria Inc., Rockville, MD, United States, [2]Protein Potential LLC, Rockville, MD, United States, [3]Aduro Biotech, Inc., Berkeley, CA, United States, [4]Infectious Disease Research Institute, Seattle, WA, United States, [5]Leiden University Medical Center, Leiden, Netherlands, [6]Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

There are >2x10^8 cases and 6x10^5 deaths due to ***Plasmodium falciparum*** (Pf) annually, despite $2B/yr spent on malaria control. The malaria vaccine, RTS,S/AS01 is safe and delays clinical malaria onset by 30-50% depending on age group. Protection may be primarily mediated by antibodies against the repeat region and some CD4+ T cell responses against the C' terminus of PfCSP. The vaccine does not induce meaningful CD8+ T cell responses. A vaccine for the military and travellers needs to provide >80% protective immunity for at least 6 months. We hypothesize that by adding highly functional, protective CD8+ T cell responses to antibody responses against the PfCSP, such long lived protective immunity can be achieved. We use live-attenuated ***Listeria monocytogenes*** (Lm) as a vaccine platform and use its properties of effectively stimulating robust, multi-functional, cell-mediated immunity, as a result of its intracellular lifecycle and ability to infect, deliver antigen and stimulate DCs ***in vivo***. Our strategy for improving protective efficacy of our recombinant (r) PfCSP vaccine as compared to RTS,S/AS01 is to, 1) Include N'-terminus sequences containing neutralizing antibody and T cell epitopes to diversify and increase potency of the antibody and cellular responses to PfCSP; 2) Conjugate rPfCSP to a carrier protein to increase antibody titers; and 3) Boost with attenuated rLm expressing PfCSP (Lm-PfCSP) to enhance CD8+ T cell responses. We demonstrate that priming with rPfCSP in adjuvant and boosting with Lm-PfCSP induces high levels of PfCSP-specific inhibitory antibodies and CD8+ and CD4+ T cells. Conjugating rPfCSP to a carrier further enhances the antibody response to PfCSP by >8 fold as compared to unconjugated rPfCSP. Most importantly, 100% of mice immunized with adjuvanted rPfCSP and boosted with Lm-PfCSP were protected against sporozoite challenge with a transgenic rodent malaria parasite which express PfCSP in place of PbCSP. The high levels of inhibitory antibodies as assessed by inhibition of liver stage development, impressive ***in vivo*** protection and assessment of long term memory provides impetus for urgent development of this strategy.

1648

RECOMBINANT EXPRESSION, PURIFICATION AND IMMUNIZATION STUDIES OF NOVEL PRE-ERYTHROCYTIC VACCINE ANTIGENS IN THE *PLASMODIUM YOELII* MOUSE MALARIA MODEL

Daniel Shaji, Charles Anderson, Weili Dai, Solomon Conteh, Dariyen Carter, Lynn Lambert, Nicholas MacDonald, Emma K. Barnafo, Kelly Rausch, Andrew Orcutt, Sarah Brockley, Holly Torano, Patrick E. Duffy

Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

The pre-erythrocytic (PE) stage is a metabolically highly active but symptomatically silent preparatory phase of the ***Plasmodium*** life cycle. Intervening to kill the parasite at this stage prevents the symptomatic blood stage of infection, and is an attractive vaccine target. Using microarray analysis and DNA vaccination, 8 genes were previously identified as up-regulated in Liver Stage parasites and able to induce partial protective immunity against PE infection. For further studies of these vaccine candidates, we prepared their ***P. yoelii*** orthologues as recombinant proteins. Five genes were expressed as recombinant protein with C terminal His tag in insect cells. Proteins Py370w and PyMIF4 were in soluble form when expressed in insect cells and could be purified under native conditions using Ni-NTA column. Proteins PyMAL7, PyLISP1 and PySHMT were initially insoluble and were purified under denaturing conditions in presence of 6M GuHCL and subsequently refolded using appropriate buffer conditions. Prior to formulation with adjuvants, the refolded PyMAL7 and PyLISP1 proteins were then passed over detergent removal column to remove detergent present in the refolding buffer, and detergent from refolded PySHMT was removed by passing over a second Ni-NTA column. Proteins PySAP1, Py1995c and Py305w were expressed and purified from ***E. coli*** under denaturing conditions and the proteins refolded using appropriate buffer conditions. Immunization studies of these proteins have been initiated in mice, and details of the results will be presented.

1649

ROLE FOR CHEMICAL CONJUGATION TO ENHANCE THE BREADTH AND QUANTITY OF *PLASMODIUM FALCIPARUM* RECOMBINANT CIRCUMSPOROZOITE PROTEIN-SPECIFIC ANTIBODIES

David L. Narum[1], Joan Aebig[1], Kelly Rausch[1], Randall F. Howard[2], Charles Anderson[1], Darrick Carter[2], Lynn Lambert[1], Steve G. Reed[2], Patrick Duffy[1], David Jones[1]

[1]National Institutes of Health, Rockville, MD, United States, [2]Infectious Disease Research Institute, Seattle, WA, United States

The circumsporozoite protein (CSP) remains a significant vaccine target due to the success of RTS,S. The antigenic component of RTS,S is comprised of about two-thirds of the native CSP including the immunodominant NANP repeat region and the thrombospondin repeat-like (TSR) domain fused to the hepatitis B surface antigen. We and others have recently shown that the N-terminal region of the CSP is also a target for antibody blockade of hepatocyte invasion. Furthermore, we observed that in Anopheles mosquitoes, a fragment of approximately 70 amino acids is cleaved from the N-termini and then within the salivary gland the CSP changes its shape to protect both the N- and C-terminal regions against antibody recognition prior to hepatocyte invasion. Thus, our development efforts have focused on the evaluation of two recombinant forms of the CSP, one mimicking the unprocessed form or full-length protein (EcCSP) and the other mimicking the cleaved form (PpCSP) identified in salivary gland sporozoites. The N-terminus of CSP is poorly immunogenic compared to the NANP repeat region and the TSR domain. This was observed regardless of the adjuvant formulation tested (Alhydrogel, oil-in-water stable emulsion or liposome), as determined by ELISA against synthetic peptides or region-specific recombinant polypeptides using sera from two rhesus monkey trials and multiple mouse studies in which immunization with either monomeric forms or chemical conjugates to ExoProtein A or other carriers was examined. To date, chemical conjugation of a recombinant CSP to a carrier protein formulated in an adjuvant other than Alhydrogel has provided the best evidence for enhancement of the breadth of the antibody response to include the processed N-terminal region as well as a 5 - 100 fold increase in the overall CSP-specific response in mice. These preclinical results are significant in context to the rationale design of a second-generation CSP vaccine.

1650

LIMITED EFFICACY OF RTS,S VACCINE AGAINST MALARIA MAY BE ATTRIBUTED TO LACK OF T CELL EPITOPE CONSERVATION

Andres G. Nunez[1], Ryan Tassone[1], Lauren Levitz[2], Jonathan J. Juliano[2], Steven Meshnick[2], Frances Terry[3], William D. Martin[3], **Anne S. De Groot**[1]

[1]University of Rhode Island, Providence, RI, United States, [2]University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, [3]EpiVax, Providence, RI, United States

In a recent clinical trial, the RTS,S vaccine against malaria achieved efficacies of 55.8% and 31.3% for protection against the first clinical episode in children (5-17 months) and infants (6-12 weeks), respectively. While promising, these results leave much room for improvement. One reason for the limited success of RTS,S may be that the strain of circumsporozoite protein (csp) included in the vaccine is poorly representative of circulating strains in endemic areas. Using sequences from 57 unique csp variants collected in Liongwe, Malawi, we applied a novel informatics algorithm called EpiCC (Epitope Content Comparison) to determine relatedness among variants at the T cell epitope level. EpiCC uses HLA-DR binding predictions generated by the EpiMatrix tool to quantify the likelihood that a candidate vaccine strain will induce protection against other strains, based on the nature and similarity of their T cell epitopes. According to EpiCC, the csp strain included in RTS,S had a low degree of T cell epitope relatedness compared to the other variants. The relationships among the variants at the T cell epitope level differed from the phylogeny of the whole genome in many cases. If the csp T cell epitopes in the RTS,S vaccine are not well conserved among the strains found in malaria-endemic areas, the vaccine may only confer partial protection. Lack of epitope coverage may explain why RTS,S has not achieved better efficacy in clinical trials. This concept can be broadly expanded to sample data over multiple malaria-endemic areas. EpiCC may provide an objective approach to aid in strain selection for vaccine development.

PRELIMINARY RESULTS OF A RANDOMIZED, CONTROLLED, DOUBLE-BLIND, SINGLE-CENTER PHASE 1 CLINICAL TRIAL TO EVALUATE SAFETY, TOLERABILITY, IMMUNOGENICITY AND EFFICACY OF CAF01 AND ALUMINUM HYDROXIDE AS ADJUVANTS FOR THE MALARIA VACCINE CANDIDATE GMZ2 IN HEALTHY ADULT AFRICAN VOLUNTEERS

Ulysse Ateba Ngoa[1], Ayola Akim Adegnika[1], Jean Claude Dejon Agobe[1], Marguerite Massinga-Loembe[1], Michael Theisen[2], Peter G. Kremsner[3], Benjamin Mordmüller[4]

[1]Centre de Recherches Médicales de Lambaréné/Albert Schweitzer Hospital, Lambaréné, Gabon, [2]Statens Serum Institut, Copenhagen, Denmark, [3]Institut für Tropenmedizin, Tübingen, Germany, [4]Institut für Tropenmedizin, Tübingen, Germany

GMZ2 is a malaria vaccine candidate consisting of conserved domains of the two ***Plasmodium falciparum*** asexual blood-stage antigens merozoite

surface protein 3 (MSP3) and glutamate rich protein (GLURP). The antigens were selected based on sero-epidemiological and functional studies and showed excellent safety, tolerability, and immunogenicity in pre-clinical studies when adjuvanted with aluminium hydroxide. The vaccine candidate GMZ2/aluminum hydroxide has been clinically developed up to Phase 2. Results of a Phase 2 trial in African children are still pending but preliminary data support the very good safety and tolerability profile of GMZ2. In general, data from the four trials suggest that improved formulations may result in stronger efficacy and a vaccine with potential health benefits. Therefore, combination of GMZ2 with a more potent adjuvant is the rational next step in the clinical development. CAF01 is a novel adjuvant, which has demonstrated good safety, tolerability and improved immunogenicity profile when combined with various vaccine candidates. The current GMZ2/CAF01 study is performed to compare safety, tolerability, immunogenicity and efficacy of GMZ2 formulated with CAF01 to a control vaccine (Rabies) and 100 µg GMZ2 in aluminium hydroxide, the best studied GMZ2 regimen so far. The study has started in April 2015. A total of 50 participants were randomized and received vaccinations. Participants receive three times control vaccine (n = 8; Group A), 100 µg GMZ2 formulated in alum (n = 12; Group B), 30 µg GMZ2 formulated in CAF01 (n = 8; Group C) or 100 µg GMZ2 formulated in CAF01 (n = 22; Groups D and E). Five weeks after completion of the vaccination regimen participants of groups A, B, C and D will receive a direct venous inoculation of 3200 PfSPZ Challenge to test for the efficacy of the vaccine. Follow up of the study participants will end six months after the administration of the last vaccine injection. We will report the result of the preliminary analysis of the GMZ2CAF01 study. The safety profile, the tolerability as well as the efficacy of the GMZ2 candidate vaccine formulated with CAF01 will be discussed.

1652

SEASONAL MALARIA CHEMOPREVENTION IMPLEMENTATION IN CHILDREN FROM THREE TO 120 MONTHS EXPERIENCE IN THE FOUR SOUTHERN REGIONS IN SÉNÉGAL

Mamadou L. Diouf, Medoune Ndiop, Mady Ba, Julie Twing, Ibrahima Diallo, Moustapha Cisse, Seynabou Gaye, Alioune Badara Gueye, Mame Birame Diouf

Ministry of Health, Dakar, Senegal

Because malaria still remains a major cause of disease and death in infants and children, NMCP strives to reduce drastically these morbidity and mortality among children. For this aim, Seasonal malaria chemoprevention (SMC) is adopted as a new intervention in malaria control policy after a long process launched in March 2012. According to WHO criteria the target areas for SMC are the four regions mentioned above. Drugs administration lays on door to door campaign strategy with community volunteers. On the first day, the volunteers, trained by health agents in health facilities, administer drugs to the children under surveillance of mothers or children guardians. For the 2 remaining days, mothers have to substitute to the volunteers. In 2014, SMC Campaign CPS was conducted in the four areas with three cycles covering the higher transmission season (August, September and November). The target was enlarged to the old children from 3 to 120 months (624 139). This enlargement of the target, compared with WHO recommendations (3 to 60 months,) was due to vulnerability sliding towards the ages from 60 to 120 months as shown by the epidemiologic data on malaria morbidity in Senegal. The campaign results were very satisfactory since the coverage rates for the 3 passages, are respectively 98, 63%, 97, 85% and 98, 04%. However, it should be noted that behind these beautiful coverage rates, many challenges have to be faced to achieve such results. Indeed, considering the innovation of the intervention, its and and the strong Community component, it was necessary to set up an operative system allowing an availability of the commodities, management tools supports and accessories on the sites and to prepare the actors to roll the strategy as recommended. In addition, regular coordination and a follow-up with an effective data collection and transmission system, was one of the key-success elements. Significant communication activities had accompanied all the process. In parallel, pharmacovigilance system strengthening was set up because of the characteristic of the drugs used and the relatively important quantity administered to children within such a short time.

1653

FIELD TESTING OF A PYRETHROID QUANTIFICATION KIT IN VILLAGES COVERED BY INDOOR RESIDUAL SPRAY IN MULEBA, TANZANIA

Lauren Wright, Harparkash Kaur, Natacha Protopopoff, Mark Rowland

London School of Hygiene & Tropical Medicine, London, United Kingdom

Insecticide treated nets (ITN) and indoor residual spraying (IRS) are two of the primary methods of malaria prevention in Africa. In order for these methods to be effective it is essential that adequate concentrations of insecticide are present on nets and wall surfaces to kill mosquitoes. There is no easy assay to quantify insecticide levels without expensive laboratory equipment and procedures. To address this, LSHTM has developed a simple field-applicable kit for monitoring pyrethroid residues on insecticide-treated nets- the Pyrethroid Quanitification Kit (PQK)-which can be adapted to other types of treated surfaces. During the initial trial the PQK kit was calibrated against a variety of sprayed surfaces and with different concentrations of lambdacyhalothrin before being taken into the field. Mosquito cone bioassay was conducted to show whether the surface concentrations of insecticide detected by the PQK were sufficient to kill a susceptible strain of mosquitoes. Houses in six villages were visited 3 months after IRS had been conducted in Muleba, Tanzania. The samples were analysed in the field using a handheld spectrophotometer. In each house, five areas of the wall were examined to give an indication of insecticide distribution and within-wall variation. Results showed that the actual spraying results differed from expectation. Preliminary results showedthat only 28% of houses had all rooms sprayed, leaving 72% of houses partially sprayed, and insecticide concentration varied dramatically across sprayed walls. The PQK is an easy to use quality assurance tool for monitoring of pyrethroid application rates and improving the quality of IRS campaigns.

1654

MULTIPLE PYRETHROID INSECTICIDES RESISTANCE MECHANISMS IN *ANOPHELES GAMBIAE* S.S. FROM MALARIA SURVEILLANCE SITES IN NIGERIA

Samson T. Awolola[1], Adedayo Oduola[2], Adedapo Adeogun[1], Abiodun Olakiigbe[1], Monday Tola[3]

[1]Nigerian Institute of Medical Research, Lagos, Nigeria, [2]Department of Zoology, University of Ilorin, Kwara State, Ilorin, Nigeria, [3]Nigerian Institute of Medical Research/University of Lagos, Lagos, Nigeria

Insecticide resistance in ***Anopheles gambiae*** sensu stricto is a major concern to malaria control. Resistance is mainly due to target-site insensitivity arising from a single point mutation, often referred to as knockdown resistance (kdr). Metabolic-based resistance mechanisms associated with elevated level of monooxygenase and Glutathione-S-Transferase (GST) have also been implicated but to a lesser extent. Here we report the co-existence of both resistance mechanisms in populations of ***An. gambiae*** s.s. from malaria surveillance sites in Nigeria. Anopheles larvae were collected from 12 malaria surveillance sites located in 3 ecological zones (north-central, south-west and south-south) in Nigeria. All ***Anopheles*** tested belonged to the ***An. gambiae*** complex. ***An. gambiae*** s.s. was predominant (82.5%) and found at the 12 sites. ***An. arabienis*** represented 17.2% but found at 3 sites. Mosquitoes from three sites located in the south-south and north-central were 100% susceptible to pyrethroid insecticides (permethrin and deltamethrin). Mosquito susceptibility level to pyrethroids was 55-70% at the remaining sites. Bioassay, synergist and biochemical analysis carried out on resistant and susceptible ***An. gambiae*** s.s. from the 12 sites revealed 35-60%

of the West African kdr mutation in the resistant mosquitoes. Resistant mosquitoes synergized using pyperonyl butoxide before insecticide exposure showed a significant increase in mortality compared with the non-synergized. Biochemical assays showed significant increased levels of monooxygenase activities in the resistant mosquito at six sites in addition to significant increased in GST level at two sites, indicating the presence of multiple pyrethroid resistance mechanisms at these malaria surveillance sites. This current survey of insecticide resistance in ***Anopheles*** provides baseline for resistance monitoring and highlights the need for routine resistance surveillance as an integral part of malaria control.

1655

INTERMITTENT PREVENTIVE TREATMENT IN PREGNANCY: INCREASING THE DOSES IN BURKINA FASO

Ousman Badolo[1], Stanislas P. Nebie[1], Mathurin Dodo[1], Thierry Ouedraogo[1], Rachel Waxman[1], **William R. Brieger**[2]

[1]Jhpiego, Baltimore, MD, United States, [2]Johns Hopkins University, Baltimore, MD, United States

In Burkina Faso, Antenatal Care (ANC) is a national platform for malaria in pregnancy prevention and control. The 2010 Demographic and Health Survey showed a good initial ANC registration rate (95%), but over 56% of pregnant women in rural areas do not register until their second or third trimester. Thus they may have missed the full regimen of ANC services including Long Lasting Insecticide-treated nets and intermittent preventive treatment of malaria in pregnancy (IPTp). In 2010 only 10.6% of pregnant women nationally and 8.4% in rural areas received two doses of IPTp. The United States Agency for International Development-supported Improving Malaria Care (IMC) project in Burkina Faso has been providing technical assistance and training to health districts and their ANC staff on implementing updated (2012) WHO IPTp guidelines. The recommended provision of IPTp at every ANC visit from the 13th week of pregnancy onward leads to the possibility of 3 or more doses per woman. The new guidance was incorporated into the update of Burkina Faso's malaria strategy and has been disseminated since September 2014. Annual data from the Health Management and information System for 2014 from three districts (Batie, Po and Ouargaye) and 61 health clinics where IMC has been working were collected and summarized. A total of 26,909 women registered for ANC. Of these 89.7%, 73.2% and 39.8% attended ANC twice, three and four times respectively. Of those registered 84.1%, 73.2% and 18.8% received IPTp once, twice and thrice. Eleven (17.7%) had not started the updated IPTp guidance. The Ministry of Health also experienced stock-outs of sulfadoxine-pyrimethamine. Based on this slow implementation and uptake of IPTp3+, the IMC project in collaboration with the National Malaria Control Program is examining ways to strengthen antenatal malaria prevention including capacity building for ANC staff and community IPTp provision.

1656

USE OF LONG-LASTING INSECTICIDE-TREATED BEDNETS IN AKWA IBOM STATE NIGERIA AFTER A MAJOR DISTRIBUTION CAMPAIGN

Enobong U. Ndekhedehe[1], John Orok[2], Bright C. Orji[1], **William R. Brieger**[3]

[1]Jhpiego, Baltimore, MD, United States, [2]Ministry of Health, Akwa Ibom State, Nigeria, Uyo, Nigeria, [3]Johns Hopkins University, Baltimore, MD, United States

While long lasting insecticide-treated nets (LLINs) have made a major dent in the incidence of malaria in Africa, LLINs need to be replaced at intervals. Akwa Ibom State Ministry of Health conducted a mass net distribution in 2010 during which 1.8 million LLINs in the 31 local government areas (LGAs/Districts). An estimated 2.7 million nets were acquired with Global Fund support for replacement distribution in November and December 2014. To learn about the outcome of the exercise, the Ministry organized a follow-up household survey in all LGAs in January 2015. The state formed a technical working group which developed a checklist and interview guide to gather follow-up information on number of households that acquired nets, hung nets, slept under nets, their reasons for not using nets and sources of information about nets. Interviewers from each LGA were trained to use the checklist and recognize appropriate net hanging and use. Twelve interviewers were assigned to each Ward of each LGA. A total of 2,696,476 net cards were issued to households based on two nets per household, and 2,626,966 nets (97.4%) were redeemed. Retention rate in sampled households was 97.1%, while hanging rate of those retained was 71.8%%. Overall 69.6% household members reported that they slept under a net the previous night. A greater proportion of pregnant women (92.1%) reported using nets compared to children below 5 years of age (82.3%) and other household members (63.3%). Main reasons for not using nets included feeling hot (44.5%), inability to hang the net (19.7%) and concern about the chemical used to treat the net (11.4%). Akwa Ibom is located in Nigeria's highest malaria transmission zone. Hence there is need to use LLINs throughout the year. In contrast between 2013 DHS (14.1% residents slept under LLIN) and current results is stark and implies that net use may likely decline as nets age. Even 1-2 months out from a campaign there are people who are not hanging and using nets. Continuous systems for community level education and reinforcement and health system-based routine distribution for periods between campaigns are needed.

1657

LLIN DISTRIBUTION CAMPAIGN PROCESSES: LESSONS LEARNED AND CHALLENGES FROM AKWA IBOM STATE, NIGERIA

John Orok[1], Bright Orji[2], Enobong Ndekhedehe[2], **William R. Brieger**[3]

[1]Ministry of Health, Akwa Ibom State, Uyo, Nigeria, [2]Jhpiego, Baltimore, MD, United States, [3]Johns Hopkins University, Baltimore, MD, United States

Long Lasting Insecticide-Treated Nets (LLINs) protect users from malaria only if they reach the home. A smoothly functioning distribution is essential to ensure nets reach their end users. Routine distribution at clinics helps to maintain supplies, but mass campaigns are also needed to replace nets on a wide scale. The recent LLIN mass campaign in Akwa Ibom State Nigeria offers lessons and challenges on this process. A State support team was set-up and estimated the total nets needed on one net to 2 people. A total of 21,167 different cadres of personnel were recruited from supervisory to outreach jobs. One-day training was conducted in batches in each of the 31 Local Government Areas (LGAs). To begin household mobilizers issued net cards and registered household members Town announcers helped in demand creation. A private firm was hired bring 2,715,160 nets to 1,242 delivery points. A reporting tool tracked and monitored the distribution process. Reports flowed from the distribution points to the Ward supervisor, the LGA team leader and on to the state technical support team. The State team met at the end of each day to review activities and address challenges and re-strategize. The distribution lasted from 18-22 December, 2104. Overall, thirty-five thousand households were mobilized, and no settlement was reported omitted. 2,715,160 nets were distributed, and 88,049 nets remained in the LGAs, while 23,080 were left in the central store for mob-up. Unfortunately 145 50-net bales were missing. Mobilization led to active involvement of the faith-based leaders, traditional rulers and members of the national youth service corps scheme. Despite advocacy, state political officials focused more on upcoming elections that the net distribution. Although demand was created and short term need was met, more attention is needed to longer term use and supplies for routine services. The remaining supplies unfortunately were affected by security lapses and lost nets and may not serve the needs of complimentary routine distribution. The State needs to assess the long term costs and sustainability of such massive efforts in terms of meeting its malaria control needs.

SUSCEPTIBILITY STATUS OF *ANOPHELES GAMBIAE S.L.* TO INDOOR RESIDUAL SPRAY INSECTICIDES FROM A SIX SITE BIENNIAL SURVEY PROJECT, UGANDA, 2009-2013

Michael Okia[1], Ranjith de Alwis[1], John Rwakimari[1], James Kirunda[1], Betty Mpeka[1], Denis Ambayo[1], Constantine Muwonge[1], Kenneth Ssaka[1], David Hoel[2], Claudia Corredor-Medina[2], William G. Brogdon[2]

[1]Abt Associates, Inc., Kampala, Uganda, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

Insecticide resistance threatens vector control interventions in Uganda, past studies having shown the development of resistance in Ugandan vector populations. We followed up on the 2009 national insecticide susceptibility study to investigate possible changes in susceptibility levels in ***Anopheles gambiae s.l.*** to DDT, six pyrethroid, two organophosphate and two carbamate insecticides collected from six sentinel surveillance sites across Uganda in 2011 and 2013 using the WHO bioassay test kit. Resistance to DDT (mortality <90%), occurred in Wakiso, Tororo and Kanungu Districts. In Apac and Kitgum Districts where IRS using carbamate insecticides occurred the prior three years, mortality to DDT was 91.5% and 94%, respectively. There was reduced mortality in ***An. gambiae s.s.*** to almost all pyrethroids tested from the six sites except for etofenprox in Kitgum District (92%). Mortality rates >98% were observed in ***An. gambiae s.s.*** populations to both organophosphate and carbamate insecticides across all test sites, except for propoxur in Tororo (81%). ***An. gambiae s.s.*** in Uganda is resistant to DDT and most pyrethroid insecticides but is susceptible to organophosphate and carbamate insecticides, while ***Anopheles arabiensis*** appears susceptible to DDT. ***An. arabiensis*** was found to predominate in the IRS districts of Apac and Kitgum following rotation to carbamate insecticides, suggesting ***that An. arabiensis*** is not resistant to DDT and indicating that IRS greatly reduced ***An. gambiae s.s.*** populations. Data from Tororo and Kanungu Districts indicate that there is reduced susceptibility to carbamates, strongly indicating the need for routine annual monitoring for insecticide resistance from around the country.

LLIN USE IN THE PYGMY COMMUNITY IN THE HEALTH OF ZONE OF WAMBA, NORTHEAST OF THE DEMOCRATIC REPUBLIC OF CONGO

Joris L. Likwela[1], Norbert Mandana[2], Marcel Lama[3], A. Brevezosek[4]

[1]National Malaria Control Program, Kinshasa, Democratic Republic of the Congo, [2]University of Uele, Isiro, Democratic Republic of the Congo, [3]Association Santé Familiale/Population Services International, Kinshasa, Democratic Republic of the Congo, [4]Nancy School of Medicine, University of Lorraine, Nancy, France

Autochthones are one of the three groups of key populations in need of malaria control interventions. A key population is defined as a community that is highly affected by malaria and which has limited access to malaria control interventions. This study assessed LLIN access and use among pygmies, an autochthone population, in the health zone of Wamba, Province Orientale in DRC. A descriptive cross sectional study was conducted among pygmy populations in the health zone of Wamba from 17-22 February 2014, 4 years after the previous LLIN distribution campaign (2010) in order to establish a baseline data prior to the 2014 LLIN distribution campaign. Data was collected through interviews with heads of households using structured questionnaires. Data was entered using EPIDATA and analysed using SPSS for Windows. 602 heads of households in pygmy populations or their representatives were interviewed. The median household size was 4. The persons surveyed lived mostly in huts (57%) or small houses (43%). The proportion of households owning at least one LLIN, the use of LLIN by pregnant women and children under 5 years old were 18.3%, 9.9% and 10.1%, respectively. Heads of households mentioned other uses of LLIN such as for fishing and protecting crops. Despite substantial progress achieved over the last seven years in malaria prevention in DRC, the use of LLIN among the pygmy populations in the health zone of Wamba remains low. LLIN mass distribution planners should develop mechanisms to reach autochthone populations including a participatory process, inclusion of these key population representatives in decision making, targeted communication, and procurement of smaller size LLIN.

USE OF GIS-BASED HOUSEHOLD MAPPING SYSTEM TO IMPROVE PLANNING, IMPLEMENTATION AND MONITORING OF MALARIA CONTROL STRATEGIES IN BIOKO ISLAND

Guillermo Garcia[1], Jason Kleps[2], Alfred W. Hoadley[3], Jose Luis Obama Nsue[1], Jose Osa Osa Nfumu[1], Telesforo Eyegue Abuy[1], Restituto Mangue Avue[1], Jeremias Nzamio Mba Eyono[1], Teobaldo Babo[1], Marcos Mbulito Ivanga[1], Rosa Patricia Richard Ateme[1], Nico Alonso-Harper[4], Roland Wango[4], Roland Wango[4], Sandra Fuentes[4], Megan Perry[4], Dianna B. Hergott[1], Christopher Schwabe[4]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]Towson University, Towson, MD, United States, [3]Medical Care Development, Inc., Augusta, ME, United States, [4]Medical Care Development International, Silver Spring, MD, United States

As it is in many malaria-endemic countries, the informal housing pattern in Equatorial Guinea without street names and building numbers makes malaria control difficult to effectively plan, implement and monitor. Beginning in 2012, the Bioko Island Malaria Control Project (BIMCP) created a geo-referenced mapping system that assigned each household a unique identifier similar to an address. The Island was divided into 1 km2 sequentially numbered map areas, which in turn were sub-divided into 100m2 sequentially numbered sectors. Using printed high resolution satellite images of each sector that clearly identified each building, a local field team assigned a sequential number to each household in each building in each sector. Buildings with more than one household were ascribed a unique number for each household. Households residing in multi-story buildings received a floor identifier. The concatenation of the map area, sector, household number, and floor level yielded a unique identifier, which was printed on a sticker glued to each household entryway, and subsequently recorded on all spray cards and LLIN distribution forms. Areas of the island where satellite images were not available were mapped using GPS by a team that drove every road, walked every footpath, and identified every building/household. The information from the field maps was then digitized in ArcGIS. Field teams updated the household database during IRS rounds in 2013 and 2014, and a mass LLIN distribution in 2015. This has enabled the BIMCP to effectively plan, implement and monitor vector control activities and respond to the substantial housing growth due to the economic boom on the Island. By being able to track IRS and LLIN supply to households and link this to annual survey data, the BIMCP has had an improved understanding of factors that contribute to increased parasite prevalence and to stratify the Island in terms of transmission characteristics and service coverage. In areas such as Bioko where informal housing patterns exist, the GIS-based mapping system instituted by the BIMCP allows for improved planning, implementation and monitoring of malaria control activities.

1661

DESIGN AND DEPLOYMENT OF A GIS-BASED CAMPAIGN INFORMATION MANAGEMENT SYSTEM FOR PLANNING, MANAGING AND MONITORING MALARIA CONTROL INCLUDING FUTURE VACCINATION ON BIOKO ISLAND

Dianna B. Hergott[1], Christopher Schwabe[1], Guillermo Garcia[2], Andrew Taylor[3], Benjamin Heasly[3], Nathan Lienhardt[3], Jessenia Knowles[2], Bruce MacLeod[3]

[1]Medical Care Development International, Silver Spring, MD, United States, [2]Medical Care Development International, Malabo, Equatorial Guinea, [3]University of Southern Maine, Portland, ME, United States

Medical Care Development International (MCDI) and the University of Southern Maine (USM) are developing an Android-based tablet application for planning, managing and monitoring community-based malaria control on Bioko Island called the Campaign Information Management System (CIMS). The CIMS is currently deployed for IRS and LLIN distribution and keep-up and will later be used for managing rapid case detection and treatment, highly focused control around residual hotspots, and possibly mass vaccination with a transmission-blocking vaccine. The CIMS includes four modules, two of which leverage pre-existing open source applications developed by USM and other partners - OpenHDS, a health and demographic surveillance system, and MOTECH, a suite of mhealth tools that include technology for integrating with telcom systems to send voice or text messages to individuals/patients based on defined calling criteria. The CIMS modules include: (1) a geo-referenced household listing and associated member census based on OpenHDS; (2) an individual identification system that uniquely identifies all residents; (3) a set of campaign participation applications developed in ODK that track individual or household participation in various campaigns; and (4) a cell phone-based notification system using MOTECH which notifies households about impending campaign events, follows-up on missed contacts, and encourages participation in future events. When engaging households during campaigns, field workers select enumerated households from a hierarchical geographic selection system. Household information can be updated in real time, accounting for population movement or construction of new houses. Campaign participation information is then entered separately for IRS, LLINs, or any other type of campaign. These data are stored in distinct data sets on a central server (cloud or local). The CIMS provide an easy-to-use, adaptable and scalable solution for planning, managing and monitoring malaria control campaigns that is particularly well suited for countries heading towards elimination.

1662

UTILIZING IQKS AND A CAMPAIGN INFORMATION MANAGEMENT SYSTEM (CIMS) FOR IMPROVED QUALITY CONTROL OF INDOOR RESIDUAL SPRAYING

Godwin Fuseini[1], Wonder Philip Phiri[1], Guillermo Garcia[1], Raul Nguema Ncogo Oyana[1], Anita Eyang Obama[1], Jesus Nazareth Buatiche[1], Arcadio Edu Mico[1], Valeriano Oluy Nsue Maye[1], Aveika Akum[1], Luis Segura[1], Dianna B. Hergott[2], Christopher Schwabe[2]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]Medical Care Development International, Silver Spring, MD, United States

IRS programs have traditionally faced challenges ensuring that: (1) sprayers do not falsify spray records; (2) rooms within houses are sprayed well (i.e. without coverage gaps and with a sufficient amount of insecticide applied); and, (3) effective insecticidal coverage has been achieved in each spray area. The Bioko Island Malaria Control Project (BIMCP) has instituted a quality control procedure to address these challenges using Insecticide Quantification Kits (IQKs) to test houses randomly selected from a Campaign Information Management System (CIMS) that maps in real time the houses reportedly sprayed each day. Sprayer performance is assessed at various intervals during a spray round by randomly selecting a house per sprayer from those recorded in the CIMS the previous day. IQKs are used to test samples from three spots arrayed from the top left to the bottom right of a sprayed wall. Six qualitative outcomes are measured ranging from "Well Sprayed" where all three samples comply with WHO concentration norms, to "Not Sprayed" where all three have no insecticide. Sprayers who do not satisfy the "Well Sprayed" outcome receive intensified training and supervision. Repeated poor performance can lead to dismissal. A first evaluation in 2014 revealed that 6% of sprayers achieved a "Well Sprayed" status and 4% a "Not Sprayed" status. Data from the current IRS round at various time intervals will be presented. Program performance is assessed using Lot Quality Assurance Sampling (LQAS) and IQKs to determine if effective insecticidal coverage has been achieved (i.e., that at least 80% of 19 randomly selected communities each in turn have at least 80% of 19 randomly selected houses sprayed with the recommended insecticide concentration). The samples from all lots are then pooled to derive an effective insecticidal coverage rate for the Island as a whole. These data for the current round will be presented. The ability to randomly select, locate and test via IQK houses reportedly sprayed the prior day has markedly improved the quality of IRS on Bioko Island, virtually eliminating falsification, and enabling the project to better evaluate its performance.

PREVALENCE OF ACUTE GASTROENTERITIS AMONG U.S. MILITARY PERSONNEL DEPLOYED TO HONDURAS DURING 2014-2015

Mark P. Simons[1], Giselle Soto[1], Faviola Reyes[2], Nathanael D. Reynolds[1], Jamie Fraser[3], Ricardo Aviles[2], David Wolken[2], David Tribble[3], Ramiro Gutierrez[4], Mark Riddle[4]

[1]U.S. Naval Medical Research Unit-6, Lima, Peru, [2]U.S. Joint Task Force Bravo, Comayagua, Honduras, [3]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [4]U.S. Naval Medical Research Center, Silver Spring, MD, United States

Acute gastroenteritis (AGE) is a leading cause of lost duty days in military personnel, and vaccine candidates against common diarrhea pathogens are in phase II clinical trials. The need for field sites to evaluate vaccine efficacy in deployed personnel is a strategic need for the U.S. military and collaborating partners. Thus, we established Soto Cano Air Base in Honduras as a field site for clinical trials in Latin America including an on-site lab for stool cultures and reference capacity at NAMRU-6 in Peru. Additionally, post-deployment surveys were integrated into medical out-processing to capture unreported cases of AGE. To date, 36/168 (21.4%) personnel evaluated in the post-deployment surveys reported experiencing diarrhea during a 6-9 month deployment (mean 3.2 different episodes, range 1-10). The most common symptoms reported were cramps (43.9%), nausea (40.3%), fever (26.3%), vomiting (14.3%), with 2 (3.5%) persons reported experiencing bloody diarrhea, and the median number of loose stools in a 24 hour period was 4 (range 2-15). Eleven (19.3%) persons reported experiencing lost duty time (range 1-4 days), 29 (50.8%) experienced decreased performance (range 1-10 days), and 8 (14.0%) reporting being sick in quarters. Further, 22 (38.6%) persons reported to the clinic and 4 (7.0%) needed IV fluids. From passive surveillance, 85 persons reported to the clinic with diarrhea and 36 (42.9%) met the case definitions of moderate-severe diarrhea. From these 36 patients, 3 (8.3%) samples were positive by primary stool culture, with ***Shigella***, ***Salmonella***, and ***Aeromonas*** each identified. The remaining samples were positive for lactose-fermenting Gram-negative rods consistent with potential pathogenic ***E. coli*** subtypes. These samples are being analyzed at NAMRU-6 by multiplex PCR using the Luminex Gastrointestinal Pathogens Panel (GPP) as well as multiplex PCR detection of pathogenic ***E. coli*** virulence factors, norovirus RT-PCR, and stools ova and parasite exam. These findings highlight the impact of diarrhea on military operations and provide the information/logistics needed to establish Soto Cano as a site for phase I-IV clinical trials.

AN ORAL CHOLERA VACCINATION CAMPAIGN COVERAGE SURVEY, HAITI 2014

Eleanor M. Burnett[1], Jeannot Francois[2], Nandini Sreenivasan[1], Kathleen Wannemuehler[1], Papa Coumba Faye[3], Rania A. Tohme[1], Paul Adrien[2], Yves Gaston Deslouches[2], Melissa Etheart[4], Amber Dismer[1], Roopal Patel[4], Kashmira Date[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Ministry of Public Health and Population, Port au Prince, Haiti, [3]Pan-American Health Organization, Port au Prince, Haiti, [4]Centers for Disease Control and Prevention, Port au Prince, Haiti

As part of a 10-year cholera elimination plan in response to the 2010 cholera outbreak in Haiti, the Haitian Ministry of Public Health and Population (MSPP) has proposed vaccinating 600,000 persons living in areas with high cholera attack rates and poor access to healthcare, clean water, and basic sanitation with a two dose oral cholera vaccine (OCV). During August –September 2014, MSPP conducted its second OCV campaign targeting 185,314 persons in certain areas of 3 departments: Artibonite, Centre and Ouest. This was the first time vaccine from the global OCV stockpile was used in Haiti. We conducted a multi-stage stratified cluster survey to assess OCV coverage by department. We sampled 80 enumeration areas (EAs) using stratified random sampling and 20 households were selected in each EA. In each selected household, a general and an individual interview were conducted; one person per age group (1-4 years, 5-14 years, and ≥ 15 years) was randomly selected for interview. Overall, 1,489 household and 3,201 individual interviews were conducted. Coverage estimates and 95% confidence intervals (CI) were calculated accounting for the design. Two-dose OCV coverage was 74% (95% CI: 64, 82), 64% (56, 72), and 48% (40, 56) in Artibonite, Centre, and Ouest, respectively, and drop-out after the first dose was 7%, 8%, and 2%, respectively. Children 1 to 14 years were more likely to be vaccinated than persons ≥15 years old ($p<0.01$); in Centre, females were more likely to be vaccinated than males ($p=0.03$). The most common reason for not receiving any OCV doses was being absent during the campaign in Centre and Artibonite and not hearing about vaccination activities in Ouest. The most common reason for receiving only one dose was being absent during the second round of campaign in all three departments. While coverage in Artibonite and Centre was comparable with that in other OCV campaigns in Haiti and elsewhere, outdated population estimates and inadequate social mobilization might have contributed to lower coverage estimates in Ouest. Future OCV campaigns in Haiti should be informed by more up to date population estimates and robust social mobilization activities.

EXPLORING REG1B AS A POTENTIAL MARKER OF INTESTINAL HEALTH

Allissia Anne Gilmartin[1], Rashidul Haque[2], William A. Petri, Jr.[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Environmental enteropathy (EE) is a gut disorder characterized by intestinal inflammation without overt diarrhea that occurs in individuals exposed over time to poor sanitation and hygiene. In children from low-income countries EE, is implicated as a cause of malnutrition, oral vaccine failure and impaired cognitive development. Unfortunately, a lack of direct and specific diagnostic tests has made it challenging to study EE. We have developed a fecal ELISA for Reg1 to test it as a potential biomarker of small intestinal health. Reg1 plays a role in gut health and is known to be up-regulated in a variety of enteric infections and inflammatory conditions. Our laboratory has previously found that fecal Reg1 predicted future stunting through the first two years of life when measured in 12-week-old children in birth cohorts from Bangladesh and Peru. We are currently testing Reg1 for its ability to independently predict gut damage in approximately 220 children from Mirpur, Bangladesh who were enrolled in the MAL-ED cohort study. We will test for fecal Reg1B in monthly and diarrheal stools for all children up to 12 months of age. We hope to assess the relationship between Reg1B and stunting in this cohort and determine a normal fecal Reg1B level in our population, an important step towards using this test in the clinical setting.

1666

CLIMATIC INFLUENCES ON ENDEMIC CHOLERA IN KALEMIE, DEMOCRATIC REPUBLIC OF THE CONGO

Kerry L. Shannon[1], Didier Bompangue[2], Andrew Azman[1], Sean Moore[1], Benjamin Zaitchik[3], Justin Lessler[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Research and Training Unit of Ecology and Control of Infectious Disease Control, Microbiology Department, Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [3]Department of Earth and Planetary Sciences, Johns Hopkins University, Baltimore, MD, United States

We examined associations of environmental factors with cholera incidence in Kalemie, a city by Lake Tanganyika in the Democratic Republic of Congo. From January 2002 to February 2012 Kalemie had a total of 20,559 suspected cholera cases averaging 39 per week (IQR 12-52). Cases appear year-round with two annual peaks, atypical of Africa. The region has a single rainy season that peaks between November and January and a single dry season from May-August. Climatic factors were estimated through remote sensing and considered as lagged variables in analyses from 0 to 30 weeks before the week of cholera incidence. Factors included Lake Tanganyika height, temperature and chlorophyll a, maximum and minimum weekly air temperatures, precipitation, solar radiation, and water in the top meter of the soil column. In univariate models, cholera incidence was most associated with chlorophyll a levels (Pearson correlation = 0.23) and maximum and minimum weekly air temperatures one week prior (Pearson correlation = 0.26 and 0.27 respectively). Multivariable negative binomial regression models including climatic factors were compared based on Akakie Information Criteria and mean-squared prediction error using 'hold one year out' cross validation. The best model by both methods included: Lake Tanganyika water level, temperature and chlorophyll a, soil water content of top meter of soil, rainfall, net solar radiation, and minimum/maximum air temperature at varying time lags. 4.4% of weekly case counts were above and 21.9% below the cross validation predictive interval. These climate factors explain 36.3% of the week-to-week variation in cholera. Cholera incidence is clearly associated with climatic factors, however, models based on solely on climate fail to predict many major variations in cholera incidence. In Kalemie, 61% of the weeks when cases exceeded the prediction interval occurred in years with documented large-scale power outages and influxes of migrant populations. Improved predictive models using increased local knowledge of factors impacting the epidemic may allow us to better evaluate effective interventions such as vaccination campaigns.

1667

HARD BLOOD AGAR IN THE ISOLATION OF *ARCOBACTER SPP*

Rito Zerpa[1], Jorge O. Alarcon[1], Lilian Patiño[2], Edwin Correa[3]

[1]Instituto de Medicina Tropical "DA Carrion", UNMSM, Lima, Peru, [2]Instituto Nacional de Salud del Niño, Lima, Peru, [3]Universidad Peruana Cayetano Heredia, Lima, Peru

Arcobacter spp., is currently considered emerging zoonotic pathogen; isolation by conventional methods in developing countries is difficult and expensive, sometimes by contamination with bacteria such as ***Proteus.*** Here, we present the hard blood agar (HBA) as a simple culture medium for the isolation of ***Arcobacter spp***. We worked with 100 human fecal samples and 100 animals (50 pigs and 50 cattle) for the isolation of ***Arcobacter spp.***; using the HBA and Columbia Blood Agar (CBA), both with the method of the filter (0.45um porosity), and microaerophilic

incubation with the method of ***Klebsiella*** and closing or sealing of the inoculated plate with rubber bands obtained from powder-free latex gloves. Incubation at 28 ° C and read after 24-48 hours. The identification of ***Arcobacter*** was only based on their phenotypic characteristics. ***Arcobacter*** was isolated 3/100 (3%) of human specimens in CBA, and 4/100 (4%) in HBA; in animals: in cattle 10/50 (20%) was isolated in CBA, and 28/50 (56%) in HBA; in 18/50 pigs (36%) was isolated in CBA, and 35/50 (70%) in HBA. Hard blood agar (HBA) is an effective, simple and inexpensive alternative culture medium for the isolation of ***Arcobacter spp.***, even in samples with ***Proteus*** passing through the filter and by swarming on cultures, masking and difficult isolation of ***Arcobacter***.

1668

VIRULENCE GENES AND ANTIMICROBIAL RESISTANCE IN *SHIGELLA* SPP. ISOLATED FROM CHILDREN WITH DIARRHEAL DISEASES REQUIRING MEDICAL CARE IN FORTALEZA, CEARA, BRAZIL

Ila F. Lima, Pedro H. Medeiros, Marjorie M. Guedes, Mariana D. Bona, Alexandre Havt, Aldo A. Lima

Federal University of Ceara, Fortaleza, Brazil

Shigella spp. is one of the most prevalent etiological agents of enteric infection. This study aimed to determine circulating species, virulence genes and antimicrobial resistance profile of Shigella spp. obtained from a cross-sectional study of moderate to severe childhood diarrhea in Fortaleza, Ceara, Brazil. Fecal specimens and clinical data were collected from May 2008 to April 2009 and 63 Shigella strains were isolated by standard microbiological methods. Immunoagglutination assay was employed for species characterization and four multiplex-PCRs were developed to detect 14 sequences encoding virulence genes (ial, set, virF, sen, sigA, pic, sepA, ipaA, ipaB, ipaC, ipaD, icsB, Stx and virB). Antimicrobial susceptibility tests were performed using the Kirby-Bauer disk diffusion method with 13 antimicrobial discs commercially available. The most prevalent ***Shigella*** species were ***S. flexneri*** and ***S. sonnei*** (43%, 27/63 for both), followed by ***S. dysenteriae*** (8%, 5/63) and S. boydii (6%, 4/63). The protease associated with mucosal binding (pic), enterotoxin 1(set) and protein associated with cell invasion (sepA) genes were significantly associated with S. flexneri infection ($p=0.0002$, $p<0.0001$ and $p<0.0001$, respectively), while other virulence genes showed no difference among species. The concomitant presence of pic, set and sepA was correlated with intense abdominal pain ($p=0.0379$) and multi-drug resistance to at least three drugs ($p=0.0028$), being sulfamethoxazole/trimethoprim + tetracycline + ampicillin + chloramphenicol the most frequent pattern. This study suggests that more severe shigellosis is caused by S. flexneri carrying the virulence genes pic, set and sepA. These strains also present multi-drug resistant phenotype, indicating a link between virulence and antimicrobial resistance pressure selection and evolution.

1669

CLINICAL PRESENTATION AND VIRULENCE GENES PROFILE FROM *CAMPYLOBACTER JEJUNI* INFECTION ISOLATED FROM CHILDREN WITH MODERATE TO SEVERE DIARRHEA IN FORTALEZA, CEARÁ, BRAZIL

Herlice N. Veras, Josiane S. Quetz, Ila F. Lima, Ana K. Santos, Pedro H. Medeiros, Alexandre Havt, Luís C. Rey, Aldo A. Lima

Federal University of Ceara, Fortaleza, Brazil

Campylobacter spp. is considered the most common cause of bacterial gastroenteritis. This study characterized ***C. jejuni*** virulence-associated genes that may play a role in ***C. jejuni*** pathogenicity in children aged 0-36 months who required emergency medical care due to moderate to severe diarrheal disease. It is part of a project entitled "'Diarrhea Enteric Card (DEC)' aiming to develop PCR-based multiplex diagnose assay for bacterial enteric pathogens. The project was approved by the local and national ethical committees in Brazil (HIAS 80/06 and CONEPE 13523/2007, respectively). DNA was extracted directly from fecal samples collected from 226 children during May 2008 and April 2009, in Fortaleza, Ceará, Brazil. A questionnaire was applied to characterize clinical symptoms. Conventional PCR was performed for detection of ***C. jejuni*** strains and investigation of nine virulence genes. The identification of ***C. jejuni*** was performed using hipO gene, providing 19,5% (44/226) of positivity. The presence of ***C. jejuni***´s virulence-associated genes encoding proteins related to pathogenesis of the micro-organism were detected in the following proportions of ***C. jejuni***-positive DNA samples: racR, 97.7% (43/44), dnaJ, 88.6% (39/44), and flaA, 79.5% (35/44); - related to bacterial adhesion and colonization; ciaB, 97.7 % (43/44); pldA, 45.4% (20/44) and pVir 0% (0/44) - related to invasion, and cdtABC in 95.4% (42/44) related to cytolethal distending toxin (CDT). These data showed that ***C. jejuni*** were detected in a significant percentage of children aged 0-36 months with moderate to severe diarrhea. Virulence genes related to bacterial adhesion, colonization and cytotoxicity were detected in a great proportion of ***C. jejuni***-positive samples, while invasion-related virulence genes were detected in lower frequency. The distribution profile of virulence genes from ***C. jejuni*** was not correlated with the clinical presentation of the disease, suggesting that maybe other virulence genes or host factors such as nutritional status are important in defining the clinical severity of diarrheal diseases associated with ***C. jejuni***.

1670

EVIDENCE FOR GASTROINTESTINAL CARRIAGE OF *CLOSTRIDIUM DIFFICILE* AMONG CHILDREN IN THE PERUVIAN AMAZON RIVER BASIN

Heather Clark[1], Rajasree Roy[1], Rosa Burga[2], Ricardo Abadie[2], Henry Montilla-Guedez[1], Anne Huyler[1], Loan Nguyen[1], Claudio Rocha[2], Hamilton Tilley[2], David Craft[1]

[1]Pennsylvania State College of Medicine, Hershey, PA, United States, [2]U.S. Naval Medical Research Unit - 6, Iquitos, Peru

Diarrheal disease is a leading cause of death and illness in developing countries and is responsible for nearly one in five child deaths worldwide each year. Unsafe water, poor sanitation, and inadequate hygiene are the major risk factors for the spread of disease. Belen is an impoverished river dwelling community without public sewage systems and trash disposal. There are few laboratory based studies on infectious gastroenteritis in this community and none on the prevalence of ***Clostridium difficile***. This study examines the prevalence of ***C. difficile*** in children ages 5 and under in Belen. With local IRB approval and informed consent from heads of households, 206 stool samples were collected from children 5 and under from May to October 2014. All samples were analyzed for ***C. difficile*** antigen (glutamate dehydrogenase) or toxin (A and B) using ***C. difficile*** QUIK CHEK (TechLab, Blacksburg, VA). All stool samples were accepted irrespective of consistency. Sixteen of 206 stool samples (7.77%) assayed showed antigenic (Ag) or toxigenic (Tox) evidence of ***C. difficile***; two samples (0.97%) for toxigenic strains (Ag+ / Tox+), 13 samples (6.31%) for non-toxigenic strains (Ag+ / Tox-), and one sample (0.49%) was positive for toxin only (Ag- / Tox+). This is the first laboratory based study assessing the prevalence of ***C. difficile*** in this community and provides strong evidence for childhood carriage of non-toxigenic, and more limited evidence for toxigenic, strains of ***C. difficile***. These studies will be augmented in the future by culture and/or nucleic acid amplification for genes coding for all virulence factors associated with ***C. difficile***. Unfortunately, symptomatic vs. asymptomatic data could not be consistently ascertained, but future studies associating symptoms and the presence of ***C. difficile*** could lead to a better understanding of the epidemiology of non-nosocomial, community-acquired ***C. difficile*** in the Amazon River Basin. To date, there is no data linking ***C. difficile*** carriage to the environment, hygiene practices or socioeconomic factors in Belen. Additional investigations of other etiologies of infectious gastroenteritis are also ongoing.

1671

INCORPORATING MODEL UNCERTAINTY INTO PREDICTIONS OF THE BURDEN OF TYPHOID FEVER

Marina Antillon, Forrest W. Crawford, Virginia E. Pitzer
Yale University, New Haven, CT, United States

Upcoming efforts in vaccination against typhoid fever require an assessment of the baseline burden of disease in countries at risk. Model-based estimates are a feasible alternative to costly and time-consuming field-based estimates of typhoid fever incidence. In most countries, typhoid incidence data is not collected, and therefore current estimates of incidence are based on interpolation of data from 32 studies. Recent estimates of typhoid burden are based on models that have not been assessed for predictive accuracy. Furthermore, estimates of age-specific incidence are based on assumptions about how the age distribution varies with incidence, rather than empirical estimates of age-specific heterogeneity. An understanding of the difference in incidence attributable to age is imperative to guide upcoming vaccine policies. Therefore, it is necessary to identify readily-available predictors of typhoid incidence, such as access to clean water, access to improved sanitation, country-level Gross Domestic Product, etc. We developed a random-intercept, mixed effects model fit to data from 32 population-based studies of typhoid incidence, 17 of which report incidence for different age groups. We used Bayesian model averaging to incorporate uncertainty around the estimates of the predictors as well as the uncertainty in model selection. The current re-analysis permits prediction of the overall as well as age-specific incidence of typhoid fever, as well as the associated uncertainty, in low- and middle-income countries.

1672

EPIDEMIOLOGIC FEATURES OF DIARRHEAL DISEASE DUE TO *AEROMONAS SPP.* AND *PLESIOMONAS SHIGELLOIDES* INFECTIONS IN KAMPONG CHAM, CAMBODIA

Andrew F. Vaughn
U.S. Naval Medical Research Unit – 2, Phnom Penh, Cambodia

To investigate the possible etiological agents of diarrheal disease in Cambodia, a cohort based study was conducted from August 2012 to March 2015. The US Naval Medical Research Unit Two (NAMRU-2) Detachment Phnom Penh in collaboration with the Cambodian National Institute of Public Health (NIPH) conducted active surveillance among four villages in Kampong Cham Province, Cambodia. Subjects self reported symptoms to study staff and were also followed on a weekly basis. Stool samples were collected from subjects if they presented with symptoms of acute diarrhea defined as 3 or more loose stools within 24 hours or 2 loose stools associated with gastrointestinal complaint within 24 hours. Study subjects were comprised of 2,921 adults and 1,749 children (aged < 18 years old). There were 258 ***Aeromonas spp.*** and 266 ***Plesiomonas shigelloides*** isolates identified from 2,603 specimens collected and tested between August 2012 and March 2015. Study data indicates that adults have a higher risk of being infected with ***Aeromonas spp.*** (OR=1.4, 95%CI: 1.1-1.9) or ***P. shigelloides*** (OR=1.9, 95%CI: 1.5-2.6). Subjects who worked in retail settings (shop owners or workers) also had a higher risk of being infected with ***P. shigelloides*** (OR=2.0, 95%CI: 1.2-3.3) whereas the participants who were students or worked at home tended to have lower risk (OR=0.7, 95%CI: 0.5-0.8). Abdominal pain and mucus laden stool are the two symptoms significantly associated with the infection of these two pathogens ($p< 0.05$). Lack of access to clean drinking water (filtered or boiled) or lack of sanitary toilet facilities were identified as increased risk factors for positive stools. 52.3% and 70.2% of ***Aeromonas spp.*** positive subjects and 55.6% and 70.3% of ***P. shigelloides*** positive subjects did not have access to clean water or toilet facilities, respectively. The prevalence of these pathogens appears to be correlated with inadequate access to sanity water and toilet facilities.

1673

ORAL CHOLERA VACCINE STUDIES IN CHOLERA ENDEMIC SETTINGS IN BANGLADESH

Firdausi Qadri
International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Bangladesh has one of the world's highest burden of endemic cholera with an estimated 350,000 cholera cases and over 4,500 deaths annually. A serious need therefore exists for control of cholera using vaccines and other preventive measures. Over the last few years large scale vaccination studies are being conducted with the whole cell oral cholera vaccine (OCV) Shanchol in high risk urban as well as rural populations. The objective of such studies is to assess the feasibility of delivery as well as effectiveness of vaccination program utilizing the existing national immunization infrastructure of Bangladesh. Vaccine coverage was 65% and protection was 53%, which was evident in all age groups and sustained for 2 years. In a study in a rural setting in Bangladesh carried out in 65,000 participants and the OCV program was successful and 92% of the vaccinees receiving the first dose of vaccine also returned for the second dose. In addition we have recently conducted a single dose oral cholera vaccine study to determine if only one dose can be protective, a strategy very important for use in epidemics and outbreaks. The oral cholera vaccines need to be stored at 2-8 °C. This is one of the limiting factors for delivery of vaccines in resource poor settings globally. We therefore studied, if storage of vaccine at higher temperatures (25°C, 37°C and 42°C) resulted in similar safety and immunogenicity compared to vaccine stored in the cold. The vaccine is safe, well tolerated and satisfactory immune response is elicited. The OCV studies were feasible and effective using government facilities. These studies demonstrate that the Shanchol can be delivered to all age groups using resources already available in the country. Strategies to plan and implement OCV uptake in national immunization programmes in high risk hotspots is needed for Bangladesh. Studies to assess vaccination strategies, target age groups for vaccination, uptake, feasibility as well as cost-effectiveness analyses need to be made using the same approach as used for other immunisation programmes which have been successful in Bangladesh and such studies are being planned.

1674

IFN-γ; HAS DIRECT ANTI-ENTEROAGGREGATIVE *E. COLI* PROPERTIES AND IS NECESSARY FOR RESILIENCE TO SEVERE EAEC-INDUCED ENTEROPATHY IN ZINC-DEFICIENT MICE

Glynis Kolling, David Bolick, **Luther Bartelt**, Richard Guerrant
University of Virginia, Charlottesville, VA, United States

Enteroaggregative E. coli is a major cause of early childhood diarrhea and growth impairment. Descriptions of EAEC-diarrhea are typically mucoid with occasional leukocyte products. While increased fecal IL-8 has been seen in symptomatic patients with EAEC infection, and mutations in the IL-8 promoter that lead to increased IL-8 expression also associate with symptomatic disease, other inflammatory mucosal pathways such as the IL23-IL17 and IFN-γ; axis relevant to other enteropathy-inducing pathogens are less well understood, and could contribute to disease during EAEC infection. In a murine model of EAEC-induced enteropathy we have previously shown that zinc deficiency both up-regulates aggR-regulated EAEC virulence genes and alters host inflammatory responses leading to increased Il8 and Mcp1 expression, mucus production, Muc2 expression, and Cftr expression, increased Il17, but decreased Il23, Il6, Tnfalpha, and Il1beta. To interrogate the role of the IL17-IL23 axis we infected zinc-deficient IL17RKO mice with the virulent EAEC042 strain. IL17RKO mice were protected from weight loss, more rapidly cleared EAEC, and demonstrated a 5-fold increased expression of IFN-γ;. Neutralization of IFN-γ; reverted the resilient IL17RKO mice to a susceptible wild-type phenotype. IFN-γ; demonstrated direct effects ***in vitro***, inhibiting EAEC growth in a dose-dependent manner. Further studies are planned to

confirm this new recognition of anti-EAEC properties of IFN-γ;, and whether genetically determined alterations in mucosal inflammatory responses may promote host resiliency to enteropathogens despite the disadvantage of severe micronutrient deficiency.

1675

ISOLATION AND SPECIES IDENTIFICATION OF GRAM-POSITIVE BACTERIA FROM THE CANNED FOOD BY SEQUENCE CHARACTERIZATION AT *GYR*B LOCUS: A PUBLIC HEALTH IMPORTANCE

Irshad M. Sulaiman, Emily Jacobs, Steven Simpson, Khalil Kerdahi

Food and Drug Administration, Atlanta, GA, United States

The primary mission of FDA is to enforce the Food, Drug and Cosmetic Act and regulate food, drug and cosmetic products. FDA uses presence of pathogenic microorganisms in these commodities as one of the regulatory action criteria and to ensure that the goods are safe for human consumption. This study was conducted to assess the effectiveness of pathogen control in a canned food facility located in the United States. A total of 9 unopened recalled canned food jars from the same lot containing Black Bean Corn Poblano Salsa were initially examined by conventional microbiologic protocols. Of these, while analyzing 8 subsamples for each sample, all subsamples of one of the containers was found positive for the presence of slow growing rod-shaped, Gram-positive facultative anaerobic bacteria. Species identification of 8 recovered Gram-positive bacterial isolates from the positive unopened jar was accomplished by our recently developed protocol based on DNA sequencing of PCR amplified ***gyr***B gene products. Multiple alignments confirmed all 8 generated ***gyr***B gene sequences to be identical. These sequences matched 99% (2-point-mutation) with the published sequence of ***Lactobacillus fermentum*** sequence available in public domain (GenBank Accession No. AP008937). Thus, the ***gyr***B-based molecular diagnostic protocol can be used as a suitable genetic marker for rapid detection of ***Lactobacillus*** in the canned food monitoring program of public health importance.

1676

STRINGENT QUALITY CONTROL MEASURES ALLOWS PROMPT IDENTIFICATION OF CRUCIAL PROBLEMS TO OPTIMIZE THE RELIABILITY OF MENINGOCOCCAL CARRIAGE SURVEYS

Jacinta Okeakpu[1], Aderonke Odutola[1], Sheikh Jarju[1], Ebenezer Foster-Nyarko[1], Anna Roca[1], Beate Kampmann[1], Umberto D'Alessandro[1], Martin Antonio[1], Caroline Trotter[2], James Stuart[3], **Olivier Manigart**[4], Brian Greenwood for the MenAfriCar Consortium[3]

[1]Medical Research Council, The Gambia Unit, Fajara, Gambia, [2]University of Cambridge, Cambridge, United Kingdom, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]London School of Hygiene & Tropical Medicine and MRC, The Gambia Unit, London and Fajara, United Kingdom

We conducted a cross-sectional study to identify carriage of ***Neisseria meningitidis*** among 1000 schoolchildren in Fajara, The Gambia, to evaluate improved detection methods. We conducted this study using quality control (QC) standards applied to clinical trials. In addition to developing Standard Operating Procedures, Study Operations and Laboratory Operations Manuals and ensuring documented training of staff, we conducted regular internal audits of field and laboratory activities. We verified the ability of the laboratory team to perform the tests through enrolment in External Quality Assessment (EQA). We performed regular monitoring of positive controls used for qualitative PCR and of standard curves used for quantitative PCR through Levey-Jennings charts (LJC). We used non-template negative controls every twenty tested samples to ensure that there was no PCR contamination. The internal audits allowed identification of several minor challenges and a major one: non-collection of critical samples, a situation that was promptly corrected. Further laboratory audits did not identify other major findings. Monitoring of positive controls through LJC allowed identification of problems with primers and probes used for qualitative PCR, triggered reagents replacement and minimized inter-assay variation. Monitoring of standard curves through LJC led to exclusion of the results from one plate out of 72, where key values of the standard curve were found to be out of the defined acceptable range. EQA results identified a risk of PCR contamination in the sodC gene and promoted development of stricter rules to be applied in our molecular biology laboratories. No non-template negative control was positive during the entire course of the study. All staff working on this cross-sectional study were trained to apply these high standards. Large-scale epidemiological studies should be conducted with QC standards approaching the ones required in clinical trials. Adopting these standards allowed us to identify critical issues during the course of a study of meningococcal carriage and to correct them promptly.

1677

DETECTION OF *NEISSERIA GONORRHEA* USING CULTURE AND NUCLEIC ACID AMPLIFICATION TEST IN FIVE HEALTH FACILITIES IN GHANA

Naiki Puplampu[1], Helena Dela[1], Eric Behene[1], Shirley Nimo-Paintsil[1], Kwesi Addo[2], Edward Owusu Nyarko[3], Cynthia Kwakye[4], Nehkonti Adams[1]

[1]Naval Medical Research Unit - 3, Ghana Detachment, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana, [3]Ghana Armed Forces Public Health Department, Accra, Ghana, [4]Ghana Health Service, Accra, Ghana

Neisseria gonorrhea is one of the major etiologies of sexually transmitted infections (STIs) and when left untreated can lead to serious complications such as pelvic inflammatory disease, ectopic pregnancy, infertility in women and sterility in men. Microscopic examination and microbial culture are common techniques used in gonorrhea diagnostics; however both are insufficiently sensitive and/or specific. Noninvasive techniques utilizing newer technology such as antigen detection by immunoassay and nucleic acid amplification tests (NAATs) have become more acceptable because of their precision, suitability and time-saving aspects. The objective of this study is to determine the percentage of ***N. gonorrhea*** positive cases occurring among Ghanaian military members using culture and NAAT. Urethral or endocervical swabs and urine samples were obtained from consenting patients presenting with STI symptoms at five health facilities. Swabs were cultured on Modified Thayer-Martin agar and colonies subcultured on chocolate agar. ***N. gonorrhea*** isolates were identified by gram staining, catalase as well as oxidase tests. Purified colonies were confirmed using the API-NH. Urine samples were tested by NAAT. Of 679 specimen screened, 25.4% was positive for gonorrhea by NAAT and 6.9% by culture. All specimens positive by culture were also positive by NAAT. Compared to culture, NAAT performed better in identifying gonorrhea in STI-symptomatic patients presenting to health facilities in Ghana. Our finding demonstrates that NAAT could be beneficial in testing high-risk groups or patients who are culture negative but have persistent symptoms.

1678

DETECTION OF *LEPTOSPIRA*-SPECIFIC ANTIBODIES USING RECOMBINANT LIPL32, LIPL41, LIGA, AND LIGB IN ENZYME-LINKED IMMUNOSORBENT ASSAY

Hua-Wei Chen, Heather Lukas, Kira Becker, Giulia Weissenberger, **Wei-Mei Ching**

Naval Medical Research Center, Silver Spring, MD, United States

Leptospirosis is caused by the infection of spirochetes of the genus ***Leptospira***. This zoonotic disease has become widespread in developing nations, particularly those located in tropical areas. In the early stage of the

bacterial infection, the disease can be treated with antibiotics. However leptospirosis is often misdiagnosed due to its nonspecific symptoms and lack of good diagnostic tests which can be easily performed at the clinical site. The current standard method for diagnosis of leptospirosis is the microscopic agglutination test (MAT). This assay requires live cultures, not only technically complex but also time-consuming. In an effort to replace MAT with a test that does not require live cultures, we produced highly purified recombinant antigens, rLipL32, rLipL41, rLigA, and rLigB, and evaluated their performance individually and a cocktail of 1:1:1:1 combination in ELISA to detect IgG and IgM antibodies specific for ***Leptospira*** using a panel of 429 human sera (337 MAT positive and 92 MAT negative sera). The positive samples had MAT titers greater than 100 against one or several of 18 serovars from 5 major pathogenic ***Leptospira*** species (***L. interrogans, L. kirschneri, L. borgpetersenii, L. noguchii, and L. weilii***). There were 145 (43%) samples that showed either detectable IgG or IgM against rLipL32; 177 (53%) samples against rLipL41; 216 (64%) samples against rLigA; and 228 (68%) samples against rLigB. There were 5, 15, 16, and 23 patient sera that had specific antibodies against only one antigen rLipL32, rLipL41, rLigA, and rLigB, respectively. Combining the detection results of IgG and IgM from these four individual antigens, the overall sensitivity is close to 90% but the specificity is only 65%, based on the MAT reference method. The overall sensitivity and specificity of the cocktail of 1:1:1:1 combination was 82% and 86%, respectively. These results showed that an ELISA using the combination of recombinant antigens has the potential to replace the reference method MAT. Further optimization of the relative amount of each antigen in the final formulation to increase the overall sensitivity by ELISA is underway.

1679

LEPROSY NEW CASE DETECTION TRENDS AND THE EFFECT OF PREVENTIVE INTERVENTIONS IN PARÁ STATE, BRAZIL: A MODELING STUDY

Haroldo J. de Matos[1], **David J. Blok**[2], Sake J. de Vlas[2], Jan Hendrik Richardus[2]

[1]Instituto Evandro Chagas, Belem, Brazil, [2]Erasmus MC, Rotterdam, Netherlands

Leprosy is still a public health problem in Brazil. Although the overall number of new cases is declining, there are still areas with a high disease burden, in particular Pará State. We aim to predict future trends in new case detection rate (NCDR) and explore the potential impact of contact tracing and chemoprophylaxis with single-dose rifampicin on NCDR in Pará State. We used SIMCOLEP, an existing individual-based model for the transmission and control of M. leprae in a population structured by households. The model was quantified to mimic the NCDR trend of leprosy in Pará state between 1990 and 2012. The baseline scenario (i.e. continuation of current control) includes multidrug therapy, passive case detection and BCG vaccination of infants. Leprosy data was obtained from the SINAN databases. We also investigated the impact of two interventions: 1) contact tracing, and 2) contact tracing in combination with administering chemoprophylaxis to contacts. All interventions start in 2015 with predictions made until 2050. The modelled trend in Pará State after 2012 shows a continuous downward trend, reaching the official elimination target of 10 per 100,000 annual new cases by 2028. Systematic contact tracing in combination with chemoprophylaxis to household contacts would bring the achievement of elimination forward to 2026. Contact tracing would increase the number of detected cases in the first 9 years, but in the long run would drop below the number in the baseline scenario. Administering chemoprophylaxis would prevent almost 10% of new detected cases since the start of the intervention in the long run. Our study indicates that the leprosy incidence will further decrease in Brazil. Elimination of leprosy as a public health problem can possibly be achieved around 2028 in Pará state. This moment could be brought forward by two years through systematic contact tracing in combination with chemoprophylaxis.

DEVELOPMENT OF A LUMINEX TREPONEMAL ANTIBODY ASSAY FOR LARGE-SCALE SURVEILLANCE AND IMPACT EVALUATION OF GLOBAL YAWS ERADICATION PROGRAM

Diana Martin[1], Gretchen Cooley[1], Brook Goodhew[1], Oriol Mitja[2], Arnold Castro[1], Cheng Chen[1], Allan Pillay[1], Patrick Lammie[1], Penias Moses[3], Tun Ye[1], Ron Ballard[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Lihir Medical Institute, LIhir, Papua New Guinea, [3]Lihir Medical University, Lihir, Papua New Guinea

Yaws, a non-venereal treponemal infection, is characterized by papillomatous and ulcerative skin lesions. Mid 20th-century mass-treatment campaigns resulted in a significant reduction in yaws cases, but resurgence of the disease occurred after the campaigns were dismantled. Recently, interest in yaws eradication was renewed after demonstration that a single oral dose of azithromycin is efficacious treatment for yaws. Serological diagnosis of yaws requires detection of two distinct antibodies: one against a treponemal antigen that indicates exposure to infection (such as the ***Treponema pallidum*** particle agglutination [TPPA] or hemagglutination [TPHA] assay) and one against a non-treponemal antigen (such as the rapid plasma reagin [RPR]) that can discriminate active from past infections. Unfortunately, the RPR test cannot be automated for use in large-scale, integrated serosurveillance platforms. We therefore sought to assess the quantitative correlation of individual treponemal antigens on a Luminex® multiplex bead-based immunoassay platform against standard serological tests for yaws. A total of 847 serum and dried blood spot specimens were collected as part of yaws surveillance projects in Ghana, Vanuatu, and Papua New Guinea (PNG). Specimens were run at 1:400 dilutions on a Luminex assay to test for IgG antibodies directed against the recombinant treponemal antigens p17 (rp17) and TmpA. Results were compared to those obtained using TPPA/TPHA assays and quantitative RPR test. Compared to the TPPA/TPHA, reactive concordance of rp17 was 98.8% (331/335), while reactive concordance of TmpA was only 84.8% (284/335). When comparing anti-TmpA reactivity against RPR titers we observed a strong correlation that was not seen with rp17 responses. A significant increase was noted in TmpA reactivity with increasing RPR titers (R^2 =0.975 for Ghana and Vanuatu and 0.94 for PNG). Our results suggest that TmpA could be used as a treponemal antigen marker for recent or active infection. Further validation will assist in development of a tool that could useful to help yaws surveillance and impact monitoring of global yaws eradication programs.

1681

LARGE THROUGHPUT SCREENING AND COMPUTATIONAL APPROACHES FOR IDENTIFYING COMPOUNDS EFFICACIOUS AGAINST THE OBLIGATE INTRACELLULAR PATHOGEN, *RICKETTSIA*

Alexander Lemenze, Alexander Perryman, James Occi, Joel Freundlich, Nancy Connell

Rutgers GSBS Newark, Newark, NJ, United States

Rickettsia is a genus of arthropod vectored, obligate intracellular bacteria that is the etiological agent of multiple spotted fevers and typhus diseases, most notably Rocky Mountain Spotted Fever and epidemic typhus. Various historical and novel Rickettsial diseases are constantly re-emerging as major human pathogens such as ***R. parkerii*** causing Tidewater Spotted Fever that is spreading with climate change up the Eastern coast of the United States. In recent years, antibiotic resistance has been documented in clinical cases requiring physicians to resort to more toxic treatments and therefore new drug compounds are needed for anti-Rickettsial development. Rickettsia's obligate intracellular nature presents challenges not usually present in drug screening protocols, which we aimed to overcome here. By transforming ***R. canadensis*** with pRMA18dRGA (Wood et al) expressing Green Fluorescent Protein we are able to utilize

fluorescence to measure inhibition of growth of ***R. canadensis*** in the Vero cell line when exposed to drug-like compounds. After validation and optimization of the conditions for compound screening, we have begun to screen 2,000 compounds from the Microsource Compound Library. Toxicity for each compound was also assessed as a factor in the obligate intracellular nature of ***Rickettsia***. The compounds that are active ***in vitro*** against ***Rickettsia*** will be further analyzed through a Bayesian algorithm to calculate predictive values for future compounds' activity or lack thereof. This Bayesian algorithm has been used previously by our and collaborating laboratories to identify compounds active against Mycobacterium tuberculosis and Staphylococcus aureus. By adapting methods for large throughput screening and combining data produced with the Bayesian algorithm we aim to find novel compounds active against ***Rickettsia*** spp, and produce a baseline database for future drug discovery.

1682

IN VITRO ANTIMICROBIAL ACTIVITIES OF "ANTIBACT", AN HERBAL MEDICINAL PRODUCT AGAINST CLINICAL BACTERIAL ISOLATES

Felix C. Mills-Robertson[1], Cynthia I. Onyeka[1], Samuel C. Tay[1], Willimas Walana[2], Salomey Acheampong[3], Michael Odame[3], Maxwell Antwi[3]

[1]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]School of Medicine and Health Sciences, University for Development Studies, Tamale, Ghana, [3]Centre for Plant Medicine Research, Mampong-Akwapim, Ghana

In vitro antimicrobial activities of ethanol and aqueous "Antibact", herbal products consisting of a combination of the leaves and branches of four different plants were evaluated against twenty one pathogenic bacteria. Saponins, reducing sugars, phenolics, polyuronides, and triterpenes were the major phyto-constituents of both the aqueous and ethanol "Antibact". The LD50 analysis revealed the products were safe (LD50>5000 mg/kg bodyweight) for ***in vivo*** use. All the isolates (100%) were resistant to at least five of the 12 antibiotics used in the study. In total, the aqueous "Antibact" inhibited the growth of 5 out of the 21 (23.81%) microbes used with an average zone of inhibition of 9.73 ± 0.35 mm while thirteen (61.90%) out of the 21 microbes used were susceptible to the ethanol "Antibact", with an average inhibition zone of 10.80 ± 0.18 mm. The minimum inhibitory concentration (MIC) of the aqueous "Antibact" ranged from 4.00 to 32.00 mg/ml and 0.50 to 8.00 mg/ml for the wild and standard strains respectively. In the case of the ethanol "Antibact" the MIC ranged from 2.00 to 8.00 and 1.00 to 2.00 mg/ml for the wild and standard strains, respectively. The average minimum bactericidal concentration (MBC) for the aqueous "Antibact" was 32.00 mg/ml while thatof the ethanol "Antibact" was ranged from 4.00 to 16.00 mg/ml and 4.00 to 8.00 mg/ml for the wild and standard strains, respectively. Thus, both aqueous and ethanol "Antibact" are safe for human use and also effective against some pathogenic bacteriaevaluated ***in vitro*** with the ethanol "Antibact" showing better antimicrobial activity.

1683

MEETING THE CHALLENGES OF BURULI ULCER IN ANAMBRA STATE NIGERIA

Amobi L. Ilika[1], Valentine C. Ilika[2], Chidozie Aniemena[1], Frances N. Ilika[3]

[1]Nnamdi Azikiwe University Teaching Hospital, Nnewi, Nigeria, [2]Anambra State University Teaching Hospital, Awka, Nigeria, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

Buruli Ulcer remains a great public health problem in riverine areas of Anambra State, Nigeria. It is a debilitating disease affecting the social and economic life of the people who are essentially poor peasant farmers. It is shrouded with myths, superstitions, stigma and discrimination which affect early and prompt health seeking behaviour. Yet it is neglected and no ongoing robust programme is targeted to control the disease. Using in-depth interviews, key informant interviews and focus group discussion, the perceptions of the people were ascertained. Clinical presentation of the ulcers were also gathered from infected persons. This lasted from January to March 2015. Male and female are equally affected in the distribution of the ulcer with the lower limb mostly affected, late presentation results in complications such as chronic ulcer, contractures and disability. Myths associated with Buruli ulcer includes that it is caused by witches and wizards, enemies and offended deities. it is believed that only native juju doctors can cure the disease. The ulcer perpetuates poverty cycle as affected people are not able to farm thereby reducing the income in addition to the treatment bills spent in appeasing the deities and paying the juju doctors. Women are mostly affected by stigma which reduces the chances of marriage of affected young women. The key challenges are, the area is inaccessible because of poor terrain, the educational status is low, medical facilities with qualified personnels are limited. There is predominance of native juju doctors and sorcerers who perpetuates the superstition and myths. Poverty also affects their health seeking behaviour. There is need for health education and enlightenment in the area to make the people understand the aetiology of the disease, remove myths and superstition and thereby encourage early health seeking, diagnosis and treatment. There is need for research in the area to know further the determinants and distribution of the disease in the area. Poverty alleviation and empowerment programmes should be provided in addition to improved Orthodox health facilities.

1684

EXAMINATION OF TETANUS VACCINATION AND SEROPREVALENCE DATA BY PROVINCE IN CHILDREN UNDER 5 YEARS OF AGE FROM 2007 AND 2013 IN THE DEMOCRATIC REPUBLIC OF CONGO

Hayley Ashbaugh[1], Sue Gerber[2], Reena H. Doshi[1], Patrick Mukadi[3], Nicole A. Hoff[1], Jean-Jacque Muyembe[3], Emile Okitolonda[4], Anne W. Rimoin[1]

[1]University of California Los Angeles, Fielding School of Public Health, Los Angeles, CA, United States, [2]Bill & Melinda Gates Foundation, Seattle, WA, United States, [3]National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, [4]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Critical evaluation of an immunization program is key to identifying areas of need and to ensuring efficacious and efficient resource allocation. We compared tetanus vaccination rates (determined by either maternal recall or vaccination card) by province for children 12-23 months of age in the Democratic Republic of Congo (DRC) from the 2007 (n=1,585) and 2013 (n=3,366) Demographics and Health (DHS) Surveys. A seroprevalence survey was also completed in tandem with the 2013 DHS Survey in which Dried Blood Spots (DBS) were collected from participants to determine IgG antibodies against tetanus for 8,116 children 6-59 months of age. Overall tetanus vaccination coverage (doses 1-3) in the 2007 DHS study for children 12-23 months of age was 70.6%, 59.1%, and 45.0%, respectively. In the 2013 study, overall tetanus vaccination coverage (doses 1-3) of children 12-23 months of age was 81.2%, 73.8%, and 60.5%, respectively. Tetanus seroprevalence was lowest in Maniema (20.1%) and Katanga (27.8%) provinces. In 2007, DTCoq vaccine coverage for children 12-23 months of age in Maniema was 51.9%, 38.3%, and 17.4%; and in Katanga was 60.4%, 51.6%, and 38.6%. In 2013, DTC/Pentavalent vaccine coverage for children 12-23 months of age in Maniema was 73.8%, 66.7%, and 47.2%; and in Katanga was 67.3%, 60.1%, and 51.3%. Tetanus seroprevalence was highest in North Kivu (51.8%) and Kinshasa (51.3%) provinces. In 2007, DTCoq vaccine coverage for children 12-23 months of age in North Kivu was 93.4%, 91.1%, and 83.3%; and in Kinshasa was 94.6%, 87.9%, and 81.1%. In 2013, DTC/Pentavalent vaccine coverage for children 12-23 months of age in North Kivu was 94.4%, 91.1%, and 87.0%; and in Kinshasa was 97.8%, 95.8%, and 83.7%. Although reported tetanus vaccination coverage has improved in the DRC, the low seroprevalence of tetanus antibodies, as well as the

divergence between reported coverage and seroprevalence warrants re-examination of current immunization and surveillance strategies. This data suggests that geographical disparities exist that may require novel or intensive strategies for effective immunization programs in certain provinces.

1685

DO TRACHOMA ASSESSMENTS PREDICT DISTRICTS ENDEMIC FOR TRACHOMA? COMPARISONS OF RESULTS FROM TANZANIA, UGANDA, BENIN AND DEMOCRATIC REPUBLIC OF CONGO

Jeremiah M. Ngondi[1], Upendo J. Mwingira[2], Edward Kirumbi[2], Patrick Turyaguma[3], Wilfrid Batcho[4], Bio A. Amadou[4], Jean Ndjemba[5], Janvier Kilangalanga[5], Achille Kabore[6], Anne Haggen[7], Jean Jacques Tougoue[6], Kathryn Crowley[6], Phil Downs[6], Lisa Rotondo[6]

[1]RTI International, Dar Es Salaam, United Republic of Tanzania, [2]Neglected Tropical Disease Control Program/MoHSW, Dar Es Salaam, United Republic of Tanzania, [3]Ministry of Health, Kampala, Uganda, [4]Ministry of Health, Cotonou, Benin, [5]Ministry of Health, Kinshasa, Democratic Republic of the Congo, [6]RTI International, Washington, DC, United States, [7]RTI International, Kampala, Uganda

Prior to SAFE implementation, baseline population based prevalence surveys (PBPS) of trachoma must be undertaken to facilitate planning. Trachoma assessments (TA) are a rational approach for prioritizing resources for PBPS. We compared: methods of TA, results of TA and results of PBPS undertaken in four countries. In Tanzania, TA in 56 districts included: review of health facility TT data; and assessment of TF and TT in two villages. PBPS were prioritized where villages had ≥ 5% TT or ≥15% TF, and districts that reported ≥30 TT cases over 5 years. In Uganda, key informant interviews and review of clinical records were done in 8 districts. PBPS criteria included: ≥10 TT cases for 2 consecutive years; >40% of health workers identified TT as a problem; and districts bordering areas with TF prevalence ≥10%. In Benin, Communes in 4 northern districts were assessed and criteria for PBPS were: bordering districts in neighboring countries with TF ≥10%; and reported TT surgery data. In Democratic Republic of Congo (DRC), TA included: investigation of TT cases seen at health facilities in Orientale, Equateur and Katanga; and assessment of TT cases seen in the community in North and South Kivu Provinces. Criteria for PBPS were: ≥10 TT cases seen at health facility; ≥10 TT cases seen in the community; and heath zones bordering countries where TF prevalence was ≥10%. PBPS were done using GTMP methods. In Tanzania, of 19 (out of 56) districts prioritized for PBPS, two had TF prevalence ≥10% and none had TT prevalence ≥1%. PBPS in four (out of 8) districts in Uganda showed TF prevalence and TT prevalence <10% and <1%, respectively. In Benin, 11 (out of 27) communes had PBPS of which two had TF prevalence ≥10% and 3 had TT prevalence ≥1%. In DRC, 32 (out of 99) health zones were prioritized for PBPS. PBPS have been completed in 10 health Zones where TF prevalence ≥10% and TT prevalence ≥1% was recorded in 4 and 8 the health zones, respectively. Results suggest that TA have been beneficial in identifying priority areas for PBPS. The PBPS provide important data for SAFE implementation; however, trachoma endemicity was low in most of the areas surveyed.

1686

WHICH DISTRICTS ARE ENDEMIC FOR TRACHOMA: METHODS AND RESULTS OF TRACHOMA ASSESSMENT IN TANZANIA

Jeremiah M. Ngondi[1], George Kabona[2], Mathias Kamugisha[3], Alistidia Simon[4], Edward Kirumbi[2], Deogratias Damas[5], Andreas Nshala[5], Kathryn Crowley[6], Lisa Rotondo[6], Upendo J. Mwingira[2]

[1]RTI International, Dar Es Salaam, United Republic of Tanzania, [2]Neglected Tropical Disease Control Program/MoHSW, Dar Es Salaam, United Republic of Tanzania, [3]National Institute for Medical Research, Dar Es Salaam, United Republic of Tanzania, [4]Sightsavers, Dar Es Salaam, United Republic of Tanzania, [5]IMA World Health, Dar Es Salaam, United Republic of Tanzania, [6]RTI International, Washington, DC, United States

By January 2014, baseline surveys of trachoma have been completed in 76 of 161 districts in Tanzania. The remaining 85 districts had unknown trachoma prevalence although most were suspected to be endemic. Establishing trachoma endemicity was needed to plan for implementation of the SAFE (surgery, antibiotics, facial cleanliness, environmental change) strategy in order to meet GET 2020 goals. We describe trachoma assessments undertaken to prioritize districts for population based prevalence surveys. The trachoma assessment was undertaken in 54 un-surveyed rural districts and two urban districts contiguous to highly trachoma endemic districts. The assessment comprised three activities: 1) key informant interviews with the district medical officers (or district eye-care coordinator or district NTD coordinator); 2) desk reviews to document data on trachomatous trichiasis over the last five years (2009 to 2013); and 3) spot checks in 2 villages per district to examine 50 children aged 1-9 years and 50 people aged 15 years and above, in each village, for active trachoma signs (trachomatous inflammation follicular [TF] and trachomatous inflammation intense [TI]), and trachomatous trichiasis (TT), respectively. Key informant interviews revealed that majority (85.7%) of the 56 districts perceived that there were areas in their district with trichiasis; however, 15 (27.8%) districts did not have any data on trichiasis. Based on the proposed criteria (proportion of TT ≥5% among 15 years and above, or active trachoma ≥15% in children aged 1-9 year, or at least 30 TT cases reported over previous five years) a total of 19 (33.9%) districts were found to be eligible for population based surveys of trachoma. The trachoma assessment provides a rational approach for deciding areas where resources for population based surveys and subsequent implementation of the SAFE strategy will be prioritized. Baseline surveys in the 19 districts will enhance Tanzania's progression toward elimination of trachoma by the year 2020.

THE SHRINKING TRACHOMA MAP IN TANZANIA: RESULTS OF BASELINE SURVEYS IN 31 DISTRICTS

Upendo J. Mwingira[1], George Kabona[1], Mathias Kamugisha[2], Bernard Kilembe[1], Edward Kirumbi[1], Alistidia Simon[3], Deogratias Damas[4], Alphonsina Nanai[5], Mwelecele Malecela[2], Maria Chikawe[1], Christina Mbise[3], Kathryn Crowley[6], Harran Mkocha[7], Patrick Masae[8], Lisa Rotondo[6], Jeremiah M. Ngondi[9]

[1]Neglected Tropical Disease Control Program/MoHSW, Dar Es Salaam, United Republic of Tanzania, [2]National Institute for Medical Research, Dar Es Salaam, United Republic of Tanzania, [3]Sightsavers, Dar Es Salaam, United Republic of Tanzania, [4]IMA World Health, Dar Es Salaam, United Republic of Tanzania, [5]World Health Organization, Dar Es Salaam, United Republic of Tanzania, [6]RTI International, Washington, DC, United States, [7]Kongwa Trachoma Project, Dodoma, United Republic of Tanzania, [8]Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, [9]RTI International, Dar Es Salaam, United Republic of Tanzania

Blinding trachoma is prevented through the surgery, antibiotics, facial cleanliness and environmental improvement (SAFE) strategy. Prior to SAFE implementation, baseline surveys of trachoma are recommended. As of 2012, only 61 out of 161 districts had been mapped from 2004

to 2006. Trachoma was suspected to be more widespread therefore further surveys were required for planning SAFE implementation. Between 2012 and 2014, trachoma baseline surveys were undertaken in 31 un-surveyed districts. In 2012 and 2013, 12 at risk districts were selected based on proximity to known trachoma endemic districts, while in 2014, trachoma assessments were undertaken and 19 districts prioritized for baseline surveys. A multi-stage cluster random survey sampling was applied whereby 20 villages (clusters) and 36 households per cluster were surveyed. Eligible participants, children aged 1-9 year and people aged 15 years and above, were examined for trachoma using the WHO simplified grading system. A total of 23,199 households were surveyed and 105,092 participants (4.3% of those enumerated) examined for trachoma signs. A total of 44,516 children aged 1-9 years were examined for trachomatous inflammation-follicular (TF) while 65,256 people aged 15 years and above were examined for trachomatous trichiasis (TT). Prevalence of TF varied by district ranging from 0.1%; 95% confidence interval [CI] (0.02-0.4) in Serengeti to 12.8%; 95% CI (8.3-19.3) in Chunya. TT prevalence was lowest in Misungwi [0.04; 95%CI (0.01-0.2)] and highest in Kibaha [2.5%; 95%CI (1.8-3.4). Two districts (Ngara and Chunya) had TF ≥10% while 3 districts (Chunya, Korogwe and Kibaha) had TT prevalence ≥1%. Based on the survey findings only two districts qualify for implementation of the full SAFE strategy. Trichiasis is still a public health problem in three districts and community based TT surgery services should be considered to prevent blindness due to trachoma. Although prevalence of trachoma was lower than previously suspected, in most districts, the findings will facilitate implementation of SAFE in endemic districts.

1688

PROGRESS TOWARDS ELIMINATION OF TRACHOMA IN TANZANIA: RESULTS OF IMPACT SURVEYS IN 28 DISTRICTS

George Kabona[1], Jeremiah M. Ngondi[2], Edward Kirumbi[1], Mathias Kamugisha[3], Alistidia Simon[4], Christina Mbise[4], Andreas Nshala[5], Patrick Masae[6], Harran Mkocha[7], Deogratias Damas[5], Alphonsina Nanai[8], Kathryn Crowley[9], Lisa Rotondo[9], Upendo J. Mwingira[1]

[1]Neglected Tropical Disease Control Program/MoHSW, Dar Es Salaam, United Republic of Tanzania, [2]RTI International, Dar Es Salaam, United Republic of Tanzania, [3]National Institute for Medical Research, Dar Es Salaam, United Republic of Tanzania, [4]Sightsavers, Dar Es Salaam, United Republic of Tanzania, [5]IMA World Health, Dar Es Salaam, United Republic of Tanzania, [6]Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, [7]Kongwa Trachoma Project, Dodoma, United Republic of Tanzania, [8]World Health Organization, Dar Es Salaam, United Republic of Tanzania, [9]RTI International, Washington, DC, United States

The World Health Organization recommends evaluation of the surgery, antibiotics, facial cleanliness and environmental change (SAFE) strategy after at least three years of implementation. We investigated the prevalence of trachomatous inflammation-follicular (TF) in children aged 1-9 years and trachomatous trichiasis (TT) in people aged 15 years and above in 28 districts. Surveys were conducted in districts where SAFE had been implemented for 3 years or more. Cluster random survey design was used to select the sample. Districts were stratified into three to four sub-districts and 10 to13 villages (clusters) randomly selected in each sub-district. Households were selected in using systematic random sampling. In sampled households, children aged 1-9 years were examined for TF and persons aged 15 years and above were examined for TT using World Health Organization (WHO) simplified grading system. A total of 41,641 households were surveyed. A total of 77,133 children aged 1-9 years and 110,763 people aged 15 years and above were examined for trachoma signs. District prevalence of TF ranged from 0.5%; 95% confidence interval [CI] (0.5-1.3) in Karagwe to 14.1%; 95%CI (10.9-18.1) in Kilindi. District prevalence of TF was below the 5% threshold for stopping mass drug administration (MDA) in 19 districts. Prevalence of TF was ≥10%, and between 5% and 9.9% in five and four districts, respectively. Prevalence of TT by district ranged from 0.1%; 95% CI (0.0-0.2) in Kondoa to 2.9%; 95% CI (2.2-3.9) in Lindi with 11 districts with TT prevalence of ≥1%. Survey findings suggest that the ultimate intervention goal for TF of <5%TF has been attained in 19 districts therefore MDA with Zithromax® should be stopped and surveillance surveys undertaken after 2 years. However, in the remaining districts at least 3 rounds of MDA and a single round of MDA are recommended in 5 and 4 districts, respectively; before further impact surveys are done. However, in many districts TT still remains a serious public health problem and therefore trichiasis surgery is required to clear the TT backlog.

1689

IMPACT OF MASS DRUG ADMINISTRATION ON TRACHOMA PREVALENCE IN 7 DISTRICTS OF THE FAR NORTH REGION IN CAMEROON

Assumpta Lucienne Bella[1], Blaise Noa Noatina[2], **Julie Akame**[3], Yannick Nkoumou[3], Ann Tarini[3], Yaobi Zhang[4]

[1]Ministry of Public Health, Yaounde, Cameroon, [2]Independent Consultant, Yaounde, Cameroon, [3]Helen Keller International - Cameroon, Yaounde, Cameroon, [4]Helen Keller International Regional Office for Africa, Dakar, Senegal

Cameroon is known to be endemic with trachoma in the northern regions. Disease mapping in 2010-2011 in the Far North region of the country identified 13 health districts (HDs) with prevalence of trachomatous inflammation, follicular (TF) of more than 10% in children aged 1-9 years. These HDs were therefore qualified for district-level mass antibiotic treatments as well as intensive implementation of other components of the World Health Organization (WHO) endorsed SAFE (Surgery, Antibiotic treatment, Facial cleanliness and Environmental improvement) strategy. Of the 13 HDs, 7 completed 3 rounds of mass drug administration with good coverage and qualified for impact assessment. A cross-sectional, descriptive, cluster randomized survey was conducted in May-July 2014 in the 7 HDs to estimate the prevalence of TF in order to determine whether the criteria for stopping mass treatment with azithromycin had been achieved. A sample of 12,377 children aged 1-9 years was surveyed. The WHO simplified trachoma grading system was used for the recording of cases. Findings showed that average prevalence of TF in 7 HDs decreased from 20.58% (95% confidence interval: 19.9% - 21.2% in 2010 to 2.04% (95% confidence interval: 1.79 - 2.30%) in 2014. The TF prevalence in each HDs was 6.49% (Meri), 5.75% (Pette), 0.37% (Bourha), 0.90% (Hina), 0.28% (Koza), 0.37% (Mogode), and 0.29% (Roua). Five out of 7 HDs surveyed reached TF prevalence of <5% and met the criteria of stopping mass antibiotic treatment. Two HDs, Meri and Pette, recorded TF prevalence from 5-9.9% and will receive one additional round of treatment before conducting an additional impact assessment survey, according to the WHO recommendations.

1690

FILARIAL/*LEISHMANIA* CO-ENDEMNICITY IN TWO DISTINCT REGIONS OF MALI

Moussa B. Sangare[1], Yaya I. Coulibaly[1], Siaka Y. Coulibaly[1], Michel E. Coulibaly[1], Ilo Dicko[1], Moussa Sissoko[2], Sibiri Samake[2], Thomas B. Nutman[3], Jesus Valenzuela[4], Ousmane Faye[5], Shaden Kamhawi[4], Fabiano Oliveira[4], Roshanak T. Semnani[3], Seydou Doumbia[2]

[1]Mali International Center for Excellence in Research, Filariasis Unit, Bamako, Mali, [2]Mali International Center for Excellence in Research, Leishmaniasis Unit, Bamako, Mali, [3]National Institutes of Health, Bethesda, MD, United States, [4]National Institutes of Health, Rockville, MD, United States, [5]Centre National d'Appui à la lutte contre la Maladie, Bamako, Mali

Filarial infections are a major public health problem that can lead to debilitating outcome such as the hydroceles and elephantiasis seen in lymphatic filariasis (LF). Phlebotomus duboscqi, the sand fly vector for Leishmania major (Lm) parasites, is found in areas endemic for LF in Mali. To determine whether there may be potential interactions between the presence of filarial infections and of Lm, the prevalence of the two major

filarial infection found in Mali (*W. bancrofti* [Wb] and M. perstans [Mp]) in two ecologically distinct regions - Tieneguebougou/Bougoudiana in Kolokani district (North Sudan savannah area) and Boundioba in the district of Kolondieba (South Sudan Savannah area) -- was assessed as was the prevalence of coincident delayed type hypersensitivity (DTH) responses to leishmanin as measured by skin test (LST). A total of 930 volunteers aged from 18 to 65 years were included from the two endemic areas. Prevalence rates for the Wb-specific circulating filarial antigen (CFA) were 7.69% (15/195), 3.04% (7/230) and 10.30% (52/505) while the Mp microfilaremia prevalence rates were 11.79% (23/195), 4.35% (10/230) and 9.50% (48/505), for Tieneguebougou, Bougoudiana and Boundioba, respectively. Interestingly, the prevalence rates based on LST for exposure to Lm infection were 25.12% (49/195), 8.88% (15/169) and 2.04% (8/393), respectively, in each of these villages. Single filarial infection was more common in the study population 15.16% (141/930) than DTH response to Lm within the filarial infected subjects 9.03% (14/155) (Chi2=4.076, p=0.044). Microfilaremia prevalence was comparable in Kolokani (7.76 %) and Kolondieba (9.50 %) (p=0.35) while CFA prevalence was significantly higher in Kolondieba (p=0.0040) as well as DTH response in Kolokani (p<0.0001). These findings establish the existence of co-endemnicity of filarial infections and Lm infections in regions in Mali. Additionally, because of the potential interaction between differing immune-mediated responses seen in chronic filarial infections and in Lm infection, more detailed and integrated approach to these infections is needed in co-endemic regions.

1691

THE EFFECTIVENESS OF AN ENHANCED ANTENATAL CARE PACKAGE FOR THE CONTROL OF MALARIA AND ANAEMIA IN PREGNANCY IN GHANA

Gifty D. Antwi[1], Harry K. Tagbor[1], Imelda Bates[2]

[1]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The prevalence of malaria and anaemia in pregnancy remains high despite efficacious antenatal care (ANC) interventions being available for more than two decades. Sub-optimal uptake of the interventions due to non-participation of pregnant women in ANC may be a contributory factor. We hypothesized that participation of pregnant women in their ANC would improve adherence to ANC recommendations and lead to better health outcomes. A cluster randomized trial was conducted to assess the effect of pregnant women's participation on the risk of anaemia and malaria parasitaemia during pregnancy. The intervention consisted of ANC staff showing pregnant women their rapid malaria test (RDT) and haemoglobin (Hb) colour scale (HCS) results to encourage their participation. The control group had routine care. We also assessed the feasibility and acceptability of the intervention. The overall mean age, gestational age and Hb at baseline were 26.4yrs, 17.3 weeks and 110 g/l, respectively, and similar in both groups; 10.7% had asymptomatic parasitaemia; 74.6% owned ITN of whom 48.8% slept under it the night prior to enrolment. The adjusted risk ratio by 8 weeks of follow up and at 36-40 weeks gestation in the intervention versus the control was 0.97 (95% CI: 0.78-1.22) and 0.92 (95% CI: 0.63-1.34) for anaemia and 1.17 (95% CI: 0.68-2.04) and 0.83 (95% CI: 0.27-2.57) for parasitaemia. The adjusted risk ratio for low birth weight was 0.93 (95% CI: 0.44-1.97) and for sub-optimal pregnancies (abortions, intra uterine foetal deaths and still births) was 0.77 (95% CI: 0.17-3.52) in the intervention group versus the control. Integration of the HCS and the RDT into ANC was feasible and acceptable. Both ANC staff and pregnant women perceived some improvement in pregnant women's adherence to ANC recommendations although clear evidence of a biological effect was not found. The effect may have been diluted out by the concurrent introduction of RDTs into routine ANC during the time of the study and some implementation challenges of the enhanced ANC package at the ANC clinics.

1692

PROVIDING SURGICAL CARE IN RURAL HAITI: LESSONS LEARNED AND PROGRESS MADE

Ruth L. Bush[1], Penelope S. Anthony[1], Katie A. Coble[1], J. Scott Thomas[1], J. Patrick Lataillade[2]

[1]Texas A&M College of Medicine, Bryan, TX, United States, [2]Living Word Haiti, Miramar, FL, United States

Surgical care in undeveloped poor countries is often lacking, only occurring at large regional hospitals. Rural residents may not have the financial means for care or the ability to travel. For the past 12 years, a team of medical professionals have been performing surgical procedures in a remote Haitian village in communication with the local Minister of Health. The College of Medicine has established a short-term global health elective for medical students and surgery residents. The purpose of this study was to review our experience providing surgical care to a profoundly underserved region. From 2003-2015, surgical procedures have been performed solely under local anesthesia. Early on, procedures were performed in a large room with separate areas for pre and postoperative care. Later, an on-site multi-room clinic was constructed with sinks, improving sanitary conditions. One surgical faculty, 4 circulating nurses, 3 nursing students, 6 surgical residents (elective began 2009), and 2 medical students (elective began 2013) have participated. Utilities are limited and alternative sterilization techniques employed. The procedures performed have included ventral and inguinal hernias (198), lipoma excisions (31), abscess drainages (31), thyroglossal duct cystectomy (2), skin cancer and large keloid excisions (15), and other (58). There have been no deaths and only 5 complications. Two hypertensive patients developed hematomas requiring evacuation and 2 patients had recurrence of their inguinal hernias prompting the change to a mesh repair in 2005. One hernia repair was aborted due to extensive scar tissue and the patient sent to a regional hospital. The global burden of surgical disease needs to be addressed on numerous fronts, including the most underserved and remote rural populations. The local conditions and volunteer expertise need to be matched so that excellent, appropriate, and safe care is provided. Trainees will benefit from the experience as well as on the addition of components of cultural education and global surgery ethics. Above all, participants must demand "Primum non nocere" or "First, Do No Harm".

1693

CHILD MALNUTRITION IN ECUADOR: RESULTS FROM THE ECUADORIAN NATIONAL HEALTH AND NUTRITION SURVEY (ENSANUT-ECU)

Winnie Chu[1], Wilma B. Freire[2], Saurabh Mehta[1], Jere D. Haas[1], Julia L. Finkelstein[1]

[1]Cornell University, Ithaca, NY, United States, [2]Ministry of Health of Ecuador and the Universidad San Francisco de Quito, Ecuador, Quito, Ecuador

The burden of child malnutrition in Latin America is high, although there is limited data from Ecuador. The recent Ecuadorian National Health and Nutrition Survey is the first national level nutrition survey since 1987, and provides a unique opportunity to examine the burden of malnutrition in children in Ecuador. Socio-demographic and anthropometric data (n=9,145) and venous blood samples (n=2,049) were collected. The prevalence of anemia, micronutrient deficiencies (zinc, vitamin A, iron, vitamin B12, folate), and stunting (LAZ<-2), underweight (WAZ<-2), wasting (WLZ1), and obesity (BMIZ>2) were calculated and mapped using ArcGIS. Binomial and linear regression models were used to examine the associations of anemia, micronutrient deficiencies, and WHO anthropometric indicators and socio-demographic characteristics. The prevalence of child stunting (25.0%), underweight (5.0%), wasting (2.3%), and overweight (30.0%) was high. Micronutrient deficiencies were common in children, particularly zinc deficiency (Zn<65.0 µg/dL; 25.0%), anemia (Hb<11.0 g/dL; 16.0%), and vitamin A deficiency (retinol0.05); however, the prevalence of anemia was higher in Coastal

Ecuador (22%; RR: 1.65, 95% CI: 1.36-2.00, p<0.01), compared to all other regions. Lower maternal education predicted increased prevalence of child anemia (19%; RR: 1.40, 95%: CI: 1.10-1.77, p<0.01) and vitamin A deficiency (19%; RR: 1.41, 95% CI: 1.11-1.79, p<0.01). The prevalence of child stunting was significantly higher in rural compared to urban areas (30% vs. 21%; p<0.01), and in the Sierra (29%, RR 1.32, CI 1.22-1.44, p<0.01). Indigenous children had the highest prevalence of stunting (39%; RR: 2.17, 95% CI: 1.97-2.39, p<0.01). Findings suggest that the burden of child malnutrition is high in Ecuador, including anemia, micronutrient deficiencies, and stunting, particularly in urban and coastal settings. Further understanding of the burden and distribution of child malnutrition will inform the design of targeted interventions.

1694

USE OF INTERFERON-Γ RELEASE ASSAYS FOR THE DIAGNOSIS OF TUBERCULOSIS IN PATIENTS WITH CONCURRENT MALARIA INFECTION IN TANZANIA

Camilla H. Drabe[1], Nyagonde Nyagonde[2], Filbert Francis[2], Michala V. Rose[1], Martha M. Lemnge[2], Ib C. Bygbjerg[1], Morten Ruhwald[3], Pernille Ravn[1], **Lasse S. Vestergaard**[1]

[1]University of Copenhagen, Copenhagen, Denmark, [2]National Institute for Medical Research, Tanga, United Republic of Tanzania, [3]Statens Serum Institut, Copenhagen, Denmark

Latent tuberculosis can be diagnosed with interferon-γ release assays (IGRAs). However, several conditions have been shown to interfere with IGRA performance, including concomitant glucocorticoid treatment, smoking, and human immunodeficiency virus (HIV) and helminth co-infection. It remains yet unknown whether concurrent malaria infection also affects IGRA performance; however, the well-established immune-modulating effects of malaria suggest this may be the case. We aimed in this clinical study in Tanzania to assess the effect of acute ***Plasmodium falciparum*** infection on the performance of two different IGRA tests: QuantiFERON-TB Gold in-tube (QFT-GIT) assay and the IFN-gamma-inducable protein 10 (IP-10) release assay. Study participants included adults with confirmed uncomplicated ***P. falciparum*** malaria attending Muheza District Hospital in north-eastern Tanzania as part of a larger trial looking at malaria treatment efficacy and safety in patients co-infected with HIV. A total of 241 adults were included: 184 patients with malaria (88 co-infected with HIV) and 57 patients with HIV infection only. Patients with malaria received the standard six-dose treatment with artemether-lumefantrine, and QFT-GIT and IP-10 release assays were performed prior to treatment on day 0 and again on day 7 and day 42 after treatment. Independently of HIV, significantly lower INF- and IP-10 responses to mitogen-stimulation were observed in patients with concurrent malaria compared to patients without malaria, with negative correlations observed between parasite density and INF- and IP-10 levels. These alterations reverted after malaria treatment. Malaria infection did not influence QFT-GIT testing results as such, while a higher proportion of IP-10 release assays showed indeterminate results during acute malaria. Our findings suggest that malaria infection interferes with IGRA performance through impairment of INF-γ and IP-10 responses. We therefore recommend being cautious when interpreting IGRA results in patients with malaria and that testing for tuberculosis be postponed until after completion of malaria treatment.

1695

DEVELOPMENT OF A REAL-TIME PCR DIAGNOSTIC FOR PATHOGENIC *LEPTOSPIRA*

Erik P. Johnson, Dale A. Schwab

Focus Diagnostics, San Juan Capistrano, CA, United States

The current gold standard for the direct detection of ***Leptospira*** in clinical specimens is culture in semi-solid media, which requires up to 26 weeks of growth. In addition, leptospires lose viability in urine, a common sample type, within hours after collection. To address these drawbacks, we have developed a real-time PCR assay for the detection of pathogenic strains of ***Leptospira***. Here, we evaluated the ***Leptospira*** Assay for analytical sensitivity and specificity as well as the stability of organism in various specimen types. Patient samples were spiked into common sample types, urine, whole blood, and cerebrospinal fluid (CSF), and stored for varying times and temperatures. Samples were then extracted using the MagNA Pure LC automated platform, and subjected to Real-Time PCR using primers and probes specific to the 16S gene of pathogenic ***Leptospira***. The ***Leptospira*** Assay, which could be completed in 5 hours, detected ***Leptospira interrogans***, ***L. weilii***, ***L. santarosai***, ***L. borgpetersenii***, ***L. kirschneri***, and ***L. noguchii***, but did not detect nonpathogenic strains ***Leptospira biflexa***, ***L. meyeri***, and ***L. wolbachii.*** The ***Leptospira*** Assay detected as little as 600 cells/ml from blood, 150 cells/ml from urine, and 75 cells/ml from CSF. Several stability studies were performed, which demonstrated that, even for molecular testing, ***Leptospira*** were stable in urine for only 1 hour after spiking at room temperature, and for less than 1 day at 4°C. However, ***Leptospira*** were stable in urine for 30 days at -20°C and stable in blood and CSF for 2 days, 7 days, and 30 days at room temperature, 4°C, and -20°C, respectively. Therefore, it is highly recommended that urine samples are shipped frozen. With a turn-around time of 24 hours and increased analytical sensitivity, especially in frozen samples, the ***Leptospira*** real-time PCR assay is an improvement over culture.

1696

ULTRASOUND FINDINGS OF TROPICAL CONDITIONS IN A COHORT OF SOUTH ASIAN IMMIGRANTS SEEN IN VICENZA, ITALY

Maria T. Giordani[1], Paolo Fabris[1], Luca Lazzarini[1], Roberta Narra[2], Enrico Brunetti[3]

[1]Infectious and Tropical Diseases Department, san Bortolo Hospital, Vicenza, Italy, [2]Department of Clinical Surgical Diagnostic and Pediatric Sciences, University of Pavia, Pavia, Italy, [3]Division of Infectious and Tropical Diseases IRCCS San Matteo Hospital Foundation-University of Pavia, Pavia, Italy

Immigrants from developing countries are a potential source of imported tropical conditions, including transmissible diseases. While illegal immigrants mostly come from sub-Saharan Africa crossing the Mediterranean sea, Asian immigrants generally travel legally to Italy and receive less medical attention. We describe the epidemiological, clinical and sonographic findings in a cohort of 145 Asian immigrants admitted to our Infectious Diseases and Tropical Medicine Department in Vicenza, Italy, from 2000 to 2014. Their countries of origin were India (45 patients, 31%),Bangladesh (72 p., 49.6%) and Pakistan (28 p., 19.3%).In all patients, point of care ultrasound (PoC-US) was performed in the first week of admission and during the hospital stay.The main diagnosis at discharge was: tuberculosis (TB) in 31 cases (21.3 %, 13 pulmonary TB, 18 extrapulmonary TB), acute viral hepatitis in 29 cases (20 %, 10 HEV, 2 HAV, 4 HBV, 2 of unknown origin); 12 patients had acute-on-chronic viral or alcoholic liver damage, in another three cases acute hepatitis was associated with Dengue Fever. 15 patients (10.4%) had typhoid or paratyphoid fever, 15 (10.4%) had pneumonia, 8 meningitis (5.51%), and 11 soft tissue infections (7.58%). Parasitic diseases (malaria, liver amebiasis, trichuriasis, toxoplasmosis and scabies) accounted for 8 cases (5.51 %). Only two patients (1.37 %) tested positive for HIV. The main ultrasonic findings were: hepatomegaly (52, 35.8%), fatty liver (48 , 33.1 %), splenomegaly (39, 26.8 %), pleural, pericardial and/or abdominal effusions (42, 28.9%), lymph nodal abscesses, both superficial and deep (12, 8.27%), coarse liver pattern (8, 5.5%) hepatic and splenic abscesses (7, 4.8%).Most patients (120, 82.75 %) had recently traveled to their country of origin or were recently immigrated and had an imported infectious condition. Immigrants from South Asia visiting friends and relatives (VFR) need more clinical attention from the ID specialist. PoC-US is helpful in diagnosing and managing tropical conditions in this population, as it allows identification of relevant, and sometimes pathognomonic findings in these conditions.

1697

CLINICAL, LABORATORY AND EPIDEMIOLOGICAL PROFILE AND TREATMENT OF SEVERE SCHISTOSOMIASIS MANSONI IN A TEACHING HOSPITAL IN SÃO PAULO CITY, BRAZIL

Maíra Reina Magalhães, Maria Cristina Carvalho Espírito-Santo, Naíma Mortari, Expedito José Luna, **Ronaldo Cesar Gryschek**

Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Schistosomiasis remains a public health problem in Brazil. The aim of this study was to evaluate the clinical, epidemiological and laboratory profile of patients with severe forms of schistosomiasis assisted at the Schistosomiasis Outpatient Clinic of the Hospital das Clinicas of the University of São Paulo. This is a case series study evaluating 42 outpatients' records. We developed a data collection questionnaire from patients' medical records and described their clinical and laboratory data. In addition, we made a comparison between patients with and without splenomegaly. The clinical, epidemiological and laboratory profile showed the following: predominance of males 57.1% (24/42); 100% (42/42) had the hepatosplenic form of the disease; 68.3% of patients (28/42) had just elementary school education and mean age of 48.24 years. Among the symptoms that led the patient to seek medical attention, presence of an enlargement in any organ was more prevalent: 55.3% (12/36). There was a statistically significant association between splenomegaly and thrombocytopenia ($p < 0.004$) between splenomegaly and leukopenia ($p < 0.046$), and only 2.5% (1/22) of patients presented with bleeding. Regarding specific treatment, 54.2% (13/24) of patients used Praziquantel and 45.8% (11/24), Oxaminiquine. Patients used the following non-specific drug therapy: 65% (26/40) Propranolol, 90% (36/40) Omeprazole, and 43.6% (39/42) Aluminum Hydroxide 92.9% (39/42) of patients required an upper endoscopy, 85% (39/40), sclerotherapy, 62.5% (25/15), elastic bandages, and 28.2% (11/39) underwent surgery. This preliminary study allowed us to observe the clinical, epidemiological and laboratory profile of patients treated in an outpatient clinic far from endemic areas for schistosomiasis, while pointing out that medical and endoscopic treatment, in combination with outpatient treatment can be effective in preventing bleeding and surgical treatment. The severe forms of this helminthiasis require an interdisciplinary outpatient follow-up.

CHIKUNGUNYA RHEUMATISM DURING THE SUBACUTE PHASE OF THE DISEASE AND ITS CORRELATION WITH IGG ANTIBODIES: FINDINGS FROM AN OUTBREAK IN COLOMBIA

Elsa M. Rojas Garrido[1], Maria C. Miranda Montoya[1], Victor M. Herrera Galindo[1], Adriana M. Gómez Bernate[1], Luisa V. Galviz Gómez[2], Luz A. Rey Caro[1], **Luis A. Villar Centeno**[1]

[1]Centro de Investigaciones Epidemiológicas, UIS., Bucaramanga, Colombia, [2]Departamento de Medicina Interna, UIS., Bucaramanga, Colombia

Chikungunya rheumatism (CHIK-r) includes a broad spectrum of disorders ranging from mere pain to frank arthritis with severe incapacity, however, the burden of this complication, its clinical features, and its relationship with the immunological response have not been fully characterized, especially in areas where the disease has been recently introduced. We evaluated 78 adults with clinical diagnosis of Chikungunya (CHIK) fever and persistent musculoskeletal symptoms after 15 days of disease's onset, in the context of an outbreak in Capitanejo, Colombia. CHIK infection was confirmed in 73 patients (mean age: 59 years; 23% male; median disease's duration: 46 days) using micro-capture ELISA for IgG. Antibody levels were expressed in NovaTec units (NTU). Patients underwent a clinical evaluation focused on the determination of rheumatic symptoms and a physical exam that included the squeeze test (in hands and feet) and the handgrip maneuver (Jamar dynamometer). The association between antibody levels and clinical signs of rheumatic involvement was evaluated using multiple logistic regression, adjusting for age, sex, and disease's duration. Arthralgia was the most frequently reported symptom at disease's onset (97%) and the time of evaluation (90%). Myalgia was also highly prevalent at both moments (90% and 48%, respectively). Squeeze test was positive in 34 (50%) and 30 (44%) patients when performed in hands and feet, respectively (kappa: 0.82, $p<0.01$). Overall, patients had low grip-strength, especially those who had positive as compared to negative squeeze tests (12.5 kg vs. 16.3 kg, $p<0.05$; respectively). A positive squeeze test (in hands), but not the grip-strength, was more likely among patients with higher antibody levels: 6% higher probability of positivity per 1 NTU increase in antibody levels (OR=1.06, 95%CI: 1.01 - 1.12). The handgrip maneuver and the squeeze test may contribute to a better characterization of rheumatic complications and correlate with the antibody's response. Whether these tools are useful to assess prognosis deserves further evaluation

1699

IMPACT OF MALARIA RAPID DIAGNOSTIC TESTS ON PATIENTS' SUBSEQUENT TREATMENT-SEEKING, COSTS AND HEALTH OUTCOMES: RESULTS FROM THE ACT CONSORTIUM

Heidi Hopkins, Philippa West, Shunmay Yeung, Clare Chandler, ACT Consortium RDTs in Context Working Group

London School of Hygiene & Tropical Medicine, London, United Kingdom

Malaria rapid diagnostic tests (RDTs) are intended to have a beneficial impact on management of suspected malaria, and on health outcomes and other patient-related outcomes. The ACT Consortium includes several studies designed to test operational strategies for artemisinin combination therapy (ACT) and RDT implementation in various settings, providing an opportunity to draw on data from multiple projects that have introduced RDTs across a range of clinical, social, and epidemiological contexts, and in public, private retail, and community health service sectors. The impact of RDTs on case management is presented in a separate abstract; this analysis focuses on events after the clinical consultation, including subsequent treatment seeking, patient costs, and self-reported health outcomes. Data were examined from eight studies comparing scenarios where RDTs were made available to control scenarios where RDTs were not made available. Preliminary analysis of three data sets shows that where RDTs were introduced, the proportion of patients seeking further care after the initial consultation increased in one high-transmission setting where community health workers offered only ACT; this was not the case in another setting in retail drug shops which offered non-ACT alternatives for RDT-negative patients. The same data sets indicate that patient or caregiver report of symptomatic recovery is approximately equivalent whether or not RDTs are available. Full results will include analysis by health care sector, epidemiology, patient age, routine and reference diagnostic results, and treatment prescribed at the initial consultation. This ongoing analysis aims to elucidate features associated with variation in post-consultation outcomes in order offer tailored guidance for policy and program development for RDT introduction in other areas.

ASSESSMENT OF RISK FACTORS FOR PRETERM BIRTH AND CONTRIBUTIONS OF PREMATURITY TO FUTURE RISK OF ADVERSE OUTCOMES IN A BANGLADESHI BIRTH COHORT

E. Ross Colgate[1], Dorothy M. Dickson[1], Marya P. Carmolli[1], Rashidul Haque[2], Masud Alam[2], Josyf C. Mychaleckyj[3], Uma Nayak[3], Mary Claire Walsh[1], Sean A. Diehl[1], Firdausi Qadri[2], William A. Petri[3], Beth D. Kirkpatrick[1]

[1]University of Vermont College of Medicine, Burlington, VT, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of Virginia, Charlottesville, VA, United States

Preterm birth has been identified by the WHO as a major global public health problem and accounts for more infant deaths in the first month of life than any other cause. South Asia has the highest rates of preterm birth. We followed a birth cohort of 700 healthy infants from the urban slums of Dhaka, Bangladesh for 2 years. We examined factors contributing

to preterm birth and whether prematurity led to increased risk for adverse outcomes related to rotavirus vaccine efficacy and any diarrheal illness in the first year of life. In our cohort, gestational age assessments using the Dubowitz-Ballard scale were completed on a subset of 381 children at enrollment (0-7 days after birth) by a trained medical officer. Among 381 children, 32% were born preterm (32-36 weeks gestation). We examined predictors of prematurity including child's gender, birth order, mother's age and BMI, and delivery status (cesarean vs vaginal). No association was found between preterm birth and infant or maternal characteristics, nor with cesarean delivery. To survey associations between prematurity and increased risk for adverse outcomes, we used univariate and logistic regression analysis to examine incidence and duration of rotavirus and all-cause diarrhea in the first year of life; infant rotavirus-specific IgA at 6 and 18 weeks of age; enteric co-pathogen burden at 10 weeks; serum zinc at 6 and 18 weeks; and incidence of diarrhea-related serious adverse events in the first year. Prematurity was not found to predict increased risk for any of these outcomes. In a population with high prevalence of childhood malnutrition, prematurity notably may explain a portion of described malnutrition in our cohort: 59% of stunted children (HAZ<-2SD) at enrollment were also assessed as premature, as were 50% of children with WAZ<-2SD and 39% with WHZ<-2SD at enrollment. Preterm birth was not associated with increased risk of malnutrition by one year of age. Future analyses will include assessment of prematurity and cognitive function outcomes up to age 2 years which may indicate clear targets for public health interventions to prevent preterm births.

1701

SAFETY EVALUATION OF FIXED-DOSE DIHYDROARTEMISININ-PIPERAQUINE COMBINATION IN A REAL LIFE SETTINGS

Abraham R. Oduro[1], Seth O. Owusu-Agyei[2], Margaret Gyapong[3], Fred N. Binka[4]

[1]Navrongo Health Research Centre, Navrongo, Ghana, [2]Kintampo Health Research Centre, Kintampo, Ghana, [3]Dodowa Health Research Centre, Accra, Ghana, [4]University of Allied Health Sciences, Ho, Ghana

Uncommon and rare reactions with delayed onset may not be detected before new medicines are licensed. Post-licensure surveillances are carried out to expand the evidence base of products characteristics for which marketing authorization were granted. Using the established INDEPTH-network safety monitoring platform the study evaluated safety of dihydroartemisinin-piperaquine as first-line treatment for malaria across different settings in Ghana. Key questions answered were the safety of the drug when used under usual conditions and assessment of the occurrence of adverse events. Health and Demographic Surveillance areas of Navrongo, Kintampo and Dodowa research centres located in the northern, middle and coastal belts of Ghana were used. From September 2013 to June 2014 a prospective, observational, study was carried out. Participants were males and females, age >6 months, weighing ≥ 5kg, ability to take oral medications, acute febrile illness and informed consent. Detailed clinical enquiry was conducted. Data analysis involved descriptive characteristics and adverse events coded using MedDRA® System Organ Class classification. The protocol received approval from the Ghana Health Service Ethics Review Committee, Ghana Food and Drugs Authority and was registered with Clinicaltrials.gov (NCT02199951). Approximately 95.5% (4563/4777) patients comprising 52% females and 48% children < 6 years of age. Overall 347 adverse with incidence rate of 76/10000 population. Characteristics associated with adverse effects were body mass index and parasite density. The commonest events according the MedDRA® Coding per 10000 population were infestations (465), gastrointestinal disorder (103), Respiratory conditions(46), thoracic disorders(44), Nervous system disorders (26) and Skin disorders (26). In conclusion, fixed-dose dihydroartemisinin-piperaquine combination is very safe in African population with malaria in real life settings

1702

NATIONAL SEROPREVALENCE OF MEASLES, TETANUS AND RUBELLA AMONG CHILDREN AGED 6-59 MONTHS IN THE DEMOCRATIC REPUBLIC OF CONGO

Reena H. Doshi[1], Nicole A. Hoff[1], Patrick Mukadi[2], Sue Gerber[3], Stephen Higgins[4], Emile Okitolonda[5], Jean-Jacques Muyembe-Tamfum[2], Anne W. Rimoin[1]

[1]University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, [2]National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, [3]Bill & Melinda Gates Foundation, Seattle, WA, United States, [4]Dynex Technologies, Chantilly, VA, United States, [5]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Serosurveys are a direct and accurate method to assess population level immunity and can provide critical insight into immunity gaps and operational program efficiency. In collaboration with the Demographics and Health Survey (DHS) we assessed population immunity to vaccine-preventable diseases in the Democratic Republic of Congo. We screened 8,117 children aged 6 to 59 months for IgG antibodies against measles, rubella and tetanus using dried blood spots (DBS) collected during the 2013 DHS. DBS were tested using the Dynex Multiplex M2 platform, an automated enzyme-linked immunosorbant assay at the National Laboratory for Biomedical Research in Kinshasa. Seropositivity rates for children in three age categories were determined for measles, tetanus, and rubella antibodies, respectively. Children aged 6 to 8 months had rates of 18.3, 46.7, and 14.0%; children 9 to 11 months had rates of 40.1, 43.6, and 23.9%; and children 12 to 59 months had rates of 73.1, 31.8 and 39.3% seropositivity for the three diseases described. VPD seroprevalence varied by province as well, ranging from 51.4-81.6% for measles, 20.1-51.8% for tetanus, and 19.3-52.5% for rubella. The lowest seropositivity rates for tetanus and measles were seen in Katanga and Maniema provinces. The prevalence of rubella was highest in Bandundu. The low seroprevalence of measles and tetanus antibodies indicate that large-scale immunity gaps exist across the DRC. The large percentage of children exposed to rubella in the absence of a vaccine, suggests widespread circulation of the virus throughout the country. In DRC, there is an immediate need to re-evaluate immunization strategies for these vaccine preventable diseases.

1703

HOSPITALIZATIONS IN IMMIGRANTS AND NON-IMMIGRANTS WITH CHRONIC HEPATITIS C INFECTION IN QUEBEC

Rhiannon L. Kamstra[1], Laurent Azoulay[2], Russell Steele[3], Marina Klein[4], Christina Greenaway[5]

[1]Centre for Clinical Epidemiology, Lady Davis Research Institute for Medical Research, Jewish General Hospital, Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, QC, Canada, [2]Centre for Clinical Epidemiology, Lady Davis Research Institute for Medical Research, Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, QC, Canada, [3]Department of Mathematics, McGill University, Montreal, QC, Canada, [4]Division of Infectious Diseases, McGill University Health Center. Department of Epidemiology, Biostatistics and Occupational Health. McGill University, Montreal, QC, Canada, [5]Division of Infectious Diseases, Jewish General Hospital, Centre for Clinical Epidemiology, Lady Davis Research Institute for Medical Research, Jewish General Hospital. Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal, QC, Canada

Chronic hepatitis C (HCV) causes considerable morbidity and mortality in Canada due to liver cirrhosis, liver failure and liver cancer that could be prevented through early screening and treatment. Immigrants are an underappreciated group at risk for HCV, often originating from high

prevalence countries. This study characterized all-cause and liver-related hospitalizations in HCV-infected immigrants compared to non-immigrants. We performed a retrospective population-based cohort study of all HCV cases in the Quebec mandatory disease reporting database from 1998 to 2007. Cases were deterministically linked to hospitalization and outpatient services databases. Liver-related hospitalizations were identified through discharge diagnoses and procedure codes. A total of 20,139 linked cases of chronic HCV were reported from 1998-2007, 9% (N=1,821) of whom were immigrants. At HCV diagnosis, immigrants were older (47.6 vs. 43.2y, p<0.05), more likely to be female (46.7 vs. 31.9%, p<0.05), and to have liver cancer (0.93 vs. 0.31%, p<0.05). The mean time to HCV diagnosis after arrival was 9.8 ± 6.9 years. Non-immigrants had a 3-10 fold higher prevalence of HCV-related risk factors, including drug or alcohol abuse, and HIV. Non-immigrants were more likely to be hospitalized at least once during follow-up compared to immigrants (49.3 vs. 35.8%, p<0.05 with hospitalization rates of 31.3 vs 18.2 /100 PY). Immigrants were as likely to have at least one liver-related hospitalization (7.8% vs. 7.1%), however in-hospital deaths were more likely to be liver related among immigrants as compared to non-immigrants (57.9% vs 41.8%, p<0.01). The most common primary discharge diagnoses for non-immigrants were mental disorders (20.5%) and injury/poisoning (10.3%) whereas for immigrants they were liver-related (11.6%) and neurologic disorders (10.2%). Higher all-cause hospitalizations in non-immigrants likely reflects more prevalent lifestyle comorbidities. The higher prevalence of liver cancer and in-hospital deaths due to liver disease in immigrants highlights the importance of early HCV screening and treatment in this population.

1704

INCIDENCE OF TROPICAL DISEASES IN THE US MILITARY 2004-2013

Elizabeth Blazes[1], Leslie Clark[2], **David Blazes**[3]

[1]Sidwell Friends School, Washington, DC, United States, [2]Armed Forces Health Surveillance Center, Silver Spring, MD, United States, [3]Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Understanding the impact of tropical disease on health is important to the US military, because many service-members travel overseas to areas where there is a high risk of acquiring these illnesses. To understand the scope of this risk, we quantified the incidence of the five most important tropical diseases in the military from 2004 to 2013 using the Defense Medical Surveillance System (DMSS), a continuously expanding relational data base that documents military and medical experiences of service members throughout their careers. Standard ICD9 codes for the following diseases were included: Dengue, Leptospirosis, Leishmaniasis, Malaria, and Helminths. Descriptive techniques were used to calculate the incidence rates in the military over the period of time between 2004 and 2013. Overall, there were a total of 10,941 cases of the five tropical diseases, and an incidence rate of 60.4 cases per 10,000 person-years. Most of those cases were Helminths, which had a total of 8,398 cases over the ten years, and an incidence rate of 46.4 cases per 10,000 person-years. Leishmaniasis was the next most common illness, at 1,327, or an incidence rate of 4.7 cases per 10,000 person-years. Malaria and leptospirosis were less common, with 860 and 95 cases respectively, yielding incidence rates of 4.8 and 0.5 cases per 10,000 person-years. In all the diseases, there seems to be a general downward trend from 2004 to 2013, possibly a result of decreasing deployments to tropical areas or better conditions encountered in those areas where travel occurred.

1705

ACUTE FEBRILE SYNDROME IN COLOMBIAN NORTHWEST

Maria F. Yasnot[1], Maria C. Velasco[2], Virginia C. Rodriguez[2]

[1]Universidad de Cordoba, Monteria, Colombia, [2]Grupo de Investigaciones Microbiológicas y Biomédicas de Córdoba, Universidad de Cordoba, Monteria, Colombia

Fever is one of the most characteristic symptoms of infectious diseases, sometimes the only one or the most important. A few time of fever, usually due to self-limited viral processes or noninfectious diseases. When fever persists more than two weeks, it is considered prolonged as a result of an infectious disease in many cases, but also in malignancy, autoimmune or hematologic diseases, metabolic disorders and vascular disorders. The febrile syndrome is the most common and nonspecific, It is defined as sudden onset of fever and less than seven days duration in patients who have not been identified signs or symptoms related to an infectious focus. Infectious disease to discard in the course of a febrile syndrome are diverse, such as tuberculosis, typhoid fever, brucellosis, sepsis, endocarditis, localized infections, urinary tract infections, rickettsia and viral processes. On this study, were evaluate five infectious agents (dengue virus, ***Plasmodium*** sp., Brucella spp., Leptospira sp., and Salmonella sp.) that are cause of febrile illness at the Córdoba department in Colombia, using molecular and immunological techniques to identified. Dengue contributes 40% of all cases, followed by malaria with 20%. Was not possible to determine the etiology of 36% of patients and 2% of leptospirosis. Only one patient showed co-infection with dengue and malaria; brucellosis and salmonellosis is not evident as the etiologic agent of febrile syndrome in this study.

1706

EPIDEMIOLOGIC CHARACTERISTICS OF ACUTE NEUROLOGIC DEFICIT IN ELDERLY PEOPLE FROM A DEVELOPING COUNTRY

Mentor Ali Ber Lucien[1], **Claudia Pierre**[2]

[1]National Laboratory of Public Health, Port-au-Prince, Haiti, [2]Quisqueya University, Port-au-Prince, Haiti

Elderly patients are vulnerable people and neurologic disorders are a very important public health problem which carries a risk of loss of autonomy. In developing countries like Haiti, few data exist about neurologic disorders. The aim of this study was to describe epidemiologic patterns of elderly people with acute neurologic deficit from Haiti. It was a retrospective cohort study conduct in the internal medicine ward from a big teaching hospital in Port-au-Prince: La Paix Hospital. The study period was 1st January 2012 to 31 October 2014. Criteria of inclusion: all adults patients admitted in the internal medicine ward with acute neurologic deficit and older than 65 years old. The criteria of exclusion were: charts non available. 525 elderly patients were hospitalized during this period and 124 had acute neurologic disorder. A systematic sampling was applied over the registry of the site. One patient over two was included in the study. Data from 62 patients were analyzed. Mean age was 75 years old, 32 (51.6%) patients were female. 45 (72.5%) had previously hypertension; 7 (11.2%) had diabetes; 8 (13%) were at their second acute episode. Only 16 (25.8%) patients came in less than 6 hours at the hospital. 18 (29%) had a blood systolic pressure > 220mnHg or a diastolic pressure > 120 mmHg. 25(40.32%) patients died and 50% of them before 3 days. 12 patients (19.35%) had a coma; 20 (32.25%) had obnubilation, 13 (20.9%) had seizure and 24 (38.70%) had speech disorders. 15 (24.19%) patients had facial palsy; 27(43.54%) had a left motor neurologic deficit, 3 (4.83%) had a neurologic deficit located at right inferior limb and 14(22.58%) had neurologic deficit at right superior and inferior limbs. All of the 17(27.41%) patients who realized a CT scan done it after 24 hours of hospitalization. 12 (70.58%) of them were ischemic stroke while the 5 (29.41%) others were hemorrhagic stroke. In our cohort, 25 (40.32%) patients died. 50% of those who survived had a length of stay of 8 days

while it was only for those who died of 3 days. It is very important to develop Point of Care technologies for neurologic emergencies at low economic cost for developing countries.

1707

PREVALENCE AND DETERMINANTS OF *TRYPANOSOMA CRUZI* INFECTION AMONG CITIZENS OF BOLIVIAN DESCENT LIVING IN MUNICH, GERMANY

Stefan Hohnerlein[1], **Miriam Navarro**[2], Nicole Berens-Riha[1], Peter Seiringer[1], Charlotte von Saldern[1], Sarah Garcia[1], Michael Hoelscher[1], Thomas Loescher[1], Michael Pritsch[1]

[1]Division of Infectious Diseases and Tropical Medicine, Medical Center of the University of Munich (LMU), Munich, Germany, [2]Fundación Mundo Sano, Madrid, Spain

Chagas disease (CD) affects 7 million humans worldwide and is responsible for 10,000 estimated deaths annually. Due to increased population mobility, CD has become an international health issue. Migration of Latin-American migrants from Spain (most CD-affected country in Europe) to other European countries is increasing lately. Germany lacks surveillance data. A cross-sectional, descriptive study was started in 2013 as a pilot project to determine the prevalence and determinants of CD among citizens of Bolivian descent living in Munich, Germany. Participants completed a questionnaire in order to collect socio-economic and medical data. Peripheral blood was drawn and specific antibodies against ***Trypanosoma cruzi*** antigens were determined by ELISA and IFAT. If positive, PCR, clinical staging and management of CD was initiated. A qualitative research was conducted through 2 interviews (one women T.cruzi+, one women with unknown serological status) and a focus group (3 subjects ***T. cruzi***-), all in Spanish language, in order to assess the impact of CD for individuals and the Bolivian community. Between June 2013 and June 2014, 43 citizens of Bolivian descent living in Munich could be enrolled. Four participants (9.3 %) were ***T. cruzi*** +, two of these also in PCR. Two of them were treated with benznidazole. Two of the ***T. cruzi*** + subjects had a mother with CD. A total of 55.8% of all participants (2 of the 4 ***T. cruzi*** +) had no knowledge about symptoms of CD and 30.2% (1/4 ***T. cruzi*** +) about ways of transmission. A total of 27.9% (0/4 ***T. cruzi*** +) had donated blood in the past without prior serological tests on CD, 62.8% (3/4 ***T. cruzi*** +) were motivated to donate blood and 53.5% (3/4 ***T. cruzi*** +) to donate organs. Regarding qualitative research, lack of knowledge about CD, stigma and fears associated with CD were identified. Regarding the lack of epidemiological data about CD in Germany and the absence of measures controlling non-vectorial transmission, the prevalence in this pilot study is alarming. Prevalence and determinants of CD in Germany have to be investigated further in a nationwide study and sensible control strategies with information campaigns should be put in place.

1708

SINGLE NUCLEOTIDE POLYMORPHISMS IN ANGIOGENIC AND INFLAMMATION PATHWAY GENES ARE ASSOCIATED WITH PATENT LYMPHATIC FILARIASIS

Jubin Osei-Mensah[1], Linda Batsa-Debrah[1], Anna Albers[2], Lydia Lust[2], Felix Brockschmidt[3], Christine Herold[4], Yusif Mubarik[1], Tim Becker[3], Holger Fröhlich Fröhlich[3], Kenneth Pfarr[2], Achim Hoerauf[2], **Alex Debrah**[5]

[1]Kumasi Centre for Collaborative Research into Tropical Medicine, Kumasi, Ghana, [2]University Hospital of Bonn, Bonn, Germany, [3]University of Bonn, Bonn, Germany, [4]Universit of Bonn, Bonn, Germany, [5]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Two-thirds of people with bancroftian lymphatic filariasis (LF) have sub-clinical disease or are asymptomatic and present as microfilaremic individuals (patent infections) or amicrofilaremic individuals who are antigen-positive (latent infections). These sub-groups are crucial to the continued transmission of ***Wuchereria bancrofti*** and have a direct bearing on the individual and overall public health burden of endemic communities. Although a clear distinction in immunogenetic profiles in response to LF is known to occur between overt clinical manifestations such as pathology and sub-clinical disease, it is unclear whether patent infections are distinct from latent states in sub-clinical disease. In a Ghanaian study, 101 single nucleotide polymorphisms (SNPs) and 1 insertion/deletion polymorphism from 48 candidate genes were selected for a case-control study. Genotyping was done for 302 patent and 389 latent unrelated individuals. SNPs in 9 genes [Caveolin-1 rs926198 (PATT = 0.03), Desmoplakin rs2076299 (PATT = 0.01), Endothelin-1 rs5370 (PATT = 0.04), GJA4 rs1764391 (PATT = 0.01), IFN-gamma rs2069707 (PATT = 0.049), IGF-1 rs2946834 (PATT = 0.002), NOD-1 rs736781 (PATT = 0.047), NOD2/Card15 rs1000331 (PATT = 0.005), TLR-4 rs5030725 (PATT = 9E-4)] and the TLR-2 gene insertion/deletion (-196 to -173 base pairs) (PATT = 0.04) were associated with patent infection. Haplotype analysis yielded haplotypes of SNPs in two genes that were significantly associated with infection status. AT in the IGF-1 gene was significantly associated with patent infection (Monte-Carlo method with 200,000 simulations), while the haplotype GT was significantly associated with latent infection (Global P = 1.5E-5). The haplotype CG in the IFN-γ gene was also associated with latent infection (Global P = 0.04). Our findings suggest that SNPs in angiogenic and inflammation genes are associated with patent infection and that the two states of sub-clinical disease are distinct chronic states in LF disease pathogenesis.

1709

MEDIATORS OF VASCULAR PERMEABILITY AND LYMPH/ANGIOGENESIS ARE MARKERS FOR HYDROCELES CAUSED BY *WUCHERERIA BANCROFTI* INFECTION

Chrisinta Weier[1], Anna Albers[1], Linda Batsa-Debrah[2], Sunny Mante[3], Sabine Mand[1], Birgit Stoffel-Wagner[1], Ute Klarmann-Schulz[1], Alex Debrah[4], **Kenneth Pfarr**[1], Achim Hoerauf[1]

[1]University Hospital of Bonn, Bonn, Germany, [2]Kumasi Centre for Collaborative Research into Tropical Medicine, Kumasi, Ghana, [3]37 Military Hospital, Accra, Ghana, [4]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Lymphatic filariasis, caused by the filarial nematode ***Wuchereria bancrofti***, is a disease that affects over 120 million people. Most individuals have no or just mild pathology, whereas others have severe pathology including lymphedema (~7% of infected individuals) or hydrocele (50% of infected men). Hydrocele is a painful swelling of the scrotum caused by accumulation of lymph fluid. The aim of this study was to identify biomarkers of hydrocele due to filarial infection. Hydrocele fluid was collected as part of a Volkswagen Foundation funded study investigating the use of doxycycline therapy in hydrocele patients. Eight hydrocele samples were analyzed: 3 treated, 3 control and 2 European idiopathic hydrocele samples. Using Isobaric Tags for Relative and Absolute Quantitation (iTRAQ) the relative protein content of the 8 samples was measured simultaneously. Placebo samples were analyzed against doxycycline and idiopathic samples. From the iTRAQ results we identified ~1000 proteins that were up- or down-regulated in the placebo samples. Prioritization of the results identified 9 proteins that were significantly higher in lymphatic filariasis hydrocele fluid (placebo): the androgen receptor, angiopoietin 2, cystatin C, fibronectin, heparan sulfate extracellular region, IGFBP-2 and -6, osteopontin and VCAM-1. These proteins are mediators or interact with mediators of vascular permeability and lymph/angiogenesis. Androgen receptor, fibronectin, IGFBP-2 and -6, osteopontin, and down-stream pathway factors are being analyzed in hydrocele fluid and plasma as markers of lymphatic filariasis hydrocele that could aid in early diagnosis and interventions to prevent or reverse disease.

1710

UTILITY THICK SMEAR OF LARGER VOLUME FOR THE DIAGNOSIS OF *MANSONELLA OZZARDI* IN THE PERUVIAN AMAZON

Salomon Durand, Dolores Rimarachin, Alejrandro Quiroz, Robert V. Gerbasi, Andres G. Lescano

U.S. Naval Medical Research Unit - 6, Callao, Peru

Although filariasis ***Mansonella ozzardi*** is very common in some regions of the Peruvian Amazon, little is known about its clinical presentations, its actual distribution in the Amazon Basin and its role in aggravation of other diseases. This filariasis is considered a neglected disease in the world. One of the major constraints to learning more about this condition is the difficulty of diagnosis. The Knott test, which is the gold standard for the diagnosis of this disease, is difficult to perform, and not done routinely in rural setting. For these reasons, we conducted a study to determine the sensitivity of the thick smear for malaria and a thick smear modified with increased blood volume compared to the Knott test for the diagnosis of this disease. The study was conducted in a rural community in the Peruvian Amazon of approximately 500 inhabitants where we knew there was a high prevalence of ***M. ozzardi***. Nearby and accessible houses were selected and after obtaining consent, samples of 5 ml of blood were taken from the arm of participants to perform a thick smear in a 6 µL volume of blood, similar to that performed for the diagnosis of malaria, and 2 thick smears of 60 µL, each of which were stained with giensa. A Knott test was also performed. The sensitivity and specificity were calculated. Samples were taken from 91 persons over 5 years. 56/91 (61.5%) of the samples were ***M. ozzardi***-positive by Knott test. The sensitivity of the thick smear was only 58.9% (CI 45.8-70.8) while the sensitivity of a thick film of 60 µL was 75.0% (CI 62.3- 84.4) and the sensitivity of two thick smear of 60 uL was 82.4% (CI 70.1-90.0). The specificities of all smears were 100%. In conclusion, the sensitivity, simplicity, and practicality of two thick smears of 60 uL would allow for sufficiently accurate diagnosis of filariasis by ***M. ozzardi*** in field studies and in rural health facilities.

1711

CHEMOKINE PROFILE OF HUMAN INTESTINAL HELMINTHIASIS IN AGBOR NIGERIA

Ebube M. Odoya[1], Onyeabuchi Patric Nmorsi[2], Reginah E. Ohenhen[2], Clement Isaac[2]

[1]Nigerian Institute for Trypanosomiasis Research, Vom, Nigeria, [2]Ambrose Alli University, Ekpoma, Nigeria

The study provides information on chemokine 5(CXCL-5) and chemokine 11(CXCL-11)profile in human intestinal helminthisis in Agbor Delta State, Nigeria.Feaces were examined using formo-ethol concentration method and Karto-Katz techniques. Sera from 72 volunteers infected with helminthes and 8 uninfected controls were subjected to chemokine evaluation using ELISA techniques.Eggs of intestinal helminthes identified were those of ***Ascaris lumbricoides*** (26.6%), ***Trichuris*** (5.8%), Hookworm (3.6%); Tapeworm and larvae of ***Strongyloides*** had 0.9% and 0.4% respectively. Plathyhelminthes had ***Schstosoma mansoni***, 7.6%; ***S. intercalatum*** 6.3% and Fasciola, 1.3%. CXCL-11 concentration showed no significant difference in expression between males and females (3500.00±42.08)pg/ml and their control subjects (2891±11.31)pg/ml. In CXCL-5, infected males (3839±2190.20)pg/ml showed no significant difference relative to male control (3549±3123.49)pg/ml ($p>0.05$). In the contrary, CXCL-5 concentration was high in infected females (7015.20±2190.20) pg/ml than in female control (1107.0±7391.77)pg/ml ($x^2=3796.20$, $p<0.001=124.84$). In conclusion, elevated concentration of CXCL-5 in serum of volunteers infected with intestinal helminthes implicates this chemokine as an important biomarker in the immunology of intestinal helminthiasis especially in subclinical cases.

CHRONIC INFECTION WITH *LITOMOSOIDES SIGMODONTIS* PROTECTS AGAINST ANAPHYLAXIS IN ORALLY SENSITIZED MICE

Laura E. Kropp, Edward Mitre

Uniformed Services University, Bethesda, MD, United States

Anaphylaxis is a life-threatening condition that can result from IgE-mediated allergy. It is becoming increasingly prevalent in western countries and results in approximately 1,500 deaths a year in the United States. In this study we investigated the therapeutic potential of helminths on systemic anaphylaxis in orally sensitized mice. BALB/c mice were sensitized by weekly oral gavage with ovalbumin (OVA) plus Staphylococcal enterotoxin B (SEB) or mock sensitized with PBS for a period of two months. Two weeks after completion of sensitization mice were infected with ***Litomosoides sigmodontis***, a rodent filarial parasite, or mock infected with PBS. Ten weeks post-infection mice were challenge by intraperitoneal injection of 0.4 mg of OVA. Basal temperature was evaluated every 5 minutes for 30 minutes following OVA-challenge. OVA-sensitized and mock-infected mice dropped an average of 2.6 degrees Centigrade by 30 minutes. In contrast, OVA-sensitized mice that were infected with ***L. sigmodontis*** experienced no change in core body temperature. As expected, PBS-sensitized mice that were infected with ***L. sigmodontis*** or mock infected exhibited no change in core body temperature during the 30 minutes post-challenge. Thus, chronic infection with ***L. sigmodontis*** appears to prevent anaphylaxis in mice with pre-existing allergy. Identifying the mechanisms underlying this phenotype could be important in developing novel therapeutics to treat allergic disease.

1713

PHARMACOKINETICS OF ORALLY ADMINISTERED DIETHYLCARBAMAZINE AND ALBENDAZOLE IN FERRETS (*MUSTELA PUTORIUS FURO*)

So Young Kim, Edward Mitre

Uniformed Services University of the Health Sciences, Bethesda, MD, United States

A major obstacle to eliminating lymphatic filariasis is a lack of effective macrofilaricidal drugs, medications that are active against the adult stage of these parasites. Drug development has been hindered by the lack of a small mammal model of lymphatic infection that develops clinical disease. We have established a previously developed ferret model of LF. In our model, 150 ***Brugia malayi*** L3's are injected subcutaneously in the right hind limb of ferrets. The adult worms reside in the lymphatic vessels, cause histologic and clinical lymphangitis, and develop permissive infections with the production of circulating L1 stage microfilarial worms. The objective of this study is to describe the pharmacokinetics of known anthelmintic drugs in our model in order to evaluate the suitability of ferrets for filarial drug testing. To achieve this, we administered a single oral dose of diethylcarbamazine (DEC) or albendazole (ALB) by gavage to healthy adult ferrets. In our experiment, 3 ferrets were given doses of: DEC 50mg/kg, DEC 250mg/kg, ALB 40mg/kg, or ALB 200mg/kg. The ferrets underwent four blood draws at baseline, 1 hour, 4 hours, and 24 hours after treatment. Plasma samples were analyzed by LC-MS/MS. The peak drug concentration for the low dose DEC was 1010 ng/ml and occurred at the 1 hour timepoint. Peak concentration for high dose DEC was 6200 ng/ml and occurred at 4 hours. Peak drug concentrations for low and high dose albendazole were 270 and 80 ng/ml, respectively. For both low and high dose albendazole the peak drug concentration was measured at 1 hour. In both DEC and ALB groups, the drugs reached the lower limit of detection by 24 hours. Based on our limited timepoints to date, we can estimate that the half-life for low dose DEC is 3-5 hours and the high dose is 12-15 hours. In humans, the half-life of DEC is 8 hours. The estimated half-life of ALB in ferrets is 2-3 hours for the high dose. In humans the half-life

of ALB is 10 hours. These findings give a foundation for determining antifilarial drug pharmacokinetics in ferrets. Future studies will utilize more timepoints and include other agents.

1714

INVESTIGATING EARLY INFECTION STATUS OF THE FILARIAL PARASITE *BRUGIA MALAYI* IN LABORATORY ANIMAL MODELS

Erica J. Burkman, Christopher C. Evans, Molly D. Savadelis, Michael T. Dzimianski, Andrew R. Moorhead

University of Georgia, College of Veterinary Medicine, Athens, GA, United States

Lymphatic filariasis (LF) is a mosquito-borne disease caused by the parasitic nematodes ***Wuchereria bancrofti*** and ***Brugia malayi***. These parasites are a major cause of morbidity globally, with an estimated 120 million people infected. ***Brugia malayi*** is the preferred laboratory model for LF due to the fact that non-primate hosts can become infected. For over 30 years, the domestic cat has been utilized as the primary non-rodent experimental model for ***B. malayi***. However, only approximately 25% of felines become patent and maintain a microfilaremia of >1000 mf/ml, which is necessary for life cycle maintenance. The primary test to determine infection status is the presence of circulating microfilariae (mf), which are detectable as early as 4 months. The cost of maintaining this animal model is relatively high, and it would be beneficial to be able to detect a biomarker to indicate infection status before mf are observed. In order to compare host susceptibility in another experimental model, we also examined ***B. malayi***-infected canines, which have been implicated as a reservoir in endemic areas. Ten male domestic cats and eight adult male and three adult female, heartworm-negative, beagle dogs were infected by subcutaneous injection of 400 (cat) or 500-1,000 (dog) ***B. malayi*** third-stage larvae. We monitored complete blood counts (CBCs), lymphedema, and microfilaremia. Filarial infections are known to induce a strong Th2 response. Therefore, we examined eosinophil levels in the blood, with the hypothesis that animals with high eosinophilia would become infected, but would not develop a patent infection. However, sequential CBCs monitored over the period of one year showed that cats maintained a high eosinophilia regardless of their infection status. Canine eosinophil levels were all within normal established reference ranges, even though 50% would become patent. These results may indicate that eosinophils do not play a role in the initial response to infection in the dog and cat and provide further insight into the role of LF pathogenesis in these animal models.

1715

HOW CAN ONCHOCERCIASIS ELIMINATION IN AFRICA BE ACCELERATED? MODELING THE IMPACT OF STRATEGY ADJUSTMENTS

Wilma A. Stolk[1], Grace Fobi[2], Afework H. Tekle[2], Honorat G. Zouré[2], Luc E. Coffeng[1], Annette C. Kuesel[3], Samuel Wanji[4], Daniel A. Boakye[2], Sake J. De Vlas[1], Jan H. Remme[5], Jean-Baptiste Roungou[2], Michel Boussinesq[6]

[1]Erasmus MC, Rotterdam, Netherlands, [2]African Programme for Onchocerciasis Control (World Health Organization/APOC), Ouagadougou, Burkina Faso, [3]World Health Organization/TDR, Geneva, Switzerland, [4]University of Buea, Buea, Cameroon, [5]Consultant, Ornex, France, [6]Institut de Recherche pour le Développement, Montpellier, France

Great progress has been made towards elimination of onchocerciasis in Africa by annual ivermectin mass treatment. Some countries are already close to elimination and might stop interventions before 2020. Other countries are lagging behind, e.g. due to a late start, very high pre-control endemicity level, implementation problems or contraindications for the implementation of ivermectin mass treatment. To eliminate onchocerciasis in these countries before 2025, interventions must be intensified or alternative treatment strategies must be implemented. We used the established ONCHOSIM model to investigate how much the time-to-elimination can be reduced by various strategy adjustments for different settings. Our results show that doubling the frequency of treatment from yearly to 6-monthly reduces remaining program duration by about 40%. Similar reductions can be achieved by continuing annual mass treatment with a more effective drug like moxidectin, or - if the achieved coverage is too low - by increasing treatment coverage to usual levels. The relative reductions in time-to-elimination do not depend much on the pre-control endemicity level and number of treatment rounds provided thus far. Test and treat approaches may be needed for ***Loa loa*** co-endemic areas where ivermectin mass treatment is contraindicated or compliance is poor due to perceived risk of side effects. We recommend that measures are taken to improve treatment coverage where needed. Further, biannual treatment should be considered when interventions are not yet fully scaled-up, or where pre-control levels are exceptionally high. Where these adjustments are expected to still be insufficient for achieving elimination by 2025, other strategies could be considered, including 3-monthly mass treatment, the addition of vector control through ground larviciding, or the use of more efficacious drugs for mass treatment or selective treatment of carriers. The cost-effectiveness, feasibility, and acceptability of different policy options should be taken into account.

1716

FIELD COMPARISON OF THE BINAX FILARIASIS NOW CARD TEST AND THE ALERE FILARIASIS TEST STRIP FOR DETECTION OF *WUCHERERIA BANCROFTI* CIRCULATING FILARIAL ANTIGENS

Cédric B. Chesnais[1], **Sébastien Pion**[1], Naomi P. Awaca[2], François Missamou[3], Gary J. Weil[4], Michel Boussinesq[1]

[1]Institut de recherche pour le Développement, Montpellier, France, [2]Ministère de la Santé publique, Kinshasa, Democratic Republic of the Congo, [3]Ministère de la santé publique, Brazzaville, Republic of the Congo, [4]Washington University School of Medicine, St. Louis, MO, United States

The Global Program to Eliminate Lymphatic Filariasis (GPELF) recommends use of tests for circulating filarial antigens (CFAs) to identify areas that require mass drug administration (MDA), to assess the impact of MDA, and for post-MDA surveillance. We compared the Binax Now Filariasis card test (ICT) with the recently released Alere Filariasis Test Strip (FTS). Comparisons were conducted in two sites that were endemic for LF: (1) a pre-MDA village in the Democratic Republic of Congo (DRC), and (2) a village in the Republic of Congo after two years of semiannual MDA with albendazole. The FTS detected 44.8% more subjects with filarial antigenemia (all subjects positive by FTS and negative by ICT were amicrofilaraemic) than the ICT (42/187 vs 29/187) in the DRC study site. The difference in the sensitivity of the tests was much higher in the community under MDA, where the FTS detected 93.2% more infected subjects (only one subject amongst the 41 who were positive by FTS and negative by ICT was microfilaraemic) than the ICT (85/697 vs 44/697); one subject (amicrofilaremic) was positive by ICT and negative by FTS. When tests were scored with a semiquantitative scale 0-3, mean scores were about 1 unit lower with the ICT compared to the FTS. A portable densitometer (Konica FD-5) was used in DRC to measure the intensity of the T line in a sub-sample of 124 FTS (from which 16, 28, 24 and 56 were visually scored 0, 1, 2 and 3, respectively). We found a significant correlation between the semi-quantitative visual scores and the intensities of the T lines assessed on the spot by the densitometer (rho = 0.93, P-value < 0.001). Intensities of the T lines were also reassessed at different intervals to assess the stability of test results. Post hoc intensity measurements showed a high correlation with the original values up to 8 days. These results confirm that the FTS is more sensitive than the ICT, especially with lower levels of infection. Densitometry can be used to objectively read FTS as a means of quality control for visual readings.

1717

EFFECT OF AN INJECTABLE LONG-ACTING FORMULATION OF IVERMECTIN ON *ONCHOCERCA OCHENGI*

Michel Boussinesq[1], Peter Enyong[2], Patrick N. Chounna Ndongmo[2], Sébastien D. Pion[1], Christophe Roberge[3], Georges Gaudriault[3], Samuel Wanji[2]

[1]Institut de recherche pour le Développement, Montpellier, France, [2]Research Foundation for Tropical Diseases and the Environment, Buea, Cameroon, [3]MedinCell S.A., Jacou, France

Additional tools and strategies are needed to reach the objective of onchocerciasis elimination set at 2025, and the most urgent requirement is the availability of a safe macrofilaricidal drug. In this context, a pre-clinical trial was conducted in Cameroon to evaluate the effects of an injectable long-acting (12 months) formulation of ivermectin on the microfilariae (mf) and adult stages of ***Onchocerca ochengi***. Ten female Gudali zebu cattle (age: 3 years) naturally infected with the parasite were injected subcutaneously with either 500 mg ivermectin (group 1, N=4), 1000 mg ivermectin (group 2, N=4) or the vehicle (group 3, N=2). Four subcutaneous nodules and a skin sample were collected from each animal at each time-point (before and 6 and 12 months after treatment). Before treatment, the average ***O. ochengi*** microfilaridermia was similar in the 3 groups (471.6, 222.4 and 263.8 mf per gram of skin, respectively). Six months after treatment, all treated animals were free of skin mf whereas the two controls (vehicle group) still showed high mf densities (mean: 319.3 mf/g). Twelve months post-dose, the same trend in the reduction of microfiladermia was observed, except for one treated animal which had one microfilaria in its skin sample. This animal had the highest mf density before treatment (1336.0 mf/g) and received the lower dose of ivermectin (500 mg). The two animals of the control group showed an average mf density of 850.4 mf/g. None of the animals showed any local or general adverse effect after injection and during the 12-month period. The viability and fecundity of adult worms will be assessed by histology and by embryograms and the plasma concentrations of ivermectin will be assessed by liquid chromatography-mass spectrometry. All these results will be presented at the meeting. Should the long-lasting effect observed on the mf densities be due to a macrofilaricidal effect, the new sustained-release formulation of ivermectin might be an additional tool to accelerate the elimination of human onchocerciasis in specific settings.

1718

ANTI-*WOLBACHIA* (A-WOL) DRUG DISCOVERY: LIGAND BASED VIRTUAL SCREENING COMBINED WITH HTS

Neil Berry[1], Paul O'Neill[1], Jaclyn Bibby[1], Steve Ward[2], Mark Taylor[2]

[1]University of Liverpool, Liverpool, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Filariasis inflicts serious health problems throughout tropical communities causing lymphatic filariasis (elephantiasis) and onchocerciasis (river blindness). These diseases infect 120 million people worldwide, ranking filariasis as one of the leading causes of global morbidity.1 Wolbachia is a bacteria that lives inside the cells of the filarial worms. As the filaria are dependent on Wolbachia bacteria survival, eliminating the bacteria with novel-antibiotic drugs would kill the filaria and deliver a new and practical solution for eradicating these debilitating diseases. Through targeting the Wolbachia bacteria, we aim to discover novel antibiotic anti-Wolbachia (A-WOL) therapy which will deliver safe macrofilaricidal activity with superior therapeutic outcomes compared with the current the current gold standard, doxycycline. Our present hit identification activities involves an iterative combination of HTS and ligand based virtual screening, with the results of each screen (active and inactive compounds) informing computational models which are utilised to select the next set of compounds for screening with the aim of improving both hit rate and diversity of the hits. We will present the background, methodology and successes of our approach in our iterative compound selection and screening approach. Through our approach we will show i) an increased hit rate, ii) expansion of SAR around hits, iii) discovery of novel hit chemotypes, iv) scaffold hopping, and v) probing new areas of chemical space. We will also present an analysis of the physicochemical properties of A-AWOL active compounds.

1719

A FIELD COMPARISON BETWEEN TWO RAPID DIAGNOSTIC TESTS FOR DETECTING *WUCHERERIA BANCROFTI* ANTIGEN IN HUMAN WHOLE BLOOD

Yao-Chieh Cheng[1], Delma Beaso[2], Nelly Sanuku[2], Lindy Marken[2], James K. Suamani[2], Samson Satofan[2], Bart Lombore[2], Peter M. Siba[2], James W. Kazura[1], Christopher L. King[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Papua New Guinea Institute of Medical Research, Maprik, Papua New Guinea

Seventy-two countries are currently endemic for lymphatic filariasis. The Global Program to Eliminate Lymphatic Filariasis uses rapid filarial antigen testing to identify endemic areas where mass drug administration (MDA) is needed and to monitor these areas in post-MDA surveillance. Two filarial antigen tests are currently available: the Alere Filariasis Test Strip and the BinaxNOW Filariasis card test. Because of lower cost and greater stability, the test strip will likely replace the card test in a few years. In only one published study from Liberia, the strip test is about 20-30% more sensitive compared to the card test. Whether the test strip compares similarly to the card test in other filarial endemic areas has not been examined. We compared the two tests using 216 samples collected from Papua New Guinean communities. Capillary blood was collected by finger prick during the night. The test strips were run using 75 µL of blood at the point of collection. The card tests were run the following morning using 100 µL of blood collected in 500 µL, EDTA-coated BD Microtainer tubes. Both test strip and card test were accessed at 10 minutes after the application of their required amounts of blood. Seventy-one of 216 subjects (32.9%) were test strip positive compared to twenty-three of 216 (10.6%) that were card test positive. For the positive test strips, 18.3% had 1+ reactivity, 36.6% had 2+ reactivity, and 45.1% had 3+ reactivity compared to 95.7%, 4.3%, and 0% respectfully for the card tests. Only individuals with strong reactivity in the test strips showed reactivity in the card tests. Microfilarial counts show that card tests may have had decreased sensitivity as three of ten microfilarial positive blood smears had negative card test readings. Although further investigation is needed for the suspected decreased sensitivity of the card tests, these initial results show that the Alere Filariasis Test Strip has much greater sensitivity compared to the BinaxNOW Filariasis card test. These could have important implications for determining cut-off thresholds for when an area is considered filariasis free or for when transmission interruption has occur.

1720

A NOVEL APPROACH TO IMPROVE THE BIOAVAILABILITY OF FLUBENDAZOLE BY USING A SPRAY DRIED FORMULATION IN JIRDS, RATS AND DOGS

Sophie Lachau-Durand[1], Marieke Voets[2], Petros Psathas[3], Peter Boeykens[2]

[1]Janssen Infectious Diseases, Beerse, Belgium, [2]Janssen Research & Development, Division of Janssen Pharmaceutica N.V, Beerse, Belgium, [3]Janssen Research & Development, LLC, Raritan, NJ, United States

Flubendazole (FBZ) is an anthelmintic with low oral bioavailability in its currently marketed formulations indicated for the treatment of Soil Transmitted Helminths. In view of the potential development of FBZ for the treatment of filariasis (onchocerciasis and lymphatic filariasis), aiming at systemic exposure, a new formulation with increased bioavailability has been developed. This new formulation of amorphous solid dispersion of FBZ, is manufactured using a modified high temperature spray dried technology (HSDT). It was administered at 1, 5, 10, 20 and 40 mg/kg as a

single dose and at 5 and 20 mg/kg for 5 days in jirds, at 20 mg/kg in rats and 35 mg/kg in dogs. Flubendazole and its 2 metabolites (Hydrolyzed and Reduced FBZ) were measured in jird, rat and dog plasma and in jird tissues (liver, lymph nodes, spleen and skin). After oral administration in jirds, C_{max} and AUC values increased less than dose proportionally, from 1 to 5 mg/kg/day, and increased dose proportionally, from 5 to 40 mg/kg/day. After repeated administration, the exposure was similar at 5 mg/kg and was lower at 20 mg/kg/day compared to the equivalent single dose. The plasma concentrations of its 2 metabolites were lower compared to FBZ. In tissues, 0.5 h after administration, FBZ was largely distributed in the liver, evenly in spleen and lymph nodes and less in skin compared to FBZ plasma concentration. Same pattern was seen in all doses and after repeated administration. The distribution of its 2 metabolites was slightly different with much higher liver concentrations than for FBZ. In rats and dogs, after oral administration, exposure was drastically increased compared to the marketed formulation. The plasma exposure of its 2 metabolites ranged between 0.55 to 0.67 compared to the FBZ exposure in rats and between 1.8 and 2.9 in dogs. In conclusion, the new FBZ formulation, using HSDT, improved drastically the bioavailability of FBZ after oral administration in jirds, rats and dogs. These encouraging data allowed to design efficacy studies in jirds with a broad range of FBZ doses and to start the toxicology program in rats and dogs.

1721

MODEL-BASED GEOSTATISTICAL MAPPING OF THE PRE-CONTROL PREVALENCE OF *ONCHOCERCA VOLVULUS* IN WEST AFRICA

Simon O'Hanlon[1], Hannah Slater[1], Robert Cheke[2], Boakye Boatin[3], Luc Coffeng[4], Sébastien Pion[5], Michel Boussinesq[5], Wilma Stolk[4], María-Gloria Basáñez[1]

[1]Imperial College London, London, United Kingdom, [2]University of Greenwich at Medway, Chatham, United Kingdom, [3]University of Ghana, Accra, Ghana, [4]Erasmus MC, Rotterdam, Netherlands, [5]Institut de Recherche pour le Développement and University of Montpellier 1, Montpellier, France

The initial endemicity (pre-control prevalence) of onchocerciasis has been shown to be an important determinant of the feasibility of elimination by mass ivermectin distribution. We present the first geostatistical map of microfilarial prevalence in the former Onchocerciasis Control Programme in West Africa (OCP) before commencement of antivectorial and antiparasitic interventions. Pre-control microfilarial prevalence data from 737 villages across the 11 constituent countries in the OCP epidemiological database were used as ground-truth data. These 737 data points, plus a set of statistically selected environmental covariates, were used in a Bayesian model-based geostatistical (B-MBG) approach to generate a continuous surface (at pixel resolution of 5 km x 5km) of microfilarial prevalence in West Africa prior to the commencement of the OCP. Uncertainty in model predictions was measured using a suite of validation statistics, performed on bootstrap samples of held-out validation data. The mean Pearson's correlation between observed and estimated prevalence at validation locations was 0.693; the mean prediction error (average difference between observed and estimated values) was 0.77%, and the mean absolute prediction error (average magnitude of difference between observed and estimated values) was 12.2%. Within OCP boundaries, 17.8 million people were deemed to have been at risk, 7.55 million to have been infected, and mean microfilarial prevalence to have been 45% (range: 2-90%) in 1975. This is the first map of initial onchocerciasis prevalence in West Africa using B-MBG. Important environmental predictors of infection prevalence were identified and used in a model out-performing those without spatial random effects or environmental covariates. Results may be compared with recent epidemiological mapping efforts to find areas of persisting transmission. These methods may be extended to areas where data are sparse, and may be used to help inform the feasibility of elimination with current and novel tools.

1722

STRENGTHENING LOCAL HEALTH SYSTEMS TO ADDRESS LYMPHATIC FILARIASIS MORBIDITY IN A RESOURCE-LIMITED SETTING: A MORBIDITY MANAGEMENT PROJECT IN THE LINDI AND MTWARA REGIONS OF TANZANIA

Deogratias Damas[1], Maria Chikawe[2], R. Shaban[3], Larry Akoko[4], Ally Mwanga[4], Sarah Craciunoiu[5]

[1]IMA World Health, Dar es Salaam, United Republic of Tanzania, [2]Ministry of Health and Social Welfare, NTD Secretariat, Dar es Salaam, United Republic of Tanzania, [3]Lindi Regional Hospital, Lindi Region, United Republic of Tanzania, [4]Muhimbili National Hospital, Dar es Salaam, United Republic of Tanzania, [5]IMA World Health, Washington, DC, United States

In Tanzania, lymphatic filariasis (LF) affects over 6 million people leading to a high burden of LF associated hydrocele: a fluid-filled enlargement of the tunica vaginalis sac around the testes. The economic, physical, and psychosocial impact of hydrocele is devastating not only for the individual, but also for the family and community. In the Lindi and Mtwara regions alone, hydrocele backlog was estimated at 8000 men awaiting hydrocele surgery in 2011. However, most patients did not access surgeries due to the following: 1) inability to pay as almost 90% of patients depend on out of pocket payment; 2) an inadequate number of skilled clinicians to perform surgeries; 3) limited medical supplies; and 4) patients' fear of undergoing a non-emergency surgery under general anesthesia. To address these obstacles, the project focused on strengthening the local health system by pooling resources from stakeholders (donor, MOH, national referral hospital, regional/district hospitals, and communities) to allow for surgeries free of charge and to provide required supplies. Experienced surgeons mentored 40 local doctors and nurses on hydrocelectomy using sac partial excision technique under local anesthesia. Also, clinicians were provided a small incentive to conduct surgeries over weekends to avoid interfering with regular weekly duties. By strengthening the local health workforce, pooling resources, and increasing availability of supplies, over 2000 patients accessed high quality, safe hydrocelectomy over 24 months; almost 6 times the annual average of hydrocelectomy surgeries performed regionally before the intervention. This intervention can be sustained through increased local capacity and ownership of the hydrocele surgery methodology within district level staff.

1723

NOVEL ANTHELMINTICS FROM FILAMENTOUS FUNGI ACTIVE AGAINST FILARIAL WORMS AND SOIL TRANSMITTED HELMINTHS

Jeffrey N. Clark[1], Meagan Tillotson[1], Jessica Carter[1], Brenda K. Hansen[1], Blaise Darveaux[1], Sheila M. Mitchell[1], Cedric J. Pearce[1], Nicolas H. Oberlies[2]

[1]Mycosynthetix, Inc, Hillsborough, NC, United States, [2]University of North Carolina Greensboro, Greensboro, NC, United States

Mycosynthetix, Inc. owns one of the world's largest (55,000), diverse and unique collections of filamentous fungi which were sourced from a variety of ecosystems worldwide. We reported previously that a number of natural product compounds and a few fungus extracts active against many nematodes which cause serious neglected diseases in humans as well infections in animals. We continue to exploit the medicinal and pharmaceutical potential of this large library. The targets of the current work include ***Brugia malayi*** microfilaria (BmMF) representing filariasis, and ***Haemonchus contortus*** L1 stage larvae (HcL1) and Strongyloides stercoralis L3 stage larvae (SsL3) representing soil transmitted helminth (STH) infections. We screened 4,048 crude fungal extracts and 90 pure compounds against these three parasites in our 96-well plate based systems. Following fungus re-growth and confirmation of activity of original extract hits, 12 (BmMF), 16 (HcL1) and 9 (SsL3) fully active extract hits were identified. Many of these hits were produced by filamentous fungi not previously shown to produce anthelmintic metabolites, including

Polyporales spp. and others. De-replication procedures to identify the chemical structures of the active metabolites are ongoing, but data thus far indicates that many are novel compounds. Of the 90 pure compounds tested, 22 were fully active against HcL1, 63 were fully active against BmMF and 11 were fully active against SsL3. The most potent compounds were active to 12.5 µM vs HcL1, 0.39 µM against BmMF and 6.25 µM vs SsL3. One of the active pure compounds we identified was enniatin D which has been shown previously to be active against parasites, thus validating our natural product de-replication/screening paradigm. We will continue to evaluate extracts and pure compounds against these three targets over the next few months and will provide an update at the meeting. In conclusion, from our fungal collection we continue to find interesting, novel and potent compounds against nematode targets of importance.

1724

EFFECTS OF FLUBENDAZOLE ON FILARIAL NEMATODES: A TRANSCRIPTOMIC APPROACH

Maeghan O'Neill[1], Cristina Ballesteros[1], Lucienne Tritten[1], Weam Zaky[2], Erica Burkman[3], Jianguo Xia[1], Steven A. Williams[2], Timothy G. Geary[1]

[1]McGill University, Ste Anne de Bellevue, QC, Canada, [2]Smith College, Northampton, MA, United States, [3]University of Georgia, Athens, GA, United States

The use of microfilaricial drugs for the control of onchocerciasis and lymphatic filariasis necessitates prolonged yearly dosing. Prospects for elimination or eradication of these diseases would be enhanced by availability of a macrofilaricidal drug. Flubendazole (FLBZ), a benzimidazole anthelmintic, is an appealing candidate macrofilaricide. FLBZ has demonstrated profound and potent macrofilaricidal effects in a number of experimental filarial rodent models and one human trial. Unfortunately, FLBZ was deemed unsatisfactory for use in mass drug administration (MDA) campaigns due to its markedly limited oral bioavailability. However, a new formulation that provided sufficient bioavailability following oral administration could render FLBZ an effective treatment for onchocerciasis and LF. Identification of drug derived effects is important in ascertaining a dosage range which is detrimental to the worm. Evaluation of drug-induced damage to tissues is challenging. In previous studies, histochemical analysis of morphological damage following exposure to FLBZ indicated that damage to tissues required for reproduction and survival can be achieved at pharmacologically relevant concentrations. However, histological damage is difficult to assess and there are individual differences in scoring of severity. The current study addressed this issue by taking a transcriptomic approach to confirm effects observed histologically and identify genes which were differentially expressed in FLBZ treated adult females worms (100 nM - 5 µM). Comparative analysis across treatment levels and time provided an overview of the processes which are affected by FLBZ exposure. The list of regulated genes correlates with reproductive effects observed via histology in previous studies. This study revealed transcriptional changes in genes involved in embryo and larval development, as well as cuticular synthesis. This data supports the indication that flubendazole acts predominantly on rapidly dividing cells, and provides a basis for selecting markers of drug-induced damage.

DECLINING HIV RATES AT A VOLUNTARY COUNSELING AND TREATMENT CENTER IN ADDIS ABABA, ETHIOPIA 2009-2014

Demetri A. Blanas[1], Chantal E. Ghanney[1], Kim Nichols[2]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, United States, [2]African Services Committee, New York, NY, United States

Voluntary counseling and testing (VCT) plays a key role in increasing access to HIV diagnosis and linkage to care. In Addis Ababa, Ethiopia's capital, where the rate of HIV is estimated to be 5%, there has been little published in the peer-reviewed literature regarding HIV epidemiologic, and behavioral trends at VCT centers. This paper reports on findings from five years of data from a VCT and treatment center in Yeka neighborhood in Addis Ababa. A preliminary analysis of intake forms from 13,192 clients demonstrated an overall rate of positive HIV tests of 7.6% with a decrease from 9.8% in 2009 to 6% in 2014. Demographic variables significantly associated with a positive HIV test included female gender, pregnancy, increasing age, presenting as an individual for testing (as opposed to with a partner), marriage or widowhood, unemployment, and lower income groups. The majority of clients reported their primary reason for testing was to plan for the future. This study adds to the currently scant peer-reviewed literature on VCT in Addis Ababa, suggests a trend of declining rates of HIV at the VCT center, and identifies demographic characteristics associated with higher HIV rates. If the proportion of people testing at VCT centers is truly declining in the area this center is located, this study may help target testing outreach efforts towards higher-risk populations.

1726

LEPROMATOUS LEPROSY AND HIV CO-INFECTION ASSOCIATED WITH PHENOMENON OF LUCIO VERSUS IMMUNE RECONSTITUTION INFLAMMATORY SYNDROME

Nora M. Cardona-Castro[1], Hector A. Serrano-Coll[1], Juan C. Beltran-Alzate[1], Sonia M. Buitrago[2]

[1]Instituto Colombiano de Medicina Tropical - CES, Sabaneta, Antioquia, Colombia, [2]Empresa Social del Estado Jose Cayetano Vásquez, Puerto Boyacá, Santander, Colombia

Diffuse lepromatous leprosy (DLL) is a severe clinical outcome of lepromatous leprosy. A new species, ***Mycobacterium lepromatosis***, was identified from a group of Mexican patients with DLL, and severe leprosy reactional state type 3 (phenomenon of Lucio). Clinically, the immune hypersensitivity triggered by bacterial antigens is associated with constitutional symptoms, necrotizing vasculitis, sepsis, and in some cases death. In addition, the advent of HIV and routine use of highly effective antiretroviral therapy (HAART) in patients with Hansen's disease, may relate to other events as immune reconstitution inflammatory syndrome (IRIS), which may occur in 40% of patients with HIV and HAART. In patients with HIV-leprosy, IRIS has been generally associated with inflammatory processes such leprosy-reactions type1, in contrast current clinical case shows a leprosy reaction type 3 or phenomenon of Lucio: Female, 37 years old, on 07/13 consulted by one month of recurrent febrile episodes and multiple skin ulcers in lower limbs. On physical examination patient has signs as pinna edema, loss of the bilateral external third of eyebrows, chronic indurated lesions in abdomen, and pigmented scarring lesions in lower limbs. In addition, patient has skin ulcers with burning pain associated with local edema and serous-hematic and purulent discharge. Patient refers weight loss of 4 kg in 6 months. She relates that seven days ago her spouse died by AIDS. Laboratory exams confirm HIV infection and leprosy. Multidrug therapy (MDT-MB) initiated with dapsone + rifampicin + clofazimine. HIV treatment abacavir/lamivudine plus lopinavir/ritonavir. After three weeks of treatment for HIV and leprosy, patient consulted with multiple skin blisters, with reticular pattern in upper limbs and proximal third of the lower limbs. Ulcer lesions in multiples sizes and different stages, dirty bottom, some of them necrotic with erythematous borders, numbness in legs and hands. DNA extracted from skin biopsy tested by Sanger sequencing technique ruling out the infection caused by M. lepromatosis. Results reported M. leprae European genotype 3-I as the cause of DLL.

1727

PERINATAL HIV INFECTION AND HEALTH RELATED QUALITY OF LIFE IN SCHOOL AGED UGANDAN CHILDREN

Allan K. Nkwata[1], Sarah K. Zalwango[2], Florence N. Kizza[1], Juliet N. Sekandi[1], Robert Kakaire[1], Robert Kakaire[1], Noah Kiwanuka[2], Christopher C. Whalen[1], Amara E. Ezeamama[1]

[1]The University of Georgia, Athens, GA, United States, [2]Makerere University College of Health Sciences, Kampala, Uganda

This study was undertaken to evaluate the impact of perinatal human immunodeficiency virus (HIV) infection on health-related quality of life (QOL) among 166 Ugandan children 6 -18 years old. We implemented a clinic-based retrospective cohort study among perinatally HIV infected and exposed children of HIV-positive women and HIV-negative perinatally unexposed children from Kampala, Uganda. Perinatal HIV infection was diagnosed by the end of breastfeeding via DNA PCR. Current negative HIV-status was confirmed by HIV rapid-diagnostic test. Child QOL was assessed with self-report version of pediatric QOL inventory. Four QOL domains (physical, emotional, social and school functioning) each with scores ranging from 0 (least QOL) to 100 (highest QOL) were defined. Descriptive analyses estimated means, standard deviations (SD), numbers and percentages by perinatal HIV status. Multivariable linear regression models were used to estimate HIV-related differences (β) in QOL scores and 95% confidence intervals (CI). HIV-infected (n=56), exposed negative (n=56) and unexposed children (n=54) were enrolled. Mean age was 10.8 (SD 3.48) years and 77(45.8%) were females. QOL scores in the social functioning domain were similar by child HIV status (p=0.9385). However, perinatally HIV-infected children performed worse than HIV-exposed negative and HIV-unexposed children in the physical (p=0.0006), emotional (p=0.0253) and school (p<0.0001) functioning domains. Perinatally HIV infected children scored significantly lower on Global QOL compared to HIV-exposed negative (β=-5.7, 95%CI: -10.7, -0.7) and HIV-unexposed (β=-6.6, 95%CI: -11.6, -1.6) after adjusting for child's age, sex, nutritional status, relationship to caregiver, and caregiver's age and educational level. QOL scores were similar for HIV exposed negative and unexposed children. In conclusion, perinatal HIV-infection is a significant predictor of low QOL. Specific interventions to mitigate HIV related disadvantage in the physical, emotional and school functioning QOL domains may enhance functional survival in children living with HIV.

1728

HIV AND TROPICAL COFACTORS: LESSONS FROM THE STI-TREATMENT TRIALS IN SUB-SAHARAN AFRICA

Larry Sawers[1], Eileen Stillwaggon[2]

[1]American University, Washington, DC, United States, [2]Gettysburg College, Gettysburg, PA, United States

Substantial evidence indicates that sexually transmitted infections (STIs) promote HIV transmission by producing genital ulcers, inflammation, and viral shedding. The burden of untreated STIs is far higher in sub-Saharan Africa (SSA) than in any other region. Ten randomized controlled trials in SSA examined the effect of STI control on HIV incidence. Only the first trial in Mwanza produced statistically significant results. Consequently, support for STI treatment for HIV prevention faded. The 9 post-Mwanza trials suffered from insufficient exposure contrast due to ethical considerations that required essential STI treatments for controls. The small differences in interventions in treatment and control arms led to small differences in STI outcomes between arms. Substantial treatments for controls also explain their reduced risky sexual behavior that in turn led to similar STIs outcomes between arms. The trials tested alternative treatments of bacterial or viral STIs but not both and were thus subject to confounding from STIs not considered in the trial design. None of the trials examined genital morbidity from infections other than STIs that could enhance HIV transmission or acquisition. Thus none of the trials addressed potential effect modification from biological interactions in the genital microbial community. None of the trials considered genital ulceration and inflammation from non-sexually transmitted pathogens, most importantly Schistosoma hematobium, which is highly prevalent in SSA. None considered ulcers infected with streptococci, staphylococci, or fungi, common in the region. Treating one genital infection may have little effect on HIV incidence when other infections are untreated. Flaws in the design of the post-Mwanza trials render them unsuitable to inform HIV-prevention policy for treatment of cofactor infections. Given the evidence that STIs and other genital infections, including urogenital schistosomiasis, promote HIV transmission and acquisition, cofactor treatment should be considered an important method for reducing HIV incidence in SSA and elsewhere.

1729

CD31 EXPRESSION ON CD4+ CELLS: A POSSIBLE METHOD FOR QUANTITATION OF RECENT THYMUS EMIGRANT CD4 CELLS IN RESOURCE-LIMITED REGIONS

Ramia Zakhour, Dat Tran, Guenet Degaffe, Cynthia Bell, Elizabeth Donnachie, Weihe Zhang, Norma Pérez, Laura Benjamins, Gabriela Del Bianco, Gilhen Rodriguez, James R. Murphy, Gloria P. Heresi

University of Texas Health Science Center, Houston, Houston, TX, United States

HIV infected individuals with combined antiretroviral therapy (cART) with long term viremia suppression may remain clinically stable or progressively deteriorate. For cART suppressed patients, conventional clinical status measurements such as CD4% or HIV viral load are poor predictors of long term clinical outcome. Measurements of recent thymus emigrant T-cells (RTE) have been shown to have predictive value. However, established methods for measurement of RTE (T-cell receptor excision circles or complex FACS) are difficult to deploy to regions where most HIV infections occur and where cART is becoming widely available. Literature review suggests that direct measurement of CD31 expression on CD4+ cells provides a simple measure of RTE CD4+ cells. To test this hypothesis, we reviewed records of 69 perinatally infected HIV+ [median (IQR) 13.0 (8.6) years, 54% female, 71% black] and 51 HIV- children [1.6 (5.6) years, 51% female, 63% black] attending UTHealth, Houston clinics between January 2010 and September 2012 for whom CD4+CD31+ were measured. HIV disease was well controlled by cART [2.2 (1.5) log10 HIV RNA copies/ml, 33% (12%) CD4+]. In HIV- and HIV+ groups CD4+CD31+% correlated negatively with age [Spearman's ρ=-0.525, p<0.001 and ρ=-0.475 (p<0.001), respectively] and values were slightly higher in females; expected patterns for RTE. And, CD4+CD31+% values fell within ranges of normal values established using conventional methodology. Our results show that direct measurement of CD4+CD31+ cells in peripheral blood gives results with numerical and biological characteristics consistent with those expected for CD4+ RTE. This technique can be easily performed in technical and budget limited settings. The capacity to measure RTE in the absence of sophisticated laboratory support should prove useful for both clinical management and research.

1730

EVALUATION OF THE OUTCOME OF CHILDREN ON ANTIRETROVIRAL THERAPY IN CAMEROON: A FOUR YEAR RETROSPECTIVE COHORT STUDY

Gabriel L. Ekali[1], Gilbert Tene[2], Joelle Sobngwi[3]

[1]National AIDS Control Committee and Biotechnology Center, Yaounde I University, Yaounde, Cameroon, [2]Centers for Disease Control and Prevention, Yaounde, Cameroon, [3]Catholic University of Central Africa, Yaounde, Cameroon

Although Antiretroviral Therapy (ART) has significantly improved the lives of those infected with Human Immunodeficiency Virus (HIV), access for children still remains low. The goal of our study was to assess 12 month outcome of HIV-infected children on ART in Cameroon. A retrospective cohort study was carried out in 25 treatment centers in 3 of 10 regions

(North West, South West and Center), harboring over 60% of pediatric patients nationwide. Children who initiated ART between January 2007 and December 2010 were included. De-identified socio-demographic, clinical and biological were extracted from hospital records and analyzed using SPSS version 16. Survival was estimated by Kaplan Meier method. $\chi 2$ and Cox proportional hazards were used to determine predictors of mortality. P values < 0.05 were considered significant and ethical clearance was obtained from the Institutional Review Board of the School of Health Sciences, Catholic University of Central Africa. A total of 1,867 children <15 years were included in the study. 50.2% were females, mean age was 62.2 ± 4.8 months. Over 50% were <60 months old, 20.7% had one or both parents dead and 63.7% had severe clinical disease (WHO clinical stage III or IV) at ART initiation. Of the 7.1% (110/1558) who had tuberculosis (TB) at baseline, only 48.2% were on TB treatment. Over half (57.8%) were on Cotrimoxazole at baseline. Complete data for outcome analysis was available for 328/1867. After 12 months, 71.3% (234/328) were still alive and in care, 9.8% (32/328) were dead and 17.4% (57/328) were lost to follow up. Severe clinical disease (Chi^2=104, p<0.001), age < 12 months (Chi^2=16.4, p=0.001), presence of TB (Chi^2=5.9, p=0.022) and hemoglobin level <8g/dL (Chi^2=13, p=0.001) were all significantly associated to death. Predictors of mortality were severe clinical disease (aHR=16.6, p<0.001), TB presence (aHR=4.1, p=0.007) and age < 12 months (aHR=5.6, p=0.009). Outcome of children on ART in Cameroon is poor. Improving retention in care, strengthening community engagement and building capacity of service providers are priorities if outcome needs to be improved.

1731

HIV, TUBERCULOSIS AND HIV/TB CO-INFECTION IN MACHALA, ECUADOR

Abigail G. Fessler[1], Saurabh Mehta[1], Efraín Beltrán-Ayala[2], Anita L. Arichábala Wilches[2], Anna M. Stewart-Ibarra[3], Julia L. Finkelstein[1]

[1]Cornell University, Ithaca, NY, United States, [2]Ministry of Health, Machala, Ecuador, [3]SUNY Upstate Medical University, Syracuse, NY, United States

Tuberculosis (TB) is a leading cause of death among HIV-infected individuals worldwide. The incidence of HIV in Ecuador has increased considerably in the past 15 years, and Ecuador has one of the highest burdens of HIV/TB co-infection in the Americas. We examined the burden of HIV, tuberculosis, and HIV/TB co-infection in Machala, Ecuador, a coastal city in southern Ecuador near the Peruvian border. A total of 398,919 records were analyzed from a citywide database of clinic visits in Machala, Ecuador in 2014. Binomial regression was used to examine the associations of HIV, tuberculosis, and HIV/TB co-infection with socio-demographic factors. There were 321 HIV cases, 1,210 tuberculosis cases, and 60 HIV/TB co-infection cases in 2014. The burden of HIV (RR: 3.16, 95% CI: 2.54-3.94, p<0.0001) and HIV/TB co-infection (RR: 4.91, 95% CI: 2.91-8.30, p<0.0001) was highest in adults aged 19 to 34 years, compared to all other age groups. In contrast, the risk of tuberculosis was highest among older adults (50-64y: RR: 3.27, 95% CI: 2.87-3.73, p<0.0001; ≥65y: RR: 2.21, 95% CI: 1.87-2.60, p<0.0001), compared to other age groups. Men had a greater risk of being infected with HIV (RR: 3.10, 95% CI: 2.48-3.89, p<0.0001), tuberculosis (RR: 3.53, 95% CI: 3.14-3.97, p<0.0001), and HIV/TB co-infection (RR: 8.70, 95% CI: 4.52-16.73, p<0.0001), compared to women. The burden of tuberculosis was higher in HIV-infected men, compared to HIV-infected women (24.9% vs. 8.9%; p<0.05). In summary, the burden of HIV, tuberculosis, and HIV/TB co-infection was relatively high in coastal Ecuador, with nearly one in five HIV-infected patients presenting with TB co-infection. Active surveillance efforts are needed to screen for HIV/TB co-infection and drug resistance in this setting.

1732

OLDER AND FORGOTTEN: MENOPAUSE SYMPTOM EXPERIENCE OF HIV POSITIVE AND NEGATIVE WOMEN IN IBADAN, NIGERIA

Olubukola Christianah Omobowale

University College Hospital, Ibadan, Nigeria

Globally,not only are people living longer with HIV/AIDS, but there is also a significant increase in older individuals becoming infected .As the human immunodeficiency virus (HIV) epidemic enters its third decade, a high percentage of women with HIV will also be entering menopause their lives extended by improvements in antiretroviral therapies.This study aims to determine and compare the menopause symptom experience and perceived health status among HIV positive and negative women. A comparative, hospital based study was conducted among HIV positive and negative menopausal women. Focus group discussions were conducted among menopausal women attending the ARV and General Outpatient clinics at the University College Hospital Ibadan, Nigeria with the use of a focus group discussion guide. Opinions of discussants on knowledge and experience of menopausal symptoms, perceptions about the menopause and the different coping strategies were explored. Six focus group discussions were conducted among women aged 40 and 60 years in each of the two groups.Data was analysed thematically. The majority of the discussants had adequate knowledge of menopausal symptoms with most of them reporting vasomotor symptoms and musculoskeletal symptoms. In both groups, perceptions about the menopause were generally positive as most of them opined that the menopause means freedom from sexual activity and child birth. Concurrent health conditions mentioned include: hypertension, osteoporosis, depression and reduced libido. Older women with HIV infection reported higher occurrences of these conditions. Coping strategies reported include belonging to a support group and seeking information from health care workers. In conclusion, menopause may induce many of the same metabolic changes that are being observed with HIV infection, and this may complicate the health and quality of life of aging women with HIV infection. There's a need for the formulation of methods and interventions that will help these women in coping with the double burden of HIV infection and symptoms of menopause.

1733

LOW NUMBER OF NERVOUS SYSTEM INFECTIONS AMONG 4012 ADMISSIONS IN SHELUI TANZANIA WITH STABLE/LOW PREVALENCE OF HIV

Gertruda Mikolasova[1], Veronika Sladeckova[2], Vladimir Krcmery[3], Martin Duris[2], Andrea Gughova[2], Kristina Badanicova[2], Zuzana Paukovova[2], **Lenka Michalikova**[4], Jaroslava Brnova[4], Emilia Mihalska[2], D. Jacko[2], Juraj Benca[1], Monika Jankechova[2], T. Oelnik[2]

[1]St. Elizabeth University, Bratislava, Slovakia, [2]St. Francis Dispensary, St. Elizabeth Tropic Programme, Shelui, United Republic of Tanzania, [3]Institution of Microbiology, Medical School, Commenius University, Bratislava, Slovakia, [4]Trnava University, Faculty of Health Sciences and Social Work, Trnava, Slovakia

In sub-Saharan Africa, several countries did substantial progress in decreasing HIV prevalence, such as Coastof Kenya, Central Tanzania and North Uganda, when HIV prevalence dropped from 20-25% in 2000-2010 to 5-10% in 2010-2015. The aim of this study has to asses prevalence/ occurrence of opportunistic HIV related in central and peripheral nervous system infections in post Highly active antiretroviral therapy (HAART), in area of central Tanzania with stable HIV transmission. Shelui region is located in central Tanzania between Arusha and Mwanza in a dry climate area in altitude of 1000 metres. HIV prevalence in 2013 was 4,3% and in 2014 was 5,6%. A decade ago, according to the local statistic of Health Dispenzary in Shinquida (50km) in 2003 was 14,7%. We separated from the 4012 admissions from January 2013 to December 2014 all neuroinfections and double checked in monthly reports their occurence in

2013 - 2014. Within12 months, 4012 patients was treated on out patients basis, in Shelui St. Francis Dispenzary, and any 79 neuro-infections (less than 1%) were repeated (majority of them 24 (61%) was herpes zoster infection (HZV) with local manifestation along the peripheral only 5 (22%) were HIV positive. 15 cases have had severe malaria, with central nervous symptomatology (coma or serious neuropsychic event (seizures)). No one case of TBC neuritis, cryptoccocal meningitis or toxoplasma encephalitis were observed among HIV positive cases. In conclusion, in time of HAART and decreasing of HIV prevalence, only minimum number of central nervous opportunistic infections appeared and therefore prophylaxis of opportunistic neuroinfections is not indicated, as it has been considered in pre/or early HAART era.

1734

DEVELOPMENT AND EVALUATION OF THE NON-INSTRUMENTED NUCLEIC ACID AMPLIFICATION (NINA) ELECTRICITY-FREE PLATFORM FOR ACUTE AND EARLY INFANT HIV-1 DETECTION IN LOW-RESOURCE SETTINGS

Robert Burton, Dylan Guelig, David H. McAdams, Steven Diesburg, Paul LaBarre

PATH, Seattle, WA, United States

In low-resource and resource compromised settings (LRS), limited access to centralized medical facilities presents a critical barrier to timely diagnosis and treatment, of infectious diseases. Inadequate diagnostic laboratory infrastructure results in inaccurate diagnoses, lost test results, delays to treatment, and loss to follow-up associated with specimen collection and transportation to centralized health centers and subsequent response. The most accurate molecular diagnostic tests with low limits of detection (LODs) and high clinical sensitivity and specificity are only available through laboratory-based testing and more recently through portable nucleic acid amplification tests (NAATs). To ensure accurate diagnostics are available to everyone, PATH has developed a non-instrumented nucleic acid amplification (NINA) device that enables disposable isothermal amplification by thermally coupling an exothermic chemical reaction to an engineered phase change material (PCM) in an easy-to-use, low-cost heater. This patented, electricity-free heating platform approach can be used to provide highly sensitive isothermal molecular diagnostics away from the traditional laboratory setting. The US Centers for Disease Control and Prevention (CDC) has developed a reverse transcription loop-mediated isothermal amplification (RT-LAMP) assay for HIV-1 that amplifies nucleic acid from a prepared whole-blood specimen. As nucleic acid amplification is the preferred method for acute HIV infection and early infant detection (EID), the introduction of this point-of-contact NAAT diagnostic will reduce the time to detection for HIV-1 infection by up to three weeks as compared to the currently used serology-based rapid diagnostic tests (RDTs). We present data on the design and manufacturing of 150 miniaturized single-use disposable NINA heaters, the lyophilization and stabilization of RT-LAMP reagents, and a qualitative HIV-1 assay. These data demonstrate our current status toward the goal of an inexpensive, easy-to-use molecular RDT for acute and early infant HIV infection detection.

1735

DEVELOPMENT AND DESIGN OF AN OBSERVATIONAL IMPACT EVALUATION OF IMMEDIATE ANTIRETROVIRAL THERAPY ON HIV INCIDENCE AMONG HIV-POSITIVE MEN WHO HAVE SEX WITH MEN IN SHANGHAI, CHINA

Joshua Mendelsohn[1], Liviana Calzavara[1], Hua Cheng[2], Mona Loutfy[3], Ann Burchell[4], Laiyi Kang[2], Canada-China Team

[1]University of Toronto, Toronto, ON, Canada, [2]Shanghai Centers for Disease Control and Prevention, Shanghai, China, [3]Women's College Hospital, Toronto, ON, Canada, [4]Ontario HIV Treatment Network, Toronto, ON, Canada

For people living with HIV and AIDS, antiretroviral therapy (ART) provides life-saving clinical benefits. Immediate ART initiation after HIV diagnosis has also been shown to be highly effective at reducing HIV transmission risk within heterosexual HIV-serodiscordant couples; however, equivalent evidence for men who have sex with men (MSM) has been limited to a few observational studies in high-income settings. Although immediate treatment after HIV diagnosis (i.e., treatment as prevention), regardless of CD4 count, is now considered best practice for key populations including MSM, the evidence in support of this policy in most real-world settings is inadequate. In China, where HIV incidence is increasing among the general population and especially among MSM, immediate ART following diagnosis is being considered by public health authorities as a possible strategy to reduce transmission. We have proposed a strategic international collaboration between the University of Toronto and the Shanghai Centers for Disease Control and Prevention (Shanghai CDC) to conduct a three-phase observational impact evaluation that will investigate: (1) background HIV care indicators (i.e., the cascade of HIV care including linkage to care, ART initiation, retention in care, adherence, and viral suppression) drawing on routinely collected surveillance data (n=9,284); (2) HIV care outcomes among HIV-positive MSM who select immediate ART (CD4>=500 cells/μL) or the current standard of care (CD4<500 cells/μL) (n=236); and (3) transmission risk among the HIV-negative partners (n=360). Methods will include a retrospective study of the Shanghai CDC database and a prospective cohort study among HIV-positive MSM and their HIV-negative partners. The present work outlines the scope of this international collaboration, elaborates upon key local and global research gaps, and presents the proposed study design, anticipated challenges, and limitations. This study is poised to make significant scientific contributions to the global evidence-base for HIV prevention and to strengthen HIV care outcomes in China and globally.

1736

ASSESSMENT OF VECTOR SURVEILLANCE CAPACITY IN THE US DEPARTMENT OF DEFENSE FOR EMERGING VECTOR-BORNE DISEASE THREATS

Koya C. Allen, Jean-Paul Chretien, Amy Peterson, Rohit A. Chitale

Armed Forces Health Surveillance Center, Silver Spring, MD, United States

With the emergence of vector-borne diseases, such as chikungunya virus (CHIKV), it is necessary to assess the state of preparedness for the US Department of Defense (DoD) to detect and respond to vector-borne disease (VBD) threats. Assessments are required for vector surveillance activities and prevention strategies for DoD personnel in areas at risk. A risk assessment was needed to evaluate the threat of CHIKV to the US, measure DoD capabilities for rapid detection of cases, and capacity for vector surveillance. The evaluation identified gaps in current capabilities for responding to emerging vector-borne disease threats, and strategies for capacity-building to apply to current surveillance programs. The four-tiered data collection and analysis strategy employed was 1) a review of DoD policy; 2) a workshop on strengthening DoD surveillance and detection for CHIKV and Dengue; 3) semi-structured interviews and observations; and, 4) a review of DoD vector surveillance programs.

Qualitative analyses of interview and field notes data included analytical coding and deductive reasoning to determine and translate themes for identifying gaps. The resultant themes were: 1) variation in capabilities; 2) a demand for resources; and, 3) a need for communication and collaboration. Major gaps identified were in operational surveillance and organizational structure. Laboratory capabilities varied by region and service, which caused ***'Reactionary Surveillance'*** instead of prevention. Moreover, military-civilian collaboration varied by need and program. The workshop resulted in six recommendations for preparedness; policy development, long-term research, improved risk assessments and improved collaboration. DoD vector surveillance capabilities for emerging threats are high; however, resources were lacking and efforts, often unstructured and disparate. Improved civilian-military collaboration can improve efficiency and effectiveness of national VBD preparedness by using an integrated approach to surveillance among biosurveillance partners.

1737

COMPARISON OF VIROLOGICAL OUTCOMES IN HIV INFECTED CHILDREN AND ADOLESCENTS ON COMBINATION ANTIRETROVIRAL THERAPY, WITH AND WITHOUT HISTORY OF TUBERCULOSIS DURING ELEVEN YEARS OF FOLLOW UP IN CAMBODIA

Andrea Shahum[1], Joseph J. Eron[1], Vladimir Krcmery[2], William C. Miller[1]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]St. Elizabeth University College of Health and Social Science, Bratislava, Slovakia

The immunological interaction between human immunodeficiency virus (HIV) and Mycobacterium tuberculosis (MTB) is bi-directional, with MTB increasing HIV viral replication possibly by inducing T-cell activation. But the impact of MTB disease on long-term virological response to combined antiretroviral therapy (cART) in MTB/HIV co-infected children and adolescents is unknown. We retrospectively analyzed a longitudinal cohort of 107 Cambodian HIV positive children (vertically infected) on cART continuously enrolled into 2 pediatric programs between 2003 and 2014. Children resided in a unique living setting that ensured a high degree of medication adherence. Median follow-up was 86 months (11-134). Median age was 7.0 years (1-15) at entry and 7.5 years (1.4-15.6) at cART initiation. Most children (n=60, 53%) had CD4 count ≤ 15% at the time of enrollment. Based on symptoms and radiographic evidence, 47 (44%) of 107 were diagnosed with active MTB infection. TB prevalence was 29.9%; the TB incidence rate was 61.5/100 children-years. From 47 co-infected children, 18 (38%) had virological failure of the first line (NNRTI-based) regimen, compared with 11 (18%) with no history of MTB (p=0.02). Total of 7 (21%) developed a recurrent episode of active MTB while on cART, 4 with evidence of virological failure (p=0.41). In a Cox proportional hazards model, children with co-infection were more likely to experience virological failure, as compared to children without MTB (HR 2.2, [95% CI 1.1, 4.2], p=0.02). After adjusting for age and using a left-truncated analysis (180 days post-cART), HR was 1.85, [95% CI 0.95, 3.8]. Active MTB infection, even if treated, appears to influence long-term virological outcomes of cART among HIV positive children and adolescents. The most apparent impact on virological outcomes was seen after 24 months of cART. High clinical recurrence of MTB among HIV positive children in both groups, with and without virological failure, suggests that standard MTB treatment was suboptimal at preventing recurrence or cART was unable to restore optimal MTB responsiveness.

1738

PEER LED DISCUSSIONS: A KEY ELEMENT OF CARE FOR YOUNG ADULTS WITH HIV

Raghuveer Puttagunta, Elizabeth Thoyakulathu, Sherri Bogard

Baylor College of Medicine, Houston, TX, United States

In the USA the incidence of HIV infection in young people (13 to 24 years old) continues to increase, accounting for 1 in 4 new infections. These newly infected young people are at a critical juncture in the management of their chronic disease while transitioning into adulthood. To support this population, we sponsored an environment for Houston's young adults with HIV that supports personal capacity building through peer support and learnt coping mechanisms. A weekly advocacy and wellness group was established in May 2014. The typical meeting agenda encompassed dinner, social activities, peer-led discussion of personal challenges and a short didactic session. On a monthly basis, individual interviews and ongoing needs assessment were conducted. Over the past 30 group meetings, the attendance ranged from 1 to 5 participants, with an age range of 18 to 27 years old. The group consists of individuals from multiple ethnicities and different education levels, sexual orientations, and sero-concordant/discordant relationships. Of the participants, 66% have attended over 5 meetings. During the meetings clients speak about their health, and specifically how HIV has affected their lives. Topics discussed include medication adherence, disclosure, grief, substance abuse, and life skills such as interview techniques and budgeting. When some feel they have nowhere else to go, the group has provided an outlet for participants to share their dreams and goals while also unloading some emotional burden. The wellness group is an opportunity for individual young adults with HIV to engage peers outside the clinical setting, empowering them to overcome personal obstacles, achieve career goals, and be an active citizen of the community.

1739

NOVEL APPROACHES IN THE DIAGNOSIS OF CUTANEOUS LEISHMANIASIS

Henk Schallig[1], Emily Adams[2], Gerard Schoone[1], Inge Versteeg[1], Maria Gomez[3], Ruby Rios[3], Ricardo Marquez[3], Alexandra Cossio[3], Yasuyoshi Mori[4], Nancy Saravia[3], Audrey Albertini[5]

[1]Royal Tropical Institute, Amsterdam, Netherlands, [2]Royal Tropical Institute and Liverpool School for Tropical Medicine, Amsterdam and Liverpool, Netherlands, [3]Centro Internacional de Entrenamiento e Investigaciones Médicas, Cali, Colombia, [4]Eiken Diagnostics, Tochigi, Japan, [5]Foundation for Innovative New Diagnostics, Geneva, Switzerland

Current methods to diagnose leishmaniasis have limitations due to the fact that they lack sufficient sensitivity and/or specificity, are difficult to conduct and often require invasive sample methods. Furthermore, variation in clinical accuracy of molecular diagnostic methods for leishmaniasis is commonly observed depending on sample source, method of DNA recovery and molecular test and few attempts have been made to compare these variables. Our research collaboration is seeking new methods in sampling and molecular methods that ultimately can be employed near patient. Swab and aspirate samples from lesions of patients with suspected cutaneous leishmaniasis (CL) were evaluated alongside standard diagnosis by microscopy or culture of parasites from lesion material. Three DNA extraction methods were compared: Qiagen on swab and aspirate specimens, Isohelix on swabs, and boil/spin of lesion aspirates. Recovery of ***Leishmania*** DNA was evaluated for each sample type by real-time PCR (18S rDNA). Swab sampling combined with Qiagen DNA extraction was the most efficient recovery method for ***Leishmania*** DNA , and the most sensitive (97%; 95% CI:91%-100%) and specific (84%; 95% CI:64%-95%) approach. Swab sampling of lesions was painless, simple to perform and coupled with standardized DNA extraction enhances the feasibility of molecular diagnosis of CL. To allow for near patient molecular testing we have developed an isothermal Pan-Leishmania LAMP assay for diagnosis of CL, which was evaluated

in a prospective cohort trial of 105 clinical CL suspects in South-West Colombia. Swab samples were processed for DNA extraction using the Qiagen Blood and Tissue kit. Microscopy was performed on skin scrapings of ulcers, aspirate samples were cultured, LAMP and qPCR performed on extracted DNA. A composite gold standard comprising of microscopy AND/OR culture positivity was used to calculate the diagnostic accuracy of LAMP and qPCR. LAMP was 95% sensitive (95% CI: 87.22 % to 98.53 %) and 86% specific(95% CI: 67.32 % to 95.88 %). This molecular test is more sensitive and specific than microscopy and culture alone.

TOOLS FOR IMPROVED MANAGEMENT OF VISCERAL LEISHMANIASIS: CLINICAL EVALUATION OF THE RK28 RAPID DIAGNOSTIC TEST AND ASSESSMENT OF AN ANTIGEN-DETECTION TEST OF CURE

Randall F. Howard[1], Maowia Mukhtar[2], Asim O. Abdoun[2], Hashim Ghalib[3], Marleen Boelaert[4], Joris Menten[4], Rosanna Peeling[5], Raodoh Mohamath[1], Malcolm S. Duthie[1], Dinesh Mondal[6], Asrat Hailu Mekuria[7], Aarthy Vallur[1], Steven G. Reed[1]

[1]IDRI, Seattle, WA, United States, [2]IEND, Khartoum, Sudan, [3]Universite de Lausanne, Epilanges, Switzerland, [4]ITM, Antwerp, Belgium, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [7]Addis Ababa University, Addis Ababa, Ethiopia

Prompt diagnosis and treatment of visceral leishmaniasis (VL) provide the best clinical outcome. The rK39 Rapid Diagnostic Test (RDT) has multiple advantages over invasive tissue biopsies and microscopy for the confirmation of clinical diagnosis, but low sensitivity (~80%) has been reported in Africa. We conducted a clinical study to validate our previous observation that an RDT based on the rK28 antigen can improve the confirmation of VL in Africa. VL was diagnosed in 206 enrolled Sudanese patients by ***Leishmania*** parasite detection in lymph node or bone marrow aspirates, while another 79 enrolled patients were negative and considered as controls. rK28 RDTs were conducted with both whole blood and sera, then evaluated by blinded interpretation. The rK28 RDT had a high specificity when developed with whole blood (WB; 100%) and serum (97.7%) and exhibited good sensitivity (WB, 92.5%; serum, 94.5%). Performance was favorable when compared with a Direct Agglutination Test performed on the same sera (92.9% specificity and 83.5% sensitivity). Two blinded readers scored a given WB or serum sample the same on the rK28 RDT 99.2% and 100% of the time, respectively. A reader scored one individual's paired WB and serum RDT results the same ("reproducibility") 93.8% of the time. As a means to monitor parasite burden and response to drug treatment, we have also developed a test, the ***Leishmania*** Antigen Detect™ ELISA (LADE), to directly detect ***L. donovani*** antigens in VL patient urine. LADE had >90% sensitivity on VL urine from Sudan (N=64), Bangladesh (N=13), and Ethiopia (N=46) and 88% sensitivity on samples from Brazil (N=43). The test had 100% specificity (N=88). To confirm LADE's utility in monitoring treatment, urine samples were collected from Ethiopian VL patients on a drug treatment plan. ELISA ODs were highest at time of diagnosis and decreased during treatment: A 95% positivity by LADE at day 0 fell to 21% at day 30, and to zero by day 180. Thus, LADE provides a non-invasive, semi-quantitative tool to detect parasite products during acute infection. Taken together, the rK28 RDT and LADE represent tools that can fill existing gaps in VL management.

DEFINING DRUG MECHANISM OF ACTION: LEVERAGING PHENOTYPIC HITS AGAINST KINETOPLASTIDS

Sonia Moniz, Susan Wyllie, Richard Wall, David Gray, Paul Wyatt, Mark Field, David Horn, Alan Fairlamb, Ian Gilbert

University of Dundee, Dundee, United Kingdom

The development of new drugs for the treatment of kinetoplastid diseases remains a challenge, hampered by few validated drug targets and an insufficient understanding of basic kinetoplastid biology. These and other challenges have left drug discovery programs heavily reliant upon phenotypic screening of compound collections against parasites in culture. However, in the absence of understanding the mode of action (MoA) or the specific targets of phenotypically active compounds, chemical optimization to improve pharmacokinetics or avoid toxicity is difficult to achieve, leading to unacceptably high attrition rates. To address these issues, we have established a multiplex platform for the determination of MoA. Several hundred anti-kinetoplastid compounds have been identified through phenotypic screening of libraries, providing well-validated cell-active chemical matter encompassing a diverse range of chemical scaffolds. The diversity of the cell-actives suggests that multiple undefined MoAs are in play. Our MoA-platform incorporates a battery of chemical, biological and genetic tools, and the orthogonal basis of the platform provides particular strength in determination of the interactions between actives and the parasite. This should yield high value insights into MoA, mechanisms of drug resistance and molecular targets. The utility of this approach will be discussed in terms of developing compounds as potential therapies and as tools for the dissection of kinetoplastid biology.

1742

ESTIMATING THE COSTS OF IDENTIFYING HUMAN AFRICAN TRYPANOSOMIASIS CASES USING A NEW DIAGNOSTIC FRAMEWORK IN UGANDA

Paul R. Bessell[1], Charles Wamboga[2], Enock Matovu[3], Robert Ssekubugu[4], Sylvain Biéler[5], Joseph M. Ndung'u[5]

[1]Epi Interventions Ltd., Edinburgh, United Kingdom, [2]Ministry of Health, Kampala, Uganda, [3]Makerere University, Kampala, Uganda, [4]Rakai Health Sciences Program, Kalisizo, Uganda, [5]FIND, Geneva, Switzerland

Human African trypanosomiasis (HAT) cases in Uganda that are caused by the ***gambiense*** subspecies of the protozoan parasite ***Trypanosoma brucei*** have been declining in recent years. To maintain this decline, HAT cases must be identified early in their infection, but prior to 2013 only four facilities were equipped with HAT screening tests. In 2013 a program was launched to strengthen the passive surveillance infrastructure, here we evaluate the cost-effectiveness of this program. The program equipped all 197 public healthcare facilities in the focus with new Rapid Diagnostic Tests (RDTs). To confirm presence of the pathogen, positives by RDT were referred to one of 12 facilities that were equipped with enhanced microscopy. For those not confirmed by microscopy, a blood sample stored on filter paper was transported by motorcycle to one of three facilities equipped with loop mediated isothermal amplification of DNA (LAMP) equipment. To estimate the costs of running the program and costs of identifying each case we use an epidemiological model of the surveillance system and incorporate costs in this model. Data on costs (incurred by the program and by those screened) and epidemiological parameters were collected during the program. By June 2014, 5,036 RDTs had been performed and had identified 7 cases from 200 positive RDTs. Facilities had been enrolled in the program gradually from August 2013 until February 2014. We estimate that over one calendar year, an average 11,162 people would be screened, identifying 16 cases per year (at contemporaneous prevalence), at a total cost of 129,700 USD which is 8,360 USD per case identified or 658 USD per facility per year. We have demonstrated that large scale passive screening can be implemented in a cost-effective manner across an entire HAT focus. This model of easy access to screening through the nearest healthcare facility is a framework that can be used in other countries. Following a shrinkage in the HAT focus, this project was streamlined by reducing the extent of coverage of RDT facilities in July 2014. These results are being updated accordingly and will be modelled to estimate costs as prevalence declines.

1743

COMPARISON OF THE PERFORMANCE OF THE SD BIOLINE HAT RAPID TEST AND CATT IN VARIOUS DIAGNOSTIC ALGORITHMS FOR GAMBIENSE HUMAN AFRICAN TRYPANOSOMIASIS

Crispin Lumbala[1], Paul R. Bessell[2], Pascal Lutumba[3], Sylvain Baloji[1], Sylvain Biéler[4], Joseph Ndung'u[4]

[1]PNLTHA, Kinshasa, Democratic Republic of the Congo, [2]Epi Interventions Ltd., Edinburgh, United Kingdom, [3]University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [4]FIND, Geneva, Switzerland

Early diagnosis of human African trypanosomiasis (HAT) relies on screening large numbers of at-risk individuals. Screening for HAT has been carried out with the card agglutination test for trypanosomiasis (CATT), which is limited by its requirement for cold storage, electricity and its multi-test packaging format. Recently, Standard Diagnostics (SD)/Alere developed an individually formatted and thermostable rapid diagnostic test (RDT). Evaluation studies found that the SD BIOLINE HAT RDT prototype was less sensitive and specific than CATT. The prototype was optimized and we present a study to evaluate the performance of CATT and the optimized RDT in the Democratic Republic of the Congo. The study followed a clinical trial format. Participants were enrolled actively by four mobile teams, and passively at four healthcare facilities in three provinces. Each participant was tested with the RDT and CATT, participants positive by CATT were retested with CATT on 1:8 diluted plasma (CATT 1:8), and positives to CATT or RDT were tested by visual inspection for motile parasites in body fluids. Cases were those with visible parasites. Results were analysed in four algorithms - RDT and CATT as standalone tests and each test followed by CATT 1:8. During five months 131 cases and 13,527 controls were enrolled. The sensitivity of the RDT was 92.0% (95% confidence intervals (CIs) = 86.1, 95.5), and was significantly higher than CATT, which was 69.1% (95% CIs = 60.7, 76.4). The sensitivity of all the algorithms decreased when followed by CATT 1:8, to 52.8% (95% CIs = 44.1, 61.3) for the RDT and 59.2% (95% CIs = 50.4, 67.4) for CATT. The specificity of the RDT was 97.1% (95% CIs = 96.8 - 97.4), significantly lower than CATT which was 98.0% (95% CIs = 97.8, 98.2). Specificity was over 99.5% when a positive screening test was retested with CATT 1:8. Agreement between readers was very good. This study has demonstrated that an algorithm in which the SD BIOLINE HAT RDT is used for screening is optimal for case detection in both passive and active screening settings. However, its lower specificity will increase the burden on screening teams by generating more false positives.

1744

ARE WE NEARLY THERE YET? MODELLING SLEEPING SICKNESS ELIMINATION

Kat S. Rock[1], Steve J. Torr[2], Matt J. Keeling[1]

[1]University of Warwick, Coventry, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The number of cases of Gambian human African trypanosomiasis (HAT) has declined in recent years, however it has previously remained unclear if elimination of the disease as a public health problem can and will be achieved by 2020. Despite being targeted by the WHO in the London 2012 declaration, no detailed quantitative assessment of the impact of existing and proposed control strategies had been carried out in relation to this aim. Here, mathematical modelling techniques are utilised to address the feasibility the WHO goals, in particular focusing on answering this question for two high-endemic health zones in the DRC. Traditional assumptions such as considering Gambian HAT to be solely anthroponotic and supposing that tsetse cannot ever acquire infection after their first blood-meal are challenged by fitting the model to human incidence data from the DRC. Using a framework which incorporates the multiple disease stages as well as current screening, diagnostics and treatment practices, this predictive model uses our current understanding of the biological processes to determine the likely incidence of HAT by 2020. Formerly these health zones have relied on detection and treatment of cases to reduce disease burden, however introducing vector control may be necessary to reach and sustain elimination of HAT. The impact of active screening campaigns as a control strategy is analysed by investigating the effect of screening frequency and proportion of the population screened upon disease prevalence. Likewise the benefit of vector control as an additional strategy is assessed. Due to the highly heterogeneous nature of disease and control strategies in different geographic ***foci*** it is key to use robust models in conjunction with high quality regional data to ensure resources are effectively used to achieve elimination.

1745

DISSEMINATED LEISHMANIASIS: AN EMERGING, SEVERE AND DIFFICULT TO TREAT DISEASE IN BRAZIL

Paulo R. Machado, Maria das Graças Brito, Luiz H. Guimarães, Albert Schriefer, Edgar M. Carvalho

Federal University of Bahia, Salvador, Brazil

Disseminated leishmaniasis (DL) has been characterized by multiple and pleomorphic cutaneous lesions, including papules, nodules and ulcerations, distributed in more than two noncontiguous parts of the body. Besides the great number of cutaneous lesions ranging from ten to hundreds, the severity of the disease is revealed by the presence of systemic symptoms like fever and chills during the dissemination phase, as well as nasal mucosal involvement in up to 44% of the cases. We have documented an increased frequency in the number of DL caused by L. braziliensis in the endemic area of Corte de Pedra, Bahia, Brazil. DL was a rare disease, responsible for 0.2% of all cutaneous leishmaniasis (CL) cases identified from 1978 to 1984. DL accounted for 1.9% and 3.9% of cases of CL from 1992 to 1998 and from 2004-2008 respectively, indicating that it has become an emerging form of leishmaniasis. Although the reasons for the development of DL have not been established, it involves a complex and poorly understood network involving L. braziliensis polymorphism, host immune response, and the environment. We have evaluated the peripheral and in situ production of cytokines and chemokines in DL, where a decrease in the type 1 immune response in the peripheral blood appears to be caused by the attraction of Leishmania-activated T cells to the multiple cutaneous lesions where few parasites may be found. Interestingly, DL patients were HIV negative and without other systemic immunosuppression. DL is a hard to treat disease and the majority of DL patients need more than three courses of meglumine antimoniate, or the use of 1.5 to 2 gr of amphotericin B deoxycholate for 45 to 60 days to cure. We have treated twenty DL patients with liposomal amphotericin B with a total dosage ranging from 22 to 35 mg/kg administered in 7 to 14 days and found 65% of cure rate, compared with 28% of cure rate using 30 days of meglumine antimoniate in its highest dosage of 20mg/kg/day. Our data show that DL in Brazil is an emerging and severe form of CL that represents a therapeutic challenge with an important socio-economic impact.

1746

DEVELOPMENT OF A HIGH SENSITIVITY LATERAL FLOW ASSAY FOR DETECTION OF *TRYPANOSOMA CRUZI* INFECTION IN LOW COMPLEXITY TESTING ENVIRONMENTS

Alejandro Castellanos[1], Omar A. Saldarriaga[1], Hayley Sparks[1], Gustavo A. Vallejo[2], Nisha Garg[1], Peter C. Melby[1], Bruno L. Travi[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Universidad del Tolima, Ibagué, Colombia

Chagas disease, despite global control efforts, still is a major health challenge in several countries of Latin America, with an estimated 8-10 million of acute or chronically infected people. Control programs have decreased vector-transmitted Chagas disease yet blood transfusion, organ transplant and principally congenital disease which accounts for >14,000 cases annually, are of major concern. Serology is frequently

difficult to interpret and of little value for congenital infections. Parasitological methods used to detect ***Trypanosoma cruzi*** infections have suboptimal sensitivity (microscopy, culture, and xenodiagnosis) or require infrastructure, equipment and trained personnel unattainable in endemic areas. PCR has shown to be more sensitive than other parasitological methods or serology to detect early infections. This is a critical aspect of Chagas management since early treatment is associated with greater therapeutic efficacy. We developed an innovative point of care molecular test to diagnose ***Trypanosoma cruzi*** infection that does not require expensive equipment and the results are read in < 1 hour. We used the kinetoplast DNA minicircle as target for designing primers and probes. ***Trypanosoma*** DNA was extracted with the Qiagen® kit and parasite detection was achieved using isothermal Recombinase Polymerase Amplification coupled with Lateral Flow (RPA-LF) assay for visual analysis of the amplification product. The test sensitivity was similar to real time PCR (reference test), detecting 0.1 ***T. cruzi*** per reaction. Preliminary results using a small number of ***T. cruzi*** (n= 10) and ***T. rangeli*** (n= 5) strains showed that the RPA-LF detected both parasite species. However, ***T. rangeli*** could be distinguished from ***T. cruzi*** when the RPA products were run in a 1% agarose gel, giving 300 bp or 190 bp band sizes, respectively. This could be relevant in regions where both parasite species are being transmitted. The RPA-LF test could be a practical tool to manage Chagas disease in endemic areas with resource-limited health infrastructure.

1747

NON-INVASIVE FUNCTIONAL CARDIAC MONITORING IN A MOUSE MODEL OF CHAGASIC CARDIOMYOPATHY TO EVALUATE A NEW THERAPEUTIC VACCINE

Meagan A. Barry, Jonathan L. Respress, Kathryn M. Jones, Qian Wang, Maria Elena Bottazzi, Michael J. Heffernan, Peter J. Hotez

Baylor College of Medicine, Houston, TX, United States

New estimates from the World Health Organization indicate that 1.17 million people suffer from chagasic cardiomyopathy in Latin America. Initially, cardiac dysfunction is characterized by conduction disorders, which can then progresses to cardiomyopathy and even sudden cardiac death. We have utilized state-of-the-art non-invasive functional cardiac monitoring offered by a core facility at Baylor College of Medicine as an innovative approach to evaluate new therapeutics in a mouse model of chagasic cardiomyopathy. Current pharmacological treatments are plagued by significant side effects and poor efficacy. There is an urgent need for new treatment modalities. A therapeutic vaccine has potential advantages that include reduced adverse effects, cost savings, and the potential to be used as a replacement for current therapies or when paired with chemotherapy. Our laboratory has previously shown promising cell-mediated protective immunity and therapeutic efficacy of a nanoparticle vaccine in an acute mouse model of Chagas disease. In order to test new treatment modalities in a model that mimics key aspects of human disease, we have optimized a mouse model of chagasic cardiomyopathy. When female ICR mice (Taconic Biosciences, Inc) are infected with 500 trypomastigotes of a H1 strain originally isolated from a patient in Yucatán, Mexico, 70% of the mice survive through the acute phase of the disease and enter into the chronic stage. Of these mice, 22% have evidence of ECG abnormalities in the early chronic stage of disease including altered basal heart rates, ectopic activity, and conduction blocks. As these mice progress further into chronic infection 17% show severe conduction blocks by echocardiography. Currently, we are evaluating our therapeutic vaccine in this mouse model of chagasic cardiomyopathy. This work optimizes a mouse model of chagasic heart disease, and utilizes non-invasive functional cardiac monitoring as a novel translational technique to evaluate new therapeutic vaccines against Chagas disease.

1748

PHARMACOKINETICS AND PHARMACODYNAMICS OF MILTEFOSINE IN CHILDREN AND ADULTS WITH CUTANEOUS LEISHMANIASIS CAUSED BY *LEISHMANIA VIANNIA*

Maria Adelaida Gomez[1], Maria del Mar Castro[1], Anke Kip[2], Alexandra Cossio[1], Adriana Navas[1], Eduardo Ortiz[1], Thomas C. Dorlo[2], Nancy G. Saravia[1]

[1]CIDEIM, Cali, Colombia, [2]Utrecht University, Utrecht, Netherlands

A population pharmacokinetics phase IV clinical trial was conducted to comparatively analyze the pharmacokinetics and pharmacodynamics of miltefosine in children and adults. The protocol was approved and monitored by the institutional ethical committee. Sixty patients presenting with cutaneous leishmaniasis, 30 children of 2 to 12 years of age, and 30 adults of 18 to 60 years of age, participated this study. Plasma and intracellular drug concentrations were measured by mass spectrometry in samples obtained during treatment and six months following initiation of treatment, at which time therapeutic outcome was defined. Fifty-two patients cured, failure occurred in 5 children, and 3 patients were lost to follow-up. Plasma and intracellular miltefosine concentrations were overall, lower in children compared to adults. Exposure to miltefosine, estimated by the area under the curve and C_{max}, was significantly lower in children ($p<0.01$). Molecular evidence of Leishmania persistence was obtained in 43% and 28% of the study participants respectively, at the end of treatment and 90 days after beginning of treatment. The dynamics of ***in vivo*** parasite clearance were not predictive of the outcome of treatment. Significant and strong inverse correlations between end of treatment (EoT) parasite loads and intracellular EoT and C_{max} concentrations were established. ***Leishmania*** strains were isolated from 76.6% of patients. Strains were isolated from 3 of 5 patients who failed treatment, of which two presented low ***in vitro*** susceptibility to miltefosine, potentially contributing to treatment failure. Our results revealed fundamental pharmacokinetic differences for miltefosine in children and adults, which evidently influence the outcome of treatment. The results include the first intracellular pharmacokinetic profiles of an antileishmanial drug in adult and pediatric patients and their relevance in the therapeutic efficacy of drugs against intracellular parasites. These findings provide the knowledge base for optimizing the therapeutic regimen in the pediatric population, while reducing the risk of loss of drug susceptibility.

1749

ANTIPARASITIC POTENTIAL OF EXTRACELLULAR METABOLITES FROM MARINE ACTINOMYCETES AGAINST *LEISHMANIA (VIANNIA) PERUVIANA* AND *L. (V.) BRAZILIENSIS*

Nadia R. Galindo-Cabello[1], Nyshon Rojas-Palomino[2], Gloria Minaya-Gómez[2], Jorge León-Quispe[1]

[1]Universidad Nacional Mayor de San Marcos, Lima, Peru, [2]Instituto Nacional de Salud, Lima, Peru

Actinomycetes are recognized as producers of pharmacological and industrial compunds. In the last decades, the discovery of new metabolites isolated from the terrestrial actinomycetes has decreased and the researches have focused on searching unexplored habitats, like the marine environment. The vast majority of compounds produced by actinomycetes are antimicrobial and few have antiparasitic activity. This study aims at determining the antiparasitic potential of actinomycetal extracellular metabolites isolated from marine actinomycetes against ***Leishmania (Viannia) peruviana*** and ***L. (V.) braziliensis***. In order to carry out this study, a preliminary evaluation of antiparasitic activity ***in vitro*** with 13A1, EIIIA, EIIB and EIIIC strains against promastigotes of two species of ***Leishmania*** has been made; the results of this test showed that EIIB strain had the higher inhibitory activity. The EIIB strain was identified as a member of the genus Streptomyces using rRNA method. The minimum concentration of butanolic extract of actinomycete EIIB who filed the

anti-***Leishmania*** activity was 15 000 µg/mL for ***L. (Viannia) peruviana*** and ***L. (V.) braziliensis***. The preliminary chemical characterization of the extract confirmed the presence of coumarins. In conclusion, the results demonstrated the production of metabolites from marine actinomycetes with antiparasitic activity, which have a great potential in the biomedical and pharmacological field.

1750

EFFECT OF THE ADDITION OF PENTOXIFYLLINE ON THE THERAPEUTIC AND INFLAMMATORY RESPONSE IN PATIENTS WITH CUTANEOUS LEISHMANIASIS: A RANDOMIZED PLACEBO CONTROLLED TRIAL

Alexandra Cossio-Duque, Maria del Mar Castro, Adriana Navas, Liliana Valderrama, Lyda Cuervo-Pardo, Ricardo Marquez, Sandra J. Jojoa, Ruth M. Castillo, Maria A. Gómez, Nancy Gore Saravia

Centro Internacional de Entrenamiento e Investigaciones Médicas, Cali, Colombia

The inflammatory response is an important factor in the therapeutic response of cutaneous leishmaniasis (CL). Co-adjuvant use of immunomodulators may improve the efficacy or outcome of treatment. This study sought to determine whether the addition of pentoxifylline (PTX) to meglumine antimonite (MA) treatment improves therapeutic response in CL patients and to determine the effect of PTX on the inflammatory response. A randomized, double-blind, "Add on" placebo-controlled trial was conducted in 2 centers in Colombia. The protocol was approved and monitored by the institutional ethical committee. Seventy-five parasitologically diagnosed patients were randomly allocated by computer. Inclusion criteria: age 18-65 years, lesion >1 month evolution, multiple lesions or single lesion ≥ 3 cm. Intervention: intramuscular MA (20 mg/ kg /day x 20 days) plus oral PTX 400 mg thrice daily (n=36). Control: MA plus placebo (n=37). Expression of inflammatory genes cxcl10,cxcl5,ccl2, IL1b, ptgs2 and csf1 was evaluated by qRT-PCR in peripheral blood mononuclear cells from CL patients, before and after antimonial treatment, in combination with either PTX (n=12) or placebo (n=12). Therapeutic response and adverse events were assessed at the end of treatment 5, 7, 13 and 26 weeks. Seventy participants (93%) were analyzed by intention to treat (ITT) and forty-eight (64%) per protocol (PP). Treatment failure was 12/34 (35.3%) for PTX vs. 9/36 25% placebo; (OR: 1.63; 95% CI: 0.58 - 4.5). PP failure rate was 6/20 (30%) for PTX and 5/28 (17.8%) for placebo (OR: 1.97; 95% CI: 0.50 - 7.68). No differences between overall frequency and severity of adverse events were found (PTX=142 vs. placebo=140). Expression of inflammatory mediators at the end of treatment was not altered by addition of PTX to MA. However, therapeutic failure was associated with significant overexpression of IL1β and Ptgs2 ($p<0.05$) irrespective of the study group. Addition of PTX to standard treatment of CL did not modify the therapeutic response in this population with early mild to moderate CL, or alter the gene expression of the evaluated inflammatory mediators.

1751

ANTIBODY DEVELOPMENT FOR *TRYPANOSOMA CRUZI* ANTIGEN DETECTION

Edith Malaga[1], **Noelia Angulo**[1], Sofia Astupina[1], Remo Gonza[1], Edgar A. Florentini[1], Ines Cabello[2], Alessandra Romero-Ramirez[1], Rosina Camargo[2], Manuela Verastegui[1], Maritza Calderon[1], Caryn Bern[3], Robert H. Gilman[4], Holger Mayta[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]University of California, San Francisco, Lima, Peru, [4]Johns Hopkins University School of Medicine, Lima, Peru

Chagas disease is an infection caused by the protozoan parasite ***Trypanosoma cruzi***. According to World Health Organization, between 8 to 10 million people in the world are infected. Currently, routine diagnosis is based on antibody detection but antibodies remain detectable even after a successful therapy and eradication of parasites. Confirmation of the presence of ***T. cruzi*** by detecting circulating antigens presents an undeniable advantage and an indication of an active infection. The present study was intended to produce polyclonal antibodies that could be further used for ***T. cruzi*** antigen detection. Three two-year old female alpacas (***Vicugna pacos***) were immunized with three different ***Trypanosoma cruzi*** antigens: TESA-antigen, somatic proteins and membrane proteins. Each animal was immunized with 300 ug of each antigen by subcutaneous route, employing Freud complete and incomplete adjuvant (50:50). Blood samples were taken before and after immunization. Sera obtained after centrifugation were stored at -20 ºC until use. Presence of specific antibodies was followed by Western-Blot using antigen obtained from ***T. cruzi*** Y strain. The antibodies showed a specific reaction against their respective antigen. The highest antibody titer was observed after the three immunization. When human urine spiked with parasite TESA antigen was tested against these whole alpaca sera, antibodies from alpacas immunized with membrane proteins performed the best. Additionally, this polyclonal antibody did not react with other human urine proteins. Antibodies induced in alpaca would represent an alternative diagnostic tool for the detection of parasite antigens in urine.

1752

USE OF IGY EGG YOLK ANTIBODIES FOR THE DETECTION OF *TRYPANOSOMA CRUZI* ANTIGENS

Alessandra Romero-Ramirez[1], Edith Malaga[1], **Edgar A. Florentini**[1], Ines Cabello[2], Rosina Camargo[2], Fernando Recuenco[2], Maritza Calderon[1], Manuela Verastegui[1], Caryn Bern[3], Robert H. Gilman[4], Holger Mayta[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]University of California, San Francisco, Lima, Peru, [4]Johns Hopkins University School of Medicine, Lima, Peru

Chagas disease, an infection caused by ***Trypanosoma cruzi***, remains one of the most important health problem especially in Latin America. Diagnosis of the disease is based on antibody detection; for a correct diagnosis the World Health Organization recommends that at least two of the so-called conventional test (indirect hemagglutination (IHA), indirect immunofluorescence (IIF) and the ELISA immunoenzymatic test) should be performed. However antibody detection is not always an indicative of current or active infection. Detection of ***T. cruzi*** circulating antigens in body fluids might be an important diagnostic tool. Circulating antigens are present only if parasites are present. The objective of the present study was to develop IgY (egg yolk antibodies) against different parasite fractions, the developed antibodies will be further tested as a tool for antigen detection in infected individuals. Eight New Hampshire strain hens were subcutaneously immunized every 14 days for two months with three different ***T. cruzi*** antigens: 1F8 (commercial flagellar antigen), TESA, and membrane proteins. Eggs were collected before and after each immunization. The IgY was extracted using chloroform or polyethylene glycol techniques. IgY yield was compared by protein concentration using Bradford. Presence of anti-***T. cruzi*** IgY was corroborated by indirect immunofluorescence using cultured ***T. cruzi*** Y strain epimastigotes. The chloroform showed to be the more efficient than the polyethylene glycol for purification of IgY from egg yolk. IgY antibodies show to be specific for their respective antigens as showed by immunofluorescence. Further studies will be oriented to determine if those antigens are useful for antigen detection in body fluids of infected individuals.

NADPH-OXIDASE AN ESSENTIAL ENZYME FOR THE EXPANSION AND ACTIVATION OF CD8+ T CELLS DURING *TRYPANOSOMA CRUZI* INFECTION

Monisha Dhiman[1], Nisha Jain Garg[2]

[1]Central University of Punjab, Bathinda, Bathinda, Punjab, India, [2]University of Texas Medical Branch, Galveston, TX, United States

We investigated the significance of NADPH oxidase in the development of protective immunity to an intracellular pathogen ***Trypanosoma cruzi*** that causes Chagas disease. C57BL/6 p47phox-/- mice, as compared to wild-type (wt) mice succumbed within 30 days post-infection (pi) to low doses of ***T. cruzi*** and exhibited inability to control tissue parasites. P47phox-/- bone-marrow and splenic monocytes were not compromised in maturation, phagocytosis and parasite uptake capacity. The deficiency of NOX2-mediated oxidative burst was compensated by higher levels of iNOS/NO. activity and inflammatory cytokine (TNF-α, IFN-γ, IL-1β) release by p47phox-/- macrophages as compared to wt controls infected by ***T. cruzi***. The splenic activation of Th1 CD4+T cells and tissue infiltration of immune cells in T.cruzi-infected p47phox-/- mice was comparable or higher than that noted in infected/wt mice. However, generation and activation of type 1 CD8+T cells was severely compromised in p47phox-/- mice. In comparison, wt mice exhibited a robust ***T. cruzi***-specific CD8+T cell response with type 1 (IFN-γ+TNF-α>IL-4+IL-10), cytolytic effector (CD8+CD107a+IFN-γ+) phenotype. Macrophage activation of NOX2 and oxidative burst is suggested to kill ***T. cruzi*** that causes Chagas disease. However, the role of NOX2 in generation of protective immunity and whether these mechanisms are deregulated in the event of NOX2 deficiency are not known, and examined in this study. NOX2/ROS activity in macrophages signals the development of antigen-specific CD8+T cell response. In the event of NOX2 deficiency, a severely compromised CD8+T cell response was generated leading to increased parasite burden, tissue pathogenesis and mortality.

SURVIVORSHIP OF *TRYPANOSOMA CRUZI*-INFECTED BED BUGS (*CIMEX LECTULARIUS*)

Renzo S. Salazar Sanchez[1], Ricardo Castillo Neyra[2], Casey Bartow McKenney[2], Katty Borrini Mayorí[1], Carlos Condori Pino[1], César Náquira[1], Michael Z. Levy[2]

[1]Universidad Peruana Cayetano Heredia, Arequipa, Peru, [2]Center for Clinical Epidemiology and Biostatistics, University of Pennsylvania School of Medicine, Philadelphia, PA, United States

The resurgence of the common bedbug (***Cimex lectularius***) has created a difficult public health problem around the world. Recently, we showed the vectorial competence of ***C. lectularius*** into laboratory conditions, proving that the common bedbug can transmit ***Trypanosoma cruzi*** to mice and can get infected when fed on ***T. cruzi***-carrying mice. ***T. cruzi*** is the causative agent of Chagas disease, a vector-borne disease transmitted by triatomine bugs and an increasing problem in many countries of the Americas. Specialized literature has reported that the infection with ***T. cruzi*** in triatomines, their natural vector, affects negatively their development, survival and reproductive index. Being the vector survival an important component of vectorial capacity, we studied the effect of the ***T. cruzi*** infection on ***C. lectularius*** survival. A cohort study of 280 ***T. cruzi***-infected bedbugs and 240 uninfected bedbugs was carried out in Arequipa – Peru, in the Zoonotic Disease Research Group lab. To get infected first instar bedbugs were fed on 4 female BALB/c mice (***Mus musculus***) previously infected by intraperitoneal inoculation with 2 x 10^3 trypomasgotes (***T. cruzi*** Arequipa strain TC35) in 100 ul. We fed them weekly for a month on mice and after that they were fed on uninfected guinea pigs until death. The same conditions were applied to the uninfected bedbug's cohorts. We evaluated weekly vector survival, nymphal development, fecundity and fertility and ***T. cruzi*** presence in the infected cohorts. The statistical results showed no difference in survivorship between the infected and uninfected bedbugs. Fecundity and fertility indexes were moderately higher in the infected cohort. The prevalence of the infection at time of death was 95% (N=274). These results suggest that ***T. cruzi*** infection does not affect negatively either the survival rate, or the fecundity and fertility indexes in bedbugs. The implications of these findings on the vectorial capacity of ***C. lectularius*** and its possible role as a vector of Chagas disease are discussed.

1755

A BAYESIAN MODEL FOR IDENTIFYING AND PREDICTING THE DYNAMICS OF URBAN INSECT INFESTATIONS

Erica MW Billig[1], Jason A. Roy[1], Michelle E. Ross[1], Drew J. Dolgert[2], Michael Z. Levy[1]

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]Cornell University, Ithaca, NY, United States

Analyses of epidemics are complicated by several factors, including the fact that the true dispersal mechanism of disease agents and the precise infection times of patients are often unobserved. Instead, we often observe the infection state of each unit at discrete time intervals. For example, consider a recent study of the Chagas disease vector Triatoma infestans in Arequipa, Peru. The data are limited to observed insect presence at each household at three time points over several years. In addition, we observe the number of insects at each household, although with measurement error. To address these challenges, we propose a novel susceptible-infected-detected-removed model that incorporates the counts of vectors at each house and complex spatial dispersal dynamics observed in Arequipa. The fully Bayesian method is used to augment the data, estimate the dispersal parameters, and determine posterior infestation risk probabilities of households for future treatment. We investigate the properties of the model with simulation studies and analyze the Chagas disease vector data to create an informed control strategy.

1756

BED BUGS AS VECTORS OF *TRYPANOSOMA CRUZI*

Michael Z. Levy[1], Renzo Salazar[2], Ricardo Castillo-Neyra[2], Aaron Tustin[3], Katty Borrini-Mayori[2], Sherrie Xie[1], Cesar Naquira[2]

[1]University of Pennsylvania, School of Medicine, Philadelphia, PA, United States, [2]Universidad Peruana Cayetano Heredia, Sede Arequipa, Arequipa, Peru, [3]Johns Hopkins, Baltimore, MD, United States

Through a series of experiments we show that bed bugs (***Cimex lectularius***) can acquire ***Trypanosoma cruzi*** by feeding on infected mice, transmit it back to susceptible animals during cohabitation (in which the mice ate them) and by the usual route (through their feces). Whether bed bugs are, or will become, epidemiologically important vectors of the parasite remains unclear. To address the issue we develop a modified Ross-MacDonald model of vector-borne ***T. cruzi*** transmission and apply it to both a traditional vector, ***Triatoma infestans***, and ***Cimex lectularius***. In relation to some key parameters of the model, such as the ratio of vectors to hosts and the biting rate of the vector, bed bugs are more worrying than ***T. infestans***. We consider the death rate of the vector, and run experiments to assess whether ***T. cruzi*** might increase mortality among bed bugs or triatomines. It does not. We consider the range of hosts and feeding preferences of each insect. We show that triatomines can only support sustained ***T. cruzi*** transmission when exposed to a rather complex host community; we discuss whether such conditions exist in houses, hotels, and other environments affected by bed bugs in the US and abroad.

1757

A CASE: CONTROL STUDY OF POSSIBLE RISK FACTORS FOR CUTANEOUS LEISHMANIASIS IN SOUTHERN SRI LANKA

Udeshika L. Kariyawasam[1], Yamuna D. Siriwardana[1], Chathura S. Edirisuriya[2], Upul Senerath[1], Nadira D. Karunaweera[1]

[1]Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, [2]Epidemiology Unit, Ministry of Health, Colombo, Sri Lanka

Leishmaniasis is a tropical disease that has not been given due priority, in spite of its importance as a parasitic disease associated with high morbidity and mortality. Cutaneous leishmaniasis (CL) in Sri Lanka is caused by ***L. donovani***. Transmission patterns were different in Southern and Northern Sri Lanka according to previous studies indicating the need for large scale studies. Therefore, current study examined the prevalence and risk factors of CL in Matara District, Southern Sri Lanka. Total of 2260 individuals from 4 District Secretariat divisions (DSDs) were screened by house to house survey using an interviewer administered questionnaire. Patients with skin lesions were investigated by light microscopy/culture/PCR. Prevalence was calculated and a case control study was conducted to identify risk factors. The study population had an age ranged between 1-90yrs (median=43 ±17.31), low monthly income (<20, 000 LKR, 52.8%) and male to female ratio of 1:2(males 31.7%, females 68.3%).Out of 80 clinically suggestive cases only 38 was laboratory confirmed. District prevalence was 0.03%. Over 50% of the patients were identified from the DS of Dickwella (55.3%), while lowest number of cases was from Devinuwara (2.6%). Case clustering nature was observed as significant in GIS map (Nearest neighbor ratio 0.46, p=0.000). The risk factors identified were un-plastered brick walls (P<0.05, OR 41.4), abysmal usage of mosquito repellents (p<0.05, OR 10.3), low income (p<0.05, OR 33.4), excessive time (>4 hrs/day) spent outdoors (p<0.05, OR 22.5) and unawareness of leishmaniasis (p<0.05, OR 10.76). Improper clothing while outdoors, common water source as the mode of water supply and having animal shelters in their gardens within 200m were not associated with the risk of acquiring the disease. Both peri-domestic and outdoor factors seem to be associated with leishmaniasis transmission in the study area. Spatial clustering of cases was observed. This may be due to the behavior of host coinciding with that of the vector, sand fly. Awareness regarding the disease and appropriate control measures are urgently required to minimize further spread.

1758

QUEUEING ANALYSIS OF A CHAGAS DISEASE CONTROL CAMPAIGN

Maria T. Rieders, Michael Levy, Karthik Sethuraman, Chagas Disease Working Group in Arequipa, Peru

University of Pennsylvania, Philadelphia, PA, United States

This work investigates the economic impact of public health intervention in an ongoing Chagas disease control campaign in Arequipa, Peru. A critical component of preventing and studying the spread of disease are door-to-door campaigns of public health inspectors, followed by insecticide application by exterminators to eradicate the vector infestation of households. The success of the campaign depends on adequate household participation as well as on the success of identifying infested households. We apply queueing theory to evaluate the rate of treatment and associated costs over time. In our queueing model, a household that is infested enters the queue of houses that will require treatment. Unlike conventional queueing systems, however, the customers (houses) joining the queue are invisible and need to be identified before being scheduled for treatment. An infested house becomes visible either via notification by its inhabitants or through a successful search by a team of public health inspectors. A multi-armed bandit procedure is being applied to optimize the search for invisible (infested) houses, based on available GIS data and findings in previous campaigns. We assume that houses in the queue will continue to spread the disease to noninfected houses at a rate that is a function of the time spent in queue. Households are being removed from the queue after successful identification and subsequent treatment with insecticides. Using stochastic queueing models, we project the rate at which household infestations can be successfully eliminated, allowing us to evaluate the cost of eliminating infestation in a neighborhood as a function of participation rates in blanket residual insecticide campaigns and the efficacy of subsequent community-based surveillance programs.

TRYPANOSOMA CRUZI IN PATIENTS WITH ESOPHAGEAL ACHALASIA IN A NON-ENDEMIC AREA OF COLOMBIA

Santiago Panesso-Gomez[1], Iván E. Rodríguez-Mantilla[1], Paola Lasso[2], Paula Pavia[2], Alejandro Orozco[3], Adriana Cuellar[4], Concepción J. Puerta[2], Belén E. Mendoza de Molano[5], John M. González[1]

[1]Grupo de Ciencias Básicas Médicas, School of Medicine, Universidad de los Andes, Bogota, Colombia, [2]Laboratorio de Parasitología Molecular, School of Sciences, Pontificia Universidad Javeriana, Bogota, Colombia, [3]Investigación y Desarrollo Sistemas Clínicos, Bogota, Colombia, [4]Grupo de Inmunobiología y Biología Celular, School of Sciences, Pontificia Universidad Javeriana, Bogota, Colombia, [5]Gastroenterology Section, Hospital Universitario Fundación Santa Fe de Bogotá, Bogota, Colombia

Esophageal achalasia is a motility disorder of the esophagus, which can be secundary to chronic ***Trypanosoma cruzi*** infection. Few studies have been conducted in Latin America regarding the prevalence of esophageal achalasia as a manifestation of Chagas Disease and none in Colombia. The main purpose of this ongoing project is to determine the prevalence of anti-***T.cruzi*** antibodies in patients diagnosed with esophageal achalasia and to detect the parasite by polymerase chain reaction (PCR) in individuals found to be seropositive who attended to the Gastroenterology section in a referral hospital in Bogotá, Colombia; a non-endemic area. This cross-sectional study was carried out in adult patients (18-65 years) diagnosed with impaired esophageal motility. Blood samples were taken to assess antibodies against ***T. cruzi*** by IFAT and presence of ***T. cruzi's*** DNA by conventional PCR and qPCR. In total 30 patients have been evaluated with an average age of 47 (± 15.8 SD) years, including 14 men and 16 women; 75% of volunteers live in Bogotá, yet only half of them were born there. Most denied to having lived in rural housing and currently all reside in urban areas. Near 90% referred no family history of Chagas disease and 70% had never undergone blood transfusion. Four out of the 30 patients were positive for anti-***T. cruzi*** by IFAT (current seroprevalence is 13.3%), and, only one of these patients had parasite DNA detected by conventional PCR and detection by qPCR was positive, but below DNA equivalent to 1x10³ parasites. The parasite genotype was identified as TcI. This is the first study that associates esophageal achalasia and ***T. cruzi*** in Colombia. ELISA test will be carried out to confirm the antibodies results.

MAPPING OF HUMAN AFRICAN TRYPANOSOMIASIS RISK IN DRC AND MODELING OF POTENTIAL PATHS TO ELIMINATION

Alexander M. Upfill-Brown[1], Caitlin A. Bever[1], Matthew Steele[2], Noelle Huskins[2], Jacquie Makabuza[3], Pascal Lutumba[4], Philip A. Eckhoff[1], Crispin Lumbala[3]

[1]Institute for Disease Modeling, Bellevue, WA, United States, [2]Bill & Melinda Gates Foundation, Seattle, WA, United States, [3]Programme National de Lutte Contre la THA, Kinshasa, Democratic Republic of the Congo, [4]University of Kinshasa, Kinshasa, Democratic Republic of the Congo

While surveillance suggests Human African Trypanosomiasis (HAT) incidence has decreased markedly over the past 15 years_from 26,318 recorded cases in 1998 to 5,983 cases in 2012_transmission remains widespread in the Democratic Republic of the Congo (DRC), which accounted for 84% of HAT cases globally in 2012. New tools - rapid diagnostic tests (RDT), low-cost vector control, and the oral drug fexinidazole - will hopefully make control of HAT far more effective

and enable diagnostic and treatment coverage of a much greater population. In preparation for renewed discussions on elimination, the geographic distribution of HAT risk and associated uncertainties must be well understood. We develop a spatial statistical model using both active and passive surveillance data for Trypanosoma brucei gambiense collected between 2000 and 2014 in DRC to assess the distribution of risk and identify important risk factors. Key uncertainties include how to appropriately address areas with limited records of functional surveillance and the impact of human migration patterns. By fitting the model only to areas reporting cases, we estimate that a substantial number of HAT infections may go undetected in remote areas. Preliminary mechanistic modeling suggests elimination will only be feasible in areas with high quality active and passive surveillance. The number of visits required by the active surveillance mobile teams to clear the parasite from the local population depends on the sensitivity of the RDT used and, as interventions reduce prevalence even further, overtreatment considerations will have to be weighed. Preventing patient drop-out (patients who fail to receive their confirmatory diagnosis or to complete treatment) will also be highly important; in that regard, newly implemented mobile technologies for data collection should enable better tracking of HAT patients through encounters with the healthcare system.

1761

EVALUATION OF INSECTICIDE-BASED CONTROL FOR CHAGAS DISEASE VECTORS IN SOUTHERN ECUADOR HIGHLIGHTS THE NEED TO FIND NEW STRATEGIES FOR LONG-TERM RISK REDUCTION OF *TRYPANOSOMA CRUZI* TRANSMISSION

Mario J. Grijalva[1], Anita G. Villacis[2], Sofia1 Ocaña-Mayorga[2], Cesar A. Yumiseva[2], Ana L. Moncayo[2], Claudia Nieto-Sanchez[3], Darwin Guerrero[2], Esteban G. Baus[2]

[1]Tropical Disease Institute, Heritage College of Osteopathic Medicine, Ohio University, Athens, OH, United States, [2]Center for Infectious Disease Research, School of Biological Sciences, Pontifical Catholic University of Ecuador, Quito, Ecuador, [3]Ohio University, Athens, OH, United States

Prevention of Chagas disease depends mainly on control of the triatomine insects that transmit infection. Developing an optimal spraying strategy requires a detailed knowledge of the vector dynamics as well as the effect of the application of this strategy in the field. A prospective study to assess the long-term impact of spraying was conducted between 2008 and 2012 in three rural communities in Loja province, southern Ecuador. Entomological searches to detect the infestation of houses with triatomines and its natural infection with trypanosomes was conducted after the application of two different intervention strategies: 1) selective insecticide spraying (2008 and 2010) and 2) community-wide insecticide spraying (2011). Out of 53 houses searched at baseline (2008), 22 (41.5%) were infested with the vector species ***Rhodnius ecuadoriensis*** and ***Panstrongylus chinai***. The overall entomological data showed a density of 12.4; crowding of 29.8 and colonization index 68.2%. Houses infested at baseline were less likely to be infested after the first round of selective insecticide spraying (POR 0.38, CI 95% 0.17-0.89). However, an increased risk was observed after two rounds of selective spraying (2011) (POR 1.40, 95% CI 0.61-3.21). Although the association as not statistically significant, our data showed that one round of community-wide intervention strategy had a protective effect on the probability of infestation (POR 0.55, CI 95% 0.25-1.25). Persistent infestations were detected in >20% of houses after both interventions. Lower infection rates with ***Trypanosoma cruzi*** were found at the baseline visit in domicile and peridomicile, 27.3% and 6.3%, respectively. However, these rates dramatically increased during following visits, especially in the peridomicile that reached > 80% in 2011 and 2012. Full coverage spraying seems to be more effective than selective spraying; however both methods failed to confer long-term protection. These results remark the need to implement long-term control strategies, such as housing improvement and frequent monitoring of domestic and peridomestic environments.

1762

MOLECULAR CHARACTERIZATION OF AVIAN INFLUENZA A/H9N2 ISOLATED FROM HUMAN RESPIRATORY SPECIMEN IN EGYPT

Mayar M. Said[1], Maha Talaat[1], Ehab Ayoub[1], Mustafa Abdel Aziz[1], Manar Mahmoud[1], Manal labib[2], Samya Omaer[2], Amel Naguib[2], Samir El Rifay[2], Emad Mohareb[1], Amr Kandeel[2]

[1]U.S. Naval Medical Research Unit - 3, Cairo, Egypt, [2]Ministry of Health and Population, Cairo, Egypt

Since the mid-1990s, two lineages of Low Pathogenic A/H9N2 influenza A viruses have circulated in domestic poultry in China and South East Asia. A/H9N2 (G1-like) lineage has circulated in Egypt since 2011. To date, few human cases had been reported in China and SE Asia and no human infections have been reported in the Middle East. In this report we characterize the A/H9N2 virus isolated from a nasopharyngeal and oropharyngeal swabs combined in 2ml viral transport medium VTM, from human case with severe acute respiratory infection (SARI), who has been enrolled in sentinel SARI surveillance in Egypt. The total nucleic acid (TNA) extracted from VTM tested positive for the matrix (M) gene of influenza A by reverse transcriptase RT-PCR, but negative for the commonly circulating subtypes in Egypt; seasonal H3 and H1, PdmH1 and avian H5 as well as to other viral etiologies. TNA was further tested for H7 and H9 by RT-PCR and was found positive for H9. MDCK cell monolayers in culture tubes were inoculated with 100µl of the combined swab-VTM and monitored for CPE every 24hrs. On day two CPE was observed indicating viral replication. TNA was used for the sequencing of the haemagglutinin (HA) while viral RNA extracted from the cell culture lysate was used to sequence the neuramidase (NA) gene by Sanger technique. HA and NA gene sequencing demonstrated a virus with 97% and 98% similarity, respectively, to those of the H9N2 G1-like lineage, the predominant lineage circulating in the Middle East. Phylogenetic analysis showed close homology to previous A/H9N2 viruses from Egyptian poultry and those from neighboring Middle-East countries. Co-circulation of A/H5N1 and A/H9N2 has been documented in Egyptian poultry since 2011. Given the risk to human population from zoonotic influenza, in addition to the specter of antigenic shift in co-infected hosts, intensified control measures within the poultry production sector and increased bird and human surveillance is warranted.

1763

AN OPERATIONAL EVALUATION OF A SOCIOECONOMIC INTERVENTION TO PREVENT TB IN IMPOVERISHED PERUVIAN COMMUNITIES

Tom Wingfield[1], Marco Tovar[2], Delia Boccia[3], Rosario Montoya[4], Eric Ramos[5], Doug Huff[6], James Lewis[3], Carlton A. Evans[7]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru and Imperial College, Lima, Peru, [2]Universidad Peruana Cayetano Heredia and Innovación Por la Salud Y Desarrollo, Lima, Peru, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Innovación Por la Salud Y el Desarrollo, Lima, Peru, [5]Universidad Peruana Cayetano Heredia, Lima, Peru, [6]School of Public Health, Tulane University, New Orleans, LA, United States, [7]Universidad Peruana Cayetano Heredia, Lima, Peru and Imperial College, London, United Kingdom

The World Health Organisation's post-2015 global TB strategy identifies social protection interventions (including cash transfers) as key pillars of global TB control but minimal rigorous evidence exists with which to guide their implementation. We designed, implemented, and refined a novel TB-specific social protection intervention that included cash transfers, which aimed to support TB prevention and cure in resource-constrained shantytowns in Lima, Peru. The design of the study was an household-randomized controlled: newly-diagnosed TB patients from 32 impoverished shantytowns of north Lima were eligible to be randomized (1:1) to receive the social protection intervention consisting of economic support and social activities. Economic support was provided to patient

households completing conditional cash transfers: screening for TB in household contacts and MDR-TB in patients; adhering to TB treatment and chemoprophylaxis; and engaging with CRESIPT social activities (household visits and community meetings). Throughout treatment, CRESIPT research nurses applied a questionnaire concerning health, socioeconomic position, and direct (out-of-pocket), indirect (lost income), and total TB-related costs. 282 patients were recruited to the study. Lost income contributed half of households' total costs. The burden of total costs was greater in poorer than less poor households (3.5 versus 2 months of that household's income respectively, p=0.0007). The 135 patients randomized to the supported arm of the intervention achieved 890 conditional cash transfers (80% of potential cash transfers), with an average total of 520 Peruvian Soles (173 US Dollars) received per household. The conditional cash transfers offset 22% of total costs and 43% of direct costs. Conditional cash transfers offset total costs to a greater extent in poorer households (23% versus 20%) and female patients (26% versus 20%, p=0.02). A novel TB-specific social protection intervention has been designed, implemented, refined, and was found to be both acceptable and equitable in a challenging, impoverished setting.

1764

COMBINATORIAL APPROACH TO PATHOGEN DETECTION IN RESPIRATORY SAMPLES OF UNKNOWN ETIOLOGY

Mariana Leguia[1], Maria Silva[1], Jane Rios[1], Cristhopher Cruz[1], Michael Wiley[2], Carla Prieto[2], Gustavo Palacios[2], Matthew R. Kasper[3], Daniel G. Bausch[1]

[1]U.S. Naval Medical Research Unit – 6 (Peru), Washington, DC, United States, [2]U.S. Army Medical Research Institute for Infectious Diseases, Frederick, MD, United States, [3]Global Emerging Infections Surveillance and Response System, Armed Forces Health Surveillance Center, Silver Spring, MD, United States

Emerging pathogens are a continuous threat to public health around the world. Respiratory pathogens in particular, such as those causing influenza-like illnesses and severe acute respiratory infections, are easily transmissible person-to-person and primarily affect children, the elderly, and confined populations, such as those in prisons or military bases. The U.S. Naval Medical Research Unit No. 6, Lima, Peru, conducts routine surveillance for respiratory pathogens throughout Latin America. About 60% of the 5,000 respiratory samples collected annually remain without an identified etiological agent, either because known pathogens are present at sub-threshold levels that render them undetectable to traditional PCR-based diagnostics or because pathogens are novel or divergent enough that they cannot be detected using existing methodologies. We used a combination of both classical (cell culture) and advanced laboratory methodologies (MassTag PCR and next-generation sequencing) to screen over 600 samples that showed cytopathic effect on cell culture but for which no pathogen could be identified. Initial screening using a highly multiplexed MassTag PCR-based approach identified potential etiologies in 41% of the samples tested, including enterovirus (39%); human parainfluenza virus 1 (2%), 2 (32%), 3 (2%) and 4 (1%); human metapneumovirus (10%); respiratory syncytial virus A (5%) and B (4%); coronavirus OC43 (3%) and 229E (1%); and influenza A virus (1%). We then conducted unbiased next-generation sequencing on selected samples and identified additional etiologies, including viruses that had never before been detected in Latin America, such as Saffold virus. Here, we describe our integrated approach to pathogen detection and report our complete findings for over 600 samples collected since 2011. This new combinatorial approach to pathogen detection enables rapid identification of known and novel pathogens present in respiratory samples in a modern and cost effective manner that should facilitate global respiratory disease surveillance efforts.

1765

COMPARISON OF THE AKONNI BIOSYSTEMS MDR-TB MICROARRAY TEST TO THE HAIN LIFESCIENCE GENOTYPE MTBDRPLUS FOR RESISTANCE TO RIFAMPIN AND ISONIAZID IN KAZAKH M. TUBERCULOSIS ISOLATES

Yuriy Skiba[1], Elina Maltseva[1], Lyazzat Musralina[1], Gulnara Ismagulova[1], Ketan Patel[2], Cynthia Zimmerman[3], Jolanta S. Jacobs[4], **Paul D. Stamper**[5]

[1]M.A. Aitkhozhin Institute of Molecular Biology and Biochemistry, Almaty, Kazakhstan, [2]Naval Medical Research Center-Frederick, Frederick, MD, United States, [3]MRIGlobal, Palm Bay, FL, United States, [4]MRIGlobal, Frederick, MD, United States, [5]MRIGlobal, Baltimore, MD, United States

Early case detection and rapid treatment reduce ***Mycobacterium tuberculosis*** (MTB) transmission. MTB is considered multidrug-resistant TB (MDR-TB) when resistant to rifampin and isoniazid, and a test which simultaneously diagnoses MTB and multi-drug resistance (MDR) is urgently needed. The Akonni Biosystems MDR-TB microarray test (Akonni MDR-TB) (Frederick, MD USA) specifically reports on the presence of ***rpoB*** (30 mutations), and ***katG*** (2 mutations) and ***inhA*** (4 mutations) mutations known to confer resistance to rifampin and isoniazid, respectively. The assay contains markers for the ***M. avium*** complex (MAC), ***M. tuberculosis*** complex, and an internal amplification and hybridization control. Similarly, the Hain LifeScience GenoType MTBDRplus (Hain MTBDRplus) (Nehren, Germany) detects the presence of mutation in ***rpoB*** (4 mutations), and ***katG*** (2 mutations) and ***inhA*** (4 mutations). MRIGlobal partnered with the M.A. Aitkhozhin Institute of Molecular Biology and Biochemistry (IMBB) to test 411 extracted isolates from the National Center of Tuberculosis Problems in Kazakhstan. Isolates indicating a mixed genotypes (26) or presence of MAC (8) were removed from the performance evaluation. The Akonni MDR-TB was compared to the Hain LifeScience GenoType MTBDRplus (377 isolates) for rifampin and isoniazid resistance mutations: percent agreement (95% Confidence Interval) rifampin 93.6% (90.7-95.9), isoniazid 97.9% (95.9-99.1); sensitivity (95% CI) rifampin 92.7% (88.9-95.6), isoniazid 98.7% (96.6-99.6); and specificity (95% CI) rifampin 95.7% (90.2-98.6), isoniazid 95.4% (88.6-99.2). Isoniazid testing on the Akonni MDR-TB resulted in 1 indeterminate result. Discrepant analysis between assays is ongoing with culture to adjudicate. The performance characteristics of these assays to detect specific resistance markers is further defined, while highlighting the advantages of using a practical and quick multiplexed microarray platform in a field forward setting for global surveillance.

1766

HIGH PREVALENCE OF *BORDETELLA PERTUSSIS* IN SEVERE ACUTE RESPIRATORY INFECTIONS IN HOSPITALIZED CHILDREN UNDER FIVE YEARS IN LIMA, PERU

Ivana Pavic-Espinoza, Sandy Bendezu-Medina, Angella Herrera-Alzamora, **Maria J. Pons**, Adrián V. Hernandez, Juana Del Valle-Mendoza

Universidad Peruana de Ciencias Aplicadas, Lima, Peru

Acute respiratory infections (ARI) are the main cause of morbidity and mortality in children under 5 years worldwide. ***Bordetella pertussis*** is a highly contagious bacterium that can cause serious illness, and approximately half of infected infants less than 1 year old are hospitalized. Also, pertussis immunization series is not completed until six months of age, leaving young infants vulnerable to pertussis. In Peru, pertussis is an increasing health problem despite immunization efforts, and the role of ***B. pertussis*** in ARI is unknown. We determined the prevalence of ***B. pertussis*** among children under 5 years old admitted to Hospital Nacional Cayetano Heredia in Lima with diagnosis of ARI between Jan-2009 and Dec 2010. Epidemiological and clinical features were collected, and presence of ***B. pertussis*** was determined by PCR (pertussis toxin and IS481 gene). A total of 596 nasopharyngeal samples among children

under 5 years were analyzed. In 114 (19.1%) samples were positive for ***B. pertussis***. 32.5% of sample positive to ***B. pertussis*** were diagnosed as viral pneumonia at diagnosis. Importantly, 71.9% of cases were under 12 months of age and 58.8% have been contact with other ARI infected people. Significant differences in clinical symptoms between the total ARI cases and ***B. pertussis*** cases were not found. The most frequent symptoms in ***B. pertussis*** cases were fever (100%), rhinorrhea 78%, cough 71.9% and respiratory distress 60.5%. One child died due to the infection. ***B. pertussis*** cases showed a seasonal distribution with peaks during the months March June and November. This study shows the high prevalence of ***B. pertussis*** in infants who were hospitalized due to severe acute respiratory infections in Lima, Peru. Epidemiologic surveillance programs for ***B. pertussis*** are essential in the future in Peru.

NOSOCOMIAL TUBERCULOSIS TRANSMISSION: IS AIR EXCHANGE ADEQUATE IN PATIENT CARE AREAS IN GULU AND MAKERERE TEACHING HOSPITALS, UGANDA

Achilles Katamba[1], Priscilla Nakiboneka[2], Gerald Obai[3], Bruce Kirenga[1]

[1]Makerere University College of Health Sciences, Kampala, Uganda, [2]Uganda Ministry of Health, Kampala, Uganda, [3]Gulu University, Faculty of Medicine, Kampala, Uganda

In Uganda like similar developing countries, tuberculosis (TB) infection rates in medical students have been found to higher than that of comparable groups including students in other University programs and adults living in suburbs of the city where the medical school is located. In addition, a steep increase in prevalence of TB infection from year one (35%) to year five (55%) in a relatively short period suggests that exposure and infection may be related to clinical work, that is exposure and infection due to nosocomial TB. Thus we undertook the study to assess the adequacy of airborne ventilation in patient areas as per WHO recommendations. We conducted a study in Gulu and Makerere University teaching hospitals. The patient areas assessed included: causality/ emergency ward, bronchoscopy rooms, sputum induction rooms, inpatient wards, laboratories, out-patient departments, and the mortuary. Using an airflow alnor velometer/anemometer placed approximately 15 centimeters form the window or door opening, we measured the air speed of each patient-care area at different times of the day in the usual working situation, when all openings are fully open, when all openings half open and all openings closed for 4 measurements per opening per day for three day. In addition data on intensity of use of the different patient areas were classified into minimum use, moderate use and maximum use. Data were computed to determine the Air changes per hour (ACH) for patient-care areas for different intensity of use of the patient care areas. Preliminary data indicate that the ACH range to as low as 5 to as high as 14 ACH. Patient care areas of old building constructed 50 or more years were more likely to have adequate ACH as per recommendation of WHO even at maximum intensity of use of patient-care areas. Inadequate ACH in patient-care settings may be responsible for nosocomial transmission of TB and may explain the high TB infection rates among medical students. Precautionary measures to prevent transmission of airborne infections are recommended. (Abstract changes to be made)

PREVALENCE OF PATHOGENS AS A CAUSE OF PNEUMONIA ASSOCIATED WITH MECHANICAL VENTILATION IN THE ADULT ICU OF A HEALTH PROVIDER MONTERÍA- ENTITY IN CORDOBA, DURING THE YEARS 2011 TO 2014

Linda M. Chams, Iisy Gracia, Maria F. Yasnot

Universidad de Córdoba, Monteria, Colombia

Pneumonia associated with mechanical ventilation (VAP) is one of the most serious infections associated with health care, not only for the prolongation of hospital stay of the patient, but also because it results in increased mortality and increases in the costs of patient care. This pulmonary complication develops after 48 to 72 hours of endotracheal intubation. To determine the prevalence of disease as a cause of pneumonia associated with mechanical ventilation in adult ICU of a health institution in Montería, Córdoba. A retrospective study in the ICU of a hospital in Montería- Córdoba. Patients with ICU stay and VM for more than 48 hours period that meet the criteria of the American Thoracic Society / Infectious Diseases Society of America (ATS / IDSA). for mechanical ventilation associated pneumonia (VAP) and which has been carried them bronchial secretion cultures or tracheal aspirate were included. For data collection 1474 medical records of patients admitted to the ICU on study time. The information was processed with statistical software SPAD, making a multivariate correspondence analysis (MCA). ***Pseudomonas aeruginosa*** and ***Klebsiella pneumoniae***, were greatest number of isolates with rates equivalent to 39.34% and 27.87%, respectively, following the order of frequency ***Acinetobacter baumannii*** with 16.39%, ***Escherichia coli*** and ***Staphylococcus aureus*** with 4.92% of isolates, the less common bacteria found correspond to ***Enterobacter aerogenes*** with 3.28% and ***Burkholderia cepacia*** and ***Serratia marcescens*** with percentages corresponding to 1.64% respectively. VAP affects up to 38.36 % (61 of 159) of patients admitted to the ICU of the institution where the study was conducted, complicating their evolution , prolonging their stay in the ICU and increasing costs of health services. For this reason, more studies should be done to better understand the epidemiology, pathophysiology and etiology to improve the chances of survival of patients.

CHALLENGES IN DIAGNOSIS OF PEDIATRIC TUBERCULOSIS: A CASE STUDY IN SIAYA COUNTY REFERRAL HOSPITAL, WESTERN KENYA

Nicholas O. Otieno[1], Stellamaris Oloo[1], Evelyne Modi[1], Vincent Omanje[1], Jacob Odeny[1], Chrispine Wasonga[1], Joan Ochieng[1], Rodney Bosire[1], Zachary S. Karim[2], Prakasha Kempaiah[2], Momchilo Vuyisich[3], Norman Doggett[3], Nick Hengartner[3], Paul Fenimore[3], Basil Swanson[3], Benjamin H. McMahon[3], John M. Ong'echa[4], Harshini Mukundan[3], **Douglas J. Perkins**[2]

[1]University of New Mexico/KEMRI Laboratories of Parasitic and Viral Diseases, SCRH, Siaya, Kenya, [2]Center for Global Health, Department of Internal Medicine, University of New Mexico, Albuquerque, NM, United States, [3]Los Alamos National Laboratory, Los Alamos, NM, United States, [4]University of New Mexico/KEMRI Laboratories of Parasitic and Viral Diseases, Kisumu, Kenya

Tuberculosis (TB) has a substantial global prevalence and results in high rates of morbidity and mortality. Kenya ranks among the top five TB-burden countries in sub-Saharan Africa. Although pediatric TB is estimated at 10.72% for all cases, this figure is likely an underestimation due to the challenges associated diagnosis of pediatric TB. Currently, pediatric TB diagnosis in Kenya relies (primarily) on patient history, physical examination, chest x-ray, and sputum smear microscopy (if available). However, challenges are substantial when TB diagnosis is based largely on clinical parameters since a number of frequent co-morbid endemic diseases present with common clinical signs and symptoms. For example, we enrolled a cohort of children (n=1,704, aged 3-36 months) at the Siaya County Hospital, western Kenya (2003-2014), who were followed longitudinally for 36 months. This particular region has holoendemic ***Plasmodium falciparum*** transmission and the highest prevalence of HIV in Kenya. Although diagnosis of malaria, HIV, and bacteremia were robust due to utilization of state-of-the-art diagnostic platforms, diagnosis of pediatric TB presented substantial challenges based on the use of clinical algorithms. In the cohort, 55 children (3.2%) presented with suspected TB. However, based on the WHO TB pediatric score chart, only 15 of the 55 suspected cases (27.3%) were confirmed as TB cases (0.88% of the cohort). Based on these challenges, we initiated development of diagnostic assays that utilize blood and/or urine samples for TB diagnosis. Towards

this end, we are currently investigating the use of novel technologies that employ detection of pathogen biomarkers coupled with sensitive measurement platforms to facilitate rapid and specific diagnosis of TB from blood and/or urine samples.

IMPACT OF PCV7 ON NASOPHARYNGEAL DENSITY, SEROTYPE DISTRIBUTION AND ANTIBIOTIC RESISTANCE OF PNEUMOCOCCAL STRAINS ISOLATED FROM PERUVIAN CHILDREN

Christiane R. Hanke[1], Carlos G. Grijalva[2], Sopio Chochua[1], Mathias W. Pletz[3], Claudia Hornberg[4], Kathryn M. Edwards[5], Marie R. Griffin[2], Hector A. Verastegui[6], Ana I. Gil[6], **Claudio F. Lanata**[6], Keith P. Klugman[1], Jorge E. Vidal[1]

[1]Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Department of Health Policy, Vanderbilt University, Nashville, TN, United States, [3]Center for Infectious Diseases and Infection Control, Jena University Hospital, Jena, Germany, [4]Department of Environment and Health, School of Public Health, Bielefeld University, Bielefeld, Germany, [5]Vanderbilt Vaccine Research Program, Division of Infectious Diseases, Department of Pediatrics, Vanderbilt University, Nashville, TN, United States, [6]Instituto de Investigacion Nutricional, Lima, Peru

Pneumococcal conjugate vaccines (PCV) have reduced the burden of pneumococcal disease (PD), and decreased nasopharyngeal carriage of vaccine-types. Few data exist from remote rural areas, so here, we investigated the serotype distribution and antibiotic resistance of carriage strains isolated from young children, before and two years after PCV7 was introduced, in a prospective cohort study conducted in the remote Peruvian Andes. Effects of PCV7 on pneumococcal nasopharyngeal density, obtained using qPCR reactions, were also assessed. Methods. Nasopharyngeal swabs were collected from a sample of children <3 years of age in both 2009 and 2011. Pneumococcal strains were isolated, quellung-serotyped and tested for susceptibility to antibiotics. Results. Nasopharyngeal prevalence of PCV7 strains decreased from 48% in 2009 to 28.8% in 2011, whereas non-PCV7 types increased from 52% to 71.2% (p=.002). Vaccination with PCV7 did not affect overall pneumococcal density in children colonized by a PCV7 type but did increase median nasopharyngeal density in those colonized with a non-PCV7 type [2009, 1.9x105 cfu/ml vs 2011, 5.5x105 cfu/ml; (p=0.046)]. The most prevalent serotypes were 19F (13.6%), 23F (12.8%), and 6B (12%) in 2009; and 19F (11.2%), 6C (11.2%), and 11A (9.6%) in 2011. A substantial 3.5-fold increase in carriage of serotype 6C was observed after PCV7 introduction (p=0.026). Overall antibiotic resistance did not change after vaccine introduction. Most pneumococcal strains were non-susceptible to tetracycline (97.2%), and to a lesser extent, to trimethoprim-sulfamethoxazole (56.4%), penicillin (34%), erythromycin (22.4%), chloramphenicol (18.8%) or clindamycin (12.4%). Conclusion. PCV7 impacted carriage of those serotypes in rural Peru. Replacement serotypes had increased density when less PCV7 serotypes were present. Peru should consider switching to the PCV13 vaccine to cover the emerging serotype 6C strain.

1771

COMMUNITY CASE MANAGEMENT OF PNEUMONIA IN ABIA STATE, NIGERIA

Ugo U. Enebeli

Federal University of Technology, Owerri, Owerri, Nigeria

This study aims at assessing community management of Pneumonia in children aged 2-59 months in Abia State using the Integrated Community Case Management (iCCM) Model. Community Resource Persons (CORPs) in the iCCM model are trained in diagnosis and treatment of Pneumonia; referring of severe cases to the health facilities; following up such cases; and advising all caregivers on protection against pneumonia by immunization. Pneumonia is defined as a cough or cold with fast breathing (counted with respiratory timers); while having chest indrawing additionally, defines Severe Pneumonia. Between November 2014 and February 2015, in 7 iCCM-eligible LGAs of Abia State: 6,455 under-fives were seen of which 2,505 had cough/difficulty breathing and 1,230 had fast breathing (Pneumonia: 19% of all children seen). Of these, 1004 cases were promptly treated with Dispersible Amoxicillin in the community; and 226 cases were referred to health facilities. Pneumonia is the leading infectious cause of death in children worldwide, and constitute 19% of the estimated 756,000 under-five deaths annually in Nigeria. iCCM is an equity-focused strategy of delivering curative treatment of childhood illnesses in the communities outside of health facilities; and is designed such that more than the hitherto estimated one-third of under-fives can access interventions and antibiotics for Pneumonia. In its 4 months of implementation in 7 LGAs in Abia State, 1004 under-fives who may not have reached the health facilities were managed in the community with antibiotics and preventable deaths averted. iCCM of Pneumonia is a veritable strategy for reducing the alarming rates of under-five mortality, as well as achievement of Millennium Development Goals in Abia State, Nigeria.

CHILDHOOD PNEUMONIA IN RURAL MOUNTAINOUS PAKISTAN: CLINICAL FEATURES AND NASOPHARYNGEAL CARRIAGE OF VIRAL PATHOGENS

Elizabeth D. Thomas[1], Julia M. Baker[1], Assis Jahan[1], Ejaz Hussain[1], Nathan F. Robinson[1], Wasiat Hasan Shah[1], Fatima Aziz[2], Shahida Qureshi[2], Uzma Bashir Aamir[3], Asad Ali[2], Syed Sohail Zahoor Zaidi[3], Syed Iqbal Azam[4], Saba Wasim[4], Zeba A. Rasmussen[1], Khalil Ahmed[5]

[1]Fogarty International Center, National Institutes of Health, Bethesda, MD, United States, [2]Aga Khan University, Department of Paediatrics and Child Health, Karachi, Pakistan, [3]National Institute of Health, Islamabad, Department of Virology, Islamabad, Pakistan, [4]Aga Khan University, Department of Community Health Sciences, Karachi, Pakistan, [5]Karakoram International University, Gilgit, Pakistan

Childhood pneumonia causes high morbidity/mortality in developing countries, including Pakistan; the role of viral pathogens is not clear. Two cohort studies of children under 5 years of age were conducted in rural Oshikhandass village by trained community research workers using weekly active surveillance and WHO defined criteria for pneumonia diagnosis. Pneumonia incidence declined from 44 episodes/100 child years (CY) in 1992-1996 to approximately 15/100 CY in 2012-2014. From 2012-2014, NP data were available for 184/207 (88.9%) pneumonia cases; 132/184 (71.7%) of these had NP viral carriage detected using Luminex® and Taqman® PCR methods, including RSV (19.6%), and influenza (5.4%). A subset of 155 cases tested with Luminex® had entero/rhinovirus (53.5%), coronavirus (7.7%) parainfluenza (7.1%), adenovirus (6.5%), metapneumovirus (5.2%) and bocavirus (1.9%). Of 207 pneumonia cases, 7 (3.4%) had severe pneumonia. Three children were <2 months of age, 50 (24.2%) were 2-11 months, and 154 (74.4%) were between 12-59 months; median age at diagnosis was 19 months. At presentation (Day 1), average duration of illness was 2.1 days, 29.0% had wheezing by exam, and 24.2% had axillary temperature>=100.4 F. Children were followed on Days 3, 5/6 and 14. Total duration of illness, defined as initial duration plus days until respiratory rate returned to normal as checked by health worker, was available for 152 cases (73.4%); mean total duration of illness was 5 days (range 3-17). Where respiratory rate was taken at each visit (84.5% of cases), most children (63.3%) recovered within 3 days of initiating antimicrobial therapy; 16.4% needed 5 days. Nine children (4.4%) needed referral, mostly on Day 1 (6/66%); 3 were hospitalized and none died. Community based pneumonia is primarily non-severe and with early detection, referral, and treatment, has low mortality. Enterovirus/rhinovirus and RSV were the main viruses detected, though multiple other viruses were found; influenza detection was relatively low. Clinical correlation with viral carriage is underway.

1773

BODY COMPOSITION AND VITAMIN D STATUS AMONG PATIENTS WITH TUBERCULOSIS IN RURAL SOUTH INDIA: THE NEED FOR INTEGRATING NUTRITIONAL MANAGEMENT IN CARE AND TREATMENT PROGRAMS

Elaine A. Yu[1], Julia L. Finkelstein[1], John Kenneth[2], Bonam Wesley[2], Saurabh Mehta[1]

[1]Cornell University, Ithaca, NY, United States, [2]Arogyavaram Medical Centre, Madanapalle, India

The evidence base for modifiable nutritional risk factors in patients with Tuberculosis (TB) remains inadequate and very little is known about TB's association with body composition and micronutrient status in populations with high prevalence of undernutrition. The objective of this study was to describe and assess the association between body composition, vitamin D, and active TB among patients at a rural center in South India. Whole and segmental body composition indicators (body fat [%, kg], fat free mass [kg], total body water [kg], impedance) were measured by 8-electrode bioelectrical impedance analysis. 25-hydroxyvitamin D serum concentration was determined by a chemiluminescence immunoassay, and < 50 nmol/L was defined as deficient. Active TB was defined by acid-fast bacilli sputum smear microscopy, per standard of care, and HIV infection was determined by TriDot rapid test. The associations between body composition indicators with vitamin D and TB were assessed in multivariate linear regressions, adjusting for other covariates (including demographic [sex, age], hemoglobin, immunological and rheological indicators). 11.6% of patients had confirmed active TB disease, and 1.5% had HIV infection. Among study participants, mean body weight was 48.7 kg (±13.5). Nearly 25% of patients had 25 kg/m2. Mean vitamin D status was 51.4 nmol/L (±26.7), and 54.7% of patients were vitamin D deficient. Average fat mass was 7.2 kg (±4.3) among individuals with confirmed TB, compared to 11.2 kg (±7.2) among patients with probable TB. Vitamin D deficiency was associated with increased body fat (%) and fat mass (kg; all $p<0.05$), after controlling for other covariates. The results highlight the rampant undernutrition among patients with TB at our clinic in South India and underscore the need for integrating nutritional assessment and counseling in TB care and treatment programs. Further, future laboratory and longitudinal studies are needed to understand the direction of linkages between vitamin D, body composition, and TB along with their relevance for long-term health.

1774

ACCURACY OF SELECTED DEVICES FOR THE DETECTION OF PNEUMONIA SYMPTOMS - RESULTS FROM LABORATORY TESTING AND FIELD EVALUATIONS OF RESPIRATORY RATE COUNTERS AND PULSE OXIMETERS WITH FRONTLINE HEALTH WORKERS IN SUB-SAHARAN AFRICA AND SOUTHEAST ASIA

Kevin Baker[1], Akasiima Mucunguzi[2], Lena Matata[3], Monica Posada[4], Tedila Habte[5], Karin Källander[1]

[1]Malaria Consortium, London, United Kingdom, [2]Malaria Consortium, Kampala, Uganda, [3]Malaria Consortium, Juba, South Sudan, [4]Malaria Consortium, Phnom Penh, Cambodia, [5]Malaria Consortium, Hawassa, Ethiopia

Globally, pneumonia remains the leading infectious cause of death in children under five years. Diagnosis of pneumonia symptoms by community health workers (CHWs) and first level health facility workers (FLHFWs) is based on counting respiratory rate (RR), which is challenging and misclassification of the observed RR is common. Malaria Consortium's Pneumonia Diagnostics project is identifying the most accurate and acceptable devices to support CHWs and FLHFWs in the detection of pneumonia symptoms in children aged 0 to 59 months in Cambodia, Ethiopia, South Sudan and Uganda. Eight pulse oximeters and four respiratory rate counters were selected for evaluation based on formative research, including focus group discussions with 24 CHWs in each country and pile sorting exercises with government stakeholders and NGO partners. CHWs in all countries expressed a 'felt' need for new pneumonia diagnostic devices and automation was a preferred device characteristic. The pile sorting exercises favoured the fingertip pulse oximeters due to ease of use and affordability.The pulse oximeters, having not been used under field conditions, underwent laboratory testing for accuracy and robustness (prototypes excluded). All laboratory tested devices passed, except one fingertip pulse oximeter. Nine devices (5 pulse oximeters and 4 respiratory rate counters) were selected overall for further accuracy evaluation. Health facility accuracy evaluations in the project countries assessed accurate use of each device by CHWs/FLHFWs against reference standards. In each country 430 children aged 0-59 months were enrolled in the study. Children were presented randomly to the CHW/FLHFW, who was blinded to their condition and true RR. The accuracy evaluation is anticipated to finish in June 2015. Preliminary results are encouraging with health workers able to use all devices being trialled. It is hoped that by identifying devices that can be used by frontline health workers to accurately detect pneumonia symptoms in children aged 0-59 months, this will increase appropriate treatment for pneumonia while improving referral rates for patients with severe pneumonia.

1775

ACCEPTABILITY OF SELECTED RESPIRATORY RATE COUNTERS AND PULSE OXIMETERS FOR USE BY FRONTLINE HEALTH WORKERS IN THE DETECTION OF PNEUMONIA SYMPTOMS IN CHILDREN IN SUB-SAHARAN AFRICA AND SOUTHEAST ASIA

Lena Matata[1], Kevin Baker[2], Akasiima Mucunguzi[3], Monica Posada[4], Tedila Habte[5], Karin Källander[2]

[1]Malaria Consortium, Juba, South Sudan, [2]Malaria Consortium, London, United Kingdom, [3]Malaria Consortium, Kampala, Uganda, [4]Malaria Consortium, Phnom Penh, Cambodia, [5]Malaria Consortium, Hawassa, Ethiopia

Diagnosis of pneumonia, the leading infectious killer of children under the age of five, by community health workers (CHWs) and first level health facility workers (FLHFWs) is presumptive and based on counting respiratory rate (RR). This process can be challenging for frontline health workers in low resource settings and misclassification of the observed RR is common. Malaria Consortium's Pneumonia Diagnostics project is identifying the most accurate and acceptable respiratory rate counters and pulse oximeters to support CHWs and FLHFWs in the detection of pneumonia symptoms in children aged 0 to 59 months in Cambodia, Ethiopia, South Sudan and Uganda. In each country a diverse sample of 16 CHWs and 6 FLHFWs are provided with a respiratory rate counter or pulse oximeter. These devices will have been selected based on results of earlier accuracy evaluations and pile sorting exercises with CHWs/FLHFWs who have previously tried the devices. The CHWs/FLHWs will use the device in routine clinical practice for two months between July and October 2015, and filmed using them. The recordings will be analysed for device procedure accuracy, and reactions of the caregiver and their child. Additionally the CHWs and FLHFWs, as well as a diverse sample of 24 parents in each country, will be asked to participate in a semi-structured interview on their perceptions of the devices. Anticipated results will give insight into the acceptability of different diagnostic devices for frontline health workers in their daily work, as well as the reactions of caregivers and their children. It is hoped that this unique study will recommend accurate and acceptable devices for detection of childhood pneumonia symptoms by frontline health workers in Sub-Saharan Africa and Southeast Asia.

1776

SCHISTOSOMA MANSONI: ASSESSING THE FUNCTION OF MAPK PATHWAY AND OF HISTONE MODIFYING ENZYMES

Marina M. Mourão[1], Luiza F. Andrade[1], Sandra G. Gava[1], Livia G. Avelar[1], Raymond J. Pierce[2], Guilherme Oliveira[1]

[1]Fundação Oswaldo Cruz, Belo Horizonte, Brazil, [2]CIIL, Inserm U1019, CNRS UMR8204, University Lille Nord de France. Institut Pasteur de Lille, Lille, France

In most organisms, Mitogen-activated protein kinases (MAPKs) and Histone Modifying Enzymes (HMEs) influence a number of important tissue-specific biological activities such as cell proliferation, survival and, differentiation. Those enzymes are increasingly approved as targets for drug development with a growing amount of inhibitors under development. However, to date, the function of HMEs and MAPKs are uncertain in the parasite Schistosoma. Here, we employed RNA interference to elucidate the roles of 16 HMEs and 5 genes involved in MAPK signaling pathway in ***S, mansoni***. First, the selected genes were chosen based in their putative function and/or for being unique members of their subfamily (ePK) in the parasite. Among the targets are included: SmERK1, SmERK2, SmJNK, SmCaMK2, and Smp38 and 1 histone deacetylases (SmHDAC8), 10 methyltranferases (HMTs), 5 demethylases (HDM), from those, 8 were chosen for experimental validation. Pharmacological inhibition and RNAi were used to elucidate the functional role of MAPK signaling pathway proteins and HMEs in ***S, mansoni***. After RNAi, mice were injected with treated schistosomula and evidenced that SmHDAC8 and SmJNK are important to the parasite transformation and survival, whereas HDAC8, PRMT3, KDM1/KDM2, SmERK, and Smp38 seems to be associated in egg production as infected mice had significantly lower egg burdens and female worms presented underdeveloped ovaries. Moreover, worms depleted in SmJNK and Smp38 exhibited large damage in the tegument and, the later enzyme, seems to be involved in the activation of detoxification enzymes. Recently, RNAseq analysis of MAPKs knockdown parasites elucidated the genes which might be under the control of this signaling pathway. Our results help characterize the importance of MAPK pathway and HMEs in the maintenance and survival of the schistosome and propose some of these enzymes as valuable drug targets to prevent schistosomiasis progress.

1777

PHARMACOLOGICAL SENSITIVITIES OF TRP CHANNELS IN *SCHISTOSOMA MANSONI*

Swarna Bais, Matthew A. Churgin, Christopher Fang-Yen, Robert M. Greenberg

University of Pennsylvania, Philadelphia, PA, United States

There is an urgent need for new or repurposed antischistosomal agents, as praziquantel is effectively the only drug available for treatment and control of schistosomiasis, a disease that affects hundreds of millions. Ion channels are validated and common targets for current anthelmintics. Transient receptor potential (TRP) channels are a diverse family of channels essential for sensory transduction and other functions. However, the roles and pharmacological sensitivities of these channels are essentially unexplored in schistosomes and other parasitic helminths. We are using TRP channel modulators and RNAi to examine the pharmacological sensitivities of TRP channels in schistosomes. The ***S. mansoni*** genome predicts representatives of most TRP channel subfamilies, with the notable exception of TRPV, the vanilloid receptor family. Nonetheless, both adult and larval schistosomes exhibit dramatic hyperactivity in response to capsaicin, a selective activator of mammalian TRPV1. Surprisingly, the majority of this response is attenuated by knockdown of TRPA expression; TRPM7 also contributes to the capsaicin response. Knockdown has no effect on 5-HT-induced hyperactivity. These results indicate that some TRPV-mediated sensory functions may be fulfilled by schistosome TRP channels from other subfamilies, and that schistosome TRP channels likely have novel pharmacological properties. We have also been exploring the role of ***S. mansoni*** TRPM8 channels, which in mammals are cold sensitive and activated by icilin. Like capsaicin, icilin induces dramatic hyperactivity in adult and larval schistosomes. Suppression of TRPM8 expression strongly attenuates this increase in icilin-induced motility, but does not affect 5-HT-induced hyperactivity. This is the first demonstration of a TRPM8 agonist-induced pharmacological effect in schistosomes and provides a novel sensitive point for exploring the pharmacology and function of this channel. Targeted disruption of these channels may provide clues about the roles they play in the parasite and possible strategies for the development of new antischistosomal therapeutics.

1778

MOLECULAR DETECTION OF SCHISTOSOME AND OTHER PARASITIC HELMINTH INFECTIONS ON A DISPOSABLE MICROFLUIDIC CASSETTE

Jinzhao Song, Changchun Liu, Thomas J. Nolan, Michael Mauk, James B. Lok, Haim H. Bau, Robert M. Greenberg

University of Pennsylvania, Philadelphia, PA, United States

Current classical and serological methods for diagnosis of parasitic helminth infections have limitations on sensitivity, specificity, and reliability, and are often labor intensive and require specialized training. Nucleic acid-based methods for detection of free parasite DNA in host blood, urine, feces, or tissues hold the promise of dramatic increases in diagnostic sensitivity and specificity, but often require infrastructure not available in the field. Self-contained, point-of-care molecular detection devices hold the promise of more extensive and accurate monitoring of infection dynamics and treatment efficacy. Here, we describe a simple, small, fully-integrated, inexpensive, and disposable microfluidic cassette adapted for molecular detection of parasitic helminth infections. The cassette, or chip, features an array of reaction chambers that house nucleic acid binding membranes. Nucleic acid capture, washing, amplification, and detection are all combined in a single multifunctional reaction chamber. The cassette is endowed with a concentration function since nucleic acids captured on a flow through membrane serve directly as templates for amplification without elution. This cassette is compatible with isothermal amplification methods such as loop-mediated isothermal amplification (LAMP) and reverse transcription (RT)-LAMP. Both monitoring the reaction and thermal control is low-cost and flexible. By adapting LAMP protocols with this cassette, we show that ***Schistosoma mansoni*** DNA is readily detectable on the chip using serum taken from mice as early as one-week post infection, several weeks prior to the onset of parasite egg production. Furthermore, we show that Dirofilaria immitis DNA is readily detected in plasma samples from infected dogs. These results provide a strategy for simple, inexpensive, and highly accurate diagnostic monitoring of schistosome and other parasitic helminth infections on site and in the clinic.

1779

BIOMPHALARIA GLABRATA EMBRYONIC (BGE) CELL SUPEROXIDE DISMUTASE (SOD) EXPRESSION PRE-AND POST-EXPOSURE TO *SCHISTOSOMA MANSONI* LARVAL TRANSFORMATION PROTEINS

Utibe Bickham-Wright, Nathalie Dinguirard, Grzegorz Sabat, Timothy P. Yoshino

University of Wisconsin, Madison, WI, United States

Schistosoma mansoni is one of several species of human blood flukes that causes schistosomiasis, which continues to afflict over 200 million people worldwide. In resistant strains of the snail intermediate host, ***Biomphalaria glabrata***, primary sporocysts are rapidly encapsulated by circulating hemocytes and killed by the release of reactive oxygen species. Superoxide dismutase (SOD) in hemocytes is responsible for the production of H_2O_2 and the destruction of encapsulated parasites. An increase in Cu/Zn SOD activity has been linked to the resistant snail strains and further

characterization has shown allele specific differences between strains. Cells of the ***B. glabrata*** embryonic (Bge) cell-line encapsulate larval ***S. mansoni*** under ***in vitro*** conditions, similar to hemocyte-sporocyst encapsulation reactions. In the present study we investigated if Bge cells, like hemocytes, possessed SOD activity, and whether exposure of cells to larval transformation proteins (LTP) affected its activity. Molecular, proteomic, and enzyme activity assays were used to investigate SOD in Bge cells and the effects of exposure to parasite proteins on its expression. Results of Cu/Zn SOD allele-specific PCR analysis in Bge cells showed that the A/C alleles, previously found to be associated with susceptible ***B. glabrata*** snails, were expressed. A quantitative real-time PCR assay showed an increase in Bge cell Cu/Zn SOD transcript levels after exposure to ***S. mansoni*** LTP although changes were not statistically significant. However, nanoLC-MS/MS mass spectrometry analysis of Bge cell proteins expressed pre- and post-exposure to LTP showed a significant increase in Cu/Zn SOD in the LTP exposed group. Finally, consistent with proteomic data, Bge cell lysates possess SOD activity, although whether or not this activity is affected by ***S. mansoni*** LTP remains to be investigated. Results of this study demonstrate the expression of Cu/Zn SOD in Bge cells and further validate the use of this cell line as a model for studying schistosome-snail immune interactions.

1780

GENETIC ANALYSIS OF TRANSMISSION-RELATED TRAITS IN SCHISTOSOME PARASITES

Winka Le Clec'h, Frédéric D. Chevalier, Tim J. Anderson

Texas Biomedical Research Institute, San Antonio, TX, United States

Parasite traits associated with transmission success, such as the number of infective stages released, are expected to be optimized by natural selection. However, in the trematode parasite ***Schistosoma mansoni***, such transmission traits vary significantly within and between different parasite populations and selection experiments demonstrate that this variation has a strong genetic basis. We are using two approaches to determine the genetic architecture of this important transmission related life-history trait. First, we used deep sequencing of pooled exomes to compare allele frequencies across the 363Mb parasite genome in low and high shedding parasites from a single outbred laboratory schistosome population (SmLE). This experiment was conducted in triplicate using large parasite populations to minimize sampling issues and inbred snail lines to minimize the impact of host genetics. Second, we are conducting three generation genetic crosses between two laboratory parasite lines (SmBRE and SmLE) that differ >10 fold in numbers of cercariae shed from snails (mean(±se) cercariae per shedding, 2929±156 vs. 253±39) for a classical QTL analysis. The exomes from parents, F1s and F2 progeny from these genetic crosses will be sequenced and the genotype and phenotype data analyzed using linkage-based methods. The combination of these two approaches is expected to reveal the genetic architecture of a parasite trait that is critical for transmission in an important human pathogen.

INDEPENDENT ORIGINS OF ALLELES CONFERRING OXAMNIQUINE RESISTANCE IN BRAZILIAN SCHISTOSOME PARASITES

Winka Le Clec'h[1], Frédéric D. Chevalier[1], Nina Eng[1], Rafael Ramiro de Assis[2], Guilherme Oliveira[2], Philip T. LoVerde[3], Timothy J. Anderson[1]

[1]Texas Biomedical Research Institute, San Antonio, TX, United States, [2]Centro de Pesquisas René Rachou - Fiocruz/MG, Belo Horizonte, Brazil, [3]University of Texas Health Science Center, San Antonio, TX, United States

The evolution of drug and pesticide resistance provides a valuable opportunity to examine adaptation in natural populations. Oxamniquine was used to treat schistosomiasis patients in the 1970s to the late 1990s and several cases of parasite infections resistant to treatment were recorded. Our group has identified the gene and mutations involved in oxamniquine resistance. The gene involved encodes a sulfotransferase, SmSULT, required for intracellular drug activation. Resistance has a recessive basis and occurs when both SmSULT alleles encode for defective proteins. Here we examine SmSULT sequence variation in a natural schistosome population in Brazil after 30 years of treatment. Our central aim was to determine (i) the frequency of resistance alleles and (ii) the number of independent origins of resistance to this drug in a single parasite population. We collected fecal material containing ***S, mansoni*** eggs, hatched miracidia and stored these on FTA cards. Following whole genome amplification of DNA, we sequenced the two exons of SmSULT from each miracidia. We amplified miracidial DNA from 189/228 samples (83% success). These included one to 11 miracidia larvae from each of 50 patients. We found four mutations that are known or predicted to impair protein function from examination of their position in the SmSULT crystal structure and/or by biochemical assays. These were (i) the amino acid deletion (Δ142) (ii) a single bp insertion in exon 1 predicted to make a truncated protein product, and (iii) two substitutions (N44H, G206V), which are predicted to impair binding of the oxamniquine and the co-factor needed for oxamniquine activation respectively. One other mutation (N215Y) is not predicted to affect drug activation. Three results are of particular interest: (i) we recovered the Δ142 mutation, responsible for resistance in our genetic cross, in field collected parasite populations (i) allele frequencies of known or predicted resistance alleles are low (0.04-0.29%), perhaps consistent with fitness costs associated with carriage of these alleles (ii) we observed 2-4 independent origins of known or predicted resistant alleles.

1782

POPULATION "EXOMICS" OF *SCHISTOSOMA MANSONI*

Frédéric D. Chevalier[1], Winka LeClec'h[1], Philip T. LoVerde[2], Rafael Ramiro de Assis[3], Guilherme Oliveira[3], Safari Kinunghi[4], Anouk Gouvras[5], Bonnie Webster[5], Joanne Webster[6], Aidan Emery[5], David Rollinson[5], Timothy J. Anderson[1]

[1]Texas Biomedical Research Institute, San Antonio, San Antonio, TX, United States, [2]University of Texas Health Science Center, San Antonio, San Antonio, TX, United States, [3]Centro de Pesquisas René Rachou - Fiocruz/MG, Belo Horizonte, Brazil, [4]National Institute for Medical Research, Mwanza, United Republic of Tanzania, [5]Natural History Museum, London, United Kingdom, [6]Imperial College, London, United Kingdom

We have developed a robust, inexpensive approach for capture and sequencing of the ~17Mb ***Schistosoma mansoni*** exome that can be used for single larval parasites isolated from feces. The approach uses whole genome amplification of miracidia larvae preserved on FTA cards, solution-based capture of exome sequences using 120bp RNA baits, and Illumina sequencing, and can be extensively multiplexed to reduce costs and simplify sequence library preparation. Here we describe population genomic analysis of exome sequence data from 146 miracidia (one from each patient sampled) from Brazil, Tanzania and two West African countries (Senegal and Niger). All the African samples come from the Schistosome Collection At the Natural History Museum (SCAN collection). We detail patterns of genetic variation in autosomal and mtDNA, we characterize SNP variation at candidate vaccine and drug resistance loci, and examine geographic differentiation in allele frequencies to identify genome regions under strong directional and balancing selection. Exome sequencing has multiple applications for investigating the population biology and evolutionary genomics of schistosomes. This approach provides several advantages over other "genome reduction" approaches (eg RADseq) because the sequence captured can be unambiguously aligned to the parasite genome, coding sequences of central interest to most biologists are determined, and unwanted contaminating DNA is removed.

1783

EFFECT OF PARASITISM ON THE DISTRIBUTION OF SEROTONIN IN THE NERVOUS TISSUES OF *BIOMPHALARIA ALEXANDRINA*

Solymar Rolon-Martinez[1], Mohamed R. Habib[2], Lee O. Vaasjo[1], Roger P. Croll[3], **Mark W. Miller**[1]

[1]University of Puerto Rico, San Juan, PR, United States, [2]Theodor Bilharz Research Institute, Cairo, Egypt, [3]Dalhousie University, Halifax, NS, Canada

Schistosomiasis, or bilharzia, is estimated to affect more than 200 million people worldwide. The digenetic trematode worm ***Schistosoma mansoni*** that causes schistosomiasis employs the freshwater snail genus ***Biomphalaria*** as its primary intermediate host. It has been proposed that the transition from the free-living ***S. mansoni*** miracidium to parasitic mother sporocyst depends upon uptake of biogenic amines, e.g. serotonin (5HT), from the snail host. However, little is known about potential sources of serotonin in ***Biomphalaria alexandrina*** tissues and its potential changes during the course of infection. The purpose of this investigation was to localize serotonin-like immunoreactivity (5HTli) in the central nervous system (CNS) of ***B. alexandrina*** and examine 5HTli at critical points of the host-parasite interaction. 5HTli fibers were observed innervating the cephalopedal integument, the major site of ***S. mansoni*** miracidium penetration and transformation. However, no peripheral 5HTli neurons were detected. Clusters of 5HTli neurons were observed in the cerebral, pedal, left parietal, left pleural and visceral ganglia, suggesting that the peripheral serotonergic fibers originate from the CNS (see also Delgado et al. 2012). Specimens infected with ***S. mansoni*** were examined at 10 days post infection (10 dpi) and during their shedding stage. The total number of central 5HTli neurons decreased from 162.2 ± 40.0 (n = 5) under control conditions to 118.8 ± 11.9 10 dpi and 130.4 ± 6.7 at the shedding stage (one-way ANOVA, $p < 0.05$). Reductions of 5HTli were most evident in the pedal ganglion (control: 33.6 ± 8.8; 18.0 ± 3.7, 10 dpi; 25.6 ± 5, shedding; $p < 0.05$) and the left pleural ganglion (3.2 ± 2.8, control; 0 ± 0, 10 dpi; 0 ± 0, shedding; $p < 0.05$). The changes in 5HTli observed following infection by ***S. mansoni*** indicate that reductions in serotonin levels can occur in specific central neurons in parasitized snails and that these changes might contribute to the modifications in several behaviors that are observed during the course of infection.

1784

SCHISTOSOMIASIS IN REPRODUCTIVE-AGE WOMEN IN RURAL ZIMBABWE

Joseph Freer[1], Andrew Prendergast[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Queen Mary, University of London, London, United Kingdom

Schistosomiasis, which is highly prevalent in Zimbabwe, has well-recognised complications. However, the epidemiology of schistosomiasis in reproductive-age women and the impact of infection during pregnancy remain poorly understood. In this study we describe the epidemiology of schistosomiasis in reproductive-age women in rural Zimbabwe. The prevalence and risk factors for infection will be described, using the rich baseline dataset that includes demographic and socioeconomic variables, together with extensive data on sanitation coverage, water collection and exposure practices. Secondly, we explore associations between maternal schistosomiasis and adverse birth outcomes, including i) prematurity ii) low birth weight iii) miscarriage iv) stillbirth and v) neonatal death, stratified by maternal HIV status. Regression analysis for each birth outcome, using schistosomiasis as the exposure variable and including a range of covariates known to be associated with adverse birth outcomes (e.g. maternal age, parity, education, hypertension, smoking and alcohol use) will be presented. Thirdly, we present the relationship between the presence of inflammatory biomarkers (C-reactive protein, interleukin-6) in the plasma of 400 pregnant women with and without schistosomiasis.

1785

PATTERNS OF REACTIVITY TO *SCHISTOSOMA MANSONI* EGG GLYCAN ANTIGENS IN A POPULATION OF TREATMENT-NAÏVE KENYAN SCHOOL CHILDREN

Nina S. Prasanphanich[1], Ryan E. Wiegand[2], Jasmine A. Landry[3], Eric M. Ndombi[4], Bernard Abudho[4], Diana K. Riner[5], Megan L. Mickum[1], Diana M. Karanja[4], Daniel G. Colley[5], Richard D. Cummings[1], W. Evan Secor[2]

[1]Emory University, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Macalester College, St. Paul, MN, United States, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]University of Georgia, Athens, GA, United States

Children in schistosomiasis-endemic areas develop partial resistance to infection as they age. This resistance is associated with immune responses, including IgE and IgG, to parasite antigens. Anti-glycan antibodies are abundant in schistosome-infected hosts, but their significance in human disease resistance is still unclear. The aim of this study was to identify glycan epitopes targeted by children in ***S, mansoni*** endemic areas, and examine trends of reactivity with age in a population of egg-positive, treatment-naïve Kenyan school children. Plasmas from both egg-positive and -negative children demonstrate reactivity with several epitopes including core xylose/core α3 fucose, F-LDNF, LDN and LDNF on schistosome glycan microarrays. To explore age-related trends of such antibodies, we measured IgG and IgM to mock- and periodate-treated ***S, mansoni*** soluble egg antigen (SEA), and two parasite cross-reactive glycoproteins, keyhole limpet hemocyanin (KLH) and horseradish peroxidase (HRP). The ratio of periodate-resistant (primarily non-glycan) versus total IgG and IgM reactivity to SEA increased with age. IgG to HRP and IgM to KLH decreased with age, while IgG to KLH increased. These trends were especially pronounced throughout adolescence. The anti-glycan antibodies detected included a mix of IgG1, G3 and G4. Our results suggest that immune recognition of some glycan epitopes is negatively correlated, and others, positively correlated with age. Future studies on the function of such anti-glycan antibodies and their pattern of expression in human infection could be informative for the improvement of diagnostics and vaccine development.

1786

GENE REGULATION OF IMMUNE RESPONSES IN *BIOMPHALARIA GLABRATA*

Judith Humphries, Briana Harter, Heather Jost, Eric Ohlrogge, Eric Weinlander

Lawrence University, Appleton, WI, United States

Biomphalaria glabrata snails act as the intermediate host to the trematode parasite, ***Schistosoma mansoni***. Following ***S. mansoni*** penetration of resistant ***B. glabrata,*** parasites are encapsulated by blood cells (hemocytes) and following are killed most likely via host-derived reactive oxygen and/or nitrogen intermediates. An immune response such as this is assumed to depend on altered gene expression to some degree. Moreover several studies have shown that the transcriptional profile of ***B. glabrata*** changes in response to stressors such as gram negative and gram positive bacteria, mechanical wounding, and metazoan parasites, as published previously. To date however, only a few transcription factors have been described in ***B. glabrata*** and an understanding of gene regulation in this species is lacking. The NF-kappaB family of transcription factors has been shown to regulate gene expression in a wide variety of biological processes, including immune and inflammatory responses. As a result, the NF-kappaB pathway is a prospective candidate for the regulation of immune-related genes in ***B. glabrata.*** NF-kappaB homologues have previously been identified in the snail and we have discovered putative kappa-binding sites in the regulatory regions upstream of immune-related genes such as p38 MAPK and Mpeg. Consequently we have examined whether these putative kappa-binding sites are recognized and bound by a ***B. glabrata*** NF-kappaB protein through electrophoretic

mobility shift assays (EMSAs). Furthermore the ability of NF-kappaB to translocate to the nucleus following exposure to PAMPS (pathogen associated molecular patterns) including ***S. mansoni*** larval transformation products was studied. Results support that NF-kappaB can function as a transcription factor and suggest its associated signaling pathway plays a role in the immune system in ***B. glabrata***.

1787

CHARACTERIZATION OF THE HUMORAL AND CELLULAR IMMUNE RESPONSES ELICITED BY THE IMMUNIZATION OF MICE WITH *SCHISTOSOMA MANSONI* CATHEPSIN B IN THE PRESENCE OF CPG OLIGODEOXYNUCLEOTIDES OR MONTANIDE ISA 720 VG

Alessandra Ricciardi, Kittipos Visitsunthorn, John P. Dalton, Momar Ndao

McGill University, Montreal, QC, Canada

Schistosomiasis is the most important human helminth infection due to its impact on public health. A vaccine could contribute to a long-lasting decrease in disease spectrum and transmission. Our previous vaccine study using ***Schistosoma mansoni*** Cathepsin B (SmCB) resulted in 59% and 60% worm burden reduction with CpG oligodeoxynucleotides and Montanide ISA720 VG as adjuvants, respectively. Furthermore, antibody production was significantly augmented in the vaccinated mice; both formulations elicited SmCB-specific total IgG endpoint titers > 120,000. In this study, the role of antibody-dependent cell-mediated cytotoxicity in SmCB-mediated protection was evaluated by incubating the parasite in the presence of pre-immune or immune sera with isolated lung CD45+ cells. These cells were obtained from mice immunized with recombinant SmCB adjuvanted with either CpG oligodeoxynucleotides or Montanide ISA 720 VG. Cells and sera from adjuvant and saline control animals were also included. SmCB + Montanide induced the highest killing when immune serum was present; suggesting the contribution of antibodies in cell-mediated parasite killing. In contrast, SmCB + CpG induced constant increased parasite killing which was independent of the addition of immune sera; implying that only cellular effects were elicited. To further investigate the immunological mechanisms, different cell populations were isolated and analyzed. CD8+ cells prominently contributed to SmCB + Montanide-induced parasite killing (67%) while CD4+ cells were the main effectors in SmCB + CpG-induced parasite killing (64%). Our results elucidate the importance of the adjuvants in influencing the immune mechanisms involved in parasite killing and protection against schistosomiasis.

CHIENGI DISTRICT, ZAMBIA OPEN DEFECATION FREE!

Vernon Ngulube[1], Rabson Zimba[2], Lambwa Chomba[3], Philippa Crooks[4], Oswell Katooka[5], David A. Larsen[6], Chinyama Lukama[5], Abel Manangi[5], Laurie Markle[2], Selenia Matimelo[5], Paul Mboshya[5], Sarrah Muleya[7], Engervell Musonda[5], Nicolas Osbert[4], John Pinfold[4], Scott Russpatrick[2], Amy Tiwari[2], Benjamin Winters[2]

[1]Ministry of Local Government and Housing, Luapula Province, Zambia, [2]Akros, Lusaka, Zambia, [3]Chomba Chiefdom, Chiengi District, Zambia, [4]UNICEF Zambia Country Office, Lusaka, Zambia, [5]Ministry of Local Government and Housing, Lusaka, Zambia, [6]Syracuse University, Syracuse, NY, United States, [7]Government Council, Chiengi District, Zambia

Open defecation is a leading risk factor for the transmission of diarrheal disease and soil-transmitted helminths. To become open defecation free (ODF) households must have access to a latrine with various adequacy parameters including a smooth, cleanable floor, a lid and a hand-washing station with soap or ash. Zambia has adopted community-led total sanitation (CLTS) as country policy in rural areas. CLTS is a behavior change communication campaign where communities are "triggered" through a discussion about open defecation and consequences of the behavior. Communities then construct their own latrines. With support from UNICEF, the Ministry of Local Government and Housing in Zambia has scaled CLTS throughout half the country. Included in the CLTS is a mobile-to-web real-time monitoring tool of ODF progress at the village level supported by DHIS2 that provides feedback to the community, district and traditional leaders. After 18 months of implementation of CLTS with the real-time monitoring the entirety of Chiengi District, Zambia has now certified as ODF despite challenges at the onset of the program. Chiengi District is the first in Zambia, and likely one of the first in all of sub-Saharan Africa to achieve ODF.

1789

THE ASSOCIATION BETWEEN SEASONALITY AND LEPTOSPIROSIS IN SOUTHERN THAILAND

Sarunyou Chusri, Edward McNeil, Khachornsakdi Silpapojakul

Prince of Songkla University, Hat yai, Songkhla, Thailand

Introduction: Leptospirosis is a worldwide zoonosis with incidence rates of between 0.86 and 5.50 per 100,000 populations per year in Songkhla Province in southern Thailand. The incidence rate per month during the monsoon season was 3-5 times higher and up to 10-15 times higher during floods. Objectives: To study the association between the number of leptospirosis cases in Songkhla Province to the seasonal pattern and climate factors. Methods: We retrospectively reviewed the number of leptospirosis cases and climate factors including rainfall, temperature, relative humidity, light, wind and documentation of flooding from 1995-2015 and used time series analysis and logistic regression to study the association between them. The time series of monthly number of leptospirosis cases and climate information were taken and put into analytic model. Results: From 1995 to 2015, there were 1023 cases of leptospirosis in Songkhla Province. We found the documentation of flooding and 1-month lag of average rainfall were associated with number of leptospirosis cases with odds ratio (95% confidence interval) of 5.3(2.8-7.8, ***p***-value =0.003) and 1.4(1.1-2.2, ***p***-value=0.04). We also found the lack of association between chronological month, temperature, light and wind. For time series analysis there was no association between any more than 2-month lag climate factors and number of leptospirosis cases. Conclusion: The trend of leptospirosis in southern Thailand was associated with flooding and rainfall within a month. This model was purposed to predict the number of leptospirosis cases accurately.

1790

CAN DIARRHEAL DISEASES BE PREDICTED IN ADVANCE?

Md Rakibul H. Khan[1], Haidar Aldaach[1], Shafqat Akanda[2], Anwar Huq[3], Antarpreet Jutla[1], Rita Colwell[3]

[1]West Virginia University, Morgantown, WV, United States, [2]University of Rhode Island, Kingston, RI, United States, [3]University of Maryland, College Park, MD, United States

Diarrheal diseases continues to pose a severe threat in tropical regions where WASH facilities remain marginal and are prone to destruction. With limited efficacy of vaccines, it is important to device alternate methods to determine environmental conditions favorable for diarrheal diseases. Outbreaks of several vibrio (V. cholerae., V. vulnificus, V. parahaemolyticus) have characteristic signatures that are associated with large scale climatic processes. Here, using cholera as one of the signature diarrheal disease, we present a framework coupling hydrological and microbiological understanding with satellite remote sensing data to predict environmental conditions for outbreak in several regions of sub-Saharan Africa. Hydroclimatic processes, primarily precipitation and temperature are found to be strongly associated with epidemic and episodic outbreak of cholera. Using spatial land surface temperature (LST) data from satellites along with water accessibility data and population data, we have developed an algorithm to classify regions at risk to cholera. A case study has been piloted to implement the algorithm in five epidemic regions e.g. Mozambique, Central African Republic, Cameroon, South Sudan and

Rwanda. Conditions for occurrence of cholera were detectable at least one month in advance. Additionally, we will present framework for prediction of V. vulnificus, V. parahaemolyticus in several coastal regions of US.

1791

POPULATION-LEVEL INDOOR PM2.5 EXPOSURE ASSOCIATED WITH HOUSEHOLD SOLID FUEL USE FOR THE ESTIMATION OF THE GLOBAL BURDEN OF HOUSEHOLD AIR POLLUTION (GBD 2013)

Astha KC, Victoria Bachman, Tiffany Ku, Mohammad H. Forouzanfar, GBD Household Air Pollution Expert Group

Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States

Published evidence suggests that there is notable heterogeneity in PM2.5 exposure distribution across geographies due to various socioeconomic and environmental factors. However, there has been limited effort to quantify average PM2.5 exposure associated with household solid fuel use while accounting for this variation. To address this evidence gap, we estimated the population-level PM2.5 exposure associated with household solid fuel use with uncertainty for 138 developing countries from 1980 to 2013.We updated the Global Household Air Pollution Database by conducting a systematic review to include studies published as of January 2015. The final database comprised of 67 studies conducted in 16 countries from 8 regions. First, mean 24-hour kitchen PM2.5 concentration was estimated using a linear mixed effect model with maternal education as a covariate and nested random effect for GBD super region, region, and country. Then, ratios of personal exposure to average 24-hour kitchen PM2.5 concentration for men, women, and children were calculated separately. Finally, average personal exposure was calculated for men, women, and children by applying the ratio of personal exposure and kitchen concentration to the average 24-hour kitchen PM2.5 concentration for all 138 countries.Our analysis showed that mean PM2.5 exposure associated with household solid fuel varies geographically. Maternal education was a significant predictor of mean 24-hour PM2.5 kitchen concentration (p-value: 0.016). The estimated mean 24-hour PM2.5 kitchen concentration was highest in Ethiopia 691 µg/m3 (95% CI: 226-1750) and lowest in Costa Rica 103 µg/m3 (95% CI: 14.5-396) in 2013. The pooled ratio of personal to kitchen area PM2.5 concentration was highest for women 0.73 (95% CI: 0.66-0.81) and lowest for men 0.43 (95% CI: 0.37-0.50).Informed by a global database spanning 16 countries our model captured geographic variation in indoor PM2.5 exposure that was instrumental in estimating the global burden of household air pollution for GBD 2013. Future estimates would benefit from more direct exposure measurements by enriching the sparse PM2.5 data landscape.

1792

CHALLENGES FOR WOMEN IN ACCESSING WATER AND SANITATION FACILITIES IN PERI-URBAN SLUMS OF KENYA

Poulomy Chakraborty, Alyson Young, John D. Anderson, Richard D. Rheingans

University of Florida, Gainesville, FL, United States

The vulnerability surrounding insecurity and threat experienced by women when they seek to meet their and their family's daily water and sanitation needs, are not much researched and addressed. A high proportion of women in the developing world are subjected to violence, assault and threat on their daily commutes to fulfill water and sanitary requirements, most of which remain undocumented. This analysis uses quantitative and qualitative data from a larger cross-sectional study on water, sanitation and hygiene (WASH) disparities in peri-urban slums of Kisumu, Kenya during 2014-15. Of the 734 interviewed women, more than 94% had access to toilets. However, more than one-third reported that they felt insecure to access their toilets at night and approximately 11% said they had faced some form of attack, threat or assault on their way to access toilets at night. Despite having toilets in their compounds, accessing them after dark presents severe threat to their personal safety. As a result, women are forced to rely on various unhygienic means of relieving themselves. Although fewer women stated they have been attacked while collecting water, more than 23% reported they felt insecure to gather water for their households at night. Data from semi-structured interviews with 20 women also revealed a fear of violence or threat in accessing WASH facilities within the community. Preliminary results demonstrate installing WASH infrastructure does not always ensure regular usage in communities, when there is an underlying threat of gender-based violence. The lack of safe toilet access at night may give rise to the use of other unsanitary methods of waste disposal, may force a woman to wait until daylight hours, and/or create psychosocial stress all of which can result in other public health risks for women and their families. A systematic and holistic approach is needed to address gender-based violence to ensure safer and higher access to WASH facilities by the women.

1793

EXPLORING THE IMPACT OF HARMFUL ALGAL BLOOMS (HABS) ON THE HEALTH OF COASTAL COMMUNITIES IN THE GULF OF GUAYAQUIL, ECUADOR

Mercy J. Borbor-Cordova[1], Gladys Torres[2], Bonny Bayot[1], J. Rafael Bermúdez[1], Luis Escobar[1], Stuart Hamilton[3], G. Cristina Recalde[1], Sadie Ryan[4], Anna Stewart-Ibarra[5]

[1]Escuela Superior Politecnica del Litoral, Guayaquil, Ecuador, [2]Instituto Oceanografico de la Armada del Ecuador, Guayaquil, Ecuador, [3]Salisbury University, Salisbury, MD, United States, [4]Department of Geography and Emerging Pathogens Institute, University of Florida, Gainsville, FL, United States, [5]Center for Global Health and Translational Science, SUNY Upstate Medical University, Syracuse, NY, United States

Here we present a methodological framework and initial findings from a transdisciplinary study of harmful algal blooms (HABs) and public health effects in coastal Ecuador. There is a growing scientific consensus that the public health and economic impacts of HABs are indicative of a global epidemic. We have developed a methodological framework to explore the natural and anthropogenic drivers of HABs (red tides) in an estuarine-coastal gradient, and the potential linkages to the public health of three coastal communities in the Gulf of Guayaquil, Ecuador. Previous research identified more than 100 "red tide" events in the gulf since 1968; about 77% of these were associated with the death of fish, birds, or shrimp; however, there is a lack of specific epidemiological information linking HABs to local public health impacts. To address this gap, we are conducting a comprehensive eco-epidemiological study through the following: a) A historical reconstruction (2000-2014) of climate-ocean and anthropogenic conditions associated with HABs events to identify potential triggers, b) an assessment of health practitioners' knowledge and risk perception to explore local health effects of HABs, and c) an ecological study of the ocean-biological conditions that favor the presence and/or dominance of algae associated with toxins through an analysis of remotely sensed imagery and prospective field data collections. This study is being conducted in partnership with Ministry of Health, as establishing a collaborative partnership with public health staff and key local stakeholders from the outset will ensure a participatory process to identify potential interventions and public health priorities surrounding this largely unexplored public health issue.

1794

POLLUTION STUDIES ON THE LOWER MISSISSIPPI MISSISSIPPI RIVER IN PORT GIBSON AREA, MISSISSIPPI DURING THE FALL OF 2013

Alex D. Acholonu, Amber Tatum

Alcorn State University, Alcorn State, MS, United States

Water is critical for the survival of living things including man. It is the driver of life. Its quality is closely associated with the surrounding

environment and the use made of it. It may also depend on whether the water body is lentic or lotic. The purpose of this study was to determine if the Mississippi River in the area of Port Gibson,MS was polluted and compare the result with the Mississippi Water Quality Criteria (MSWQC) and/or the Environmental Protection Agency(EPA) Standard. Water samples were collected from the Mississippi River in Port Gibson Area in the Fall of 2013 for three consecutive times and tested with the LaMotte water pollution test kits. The physical characteristics of the river were taken including the temperature and recorded. The following chemical parameters were tested and analyzed: total alkalinity, ammonia-nitrogen, calcium, carbon dioxide, chlorine, cooper, dissolved oxygen, magnesium, nitrate, hardness, pH, phosphate, and salinity. The parameters tested met the Mississippi Water Quality Criteria (MSWQC) with the exception of total alkalinity, hardness, and phosphate which exceeded the criteria. Coliform bacteria were present in the river water showing evidence of bacteria contamination and the fact that the water was not potable or was unsanitary for human domestic use.

1795

ANTIBIOTIC RESISTANCE OF ENTEROBACTERIA IN TWO WASTEWATER TREATMENT PLANTS OF TWO PERI URBAN COMMUNITIES OF LIMA, PERU

Francesca Schiaffino[1], Noelia Angulo[1], Alejandro Florentini[1], Josmel Sevillano[1], Cusi Ferradas[1], Margot Faustino[1], Lilia Cabrera[2], Martiza Calderón[1], Pablo Tsukayama[3], Gautam Dantas[3], Robert H. Gilman[4]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Biomedical Research Unit, A.B. PRISMA, Lima, Peru, [3]Dantas Lab, Washington University in St. Louis, St. Louis, MO, United States, [4]Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The increased use of antibiotics in human medicine and agriculture in recent decades has introduced significant selective pressures on bacterial populations in virtually all human-associated environments and lead to the evolution of multidrug-resistant bacteria that compromise our ability to treat infectious disease. Build environments, such as wastewater treatment plants (WWTP) have already been identified as reservoirs of antibiotic resistance genes with high potential for introduction into natural environments. Previous studies regarding the presence of antibiotic resistance bacteria have not been performed in sewage and WWTP in the peri urban shantytowns of Lima, Peru. This is the first report of the isolation and antibiotic resistance of specific Enterobacteria from two WWTP of the districts of San Juan de Miraflores (SJM) and Villa El Salvador (VES), Lima, Peru. A longitudinal sampling was performed from September 2014 until February 2015 in the WWTP of SJM and VES, Lima, Peru. Influent and effluent water samples were taken during each sampling date from each WWTP. Total coliforms, strain isolation and antibiotic resistance to 12 different antibiotics was determined. Antibiotic resistance ranged as follows: 10 to 80% for affluent VES samples, 80 to 100% for VES effluent samples, 30 to 100% for affluent SJM samples and 70 to 80% for effluent samples. Regarding individual antibiotic resistance, SJM affluent and effluent samples were 100% resistant to CF and SXT while effluent samples where 66.6% resistant to CTR. Affluent and effluent samples from VES where 100% resistant to CIP and effluent samples had high resistance percentages to CXM (85.7%), NIF (85.7%) and SXT (87.5%). Isolated bacterial strains included ***E. coli, Enterobacter*** spp., ***Citrobacter*** spp., ***Serratia*** spp., ***Klebsiella pneumonie,*** and ***Salmonella*** spp. In conclusion, results show that effluent waters do carry rasistant bacterial strains into the environment, including pathogenic bacteria. Further studies are needed to evaluate bacterial resistance genes and their behavior in WWTP and their re-entrance into the community's environment.

1796

UNDERNUTRITION, DIARRHEA AND BREASTFEEDING IN UNDER-FIVE - BENGO PROVINCE, ANGOLA

Miguel Brito[1], Ânia Soares[2], Cláudia Fançony[2], António Martins[3]

[1]CISA - Health Research Centre in Angola/ESTeSL, Caxito, Angola, [2]CISA - Health Research Centre in Angola, Caxito, Angola, [3]Diretor Provincial de Saude, Caxito, Angola

New interventions to reduce undernutrition should be design taking into account their basic, underlying and immediate causes, since nutrition is capable of maximize health and minimize morbidity and mortality in early childhood. This study aims to identify factors associated with undernutrition (wasting, stunting and underweight) among children aged less than 5 in Bengo province, Angola. A total of 803 children aged 0 to 59 months were surveyed. Logistic regression analysis was used to examine undernutrition against a set of variables associated with health and water. Children nutritional status was classified as underweight, stunted and wasted if their Z-scores for weight-for-age (WAZ), height-for-age (HAZ) and weight-for-height (WHZ) were less than -2.0 SD of WHO (2006) standards. Children in this study aged mainly 0-23 months (43%), 50.8% were males, 36% were currently breastfeeding, 34% had diarrhea in the last two weeks and 53.4% of the mothers does not treat water. The prevalence of wasting was 5,6%, stunting 30.7 % and underweight 29.0%. The most significant factors for wasting were age (OR 4.5, 2.1-9.3 risk for 0-23 age), being breastfeed (OR 4.0, 2.0-7.7) and having diarrhea episodes (OR 2.0, 1.0-3.7). The most significant factors for stunting were mother´s education (OR 0.5, 0.2-0.9 for mother with secondary or higher education), age (OR 0.5, 0.4-0.8 risk for 0-23 age) and being breastfeed (OR 0.4, 0.3-0.6). The most significant factors for underweight were age (OR 1.7, 1.1-2.6 risk for 0-23 age class), being breastfeed (OR 1.7, 1.1-2.7) and having diarrhea episodes (OR 1.9, 1.3-3.1).The high frequency of reported untreated drinking water in this study may be related to the occurrence of enteric pathogens, and consequently to the occurrence of the diarrhea episodes reported here. On the other hand, our results suggest that breastfeeding may have a protective effect on the occurrence of stunting. Despite the need further investigation, our results suggest the existence of preventable morbidity triggered by undernutrition. Community-based education intervention could represent good strategies to reduce undernutrition.

LABORATORY SURVEY FOR THE PREVALENCE OF ENTERIC BACTERIA IN RESTAURANTS IN THE PERUVIAN AMAZON (IQUITOS, PERU)

Colin R. Andrews[1], Mona Lotfipour[1], Andrew Rogers[1], Melita Pizango[2], Ricardo Abadie[2], Rosa Burga[2], Claudio Rocha[2], Hamilton Tilley[3], David Craft[1]

[1]Pennsylvania State University College of Medicine, Hershey, PA, United States, [2]Navy Medical Research Unit No. 6, Lima, Peru, [3]Navy Medical Research Unit 6, Lima, Peru

Food and water-borne pathogens are a common and preventable source of diarrheal illness and death worldwide, especially in countries with limited public health infrastructure. A contributing factor to diarrheal illness may be the hygiene and sanitation practices of restaurants. This study investigates the prevalence of pathogenic and commensal enteric bacteria in restaurants in Iquitos, Peru. A total of 17 restaurants were asked to consider participating in the study. Sixteen gave permission to team members to collect an average of 9 food and food preparation contact surface sites for microbiological analysis. Samples were collected by swab in transport media and delivered that day to the microbiology laboratory. A total of 1,280 restaurant samples were cultured for enteric bacterial pathogens (***Salmonella, Shigella, Campylobacter*** and ***Aeromonas***) and also for the presence of normal enteric flora using standard culture techniques. Culture results were then stratified by average cost per meal at the restaurants. Water was also collected

from each restaurant for fecal coliform analysis. ***Salmonella, Shigella, Campylobacter***, and ***Aeromonas*** spp. were isolated from 16 samples (0, 3, 0, and 13, respectively) at 10 of 16 (63%) restaurants. Other fecal flora, most commonly E. coli, Proteus, Enterobacter, or Klebsiella, were isolated from 30 foods/juices and 35 surface sites at 15 of 16 (94%) restaurants. Five of 16 (31%) restaurants yielded positive coliform counts from their water sources including at least one restaurant in each cost stratified group (1 low, 1 medium, 1 high, and 2 very high cost). Our study demonstrates the presence of enteric pathogens and normal human fecal flora in the food, water, and preparation surfaces in restaurants in Iquitos, Peru. While this study does not clarify the relationship between enteric contamination in restaurants and community diarrheal disease, there was no significant correlation between average cost of meal and the presence of enteric bacteria. Future studies include observational and laboratory assessments longitudinally and development of public health based intervention and education strategies.

1798

FLIPPING THE SWITCH TO ACCURATELY DIAGNOSE MALARIA: A COMPARISON OF CLINICAL DIAGNOSIS, RAPID DIAGNOSTIC TEST (RDT), MICROSCOPY AND PCR IN THE DIAGNOSIS OF MALARIA IN CAMEROON

Kenji O. Mfuh[1], Olivia A. Achonduh-Atijegbe[2], Rose G. Leke[3], Diane W. Taylor[1], Vivek R. Nerurkar[1]

[1]Department of Tropical Medicine Medical Microbiology and Pharmacology University of Hawaii, Honolulu, HI, United States, [2]Northern Pacific Global Health Program, University of Hawaii, Honolulu, HI, United States, [3]Biotechnology Center-University of Yaounde I, Yaounde, Cameroon

Accurate diagnosis of malaria is vital for effective disease management and control. In Cameroon, presumptive diagnosis, RDT and microscopy are commonly used in malaria diagnosis. However, these methods lack sensitivity to detect low grade asymptomatic infections. PCR on the other hand permits the detection of sub-microscopic parasitemia that could be a potential roadblock as malaria endemic countries progress towards malaria elimination. In this study we compared the diagnostic test performance of clinical diagnosis, microscopy and RDT against PCR in the diagnosis of malaria. Blood samples were collected from 380 febrile children from Yaoundé and Maroua, Cameroon between February 2014 and October 2014 and their files were reviewed at the end of their hospital visit for clinical diagnosis of malaria. Microscopy, RDT and PCR based prevalence of malaria was 40% (151/380), 56% (213/380) and 63% (239/380), respectively. However, 95% (361/380) participants were presumed to have malaria based on fever, of which 34% (122/361) were negative by PCR and 85% were prescribed quinine. PCR detected 88 and 26 more malaria infections than microscopy and RDT, respectively. As compared to PCR, the sensitivity of microscopy, RDT and clinical diagnosis was 51%, 72% and 99%, respectively; however the specificity was 93%, 62%, and 3.3%, respectively; positive predictive value was 94%, 88% and 63%, respectively; negative predictive value was 55%, 38% and 70%, respectively. Thus, 34% of cases diagnosed as malaria were actually fever cases caused by other pathogens. Eighty-eight (88) sub-microscopic infections were identified by PCR in the study population, suggesting that PCR may be the best tool for accurate diagnosis and control of malaria since the presence of sub-microscopic malaria infections may be a potential hindrance towards malaria elimination. The development of a rapid PCR based test to diagnose malaria could flip the switch to accurate diagnosis, control and elimination agenda of malaria.

1799

IN FIELD ASSESSMENT OF MALARIA RAPID DIAGNOSTIC TEST PERFORMANCE BY COMMUNITY HEALTHCARE WORKERS

Nora Zwingerman[1], Marcela Cancino[2], Santiago Ferro[2]

[1]University of Toronto, Toronto, ON, Canada, [2]Fio Corporation, Toronto, ON, Canada

Under ideal conditions, the accuracy of malaria rapid diagnostic tests (RDTs) is considered equivalent to routine microscopy. However, in the field inaccurate test results may occur because of defective RDTs, human processing errors and/or errors reading test results. Data ascertained from 9 implementation studies of Fionet system was used to evaluate the frequency of these errors during routine use of malaria RDTs by healthcare workers. In each study, healthcare workers received training on processing RDTs and integrated an automated RDT reader into their point-of-care case management. The reader features in-process quality control and automated test interpretation for malaria RDTs. In 4 of the 9 studies the workers were blinded to device results allowing an evaluation of in field reading of test results. In these four studies, a total of 19,212 malaria RDTs were processed and had overall agreement of 91.76% (kappa=84.45%). A stronger agreement (96.39%; kappa=92.45%) was observed when the device had a positive or negative test result, consistent across all studies. The discordant results predominantly occurred when the device indicated a quality control warning and the user interpreted that RDT. All nine studies were used to evaluate the proportion of RDTs with quality control warning. The quality control issues were categorized into two main groups: faulty RDTs (e.g. no control line, smearing) and human processing errors (e.g. incorrect volume or placement of solutions, delayed reading, interpreting the wrong RDT). A total of 31,705 tests conducted by 151 healthcare workers were analyzed. There were approximately twice as many (~2200) human processing errors compared to any other error type. A random-effects meta-analysis, using Freeman-Tukey transformation, was used to estimate the average proportion of errors across users and studies. The meta-analyses estimated 7.61% (95% CI: 6.57%, 8.76%) errors due to human processing across. RDT brand was associated with the proportion of defective RDTs. These errors can jeopardize the accuracy of the results. Quality assurance devices would help prevent the use of compromised test results.

EFFECTS OF INTRODUCING MALARIA RAPID DIAGNOSTIC TESTS IN DRUG SHOPS: FINDINGS FROM THE EVALUATION OF A CLUSTER RANDOMIZED TRIAL IN UGANDA

Anthony K. Mbonye[1], Pascal Magnussen[2], Eleanor Hutchinson[3], Kristian S. Hansen[3], Sham Lal[3], **Sian E. Clarke**[4]

[1]Ministry of Health/Makerere University School of Public Health, Kampala, Uganda, [2]Centre for Medical Parasitology, University of Copenhagen, Copenhagen, Denmark, [3]ACT Consortium, London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

WHO recommends universal access to malaria diagnosis, encompassing all treatment providers, including the private sector. Rapid diagnostic tests (mRDTs) provide a feasible means of confirming malaria diagnosis in drug shops. As yet, there is limited evidence of the effect of diagnostic testing on antimalarial sales and referral practices by drug shops in Africa. A cluster-randomised trial to evaluate the impact and cost-effectiveness of using mRDTs, compared with presumptive treatment, undertaken in 65 registered drug shops in Mukono District, Uganda in 2010-12, was one of the first investigations of the impact of introducing mRDTs in the private retail sector. Analysis of data routinely recorded by drug shop vendors (DSVs) during the trial found use of mRDTs in drug shops was highly acceptable to both vendors and clients; a finding confirmed by household interviews in a random sample of patients. Adherence to mRDT test results

by DSVs was high with over 95% of treatment decisions consistent with mRDT result, reducing sales of ACTs by 40% compared to drug shops using presumptive diagnosis. Validation of DSV treatment decisions by expert microscopy demonstrated that mRDT testing substantially improved the targeting of ACTs to patients with malaria parasites (72.9% of ACT treatments in shops using mRDTs were correctly targeted vs 33.7% in shops using presumptive diagnosis, P<0.001). Qualitative and economic evaluations amongst drug shop vendors, patients and local health staff, conducted alongside the trial, revealed how pre-existing relationships between DSVs and their clients, and between DSVs and the wider health system shaped the response of drug vendors to the intervention and may have contributed to the high adherence to mRDT results. Potential for less desirous unintended consequences was also revealed. A synthesis of the insights generated by this early ground breaking trial in the retail sector will be presented, drawing evidence from across the epidemiological, ethnographic and economic investigations conducted as part of the study, to illustrate the potential benefits and pitfalls of introducing mRDTs into drug shops.

1801

PERFORMANCE OF MALARIA RAPID DIAGNOSTIC TESTS FOR SCREENING OF PATIENTS TO BE ENROLLED IN CLINICAL TRIALS AND RELATED STUDIES

Deus S. Ishengoma[1], Alex Shayo[2], Celine Mandara[1], Vito Baraka[1], Rashid Madebe[1], Deogratias Ngatunga[2], Erasmus Kamugisha[3], Samuel Gesase[1], Esther Ngadaya[4], Janneth Mghamba[5], Ritha Njau[6], Renatha Mandike[7], Sigsbert Mkude[7], Ally Mohamed[7], Joram Buza[2], Martha Lemnge[1]

[1]National Institute for Medical Research, Tanga, United Republic of Tanzania, [2]The Nelson Mandela African Institution of Science and Technology, Arusha, United Republic of Tanzania, [3]Catholic University of Health and Allied Sciences, Mwanza, United Republic of Tanzania, [4]National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, [5]Ministry of Health and Social Welfare, Dar es Salaam, United Republic of Tanzania, [6]World Health Organization Country Office, Dar es Salaam, United Republic of Tanzania, [7]National Malaria Control Programme, Dar es Salaam, United Republic of Tanzania

Malaria rapid diagnostic tests (mRDTs) are widely used for malaria diagnosis, but their applicability in clinical trials for patients screening and management has not been well assessed. This study assessed the performance of mRDTs when used for screening of patients to be enrolled in clinical trials and other studies, particularly in areas with progressively declining malaria burden. The data was obtained from studies conducted at five health facilities (HFs) of Mkuzi and Muheza, Nachingwea, Rubya and Ujiji in four districts of Muheza, Nachingwea, Muleba and Kigoma, respectively. Patients aged ≥6 months were screened with mRDTs followed by microscopy for possible inclusion in clinical trials and other studies. The performance of mRDTs was compared with microscopy as a gold standard, and factors affecting their accuracy were explored using multivariate logistic regression models. Of the 1,914 participants screened; 1,188 (62.1%) and 1,019 (53.2%) were positive by mRDTs and microscopy, respectively. Parasite positivity rates (by microscopy) were higher at all sites (>50.0%) except Nachingwea (with 35.8%). mRDTs had high sensitivity (>97% at all sites) while the specificity was relatively lower (64.9% - 88.7%). After adjusting for age of patients, fever status , site and the study type, the sensitivity of mRDT was significantly higher in patients with parasite density ≥4000 asexual parasites/ul (OR=6.30, p=0.003). The specificity of mRDT was lower (64.9 - 87.7%) and similar at all sites even after adjusting for the effects of fever status and age of participants (p≥0.525), except at Muleba and Ujiji where the specificity was significantly lower (p≤0.007) due to high rates of false positive mRDT results. In conclusion, the high sensitivity of mRDTs indicate that they can be useful for screening to exclude majority of the patients without malaria and save time and other resources which would be used for microscopy. Due to low specificity which could lead to enrolment of patients without malaria parasites, mRDTs should only be used for initial screening and all positive cases must be confirmed with microscopy.

A NON-AMPLIFICATION, OLIGONUCLEOTIDE-BASED SANDWICH HYBRIDIZATION ASSAY FOR THE DETECTION OF PATHOGENS IN BLOOD

Bryan Grabias, Sanjai Kumar

Food and Drug Administration, Silver Spring, MD, United States

Novel technologies for the sensitive and reliable detection of infectious agents in blood are still needed. While the standard method of nucleic acid-based pathogen detection generally relies on PCR amplification of target DNA or RNA, complex genome sequences can be resistant to amplification, due to factors such as secondary or tertiary structure, and the potential for nonspecific amplification or sample interference could result in false positive or false negative results. Here, we describe a novel nanoparticle-based sandwich hybridization assay (SHA) for the detection of ***Plasmodium falciparum*** and ***Babesia microti*** parasites without the need for amplification of target sequences in genomic DNA. A uniquely identifiable "barcoded" magnetic microbead and biotinylated silica nanoparticle are conjugated to either ***P. falciparum***- or ***B. microti***-specific 30-mer oligonucleotides corresponding to sequences of the 18S ribosomal gene. For each parasite, the magnetic microbead and silica nanoparticle bead sets hybridize to a unique but adjacent region in the genome. Parasite burden can then be quantified and analyzed upon the binding of an Avidin-PE fluorophore to the target capture complexes via a Bio-Plex 200 instrument. Determination of the analytical sensitivity of the SHA for short complementary oligonucleotide sequences revealed a limit of detection of 10^{-10} M for both ***P. falciparum*** and ***B. microti*** probe sets. Analytical sensitivity studies conducted by spiking human blood with known counts of parasites revealed that SHA can reliably detect up to 10 ***P. falciparum***- or ***B. microti***-infected red cells per mL of blood. For comparison, in our hands PCR can detect 100 ***P. falciparum***- or 1000 ***B. microti***-infected red cells per mL of spiked blood. Thus, SHA offers a 10-100 fold enhanced sensitivity for the detection of these two intraerythrocytic parasites of global public health significance. Studies to determine the clinical sensitivity of SHA for these pathogens are in progress. Details of the method development and sensitivity and specificity data will be presented.

1803

AUTOMATED DETECTION OF MALARIAL RETINOPATHY FOR HIGHLY SPECIFIC DIAGNOSIS OF CEREBRAL MALARIA

Vinayak Joshi[1], Carla Agurto[1], Sheila Nemeth[1], Eduardo Simon Barriga[1], Peter Soliz[1], Ian MacCormick[2], Terrie Taylor[3], Susan Lewallen[4], Simon Harding[2]

[1]VisionQuest Biomedical LLC, Albuquerque, NM, United States, [2]University of Liverpool, Liverpool, United Kingdom, [3]Michigan State University, East Lansing, MI, United States, [4]Kilimanjaro Centre for Community Ophthalmology, Cape Town, South Africa

Cerebral malaria (CM) is a lethal clinical syndrome that claims the lives of about 584,000 people annually, 75% of whom are African children. As many as 23% of these cases are misclassified when the standard clinical case definition for CM is used. When malarial retinopathy (MR) detection is included in the case definition, the specificity and positive predictive value (PPV) of the CM diagnosis is greatly increased, and other causes of coma can be sought in patients who are retinopathy-negative. Detection of MR currently requires expensive equipment and well-trained personnel and is thus limited only to research settings in malaria-endemic areas in Africa. We used retinal images from 175 Malawian pediatric patients with MR, captured using a Topcon 50-EX camera to develop and test software algorithms for detecting the presence of MR, and of its associated retinal lesions. Performance assessment was made against manual image grading

as the reference standard. The software achieved specificity of 100% and sensitivity of 95% for MR detection. The individual specificities for detecting retinal abnormalities associated with MR were 91% for retinal whitening, 100% for vessel discoloration, and 96% for white-centered retinal hemorrhages. The system also detects papilledema, a condition associated with death due to raised intracranial pressure, with 100% sensitivity and 81% specificity. The proposed MR detection system can improve the PPV for diagnosis of CM from 68% (using current clinical standard) to 98%. Our MR detection system integrates a low-cost and portable retinal imaging camera with software developed to detect MR. This system is designed to be used by non-ophthalmic personnel with minimal training in low-resource clinical environments.

1804

LOT TESTING OF MALARIA RAPID DIAGNOSTIC TESTS: ACHIEVEMENTS AND LESSONS LEARNED FROM A SEVEN YEARS-LONG EXPERIENCE

Sandra Incardona[1], Jennifer Luchavez[2], Sina Nhem[3], John Barnwell[4], Nora Champouillon[1], Peter Chiodini[5], Christian Anthony Luna[2], Didier Ménard[3], Rathana Meth[3], Roxanne Rees-Channer[5], Johanna Beulah Sornillo[2], David Richard Bell[6], Jane Cunningham[7], Iveth Jimena Gonzalez[1]

[1]Foundation for Innovative New Diagnostics, Geneva, Switzerland, [2]Research Institute for Tropical Medicine, Manila, Philippines, [3]Institute Pasteur of Cambodia, Phnom Penh, Cambodia, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Hospital for Tropical Diseases, London, United Kingdom, [6]Intellectual Ventures, Seattle, WA, United States, [7]World Health Organization, Geneva, Switzerland

Malaria Rapid Diagnostic Tests (RDTs) have played a key role in fever case management since the 2010 WHO recommendation that every suspected malaria case should be confirmed by parasitological diagnosis before treatment. Sales of RDTs have increased from 46 million in 2008 to 319 million in 2013. The wide range of commercially available products, with variable quality reported in field studies, led to the creation of the WHO-FIND Malaria RDT Evaluation Programme that aims at providing independent comparative performance data to guide procurement (Product Testing) and comprehensive lot verification prior to deployment in countries (Lot Testing). The Lot Testing Programme specifically, with its two reference laboratories in Cambodia and the Philippines, has provided quality data for more than 3600 RDT lots since 2007. RDTs are tested against frozen blood samples collected from malaria patients, standardized at 200 parasites per microliter of blood. The observed mean failure rate of 1.85% is notably low, reflecting the fact that Lot Testing is mainly requested by large funding/procurement agencies selecting only products meeting the WHO recommended minimum performance criteria for procurement. The number of lots tested annually has increased from 59 to 927 in the last 7 years, with the 2014 testing volume covering an estimated 210 million RDTs, equivalent to 66% of the RDT market. Lot-tested RDTs were distributed in 48 countries, with 88% of RDTs destined for sub-Saharan Africa. Lot Testing informs not only parasite detection but also may reveal RDT anomalies, such as red background, incomplete clearing, or problems with kit accessories. The reporting of issues observed on single-use buffer vials in particular has triggered the release of an Information Note to Users by the WHO and field corrective actions by RDT manufacturers. The Lot Testing Programme plays a key role in encouraging manufacturers to maintain the required level of quality from lot to lot. Work is now underway to transition to a decentralized self-funding system, and build local capacity in 12 pilot countries for lot testing in national reference laboratories.

1805

CONDITIONS THAT LEAD TO POLYANDROUS BEHAVIOR IN THE YELLOW FEVER MOSQUITO *AEDES AEGYPTI*

Ethan C. Degner, Laura C. Harrington

Cornell University, Ithaca, NY, United States

Upon insemination, ***Aedes aegypti*** females receive seminal fluid proteins from males that render them refractory to subsequent mating. This response is often assumed to be immediate, complete, and lifelong. Nonetheless, several studies have found that polyandry can occur in ***Ae. aegypti***, but little attention has been paid to the circumstances that result in polyandry. This promiscuity could have far-reaching implications. For example, polyandrous behavior could hinder inundative release strategies, which often rely on the assumption of monandry. To our knowledge, no study has determined the timing of the onset of refractoriness, and the degree to which monandry is maintained over time remains unresolved. By using males with fluorescently labeled sperm to identify polyandrous females, we determined how soon females become refractory to additional inseminations and how this refractoriness wanes as females age. We also determined the reproductive success of first and second males under these circumstances. This study clarifies the role of polyandry in the mating system of this important vector and will ultimately guide vector control strategies, predictive models, and experimental design.

1806

HUMAN ADAPTATION TO CLIMATE CONTRIBUTES TO *AEDES AEGYPTI* ABUNDANCE IN THE SOUTHERN MARGINS OF ITS AUSTRALIAN DISTRIBUTION

Brendan Trewin[1], Jonathan Darbro[2], Myron Zalucki[3], Greg Devine[2], Cassie Jansen[4], Nancy Schellhorn[1]

[1]CSIRO, Brisbane, Australia, [2]QIMR Berghofer, Brisbane, Australia, [3]University of Queensland, Brisbane, Australia, [4]Queensland Health, Brisbane, Australia

The dengue vector ***Aedes aegypti*** has been identified in new areas south of the species' core Australian distribution. It has been hypothesized that an expansion by ***Ae. aegypti*** into these regions would require large water bodies that buffer extremes in temperature and humidity. As part of the human response to drought in the early 2000s, government rebates were offered on large water storage containers such as rainwater tanks (RWT). The installation of over 200,000 RWT has resulted in new habitats for container-breeding mosquitoes throughout the region. Surveys have demonstrated that RWT are key containers for mosquito breeding, however little is known about the role RWT play in vector abundance in cool and dry range margins. The current study was designed to investigate how RWT can contribute to a localized population of ***Ae. aegypti***. To do this we divided the urban landscape into three categories: premises with an exposed RWT, those with a sealed RWT and those with no RWT. Ovitraps and Gravid Aedes Traps (GAT) were used to measure adult population abundance. Traps were retrieved and reset fortnightly for ten weeks, and eggs were counted and reared to fourth instar for counting and identification after each collection. Inspections of study site and surrounding premises documented characteristics of house construction and surrounding urban environment. A multivariate time-series analysis will be performed to examine the effect of the predictor variables on each of the response variables at the scale of the study premises and the study premises plus their neighbours. Results will be presented. Our results show the effect that exposed RWT have on the abundance of ***Ae. aegypti*** when compared with a sealed RWT or no RWT present. The current trend of water storage in Australia is similar to a century ago, when ***Ae. aegypti*** was present and dengue epidemics occurred. Likewise, similar rebate schemes and drought conditions in the United States are increasing the number of large water containers in urban environments, and could provide a potential new habitat for the establishment of ***Ae. aegypti*** and other disease vectors.

1807

EXPLORING HOST ORIENTED FLIGHT AND SPATIAL ASPECTS OF INDOOR MOVEMENT OF *ANOPHELES GAMBIAE* USING INFRA-RED VIDEO TRACKING

Josephine E. Parker[1], Natalia Angarita-Jaimes[2], Matthew Hall[2], Maurane Riesen[1], Fabian Mashauri[3], Jackline Martine[3], Catherine E. Towers[2], David Towers[2], Philip J. McCall[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Optical Engineering Group, School of Engineering, University of Warwick, Coventry, United Kingdom, [3]National Institute for Medical Research, Mwanza, United Republic of Tanzania

Fundamental to security and shelter, the human home is exploited by many parasitic arthropods, including many vectors of malaria that spend the majority of their adult life bloodfeeding or resting in this environment. Successful vector control methods like indoor residual spraying (IRS) and long-lasting insecticide-treated bednets (LLINs) exploit this behavior. Though central to malaria reduction and elimination plans worldwide, they have limitations with a further serious threat presented by rapidly emerging insecticide resistance. Identifying possible routes to improve control of nocturnal indoor transmitted malaria is a recognized priority. We investigated spatial activity of African ***Anopheles sp.*** during nocturnal host orientation to human subjects, within or without LLINs, using a video system to track flight activity of multiple mosquitoes at high resolution over periods of 60 minutes or more. In tests exploring responses to human-occupied LLINs carried out in a hut in rural Tanzania, behavior of local ***An. arabiensis*** populations was remarkably similar to ***An gambiae s.s.*** Kisumu strain mosquitoes tested in the same environment and as previously reported in our laboratory tests. In the absence of a bed net, approach, landing and biting activity of ***An. gambiae s.s.*** at unprotected human hosts revealed consistent spatial behaviors during approach and departure from the host, most likely in response to thermal and odor cues emanating from the supine human host. We used a different video-tracking system incorporating retro-reflective screens to obtain 3D flight tracks of ***An. gambiae*** as they approached and entered through a 'window' in response to a human host, in the laboratory. Analysis of flight trajectories provided evidence that trajectories passing through the window showed consistent patterns in flight elevation change during room entry and exit. The value of these and related studies on the spatial aspects of mosquito behavior in the domestic environment is considered in terms of its contribution to basic knowledge of vector biology and to the search for new vector control tools and strategies.

1808

POSITIVE AND NEGATIVE EFFECTS OF *WOLBACHIA* INFECTION ON ARBOPATHOGEN TRANSMISSION

Jason Rasgon[1], Brittany Dodson[1], Laura Kramer[2], Grant L. Hughes[3]

[1]Pennsylvania State University, University Park, PA, United States, [2]Wadsworth Center, Albany, NY, United States, [3]University of Texas Medical Branch, Galveston, TX, United States

In field trials across the globe, a revolutionary experiment in vector-borne disease control is underway. Artificial Wolbachia infections have been shown to render mosquitoes resistant to transmission of many human pathogens. Wolbachia-infected mosquitoes are currently being released in multiple countries in an attempt to control dengue virus. However, it has become clear that Wolbachia infection does not always lead to pathogen suppression in insects. Multiple studies in a wide variety of vector and non-vector insect species suggest that Wolbachia can enhance certain parasites and viruses in arthropods; a sobering reminder that the pathogen inhibitory effects resulting from Wolbachia infection in some insects cannot and should not be generalized across vector-pathogen systems. I will present mechanistic data demonstrating how Wolbachia can act directly or indirectly to cause enhancement or suppression of vector-borne pathogens. Understanding the specific mechanisms leading to pathogen enhancement and suppression is critical for identifying systems where Wolbachia-based control is likely to succeed, for identifying potential points where Wolbachia-based control is likely to break down and fail in the field, and for planning risk mitigation strategies in the case of unforeseen harmful outcomes.

1809

A CROSS-OVER STUDY TO EVALUATE THE DIVERSION OF MALARIA VECTORS IN A COMMUNITY WITH INCOMPLETE COVERAGE OF SPATIAL REPELLENTS IN THE KILOMBERO VALLEY, TANZANIA

Marta F. Maia[1], Katharina Kreppel[2], Deogratius Roman[3], Valeliana Mayagaya[3], Emanuel Simfukwe[3], Neil Lobo[4], Amanda Ross[1], Sarah Moore[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]University of Glasgow, Glasgow, United Kingdom, [3]Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, [4]University of Notre Dame, Notre Dame, IN, United States

Malaria elimination is unlikely to occur if vector control campaigns rely entirely on treated bed-nets and indoor residual spraying. There is a need for vector control tools that address vectors that bite outside sleeping hours. Spatial repellents may be able to fill this gap. However it is unclear if malaria vectors will be diverted from households that use spatial repellents to those that do not. The present study was performed for a period of 24 weeks in rural Tanzania. A total of 90 households were recruited and a cross-over design was used to measure the density of resting and blood-engorged mosquitoes in 3 coverage scenarios using 0.03% transfluthrin coils: 1) no coverage; 2) complete coverage and; 3) incomplete coverage. Human blood index of each malaria vector species was calculated for each scenario. Human landing collections were performed and vector biting times were recorded. The main vectors were found to be ***Anopheles arabiensis*** and ***Anopheles funestus*** s.s.. Both species fed outdoors, outside sleeping hours and on humans as well as animals. Data from human landing catches showed that the repellent coils reduced the number of ***An arabiensis*** by 80% but did not reduce the number of host seeking ***An. funestus***, this may be due to potential development of pyrethroid resistance which has been documented in the area. The repellent coils did not reduce indoor and outdoor resting densities of Anophelines nor cause a shift in the human blood index. No diversion of malaria vectors was measured. On the other hand, the spatial repellent coils reduced the household densities of ***Culex*** spp. by 26%, and contributed to 19% diversion of ***Culex*** spp. to non-repellent users. There is strong evidence that large proportion of malaria exposure is not controlled by the current vector control strategy in the Kilombero Valley. The use of 0.03% transfluthrin coils in this area is unlikely to result in malaria reduction since much biting occurred in the morning after coils had gone out. The behavioural responses of pyrethroid resistant mosquitoes and ***Anopheles funestus*** to spatial repellents needs to be further investigated given the increasing importance of this vector in the area.

1810

INSECTICIDES AND POLLUTION EXERT STRONG SELECTION ON NEW CRYPTIC SUBGROUPS OF *ANOPHELES GAMBIAE*

Colince Kamdem, Caroline Fouet, Stephanie Gamez, Bradley J. White

University of California Riverside, Riverside, CA, United States

Ongoing ecological adaptation and lineage splitting within the Afrotropical malaria vector ***Anopheles gambiae s.l***. has the potential to mitigate the effectiveness of both traditional and novel vector control tools. We explored the population structure and identified targets of natural selection in 888 individuals of this species complex collected from contrasting environments. We provide evidence for clear subdivisions within the two sister taxa ***An. coluzzii*** and ***An. gambiae sensu stricto***.

Genome scans of all the new cryptic subgroups reveal pervasive signatures of strong selection around genes involved in metabolic or target-site resistance to insecticides. Notably, a selective sweep containing at least eight detoxification enzymes contributes to local adaptation of urban subgroups that thrive in polluted breeding sites. Our results show that human-induced selection can play a prominent role in driving mosquito population differentiation during the early stages of adaptive evolution with potentially dire consequence for malaria control.

DIRECT, HOUSEHOLD-LEVEL EFFECTS OF SPATIAL REPELLENTS FOR DENGUE CONTROL - A MODELING ASSESSMENT

Quirine A. ten Bosch[1], Nicole L. Achee[1], John P. Grieco[1], Neil F. Lobo[1], Amy C. Morrison[2], Robert C. Reiner Jr.[3], Thomas W. Scott[2], Steven T. Stoddard[2], Alex P. Perkins[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]University of California, Davis, CA, United States, [3]Indiana University Bloomington, Bloomington, IN, United States

In the absence of effective drugs or vaccines, efforts to control and prevent dengue currently rely on interventions acting on the mosquito vector, ***Aedes aegypti.*** Thus, there is need for the development of new, broadly applicable vector control tools to augment the currently available options. Studies to date have shown that spatial repellents (SR) have the potential to reduce malaria transmission, but their impact on other vector-borne diseases, such as dengue, is uncertain. To make accurate quantitative projections of its epidemiological impact, a crucial need is to enhance the understanding of the mechanisms of action underlying its epidemiological impact. SR products could potentially impact multiple components of vectorial capacity (VC), a classical metric that relates different aspects of mosquito life history to transmission potential. VC however, relies on the assumption that each individual has an equal probability of being bitten. The effects of SR on mosquito movement and biting behavior explicitly violate this assumption by potentially causing a reduction as well as a redistribution of bites. This impedes the use of VC in this context. Individual-based models (IBM) are free from key simplifying assumptions of the classical formulation of VC and thus offer an opportunity to explore the epidemiological impact of SR on dengue transmission in a more realistic way. We present a novel adaptation of an IBM for dengue transmission in Iquitos, Peru, to simulate fine-scale heterogeneities in transmission, as informed by extensive entomological and epidemiological data. SR effects on movement, biting behavior, blood feeding and oviposition are incorporated in the model using probabilistic descriptions fit to data from laboratory experiments and experimental hut studies under natural field conditions in disease-endemic settings. We highlight the key factors that underlie the discrepancy between projections from the IBM and VC and demonstrate a positive effect of SR on reducing transmission at the household level. The results from this simulation study warrant further testing and assessment of SR products on a population level.

REVERSE MOLECULAR EPIDEMIOLOGY: INSIGHTS INTO THE INFECTION DYNAMICS OF BLOOD-BORNE HUMAN PARASITES IN A *LOA LOA-, MANSONELLA PERSTANS-* AND *PLASMODIUM FALCIPARUM*-ENDEMIC REGION OF CAMEROON

Papa M. Drame[1], Celine Montavon[2], Sebastien Pion[2], Michael Fay[1], Joseph Kubofick[1], Thomas B. Nutman[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]Institut de Recherche pour le Developpement, Montpellier, France

Interactions among co-infecting parasites can modify the epidemiology of parasitic infections. We conducted an epidemiologic assessment of prevelances and infection intensities of (co)-infections with ***Loa loa*** (Ll), ***Mansonella perstans*** (Mp), ***Wuchereria bancrofti*** (Wb) and ***Plasmodium falciparum*** (Pf) in 8 villages of eastern Cameroon using highly sensitive and specific quantitative PCR (qPCR) for multiple parasites on archived dried blood spots (20 ul whole blood equivalent per 6mm spot per individual). Resident populations (n=1,144; age range: 2-90 years old) were parasitized with Mp (76%), Ll (38%) and Pf (33%), but not with Wb. Co-infections (49%) were more common than single infections (40%), with 21% having Ll and Mp, 3% with Ll and Pf, 15% with Mp and Pf, and 10 % with Ll, Mp and Pf. Interestingly, those with all three infections (Ll/Mp/Pf) had significantly higher Ll microfilariae (mf) counts than either single Ll (P=0.01) or double Ll/Mp (P=0.03) and Ll/Pf (P=0.05) infected individuals. The estimated counts of Ll mf were positively correlated with the intensities of Mp mf (Regression coefficient =1.43; P<0.0001). Population assessments at the community level showed that despite Mp and Ll both having overdispersed distributions -typical of most filarial infections - the population dynamics of Ll showed much greater overdispersion than did Mp. These data suggest a possible shared host susceptibly to Ll and Mp infection and also provide a method we are terming "reverse molecular epidemiology" that should be broadly applicable to many environmental niches containing infectious organisms for which molecular targets are defined.

1813

THE PREVALENCE OF LYMPHATIC FILARIASIS RELATED HYDROCELE, LYMPHEDEMA AND INFECTION IN MANDALAY REGION, MYANMAR

Benjamin F. Dickson[1], Patricia M. Graves[1], Ni Ni Aye[2], Thet Wai Nwe[2], San San Win[3], Janet Douglass[1], William J. McBride[1]

[1]James Cook University, Cairns, Australia, [2]Ministry of Health, Naypyitaw, Myanmar, [3]World Health Organization, Yangon, Myanmar

Lymphatic filariasis (LF) is highly endemic within Myanmar. Despite the establishment of an elimination programme in 2004, little remains known about the prevalence of LF related morbidity in the country. We therefore conducted a cross-sectional survey to determine the prevalence of LF infection and morbidity and their associated risk factors in 24 randomly selected villages in four endemic townships within the Mandalay region of Myanmar - Amarapura, Patheingyi, Tada-U and Wundwin - between February and March 2015. Within each village, twenty households were randomly chosen for inclusion. Household members one year and older were tested for antigenemia with rapid immunochromatographic card tests (ICT). A night-blood slide was done for those with positive ICT results to quantify microfilaremia. Ultrasound assisted clinical examination was done on household members 15 years and older for signs of LF-related morbidity. Household questionnaires and GPS mapping were completed for risk factor analysis. Of those tested with ICT in 414 households, 45 of 1018 individuals (4.4%, 95% confidence interval (CI) 3.2 to 5.9%) were positive. ICT antigenemia was highest in Amarapura (32/294, 10.9%, 95% CI 7.6 to 15.0%) followed by Tada-U (8/267, 3.0%, 95% CI 1.3 to 5.8%), Wundwin (4/343, 1.2% 95% CI 0.3 to 3.0%) and Patheingyi (1/114, 0.9%, 95% CI 0.02 to 4.8%). Eighteen of the 289 males (99% of those eligible for scrotal examination) had hydroceles (6.2%, 95% CI 3.7 to 9.7%). Thirteen were unilateral and five were bilateral. Of the 23 hydroceles, 14 were stage one, seven were stage two and two were stage three. No cases of limb lymphedema or elephantiasis were found in the 827 individuals examined (0%, 97.5% one-sided CI 0 to 0.4%). The results of this study indicate a high prevalence of LF infection and hydrocele with low levels of limb lymphedema in the Mandalay Region of Myanmar. These results highlight the strong need for further rounds of mass drug administration as well as targeted surgery and morbidity alleviation programmes in the region. Further LF morbidity prevalence studies are needed to elucidate the burden in the remainder of the country.

1814

PROGRESS TOWARD ELIMINATION OF LYMPHATIC FILARIASIS IN HAITI: PRE-TRANSMISSION ASSESSMENT SURVEY ACTIVITIES

Abdel Direny[1], Luccene Desir[2], Franck Monestime[3], Carl Fayette[3], Jean Frantz Lemoine[4]

[1]IMA World Health, Washington, DC, United States, [2]University of Notre Dame/Hospital St. Croix, Leogane, Haiti, [3]IMA World Health, Port au Prince, Haiti, [4]Programme National de Malaria et de Filariose Lymphatique (PNCM), MSPP, Port au Prince, Haiti

Lymphatic filariasis (LF) is one of the world's most debilitating parasitic diseases; worldwide 120 million people are believed be infected with LF. In Haiti, 11 million people are at risk for LF and the disease remains a serious public health problem. The Ministry of Health aims to eliminate LF by 2020, through annual MDA with albendazole and diethylcarbamazine citrate (DEC). MDA started initially in the areas of highest endemicity called "red zones," where Immunochromatographic (ICT) test positivity among school children was 10-45% when mapped in 2000. Despite a number of critical challenges, including the low level of public health infrastructure, loss of donor funding, and the 2010 earthquake, which disrupted health services throughout the country, the Haiti NTD Program has scaled up progressively. Since 2012, the program has achieved 100% geographic coverage, with reported and surveyed coverage well above the 65% target for disease elimination. In order to assess the program's readiness for transmission assessment surveys (TAS), blood specimens were collected to detect W. bancrofti infection among persons aged ≥2 years. Twenty sentinel and spot check sites were chosen to represent 52 endemic districts; all sampled districts had completed at least 5 consecutive MDA rounds. At each site, approximately 500 samples were taken and tested using ICT. Results showed a significant reduction of filarial infection: 40% of the "red zones" had ICT prevalence of <2% and 48 endemic districts qualified for TAS to determine if transmission has been interrupted. The remaining 4 districts, which had ICT positivity between 31-39% when mapped, now have ICT positivity of 2.35-6.5%. While not yet eligible for TAS, these districts demonstrate a significant reduction in LF infection after 6 rounds of MDA. The Haiti NTD Program is optimistic that these districts will be eligible for TAS after two more MDA rounds. The program has made tremendous progress towards LF elimination in spite of multiple challenges. Haiti expects to reach the 2020 goal to eliminate LF; one of the greatest achievements for the poorest country in the Caribbean.

1815

A COMMUNITY STUDY OF THE IMPACT OF SEMIANNUAL ALBENDAZOLE ON LYMPHATIC FILARIASIS IN CENTRAL AFRICA

Sebastien D. Pion[1], Cédric B. Chesnais[1], François Missamou[2], Gary J. Weil[3], Michel Boussinesq[1]

[1]Institut de recherche pour le Développement, Montpellier, France, [2]Ministère de la santé et de la population, Brazzaville, Republic of the Congo, [3]Washington University School of Medicine, Saint Louis, MO, United States

Implementation of mass drug administration (MDA) with ivermectin plus albendazole (Alb) for lymphatic filariasis (LF) has been delayed in Central Africa, because ivermectin can induce serious adverse events in people with very high ***Loa loa*** microfilaremia . Albendazole has activity against ***Wuchereria bancrofti***, and it is safe for use in patients with loiasis. In 2012, the WHO recommended use of Alb MDA together with vector control to combat LF in areas with co-endemic loiasis. In September 2012, we started a 3-year community trial of semi-annual Alb alone on LF in a village with a population of 1055 in Madingou District in the Republic of Congo. Infection with W. bancrofti was diagnosed using the Binax Now Filariasis card test (ICT) for antigenaemia; persons with positive card tests were tested for microfilaraemia (Mf) by night blood smears. We are now presenting results from 24 months, and the final 36 month results will be presented at the meeting. Therapeutic coverage for the population aged >2 years was >80% in all four treatment rounds. Baseline results from 773 subjects aged ≥5 years old revealed a filarial antigenaemia rate of 17.3% and a Mf rate of 5.3%. Evaluation at 24 months (697 tested) showed dramatic reductions in ICT and Mf rates (6.3% and 1.4%, respectively). Mf counts were reduced by 86.3% from baseline values (geometric mean decrease from 202.2 to 27.7 mf/ml, P = 0.01), and total clearance of microfilaraemia was achieved in 71% of those individuals who were microfilaraemic in 2012. We are currently conducting a parallel trial in an area with higher baseline infection rates (31.6% for antigenemia and 11.8% for microfilaremia) in the Democratic Republic of Congo, and 12 month results from that study will be presented at the meeting. These studies will provide strong evidence regarding the use of semiannual MDA with Alb for elimination of LF in central Africa.

1816

HIGHLIGHTING HIGH LYMPHATIC FILARIASIS TRANSMISSION AREAS USING AN SMS REPORTING TOOL: A MORBIDITY MAPPING SURVEY IN DAR ES SALAAM

Upendo Mwingira[1], **Maria Chikawe**[1], Cecelia Uisso[1], Irene Mremi[1], Wilfred Lazarus[1], Alpha Malishee[1], Mwelecele Macelela[2], Charles Mackenzie[3], Hayley Mableson[3], Louise A. Kelly-Hope[3], Michelle C. Stanton[3]

[1]Ministry of Health and Social Welfare, Dar es Salaam, United Republic of Tanzania, [2]National Institute of Medical Research, Dar es Salaam, United Republic of Tanzania, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The Tanzania Lymphatic Filariasis (LF) Elimination program was launched in 2000 with the aim of distributing Ivermectin and Albendazole to LF endemic populations. The program, which is now integrated with other neglected tropical diseases (NTDs), covers 107 districts, and LF prevalence is now showing signs of decreasing. There is however limited information on the number of people with clinical symptoms of LF i.e. lymphedema and hydrocele cases in Tanzania. This information is required for better planning of morbidity management in the country. The national NTD control program, in collaboration with Liverpool School of Tropical Medicine, conducted a morbidity survey in March 2015, in Temeke municipality, Dar es Salaam (population 1.5 million). The survey was conducted using a bespoke SMS reporting tool, MeasureSMS, which enabled survey data summaries to be viewed instantaneously through a web browser, and downloaded for further analysis. During the survey, community drug distributors visited every house in their designated catchment area, and recorded information on each lymphedema and hydrocele case identified using a paper form. These forms were collated by supervising front line health workers, who then reported the information by SMS to the local phone number allocated to the MeasureSMS tool. Progress was monitored by the national NTD control program throughout the survey using a webpage, and by directly downloading the reported SMS messages to check for missing reports. For data quality assurance, a random subset of reported cases were visited, and their conditions verified. A total of 2547 patients were identified; 987 of patients had lymphedema cases, 1743 had hydrocele, of these 183 had both conditions. Verification is ongoing and will be completed in May 2015. To date, 28 reported hydrocele cases have been verified, of which 88% (25/28) were confirmed to have the condition. Given the high reported morbidity burden in this area, it is now vital that services such as hydrocele surgery and lymphedema management are made accessible to the affected population.

MICRO-MAPPING DISTRIBUTION POINTS, RISK POPULATIONS TO TREATMENT NUMBERS TO MAXIMIZE COVERAGE TO IMPACT OF MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS IN URBAN DAR ES SALAAM, TANZANIA

Upendo Mwingira[1], Maria Chikawe[1], Cecilia Uisso[2], Irene Mremi[2], Wilfred Lazarus[2], Alpha Malishee[2], Mwelecele Malecela[3], Joan Fahy[4], Michelle Stanton[4], Hayley Mableson[4], Louise Kelly-Hope[4]

[1]Neglected Tropical Diseases Control Programme - National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania, [2]Neglected Tropical Diseases Control Programme, Dar es Salaam, United Republic of Tanzania, [3]National Institute of Medical Research, Dar es Salaam, United Republic of Tanzania, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The large rapidly growing urban centre of Dar-es-Salaam in Tanzania has a significant risk of lymphatic filariasis (LF), which is transmitted by Culex spp. mosquitoes that thrive in human domestic environments. Prior to the recent scale up of mass drug administration (MDA) to interrupt transmission, the overall LF infection rate was estimated to be 10%, with young adult males, and informal and peri-urban areas at a significantly higher risk of infection than other sub-groups and areas. In order to improve MDA coverage rates to those at greatest risk, this study aimed to map and examine the spatial patterns of the MDA distribution points, risk populations, and treatments numbers across the three districts of the city with an estimated 4.4 million population at risk. Environmental assessments were also conducted to identify characteristics of low coverage areas, and the specific factors that may place sub-groups at higher risk of infection, including potential breeding sites of Culex spp.. In Temeke district 73 distribution points reported an average coverage of 149%, in Kinondoni district 105 distribution points reported an average coverage of 105% and in Ilala district 63 distribution points reported an average coverage of 101%. Coverage throughout the three districts ranged from 9% (~10 times under) to over 1000% (~10 times over) at specific locations. These excessive coverage values are indicative of population movement both within and into the city. The great variation and distinct spatial patterns found at a micro level suggest that urban populations move dramatically within small geographical areas, as well as at different rates across the different areas of the city, thus making MDA implementation and reaching high coverage challenging. This study takes one important step forward to better understanding and being able to predict the problem areas in a highly dynamic and densely populated city. This is critical and will help the LF Programme to specifically target and increase human resources, training, social mobilisation to where they are needed most.

1818

MULTIPLE IVERMECTIN DOSES ARE MACROFILARICIDAL: IMPLICATIONS FOR THE ELIMINATION OF ONCHOCERCIASIS

Martin Walker[1], Sébastien D. Pion[2], Hanwei Fang[3], Thomas S. Churcher[1], Jacques Gardon[4], Joseph Kamgno[5], Maria-Gloria Basáñez[1], Michel Boussinesq[2]

[1]Imperial College London, London, United Kingdom, [2]Université de Montpellier, Montpellier, France, [3]University of Oxford, Oxford, United Kingdom, [4]IRD, La Paz, Plurinational State of Bolivia, [5]University of Yaounde, Yaounde, Cameroon

The predominant strategy for achieving the World Health Organization's control and elimination goals for human onchocerciasis is based on mass drug administration (MDA) with ivermectin. The feasibility of achieving these goals crucially depends on the long-term effects of multiple doses of ivermectin on the long-lived ***Onchocerca volvulus*** filarial nematode, which causes onchocerciasis. A single dose of ivermectin rapidly kills the microfilariae while also exerting a temporary sterilization (embryostatic) effect on the female adult worms (macrofilariae). Multiple doses of ivermectin are thought to cause a cumulative effect on macrofilariae manifesting either as permanent reductions in fecundity or a shortened life-span. These assumptions have been incorporated into mathematical models to support elimination efforts. Yet, for decades the nature of this presumed cumulative action has avoided rigorous investigation because scarce longitudinal data on macrofilariae have not been interrogated with suitably powerful analytical techniques. Here, we analyse data on the fecundity and vitality of female worms from the most comprehensive clinical trial of multiple doses of ivermectin treatment (comparing 3-monthly with annual treatment rounds administered during three years in Cameroon) using a recently developed state-of-the-art modelling framework. We demonstrate that multiple doses of ivermectin treatment have a substantial macrofilaricidal effect, even at the doses and frequencies used for routine MDA. We find no evidence that the anti-fecundity activity of ivermectin is enhanced by multiple treatments. We discuss our results in the context of the feasibility to eliminate onchocerciasis in the timeframes set by the global health community.

1819

MODELING EFFECTIVENESS OF DRUG ADMINISTRATION ON A POPULATION INFECTED WITH *SCHISTOSOMA MANSONI*

Roberta O. Prado[1], Sonia P. Carvalho[2], Sylvie M. Kamphorst[2], Rodrigo C. Oliveira[3], Andréa Gazzinelli[1]

[1]Escola de Enfermagem UFMG, Belo Horizonte, Brazil, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]Centro de Pesquisas René Rachou, Belo Horizonte, Brazil

Schistosomiasis is one of the most important public health problems that affect human populations, especially those living in poorer regions, with low socioeconomic environment, without adequate sanitation and clean water. WHO recommends treatment without prior diagnosis of the most vulnerable individuals such as school children and adults in endemic areas. In Brazil treatment is based on the infection prevalence. In areas of low and medium prevalence treatment is given only for positive individuals and in situations where the prevalence is greater than 50% treatment is directed to the entire population. The objective is to develop a non-linear mathematical model to evaluate the effectiveness of mass treatment of a population infected with ***S. mansoni***. The evolution of infected and non-infected persons with time was studied by building a 2-dimensional system of differential equations. We consider that a) children born without infection, b) the population is growing with a growth of logistical type, without having reached its maximum growth and c) once treated an individual will be free of infection unless it re-infects. The population was divided into two strata: P0 (t), which corresponds to the number of uninfected persons in year (t) and P1 (t) and those corresponding to the number of infected people during the year (t). It was possible to develop a mathematical model, consisting of a system of differential equations that has in its domain, single global attractor. The 2-dimensional system has a unique global attractor where the number of infected persons is non-zero, due to the re-infection effect. It is proved that the model got its equilibrium. The modeling results suggest that if the treatment is the only intervention in the population, that is, without additional Investments in better sanitation and health education programs, even treating the whole population or just those infected, the prevalence always will be around 10%. The model also suggests that in this way overtime prevalence tends to always keep this level with few possibilities of over spreading disease in the area.

1820

MODELLING EGG COUNTS TO COMPARE EGG REDUCTION RATES IN RANDOMIZED COMPARATIVE TRIALS OF TREATMENTS OF INTESTINAL SCHISTOSOMIASIS

Michel T. Vaillant[1], Anna Schritz[1], Piero L. Olliaro[2]

[1]Luxembourg Institute of Health, Strassen, Luxembourg, [2]UNICEF/UNDP/WB/World Health Organization Special Programme for Research and Training in Tropical Diseases, Geneva, Switzerland

Treatment efficacy for schistosomiasis and soil-transmitted nematodes is customarily assessed as egg reduction rate (ERR) based on the difference in grouped means between pre- and post-treatment egg counts. This however does not allow comparison of treatment effects in controlled trials. Here, we assess whether Poisson-type modelling could be used to compare efficacy between treatments using a database from 24 trial enrolling 4,740 individuals infected with ***Schistosoma mansoni***, ***S. haematobium***, or ***S. japonicum***, and treated with 40-80 mg/kg praziquantel. Sensitivity analysis used a subset of 856 subjects in a trial comparing 40 vs 60 mg/kg praziquantel. Gender, age, treatment, species, follow-up duration and baseline egg counts were entered in all models as factors. The number of Kato-Katz smears (differences across studies) was used as a proportionality constant (offset) in the models to analyse the sum of counts. Alternative models (quasi-Poisson, negative binomial & zero-inflated Poisson) were fitted and compared. Random variation in risk between individuals and random variation between slides were also allowed for in a multi-level model with the same distributions. 1050 patients with 3577 measurements were analysed. 92% of the observed post-treatment data were zero. The Poisson model of the sum of egg counts and the quasi-Poisson model proved unsuited due to over-dispersion. The negative binomial and the zero-inflated model showed a better fit and predicted 92.07% and 91.98% of zeros. With the multilevel modelling strategy, the Poisson model performed best (95.05% of zero counts predicted). Praziquantel at 40mg/kg, 60mg/kg or 80mg/kg reduced the egg counts with no significant difference between treatments. Baseline counts were significant predictors of post-treatments counts. The sensitivity analysis showed similar results. This study shows that adequate modelling of the sum of post-treatment egg counts or raw egg counts could be useful for comparing treatment effects of anthelmintic treatment.

1821

COST-EFFECTIVENESS OF CHANGING PREVALENCE THRESHOLDS FOR MASS DRUG ADMINISTRATION AGAINST SCHISTOSOMIASIS TO SOIL-TRANSMITTED HELMINTHIASIS

Nathan C. Lo[1], Isaac I. Bogoch[2], Giovanna Raso[3], Jean T. Coulibaly[4], Jürg Utzinger[3], Jason R. Andrews[1]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]University of Toronto, Toronto, ON, Canada, [3]Swiss Tropical and Public Health Institute and University of Basel, Basel, Switzerland, [4]Université Félix Houphouët-Boigny, Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Swiss Tropical and Public Health Institute, and University of Basel, Abidjan, Côte D'Ivoire

Current WHO guidelines on mass drug administration (MDA) against helminth infections do not recommend MDA for schistosomiasis and soil-transmitted helminthiasis (STH) below a prevalence of 10% and 20%, respectively, and use separate treatment guidelines for these two helminthiases. We evaluated the cost-effectiveness of changing prevalence thresholds for integrated, annual MDA to school-age children (SAC) and the entire community. We developed a dynamic, age-structured transmission and cost-effectiveness model that simulates integrated MDA programs for schistosomiasis and STH. We simulated a 5-year treatment program with praziquantel plus albendazole at 75% coverage among: (i) SAC alone or (ii) entire community (pre-SAC, SAC, and adults). We tested prevalence values of 1%, 5%, 10%, and 15%. We simulated settings of 10,000 pre-SAC, SAC, and adults with a range of helminth-specific intensities of infection and corresponding transmission parameters. Treatment costs for SAC and pre-SAC/adults were estimated at US$ 0.74 and US$ 1.74, respectively. The incremental cost-effectiveness ratio (ICER) was calculated in 2015 US$ per disability-adjusted life year (DALY) averted, comparing treatment strategies against current WHO recommendations of no treatment. We defined strategies as highly cost-effective if the ICER was less than the World Bank classification for a low-income country (GDP per capita: US$ 1,035). An integrated MDA program against schistosomiasis and STH was highly cost-effective in treating SAC alone at a prevalence of 5% (ICER: US$ 396/DALY averted), 10% (ICER: US$ 297/DALY averted), and 15% (ICER: US$ 285/DALY averted) compared to no treatment. Expanded community-wide coverage was highly cost-effective at a prevalence of 10% (ICER: US$ 902/DALY averted) and 15% (ICER: US$ 796/DALY averted) compared to treatment of SAC alone. Integrated annual MDA programs against schistosomiasis and STH may be highly cost-effective at prevalence thresholds lower than WHO guidelines. These results support re-evaluating global guidelines to consider lowered prevalence thresholds for integrated treatment.

1822

IMPROVING TREATMENT COVERAGE - MASS DRUG ADMINISTRATION AS SEEN FROM THE COMMUNITY HEALTH WORKERS' PERSPECTIVE

Sarah Nogaro[1], Michelle Clements[1], Alexandra Weldon[1], Abou N'dri[2], Esther Comoe[2], Sei Adou[2], Elvis Allo[2], Alain Toh[2], Fiona Fleming[1]

[1]SCI, Imperial College, London, United Kingdom, [2]University Felix Houphouet-Boigny, Abidjan, Côte D'Ivoire

National-scale schistosomiasis control programmes have now been implemented in many endemic countries using mass drug administration with praziquantel. Results from a validated treatment coverage survey after the first mass drug administration in Cote d'Ivoire (CDI) in 2013, highlighted that some districts were under-performing and below the World Health Organization target of treating at least 75% of school aged children. To understand the reasons behind this low coverage, structured interviews were conducted with community health workers (CHWs) in 12 villages in CDI (1 per village). Accounts given by the CHW were captured both on paper and on a digital audio recorder. Transcripts were then translated into English and the data analysed using NVIVO software. To ensure that the information portrayed by the CHW was a true reflection of their thoughts, the interviews were done on a one-to-one basis following free and informed consent. The interviews were led by an independent social scientist and allowed for privacy. Across all interviewees, four themes were repeatedly reported: negative perception by the communities of free medication; limited time for drug distribution due to insufficient human resources; loss of income during campaigns, and inadequate social mobilisation. Other issues were raised but are considered to be country-specific. Results from this survey highlight potential issues which, if addressed, can improve preventive chemotherapy (PCT) coverage. The presenter will discuss the sustainability, the cost and efficiency of proposed solutions. With the emphasis now being on eliminating schistosomiasis, findings from this study are applicable to many PCT control programmes, which will inform national guidelines to fine tune their strategy to ensure that the 2020 targets are met.

1823

THE USE OF A MARKOV TRANSITION PROBABILITY MODEL AS A PROGRAMMATIC TOOL FOR THE CONTROL OF SCHISTOSOMIASIS

Arminder K. Deol[1], Maria-Gloria Basáñez[2], Martin Walker[2], Antonio Montresor[3], Michael French[1]

[1]Schistosomiasis Control Initiative, London, United Kingdom, [2]Imperial College London, London, United Kingdom, [3]World Health Organization, Geneva, Switzerland

The World Health Organization (WHO), in partnership with the global community, have set ambitious targets for the control and/or elimination of schistosomiasis by 2020. To be able to achieve this it is essential that control programme managers can monitor the impact of treatment and identify areas that are not responding as expected. This will allow suitable adjustments to be made to maximise the impact of the intervention. With this objective, in 2014 a programme-friendly Markov transmission model was developed at the Schistosomiasis Control Initiative (SCI) in collaboration with the WHO to model the changes in the levels of schistosomiasis infection following successive rounds of treatment. The model was parameterized using data obtained from the monitoring and evaluation components of the large-scale deworming programmes in Uganda and Mali. This model is an extension of an earlier Markov model developed for soil-transmitted helminth infection by WHO. Results showed that the transition probabilities derived from baseline and year 1 data can be used to predict the prevalence of each infection intensity group in the following year. The capacity of the model to predict changes in infection prevalence following successive rounds of treatment was then tested on various data sets from 2 countries in sub-Saharan Africa. These data were not used to develop and validate the model, so that only new scenarios could be tested. The model was tested to observe whether it could provide an early warning of the treatment campaigns that failed to meet their targets. The performance of the model was also tested against different parasite species (***S. mansoni*** and ***S. haematobium***), location and underlying endemicity as well as host age. The outputs of the model post-validation will be discussed as well as its suitability as a user-friendly programmatic tool to facilitate the monitoring of schistosomiasis control programmes.

1824

HOTSPOTS OF *SCHISTOSOMA MANSONI* TRANSMISSION TEN YEARS INTO A MASS DRUG ADMINISTRATION PROGRAM

Poppy H. Lamberton[1], Kate Mitchell[1], Charlotte M. Gower[1], Moses Adriko[2], Moses Arinaitwe[2], Annet Enzaru[2], Annet Namukuta[2], Thomas Crellen[1], Edridah M. Tukahebwa[2], Narcis B. Kabatereine[3], Alan Fenwick[1], Joanne P. Webster[4]

[1]Imperial College London, London, United Kingdom, [2]Vector Control Division, Ministry of Health, Kampala, Uganda, [3]Schistosomiasis Control Initiative at Vector Control Division, Ministry of Health, Kampala, Uganda, [4]Royal Veterinary College, London, United Kingdom

The Schistosomiasis Control Initiative began mass drug administration (MDA) with praziquantel in Uganda in 2003 with great reductions in infection prevalence, intensities and associated morbidity. However, possible treatment failures have been recorded. In addition, theoretical models have indicated that cessation of MDA may result in higher egg counts than pre-intervention levels in certain individuals. Prevalence and intensity of infection by Kato-Katz were recorded for ***Schistosoma mansoni*** in children from three primary schools in Mayuge District, Uganda. Data were collected pre-, one-week-post- and four-weeks-post-praziquantel in 2004, 2005 and 2006, and pre-, one-week-post- and three-weeks-post-praziquantel in 2013 and pre-praziquantel in 2014. In 2004 and 2013 point-of-care circulating-cathodic-antigen tests (POC-CCA) were also performed. Mean egg reduction rates by three/four-weeks-post-praziquantel from 2004, 2005, 2006, and 2013 were 94.5%, 97.8%, 97.1%, and 95.0% respectively and cure rates 72.3%, 75.7%, 80.7% and 87.2%. Cure rates by POC-CCA in 2004 and 2013 were however significantly lower at 47.8% and 9.4% respectively. Infection prevalence and intensities in 2013 and 2014 were higher than at baseline. We indicate that drug efficacy measured by Kato-Katz has not reduced with MDA, but that cure rates measured by POC-CCA are lower. Although cure rates are often considered to be a less important criteria for morbidity than a reduction in egg output, it is imperative that the causes for the significant differences between Kato-Katz and POC-CCA results, and the higher infection intensities after ten years MDA, are elucidated so we can understand any risks of MDA strategies as well as measure their benefits. Results presented will include model outputs to predict if higher infection intensities observed ten years into the MDA programme are due to high transmission, reduced drug efficacy, or reductions in the development of protective immunity, as control programmes progress.

CONQUERING SCHISTOSOMIASIS IN CHINA: THE FINAL CHAPTER

Donald P. McManus[1], Darren Gray[2], Yue-Sheng Li[1], Gail M. Williams[3], Catherine Gordon[1], Donald Harn[4], Zeng Feng[5], Remigio Olveda[6], Allen Ross[7]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]Australian National University, Canberra, Australia, [3]University of Queensland, Brisbane, Australia, [4]University of Georgia, Athens, GA, United States, [5]National Institute of Parasitic Diseases, Chinese Centre for Disease Control and Prevention, Shanghai, China, [6]Research Institute for Tropical Medicine, Manila, Philippines, [7]Griffith University, Gold Coast, Australia

Major control efforts over many decades have resulted in a substantial reduction in the prevalence of schistosomiasis japonica in the People's Republic of China, although pockets of new infection continue to arise, particularly in the mountainous areas of the south. As well, the completion of the Three Gorges Dam, which crosses the Yangtze River and other large irrigation projects underway, may have significant environmental and ecological impacts likely resulting in expansion of the habitats for the intermediate snail host ***Oncomelania hupensis*** in some areas, thereby increasing the risk of human and bovine infection, and resulting in potentially new challenging consequences for control. The epidemiological picture for China will be briefly summarised and the current effective control strategies highlighted. The situation in the Philippines will also be briefly outlined but the picture is far less encouraging as there is limited national funding for schistosomiasis control; since the termination of the World Bank Loan program for schistosomiasis control in the late 1990's, both schistosome prevalence and the associated morbidity have rebounded to former levels. Some results of recent surveillance studies we have undertaken in the Philippines will be described which indicate that schistosomiasis japonica is now far more prevalent, both in humans and bovines, than has been appreciated. Results of a large intervention trial we have completed in China - in the highly endemic Dongting Lake area downstream of the Three Gorges Dam, aimed at field-testing integrated strategies, including the use of a bovine transmission blocking vaccine, for schistosomiasis control, will be presented. The results of the trial in China will provide parameters for mathematical modelling of future control methods so as to define the long-term impact and cost-effectiveness of integrated control measures for both China and the Philippines. We believe that such an integrated approach, incorporating bovine vaccination, can lead to the future elimination of schistosomiasis from China.

1826

PLASMODIUM FALCIPARUM GENETIC CROSSES WITHOUT CHIMPANZEES

Richard S. Pinapati[1], Ashley M. Vaughan[2], Ian H. Cheeseman[3], Lisa A. Checkley[1], Carolyn A. Hutyra[1], Nelly Camargo[2], Matthew Fishbaugher[2], Shalini Nair[3], Francois H. Nosten[4], Timothy J. Anderson[3], Stefan H. Kappe[2], Michael T. Ferdig[1]

Experimental genetic crosses in ***Plasmodium falciparum*** have played a pivotal role in the discovery of genes underlying several important phenotypic traits including drug resistance and host specificity. Previously, ***P. falciparum*** genetic crosses were carried out in splenectomized chimpanzees and in spite of the fact that three successful experimental crosses were generated, ethical and logistical concerns have now rendered this technology obsolete. Here we demonstrate a new model for ***P. falciparum*** experimental genetic crosses: a human hepatocyte-liver chimeric mouse (FRG huHep mouse) injected with human red blood cells (huRBCs) that allows for complete ***P. falciparum*** liver stage development and the transition of exo-erythrocytic merozoites to asexual blood stage development. Using this novel and versatile model, we have rapidly generated and analyzed three experimental crosses, including the identification of unique recombinant progeny from each cross. A chloroquine (CQ) sensitive transgenic strain, NF54HT-GFP–luc, was used as a parent in all three of our new experimental crosses and was crossed with three different strains: GB4 and 7G8, two strains used in a previous chimpanzee experimental cross, and NHP*, a recent field isolate from Southeast Asia. We characterized all crosses using microsatellite markers and further characterized progeny from the NF54HT-GFP–luc × NHP* cross using thousands of single nucleotide polymorphisms (SNPs) from next-generation sequence data and custom genotyping microarrays. These data were used to generate genetic maps and compute recombination rates across the genome. The high-density SNP-based linkage map will be used in conjunction with quantitative trait loci (QTL) mapping to assay a wide variety of quantifiable phenotypes such as drug responses, thus facilitating the study of complex genetic traits in ***P. falciparum***.

1827

DETERMINING THE MECHANISM OF ACTION OF THE IMIDAZOLOPIPERAZINES, A NOVEL CLASS OF ANTIMALARIALS

Gregory LaMonte, Melanie Wree, Marie Nachon, Greg Goldgof, Victoria Corey, David Plouffe, Edgar Vigil, Elizabeth Winzeler

University of California, San Diego, La Jolla, CA, United States

Malaria, despite ongoing public health intervention worldwide, remains a tremendous burden globally. While progress has been made recently against malaria, the emergence of artemisinin resistance in ***Plasmodium falciparum*** has accelerated the search for both new and more effective antimalarial drug candidates. One of the most promising new compound classes in clinical development are the Imidazolopiperazines (IZPs), which are not only effective against all stages of ***Plasmodium*** infection, but also prevent transmission and dramatically reduce the rate of future infection. The lead compound of the IZPs, GNF156, is currently in phase IIb clinical trials. Unfortunately, the development of this class of compounds is hampered by a limited understanding of their mechanism of action. Previous ***in vitro*** evolution studies identified a previously uncharacterized gene, designated the ***P. falciparum*** cyclic amine resistance locus, as a potential target for the IZPs. More recent studies, however, have implicated several additional genes/pathways as potential targets of the IZPs. Given this ambiguity about the target and activity of the IZPs, this study will therefore first validate putative drug targets, then go on to examine both the localization and function of those validated targets. We have used the CRISPR/CAS9 system to validate several genes, including PfCARL, in which mutations convey resistance. In addition, we showed that these same mutations protected ***P. falciparum*** gametocytes from IZP activity and that PfCARL protein is localized to the endoplasmic reticulum/Golgi apparatus. Finally, we utilized Saccharomyces cerevisiae as a model to identify several pathways affected by IZP exposure, which were then functionally validated in ***P. falciparum***. By determining the mechanism of action of the IZPs, this study will significantly advance efforts against malaria, both by improving the utility of a promising new class of antimalarials and by identifying new targets for antimalarial intervention.

DEEP SEQUENCING OF *ANOPHELES GAMBIAE* FROM NATURAL POPULATIONS SPANNING SUB-SAHARAN AFRICA - A RESOURCE FOR VECTOR CONTROL RESEARCH

Alistair Miles[1], Dominic Kwiatkowski[2], The Anopheles gambiae 1000 Genomes Consortium[3]

[1]University of Oxford, Oxford, United Kingdom, [2]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [3]Institutional affiliations are listed at http://www.malariagen.net/ag1000g, United Kingdom

The ***Anopheles gambiae*** 1000 genomes project (Ag1000G) is using whole-genome sequencing to study genome variation in wild-caught mosquitoes from populations across Africa. In phase 1 of the project high throughput sequence data from 765 specimens from 8 countries have been generated. The sequence data have been used to discover over 52 million single nucleotide polymorphisms - on average 1 SNP every ~2 accessible bases - providing the first genome-wide view of the spectacular natural diversity within and between natural populations. These data have been publicly released and comprise the largest open access genomic resource available for any vector species. Here we provide an overview of the Ag1000G phase 1 data resource and initial results of population genetic analyses, focusing on applications to malaria epidemiology and vector control. First, analyses of population structure in the Ag1000G cohort reveal a complex mosaic, with incomplete speciation, geography, ecology and demography all influencing gene flow across the species' range. These data could be integrated into models informing vector control strategy, and we discuss steps towards this goal. Second, these data enable high-resolution analyses of loci under strong recent selection, including discovery of novel insecticide resistance mutations. We illustrate this with data from the voltage-gated sodium channel gene, and show that multiple independent haplotypes within both West and East African populations have been involved in selective sweeps, cutting across species barriers and major geographic features. We also present preliminary evidence for novel resistance mutations, and discuss how haplotype data from Ag1000G could be used to diagnose the origin and track the spread of insecticide resistance. Finally, we present data from the Ag1000G coastal Kenyan population, where all individuals exhibit long runs of homozygosity consistent with a severe recent population bottleneck. These data demonstrate that demographic events leave a strong genetic signal, and we discuss how genomic data could be used to provide feedback about the impact of vector control interventions.

As artemisinin resistance in ***Plasmodium falciparum*** continues to simultaneously spread and emerge in new areas throughout Southeast Asia, plans are underway for targeted malaria elimination. Achieving regional elimination will require effective antimalarial drugs, an efficacious vaccine, or both; however, few drugs remain effective in Southeast Asia and currently there is no vaccine. The discovery of new drugs and vaccines is necessary if elimination is to be successful. To identify candidate drug and immune targets, we used three methods - two long-haplotype tests and population differentiation using FST - to locate regions of the ***P. falciparum*** genome that are potentially under positive directional selection among Southeast Asian parasites. Literature review of the previous use of these methods in malaria parasite genomic studies showed little overlap among genes, and differing sampling and genotyping methods prohibit meta-analyses. We genotyped approximately 30,000 loci in over 2,000 samples from 19 geographic sites across the Greater Mekong Subregion using a DNA microarray and whole-genome sequencing. Regions under selection within each geographic site were identified, and meta-analyses identified the most highly-selected genomic regions shared across all sites. Across all analyses there are 245 genes within the most highly-selected regions, including genes associated with drug resistance and encoding current vaccine antigens. Many genes with potential impact in public health are present including genes involved in drug export, vesicle transport, and red blood cell binding. The genes identified in our scans could be under selection for many reasons including association with drug resistance as well as human, vector, or environmental factors. Evidence of positive directional selection may be a useful criterion for selecting new vaccines and drugs for further development and testing. (Additional authors will be listed in the presentation).

EXPLORING UNKNOWN GENES IN MALARIA PARASITES BY A ROBUST GENE REGULATORY SYSTEM

Suresh Maddur Ganesan, Alejandra Falla, Sebastian Nasamu, Jacquin C. Niles

Massachusetts Institute of Technology, Cambridge, MA, United States

Malaria is a major health problem in tropical and subtropical countries. The most severe form of malaria is caused by the parasite, ***Plasmodium falciparum***. A limited set of antimalarial drugs is used to treat the disease, but drug resistance is spreading at alarming rate. Hence, there is an urgent need for identification of novel anti-malarial drugs. A major challenge in new antimalarial drug development is identification and prioritization of potential targets for drug discovery. This is mainly due to lack of reliable functional genetics tools for investigating parasite genes. To address this need, we have developed a RNA-protein interaction system that facilitates robust and inducible regulation of target gene translation in eukaryotic organisms, including ***Plasmodium***. Here, we present the application of protein engineering approaches to integrate our synthetic control system with native ***Plasmodium*** translational regulatory mechanisms. In so doing, we have achieved substantially increased regulatory dynamic ranges (up to 200-fold) compared to a 5-10 fold range of the original system. As a proof-of-concept, we have successfully used this system to generate parasite lines in which various proteins of interest can be knocked down to reveal clear growth phenotypes. In addition, we have successfully combined this approach with CRISPR/Cas9 genome editing technology to rapidly validate essential genes. We are currently applying these genetic tools to broadly study parasite genes of unknown function. Since ~60% of the encoded ***P. falciparum*** genes have no known homologs in other eukaryotes, we believe that understanding their functions will aid in identifying potential targets for novel antimalarial drug development.

1831

PARTICIPATION OF INNATE IMMUNE CELLS IN MODULATING BLOOD FLUKE DEVELOPMENT

Ellen C. Fox, Stephen J. Davies

Uniformed Serivces University, Bethesda, MD, United States

Schistosomes develop in the blood stream of their hosts, where they feed on blood cells and produce eggs that cause severe pathology. Previous work has demonstrated that host immune function is required for normal schistosome development, as parasite development is dramatically impaired in some immunodeficient settings. Recently, we presented evidence that regulation of innate inflammatory responses is a requirement for schistosome development to proceed as administration of innate immune stimuli such as LPS, MSU and IL-4 restored parasite development in RAG-1-/ animals. - Here we review our recent progress toward identifying the innate immune cells that are implicated in these host-schistosome interactions. Following administration of various innate immune stimuli to RAG-1-/- mice, splenic neutrophils, monocytes, macrophages and non-classical macrophages were assessed for changes in expression of activation markers and Relm-α by flow cytometry. Administration of pro-inflammatory stimuli LPS and MSU resulted in significant decreases in surface expression of CD204 and CD206 in all cell populations, while treatment with IL-4 cytokine complex resulted in significant increase in CD204 and CD206. Poly I:C, a TLR 3 agonist that did not rescue parasite development, resulted in no significant changes in CD204 and CD206 expression. Taken together, these data suggest that while innate immune cells are likely important environmental factors for parasite development, we are unable to identify changes in innate cell phenotype that correlate with successful completion of the parasite's

developmental cycle. Ongoing studies are assessing changes in innate immune cell metabolism as a possible mechanism facilitating schistosome infection.

1832

THE ADIPOSE TISSUE DERIVED STEM CELLS (ASC) SHOWS IMMUNOREGULATION FUNCTIONS IN SCHISTOSOMIASIS INFLAMMATION ENVIRONMENT

Adriana Bozzi Melo[1], Dirli Emmerick Eller[1], Lorena Cassia Ferraz[1], Talita Rocha Gomes[2], Vitor Hugo Miranda[1], Carlos Eduardo Calzavara-Silva[1], Alfredo Miranda Goes[2], Rodrigo Correa-Oliveira[1]

[1]Centro de Pesquisas René Rachou/FIOCRUZ-MG, Belo Horizonte, Brazil, [2]Instituto de Ciências Biológicas da UFMG, Belo Horizonte, Brazil

Numerous reports have shown that mesenchymal stem cells (MSC) appears to be important in therapeutics to regulate immune response invoked in settings such as tissue injury, transplantation and autoimmunity. In this study we investigated the effect of these cells on the immunoregulation activities of adipose tissue derived stem cells (ASC) in a ***Schistosoma mansoni*** experimental model. The ASC were isolated from C57BL/6 mice, expanded ***in vitro*** and phenotypic and functionally characterized. These cells were injected via the tail vein into C57BL/6 mice (n=6) two weeks after ***S. mansoni*** infection. The splenocytes were obtained and the ***in vitro*** proliferative response was determined after six days of culture of splenocytes in the presence or not of ASC, and stimulated with Schistosoma egg crude antigens (SEA) or adult worms (SWAP) or concanavalin A. After thirty days of ASC injection, ***in vitro*** stimulation of splenocytes in the presence of ASC led to a significant increase on proliferation. On the other hand, the addition of ASC to spleen cell cultures from infected mice that did not receive ASC ***in vivo*** showed a decreased proliferative response. Interestingly, a decrease in ***in vitro*** splenocyte proliferation was also observed after sixty days post-ASC injection, even in the presence of fresh ASC. CD4+ T cell activation was analyzed (CD25, CD69, CD28 and CTLA-4) after fifteen, thirty and sixty days post-ASC injection. We observed a decrease in activation of T CD4+ subpopulation, mainly after fifteen and thirty days post-ASC injection. In conclusion, in mice infected with ***S. mansoni***, the ASC were able to modulate the immune response during the early inflammatory process, in a time-dependent manner. These data emphasize the putative role of these cells as candidates for cellular therapy, including the control of inflammation caused by parasitic diseases.

1833

LOW TO MODERATE INTENSITY *SCHISTOSOMA MANSONI* INFECTIONS DO NOT ALTER PROTECTIVE ANTIBODY RESPONSES TO TETANUS TOXOID BOOSTER IMMUNIZATIONS

Diana K. Riner[1], Eric M. Ndombi[2], Jennifer M. Carter[1], Nupur Kittur[1], Emmy Kavere[2], Harrison K. Korir[2], Amos Omondi[2], W. Evan Secor[3], Diana Karanja[2], Daniel G. Colley[1]

[1]University of Georgia, Athens, GA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States

Helminths such as schistosomes are remarkable in their ability to modulate host immune responses, which promotes their survival. Immunoregulation begins early in schistosome infection and has been characterized by hyporesponsiveness to parasite antigens and bystander antigens, suggesting schistosome infection at the time of immunizations could lower the protective response to vaccines. To investigate the impact that concurrent helminth infection might have on an individual's responses to vaccine antigens, we recruited participants from Kisumu Polytechnic College in western Kenya. Participants were enrolled, consented and screened for schistosomiasis and soil transmitted helminths (STHs) and assigned to groups based on helminth status. Tetanus toxoid (TT; single dose), hepatitis B (doses at 0, 1 and 6 months), and meningococcus A+C (doses at 0 and 2 months) vaccines were administered. Helminth infections were treated a week after the second hepatitis B immunization. Participants were bled at baseline, 2 months after the start of immunizations and 2 months after the final hepatitis B immunization to evaluate humoral and cellular immune responses to the vaccine antigens using both antibody and cytokine ELISAs. CD3+/CD4+/CD25high T regulatory (Treg) cell levels were also determined at each time point to assess their relationship to vaccine responses. As we have previously reported participants with schistosomiasis had significantly higher proportions of circulating Treg cells than uninfected controls at baseline. These levels increased 1 week after praziquantel treatment, but decreased to uninfected control levels by 7 months after treatment. Anti-TT antibody levels in both infected and uninfected groups were comparable at all measured time-points indicating that schistosome infection did not alter IgG recall responses to this immunization. Preliminary analyses of antibody responses to hepatitis B surface antigen indicate a somewhat lower responsiveness to the primary and booster immunizations in those with ***S. mansoni*** infection. Further analyses are ongoing.

1834

TARGETING THE BURDEN OF SCHISTOSOMIASIS IN MADAGASCAR: GYNAECOLOGICAL MANIFESTATIONS OF SCHISTOSOMIASIS IN AN AREA SCALING UP MASS DRUG ADMINISTRATION OF PRAZIQUANTEL

Bodo S. Randrianasolo[1], Peter M. Jourdan[1], Pascaline Ravoniarimbinina[2], Charles E. Ramarokoto[2], Fanjasoa Rakotomanana[2], Vololomboahangy E. Ravaoalimalala[2], Svein G. [1]Schistosomiasis Control Initiative, Imperial College London, London, United Kingdom, [2]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [3]University of Agder, Kristiansand, Norway, [4]Charité University Medicine, Berlin, Germany, [5]University of Copenhagen, Copenhagen, Denmark, [6]Leiden University Medical Center, Leiden, Netherlands, [7]Oslo University Hospital, Oslo, Norway, [8]Aarhus University Hospital, Aarhus, Denmark, [9]University of KwaZulu-Natal, Durban, South Africa

Schistosoma haematobium infection frequently causes morbidity in the genital tract, and the disease may increase the risk of HIV transmission. Genital schistosomiasis in women of reproductive age living in endemic areas is under-diagnosed, and efforts are needed to better understand the pathophysiology and to provide control measures for the disease. A study was undertaken in order to determine the female genital morbidity caused by schistosomiasis, and to describe its histopathological correlates in an area of Madagascar prior to mass drug administration (MDA) of praziquantel. Women aged 15-35 years living in an ***S. haematobium***-endemic area in Madagascar underwent pelvic and colposcopic examinations. Women were grouped according to intensity of urinary ***S. haematobium*** infection, and small biopsies were taken from genital lesions and examined microscopically using standard haematoxylin and eosin stain. Updated mapping data of schistosomiasis was collected for the strategic planning, implementation and review of MDA of praziquantel in the same region of Madagascar. Genital lesions named sandy patches and rubbery papules were found in 41 of 118 women (35%). Rubbery papules only reported and described in this study contained an intense cellular immune reaction dominated by eosinophils, epithelial erosion, and viable ova. There was a significant decrease in the prevalence of rubbery papules with age, even after adjustment for urinary ova excretion. The sandy patches with grains showed moderate cellular immune reaction and ova (viable and/or calcified), and were most prevalent in women with low-intensity urinary ***S. haematobium*** infection. These findings in women living in an endemic area of Madagascar indicate a dynamic evolution of inflammatory genital lesions caused by ***S. haematobium*** and a clear need for preventive chemotherapy in school-age children as recommended by the World Health Organization. The authors present the results in light of

the current scale-up of MDA of praziquantel in Madagascar put in place by the Ministry of Health and the Ministry of Education, and supported by the Schistosomiasis Control Initiative (SCI).

1835

LENTIVIRUS HIV-1 INTEGRATES WIDELY THROUGHOUT THE GENOME OF THE HUMAN BLOOD FLUKE *SCHISTOSOMA MANSONI*

Paul J. Brindley[1], Sutas Suttiprapa[1], Gabriel Rinaldi[1], Isheng J. Tsai[2], Sergei Iordanskiy[1], Victoria H. Mann[1], Larisa Dubrovsky[1], Hong-bin Yan[1], Nancy Holroyd[2], Tatiana Pushansky[1], Matthew Berriman[2], Michael I. Bukrinsky[1]

[1]George Washington University, Washington, DC, United States, [2]Wellcome Trust Sanger Institute, Hinxton, United Kingdom

Lentivirus-mediated gene expression manipulation offers advantages for functional genomics of the schistosome, allowing to establish informative lines of transgenic schistosomes and to elucidate gene functions of these pathogens. To investigate the ability of lentiviral vectors to integrate into the schistosomal genome, blood stream forms of the human schistosome, ***Schistosoma mansoni***, including schistosomules and adult female and male parasites were exposed to vesicular stomatitis virus glycoprotein pseudotyped virions of HIV-1. Reverse transcription of the lentiviral RNA genome proceeded, as confirmed by the presence of strong-stop and positive strand cDNAs, in turn confirming the internalization of the lentiviral nucleocapsid into the cytoplasm of schistosome cells. Integration of HIV provirus into chromosomes of the schistosomes followed, as established by anchored PCR targeting integrated provirus in the vicinity of endogenous mobile elements, by high throughput sequencing of lentivirus-anchored PCR products, and by whole genome sequences of the schistosomes. On a population scale, integrations of lentiviral provirus were widely distributed throughout the eight pairs of chromosomes of the schistosomes. Density of integrations was frequently > 10 events per 100 kilobase pair windows. Integration site preference was biased to non-coding regions of the schistosome genome, a preference dissimilar to that of HIV in human T cells. Integrations into exons and introns of protein-encoding loci were also seen. The ability of HIV-1 to complete biochemical processes essential for lentivirus replication was notable and unexpected given that schistosomes are phylogenetically far distant from primates and other mammals naturally infected by the genus Lentivirus.

1836

DEVELOPMENT OF A BIOSENSOR-BASED RAPID URINE TEST FOR DETECTION OF UROGENITAL SCHISTOSOMIASIS

Kathleen Mach[1], Ruchika Mohan[1], Shailja Patel[1], Pak K. Wong[2], **Michael Hsieh**[3], Joseph C. Liao[1]

[1]Stanford University, Stanford, CA, United States, [2]University of Arizona, Tucson, AZ, United States, [3]Biomedical Research Institute, Rockville, MD, United States

Schistosomiasis affects up to 300 million people with serious and diverse sequelae arising from infection. Diagnosis of urogenital schistosomiasis (***Schistosoma haematobium*** infection) relies on microscopic identification and enumeration of parasite eggs in urine, however this is time consuming and requires technical skill. A point-of care device for detection of ***S. haematobium*** would significantly reduce the time-to-result with the potential to improve patient care. In this work, we demonstrate the use of our established biosensor platform for bacterial identification for the detection of ***S. haematobium*** in urine. We developed capture and detector probes targeting ***S. haematobium*** rRNA, a robust egg lysis protocol and integration into our established platform. Using the biosensor assay, we demonstrated direct detection of ***S. haematobium*** eggs spiked in human urine at clinically relevant ranges with detection of as few as 30 eggs/ ml urine.

1837

AN ULTRA-SENSITIVE URINE-BASED ASSAY TARGETING THE CIRCULATING ANODIC ANTIGEN (CAA) FOR DIAGNOSIS OF UROGENITAL TO INTESTINAL SCHISTOSOMIASIS IN LOW-ENDEMIC AREAS

Govert J. van Dam, Claudia J. de Dood, Dieuwke Kornelis, Lisette van Lieshout, Paul L. Corstjens

LUMC, Leiden, Netherlands

The recent renewed interest in mapping, intensified control and elimination of schistosomiasis has put the need for highly accurate diagnostic assays high on the agenda. The well-studied schistosome antigen detection assays CCA- and CAA-ELISA have now been transformed into a Point-of-Care rapid test (POC-CCA) and an ultra-sensitive UCP lateral flow based strip assay (UCP-CAA), resp. The simple field applicable POC-CCA test may replace the Kato-Katz testing for prevalence mapping of community-level ***Schistosoma mansoni*** infections using a single drop of urine as well as evaluate quickly (within days) the efficacy of treatment. However this test shows variable sensitivity in the diagnosis of ***S. haematobium***. The recently developed UCP-CAA assay detects antigen in serum or urine of all schistosome species at sub-pg levels, a sensitivity allowing detection of single worm infections. The assay has been transformed into a robust, dry-reagent based test, and is currently used in several low-resource settings in Africa. In combination with optimized sampling schedules involving pooled urines this would allow rapid identification of ***foci*** of low prevalence/intensity ***S. haematobium*** and ***S. mansoni*** infections. Recent studies using the 2 ml urine dry reagent UCP-CAA format performed in low prevalence (<2%), ***S. haematobium*** settings (near elimination) show an over 10-fold increase in the prevalence of active schistosome infections. Similar results have been shown for ***S. japonicum*** settings in China and ***S. mansoni*** settings in Brasil and Africa. The UCP-CAA strip assay therefore is a valuable highly sensitive diagnostic tool, applicable for screening and case finding in very low prevalence areas, including pre-elimination settings.

1838

EVALUATING THE IMPACT OF PULSE OXIMETRY ON PNEUMONIA MORTALITY IN CHILDREN UNDER FIVE IN RESOURCE-POOR SETTINGS

Jessica Floyd[1], Lindsey Wu[2], Rasa Izadnegahdar[3], Deborah Burgess[3], David Mukanga[3], Azra Ghani[1]

[1]Imperial College London, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]The Bill & Melinda Gates Foundation, Seattle, WA, United States

Despite available interventions, pneumonia is still responsible for an estimated 15% of childhood deaths worldwide. Recent research has shown that hypoxia and malnutrition are strong predictors of mortality in children hospitalized for pneumonia. This has led to increasing support for the use of oxygen therapy and monitoring oxygen saturation in the management of severe cases. It is estimated that 15% of children under five hospitalised for pneumonia have hypoxemia and that approximately 1.5 million children with severe pneumonia require oxygen treatment each year. We present a deterministic compartmental model to assess the impact of introducing pulse oximetry as a prognostic to distinguish severe from non-severe pneumonia in under-fives across 15 of the highest-burden countries. Incidence of pneumonia in each country was fitted to data on the mortality rates in each country. The impact of this improved prognostic was compared to the current mortality rates under Integrated Management of Childhood Illness (IMCI) guidelines. We found that, assuming access to supplemental oxygen, pulse oximetry has the potential to avert an estimated 200,000 deaths if implemented across the 15 countries, whereas IMCI was found to have a relatively small impact on mortality. Pulse oximetry can significantly increase the incidence of correctly-treated cases as well as reduce the incidence of incorrect

treatment with antibiotics. We also found pulse oximetry to be highly cost-effective, with median estimates ranging from $2.46 to $9.43 per DALY averted in 14 of the 15 countries analysed (US$). This combination of significant burden reduction and high cost-effectiveness makes pulse oximetry a promising candidate for an intervention against pneumonia in resource-poor settings.

1839

HOUSEHOLD-LEVEL RISK FACTORS FOR SECONDARY INFLUENZA-LIKE ILLNESS IN A RURAL AREA OF BANGLADESH

Anne M. Weaver[1], Manoshi Islam[2], Kaniz Khatun-e-Jannat[2], Emily Cercone[3], Margaret A. DiVita[4], Kimberly Krytus[3], Badrul Munir Sohel[2], Makhdum Ahmed[2], Abid Mahmud Rahman[2], Mustafizur Rahman[2], W. Abdullah Brooks[5], Eduardo Azziz-Baumgartner[6], Jihnhee Yu[3], Alicia M. Fry[6], Stephen P. Luby[7], Pavani K. Ram[3]

[1]Indiana University, Indianapolis, IN, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of Buffalo, Buffalo, NY, United States, [4]State University of New York, Cortland, Cortland, NY, United States, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]Stanford University, Stanford, CA, United States

Influenza-like illness (ILI) is an important public health concern in Bangladesh. Individuals with ILI are likely to transmit their illness to close contacts, including household members. Household-level risk factors for secondary ILI in a low-income, vulnerable population have not been characterized. We conducted secondary data analysis from participants in the control arm of a randomized controlled trial of handwashing and secondary ILI. We recruited index case-patients with ILI--fever (<5 years), fever, cough or sore throat (≥5years)--from health facilities, collected information on household factors, and conducted syndromic surveillance on all household contacts for ten days after resolution of index case-patients' symptoms. We conducted multivariable negative binomial regression to evaluate the effects of household factors on risk of secondary ILI among household contacts and accounting for clustering by household. A wealth index was created using principal components analysis of household assets. We analyzed data from 1491 household contacts of 184 index case-patients. Mean age was 26 years. Most (71%) reported that smoking occurred in their home, 27% shared a latrine with 1 other household, and 36% shared a latrine with >1 other household. A total of 114 participants had symptoms of ILI during follow-up. Smoking in the home (RRadj 1.91, 95% CI 1.23-2.96), and sharing a latrine with 1 other household (RRadj 2.07, 95% CI 1.18, 3.64) or >1 household (RRadj 3.08, 95% CI 1.81-5.23) compared to not sharing, were independently associated with increased risk of secondary ILI, even after adjustment for wealth. These results suggest that efforts to reduce tobacco use in homes could reduce respiratory illness in Bangladesh. The association between use of shared latrines and household ILI transmission had not previously been demonstrated. It is possible that certain respiratory pathogens could be transmitted effectively through contact with feces or contaminated fomites present in shared latrines; future research could investigate these mechanisms in more depth.

RESPIRATORY VIRAL DETECTIONS DURING SYMPTOMATIC TO ASYMPTOMATIC PERIODS IN YOUNG ANDEAN CHILDREN

Leigh M. Howard[1], Monika Johnson[1], John V. Williams[2], Yuwei Zhu[3], Ana I. Gil[4], Kathryn M. Edwards[1], Marie R. Griffin[5], **Claudio F. Lanata**[4], Carlos G. Grijalva[6]

[1]Division of Infectious Diseases, Department of Pediatrics, Vanderbilt University, Nashville, TN, United States, [2]Department of Pathology, Microbiology, and Immunology, Vanderbilt University, Nashville, TN, United States, [3]Department of Biostatistics, Vanderbilt University, Nashville, TN, United States, [4]Instituto de Investigacion Nutricional, Lima, Peru, [5]Department of Pediatrics, Vanderbilt University, Nashville, TN, United States, [6]Department of Health Policy, Vanderbilt University, Nashville, TN, United States

Viruses are commonly detected in children with acute respiratory illnesses (ARI) and in asymptomatic children. Longitudinal studies of viral detections during asymptomatic periods surrounding ARI could facilitate interpretation of viral detections but are currently scant. Methods. We used reverse transcription-polymerase chain reaction (RT-PCR) to analyze respiratory samples from young Andean children for viruses during asymptomatic periods within 8-120 days of index ARI (cough or fever). We compared viral detections over time within children and explored RT-PCR cycle thresholds (CT) as surrogates for viral loads. Results. At least one respiratory virus was detected in 367 (43%) of 859 samples collected during asymptomatic periods, with more frequent detections in periods with rhinorrhea (49%) than those without (34%, p<0.001). Relative to index ARI with human rhinovirus (HRV), adenovirus (AdV), respiratory syncytial virus (RSV), and parainfluenza virus (PIV) detected, the same virus was also detected during 32%, 22%, 10%, and 3% of asymptomatic periods, respectively. RSV was only detected 8-30 days after index RSV ARI, whereas HRV and AdV were detected throughout asymptomatic periods. Human metapneumovirus (MPV) and influenza were rarely detected during asymptomatic periods (<3%). No significant differences were observed in the CT for HRV or AdV during asymptomatic periods relative to ARI. For RSV, CT were significantly lower during ARI relative to the asymptomatic period (p=0.03). Conclusions. These findings indicate that influenza, MPV, PIV, and RSV detections in children with ARI usually indicate a causal relationship. When HRV or AdV is detected during ARI, the causal relationship is less certain.

DESCRIPTION OF THE POPULATION STRUCTURE TO GENETIC DIVERSITY OF *MYCOBACTERIUM TUBERCULOSIS* AMONG PATIENTS OF HAITIAN ORIGIN LIVING IN FLORIDA

Marie N. Seraphin[1], Alice M. Abernathy[1], Richard T. Doggett[2], J. Glenn Morris[1], Michael Lauzardo[1]

[1]University of Florida, Gainesville, FL, United States, [2]Florida Department of Health, Tallahassee, FL, United States

Individuals of Haitian origin have one of the highest tuberculosis (TB) case rates in Florida. However, literature on the propensity of certain M. tuberculosis strains to transmit faster than background rate in this population is limited. We investigated the genetic diversity, occurrence of strain emergence, and determinants of emergent strains among Haitians living in Florida. All culture confirmed TB cases reported to the Florida Department of Health (FDOH) are genotyped using spoligotyping and MIRU. We analyzed data on 482 TB cases of Haitian origin reported to FDOH from 2002 to 2014. We used the web application MIRU-VNTRplus for strain family and shared international types (SIT) assignment. We used SpolTools and the program DESTUS to asses strain emergence, recent transmission index and genetic diversity. In multivariate regression, we measured the socio-demographic and clinical determinants of strain emergence. Of the 482 strains, 136 (28.2%) belonged to the Haarlem lineage, 130 (27.0%) to the LAM lineage and 91 (18.8%) to the T lineage. SIT50, H3 sub-lineage, was the most common spolygotype with 59

strains (12.2%). Sixty two spoligotypes were identified as orphans. The different isolates were characterized into 114 genotypes with average cluster size of 4.2, recent transmission index and clustering rate of 0.76 and 0.24 respectively, and a virtual heterozygosity of 0.040. Adjusting for false discovery rate, The H3 sub-lineage, was identified as emergent (θ=46.84, p=2.44×10-04, q=0.02785), i.e. spreading faster than background transmission rate. A history of incarceration (AOR=7.63, CI: 1.17, 49.79; p=0.0337) was the strongest predictor of strain emergence after controlling for age, gender, years in the US, HIV status, initial drug resistance, site of disease, illicit drug and alcohol use, and homelessness. The H3 sub-lineage seems to be emerging in Haitian communities in Florida, largely driven by exogenous infection among individuals with a history of incarceration. Renewed efforts to track and treat TB patients of Haitian origin are warranted to curtail the spread of this Mtb clone.

1842

EXPANSION OF TYPE 1 CYTOKINE PRODUCING CD4+T CELLS OCCURING IN DISTINCT MEMORY COMPARTMENTS DELINEATES LATENT VS. ACTIVE TUBERCULOUS DISEASE

Soumya Chatterjee[1], Pavan Kumar[2], Subash Babu[2], Thomas B. Nutman[1]

[1]National Institutes of Health/National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]NIH-ICER/NIRT, Chennai, India

Optimal CD4+ responses in the control of tuberculosis (TB) caused by Mycobacterium tuberculosis (Mtb) depends on antigen-specific, protective type 1 cytokine producing stable precursor memory pool. The quality of these responses in active pulmonary (PTB) versus latent TB (LTBI) is, however, poorly understood. We used multiparameter flow cytometry on whole blood from 9 LTBI and 10 PTB subjects to assess the nature of Mtb antigen (Ag) (ESAT6 and CFP10, E6/C10)-specific memory T cell responses. At baseline, PTB subjects compared to LTBI had increased frequencies of total CD4+IFN-γ+ cells (median frequency 0.4 % vs. 0.11, p= 0.01) as well as CD4+IFN-γ+TNF-α- (median frequency 0.35 % 0.1%, p= 0.004) and CD4+IFN-γ+IL-2- cells (median frequency 0.05 % 0.23%, p= 0.04). No differences were seen in the absolute frequencies of total CD4+TNF-α+ or CD4+IL-2+ cells. Interestingly, within CD4+IFN-γ+ cells, PTB subjects showed increased frequencies of cells with a naïve-like phenotype (CD45RA+CCR7+, NV, median frequency 9.2% vs. 2.7%, p=0.05) as well as stem cell like memory cells (CD45RA+CCR7+CD27+CD95+, TSCM) (median frequency 1.5% vs. 0.001%, p=0.02). The PTB group showed increased CD4+IFN-γ+TNF-α- cells frequencies in the TSCM compartment (median frequency 0.6% vs.% 0.001%,p=0.03) while increased CD4+ IFN-γ+IL-2- cells were seen in the TEMRAs (CD54RA+CCR7-) (median frequency 8.3% vs. 2.2 %, p= 0.01). On E6/C10 stimulation, however, LTBI subjects showed an increased net frequency of CD4+IFN-γ+ cells in Central memory (CD45RA-CCR7+, TCM) (median net frequency 8.5 % vs. -3.3%, p=0.05) and TSCM cells (median net frequency 0.01 % vs. -0.4%, p=0.03) compared to PTB. Finally, the LTBI group showed E6/C10-specific increased net frequencies of CD4+IL-2+ cells in the NV compartment (median net frequency 3.09% vs. 0.8% PTB, p=0.05). These data suggest that although increased baseline CD4+ IFN-γ+ responses in are seen in subjects with PTB, Mtb- antigen specific increased IFN-γ and IL-2 within precursor CD4+ memory cells (TCM and TSCM) as seen in LTBI subjects might be associated with infection containment.

INCIDENCE TO RISK FACTORS FOR RESPIRATORY SYNCYTIAL VIRUS TO HUMAN METAPNEUMOVIRUS INFECTIONS AMONG CHILDREN IN THE REMOTE HIGHLANDS OF PERU

Andrew Wu[1], Philip J. Budge[2], John V. Williams[3], Marie R. Griffin[4], Kathryn M. Edwards[5], Monika Johnson[6], Yuwei Zhu[7], Stella Hartinger[8], Hector A. Verastegui[9], Ana I. Gil[9], **Claudio F. Lanata**[9], Carlos G. Grijalva[4]

[1]School of Medicine, Vanderbilt University, Nashville, TN, United States, [2]Division of Infectious Diseases, Washington University School of Medicine, St. Louis, MO, United States, [3]Department of Pathology, Microbiology, and Immunology, Vanderbilt University, Nashville, TN, United States, [4]Department of Health Policy, Vanderbilt University, Nashville, TN, United States, [5]Vanderbilt Vaccine Research Program, Division of Infectious Diseases, Department of Pediatrics, Vanderbilt University, Nashville, TN, United States, [6]Department of Pediatrics, Vanderbilt University, Nashville, TN, United States, [7]Department of Biostatistics, Vanderbilt University, Nashville, TN, United States, [8]Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland, [9]Instituto de Investigacion Nutricional, Lima, Peru

The disease burden and risk factors for respiratory syncytial virus (RSV) and human metapneumovirus (MPV) infections among children living in remote, rural areas remain unclear. Methods: We conducted a prospective, household-based cohort study of children aged <3 years living in remote rural highland communities in San Marcos, Cajamarca, Peru. Acute respiratory illnesses (ARI), including lower respiratory tract infection (LRTI), were monitored through weekly household visits from March 2009 through September 2011. Nasal swabs collected during ARI/LRTI were tested for RSV, MPV, and other respiratory viruses using real-time RT-PCR. Incidence rates and rate ratios were calculated using mixed effects Poisson regression. Results: Among 892 enrolled children, incidence rates of RSV and MPV ARI were 30 and 17 episodes per 100 child-years, respectively. The proportions of RSV and MPV ARI that presented as LRTI were 12.5% and 8.9%, respectively. Clinic visits for ARI and hospitalizations were significantly more frequent (all p values <0.05) among children with RSV (clinic 41% and hospital 5.3%) and MPV ARI (38% and 3.5%) when compared with other viral infections (23% and 0.7%) and infections without virus detected (24% and 0.6%). In multivariable analysis, risk factors for RSV detection included younger age (RR 1.02, 95% CI: 1.00-1.03), the presence of a smoker in the house (RR 1.63, 95% CI: 1.12-2.38), residing at higher altitudes (RR 1.93, 95% CI: 1.25-3.00 for 2nd compared to 1st quartile residents; RR 1.98, 95% CI: 1.26-3.13 for 3rd compared to 1st quartile residents). Having an unemployed household head was significantly associated with MPV risk (RR 2.11, 95% CI: 1.12-4.01). Conclusion: In rural high altitude communities in Peru, childhood ARI due to RSV or MPV were common and associated with higher morbidity than ARI due to other viruses or with no viral detections. The risk factors identified in this study may be considered for interventional studies to control infections by these viruses among young children from developing countries.

PNEUMONIA FORGOTTEN NO MORE: PNEUMONIA.ORG.AU

Brian Greenwood

London School of Hygiene &Tropical Medicine, London, United Kingdom

In 1992, pneumonia was described as the "forgotten pandemic" and remains the most common cause of childhood mortality in the developing world. In 2006 at ISPPD5 in Alice Springs, Australia, a declaration was issued for the development of a global action plan against childhood pneumonia. In 2009, at a Tri-Nation (Indonesia, Papua New Guinea and Australia) meeting held in Sydney, Australia, it was resolved to establish a journal dedicated to pneumonia. The pneumonia journal (www.pneumonia.org.au) was launched in 2012. Since that time, pneumonia has strived to be internationally recognised as the premier, open access,

peer-reviewed Journal for publishing on the topic of pneumonia. In December 2014, a Gates Foundation Grant was awarded to the Journal to assist with the development of a sustainable business platform. The esteemed Editorial Board currently has over 40 international members and regional Deputy Editor-in-Chiefs appointed in Australiasia, North and South America, Asia, Africa and Europe. pneumonia is indexed by Google Scholar and the Directory of Open Access Journals. An application has been made for Scopus listing and systems are in place for an application to MEDLINE and PubMed. Recognising the importance of rapid dissemination of research, a continuous publication model is used. To date over 20 manuscripts have been published with as many in the pipeline. The Journal site has been accessed from over 150 countries across all continents and has had over 80,000 page views with greater than 65% of these visits being from new visitors. pneumonia is currently partnered with the Lung Foundation Australia, the Influenza Specialist Group (Australia) and the World Pneumonia Day Coalition to advocate for and increase the awareness of pneumonia appropriate to a broad range of communities globally. pneumonia is published by Griffith University ePress and is supported by the University and philanthropic sources. pneumonia has a major commitment to becoming the international forum for the distribution of quality, peer-reviewed content on pneumonia and raising the global profile of the disease - to be forgotten no more!!

THE ROLE OF VASCULAR REMODELING IN THE IMMUNOPATHOLOGY OF *LEISHMANIA* INFECTION

Tiffany S. Weinkopff, Christoph Konradt, David Christian, Phillip Scott

University of Pennsylvania, Philadelphia, PA, United States

Cutaneous leishmaniasis is caused by intracellular protozoan parasites, and has a wide spectrum of clinical presentations mediated in large part by an exaggerated inflammatory response. Since vascular remodeling contributes to the magnitude of the inflammatory response, we hypothesized that manipulation of the cellular and molecular mediators promoting vascular remodeling might provide a novel approach to limit pathology in leishmaniasis. To address this, we first characterized the vascular remodeling that occurs in mice infected with ***Leishmania major***. We found dramatic changes in vessel morphology, structure, and number within leishmanial lesions, and using intravital imaging we visualized a significant increase in vascular permeability that is a consequence of vascular remodeling in leishmaniasis. At the peak of infection, VEGF-A and VEGFR-2 expression were upregulated and correspondingly endothelial cells were proliferating at the site of infection. To determine if these VEGF-mediated responses contributed to the magnitude of the pathology in the disease, we treated ***L. major*** infected mice with neutralizing antibodies directed against VEGFR-2. This treatment led to a decrease in the pathology seen in ***L. major*** infected mice compared with control animals. Taken together these data suggest that VEGF-A-mediated vascular remodeling occurs in leishmaniasis and that blockade of this remodeling can lessen the magnitude of the immunopathology associated with this disease.

1846

SKIN RESIDENT MEMORY CD4+ T CELLS ENHANCE PROTECTION AGAINST *LEISHMANIA MAJOR* INFECTION

Nelson D. Glennie[1], Venkata A. Yeramilli[1], Daniel P. Beiting[1], Susan W. Volk[1], Casey T. Weaver[2], Phillip Scott[1]

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]University of Alabama at Birmingham, Birmingham, AL, United States

Leishmania-infected patients become refractory to reinfection following disease resolution, and following a primary infection with ***Leishmania major*** C57BL/6 mice are highly resistant to reinfection, yet effective immune protection has not been achieved by vaccines. While circulating Leishmania-specific T cells are known to play a critical role in immunity, the role of memory T cells present in peripheral tissues has not been explored. We have identified a population of Leishmania-specific memory CD4+ T cells present in the skin of mice that have resolved a primary infection with ***L. major***. These cells are present in skin distant from the primary infection, and produce IFNγ in response to ***L. major*** stimulation. Using skin grafts we show that they are resident in the skin, rather than recirculating. Following ***Leishmania*** challenge, these cells enhance the early recruitment of circulating T cells to the skin in a CXCR3 dependent manner, resulting in better control of the parasites. Our findings indicate that protective immunity to Leishmania, and thus the success of a vaccine, may depend on generating both circulating and skin-resident memory T cells.

1847

LEISHMANIA MAJOR INFECTION INDUCES TRANSMISSIBLE ALTERATIONS IN THE SKIN MICROBIOME

Ciara Gimblet, Michael A. Loesche, Elizabeth A. Grice, Phillip Scott

University of Pennsylvania, Philadelphia, PA, United States

Cutaneous leishmaniasis is a disease characterized by ulcerating skin lesions, the resolution of which requires an effective, but regulated, immune response that limits parasite growth without causing permanent tissue damage. Studies have shown that skin commensals enhance the immune response to ***L. major***, but how the microbiome changes during infection has not been characterized. Using analysis of the 16S ribosomal RNA gene, we found that infection with ***L. major*** causes a loss in bacterial diversity during the peak of infection, resulting in a dominance of the genus Staphylococcus. However once the lesions resolved, bacterial diversity returned to pre-infection levels. Alternatively, when mice developed more severely ulcerated lesions, the proportion of Streptococcus significantly increased on the lesions, demonstrating that ***L. major*** induced alterations in the skin microbiome can vary depending on the severity of disease. Strikingly, we observed similar changes in the microbiome on non-inflamed skin distant from the infection site, as well as in skin from cohoused naïve mice. These results indicate that the altered skin microbiome present at the site of infection is transmissible to uninfected skin despite having different immune responses at these sites. Current studies are directed at defining what factors mediate the changes in the skin microbiome during ***L. major*** infection and how this transmissible microbiome influences disease.

1848

FACTORS ASSOCIATED WITH PROTECTION OR SUSCEPTIBILITY TO DEVELOPMENTS OF DISEASE IN HOUSEHOLD CONTACTS OF CUTANEOUS LEISHMANIASIS PATIENTS

Edgar M. Carvalho[1], Aline Muniz[1], Ednaldo Lago[1], Luiz Henrique Guimarães[1], Lucas Carvalho[1], Paulo Machado[1], Augusto Carvalho[1], Olívia Bacellar[1], Marshall Glesby[2]

[1]Federal University of Bahia, Salvador, Brazil, [2]Cornell University, New York, NY, United States

The majority of infected subjects in an area of L.braziliensis transmission have an asymptomatic or subclinical (SC) infection. While the Th1 response is important for ***Leishmania*** killing, in patients with cutaneous leishmaniasis (CL) T cell activation and production of pro-inflammatory cytokines are associated with pathology. To better determine factors related to susceptibility and resistance to disease we have established a cohort of 308 household contacts (HC) of CL patients without previous or current evidence of CL in the endemic area of Corte de Pedra, Bahia, Brazil. Chemokine and cytokine levels and ***Leishmania*** skin test (LST) were performed at entry and in the years 2 and 4, and the association of the immune response with clinical outcome was analyzed. The immunologic response of HC who develop disease with those who remained disease free was also compared. Based on LST and, or ***in vitro*** IFN-γ production in cultures stimulated with SLA 114 (37%) subjects had evidence of exposure

to L.braziliensis. In 55 (17,8%) of them the LST was positive but in these, IFN-γ was only detected in 36 (65,4%). Moreover in 59 HC only IFN-γ production was observed. After 4 years of follow up CL was documented in 44 (14,2%) of 308 HC. The incidence of CL per 100 persons-years was 0,92 in those who only produce IFN-γ and 4.2 in those with positive LST. The major source of IFN-γ were NK and CD4+ T cells. Monocytes from subjects with SC infection produce less oxidative burst than cells of CL patients upon L. braziliensis infection, but they had great ability to kill ***Leishmania*** independent of ROS and NO production. Our data indicate that a positive LST do not protect against CL due to L. braziliensis. Control of the infection was associated with IFN-γ production and negative LST and greater ability of monocytes to kill leishmaniasis.

1849

DYNAMICS OF ANTIGEN SPECIFIC CD4+ MEMORY T CELL RESPONSE DURING ACTIVE CUTANEOUS LEISHMANIASIS TO SIX MONTHS AFTER TREATMENT

Kenneth J. Gollob[1], Tatjana S. Keesen[2], Erica Vieira[3], Paulo Machado[4], Luis Guimarães[4], Edgar Carvalho[4], Walderez O. Dutra[3]

[1]Hospital Santa Casa-BH, Belo Horizonte, MG, Brazil, [2]Federal University of Paraiba, Paraiba, Brazil, [3]UFMG, Belo Horizonte, MG, Brazil, [4]UFBA, Salvador, Bahia, Brazil

Human cutaneous leishmaniasis is a devastating tropical disease that affects millions globally and for which no effective vaccine exists. While there are effective treatments, problems with toxicity, compliance and resistance are serious issues that point to the need for the development of new treatments and vaccines. The immunoregulatory environment in individuals actively infected with L. braziliensis is a key factor associated with development or resolution of disease. Our understanding of the balance between memory cell compartments in active disease and following cure is not well understood. Thus, we undertook studies designed to investigate the balance between antigen specific CD4+ T cell memory subpopulations during active disease and six months after treatment. We report findings of CD4+ T cells from three compartments: central memory (CM (CD45RA-,CCR7+)), effector memory (EM (CD45RA-,CCR7-)) and naïve (CD45RA+,CCR7+) as defined using multiparameter flow cytometry in a group of 13 CL patients following overnight cultures in media, with Soluble ***Leishmania*** Antigen (SLA) or polyclonal stimuli (anti-CD3/CD28). Our results indicate that in active disease and 6 months following treatment, the distribution of CD4+ subpopulations did not change and was on average; 30% CM, 45% EM and 20% naïve. We demonstrated significant increases in the frequency of cells expressing CD69, and the inflammatory cytokines; IFN-gamma and TNF-alpha, within the EM cell population following SLA stimulation. Interestingly, IL-10 producing cells where were not biased to the EM population and distributed between EM and CM. Six months post treatment, cultures stimulated with SLA showed a decrease in EM cells expressing CD69, IL-17 and IL-10, while IFN-gamma, TNF-alpha and granzyme A producing EM T cells were maintained at similar levels or increased to that seen in active disease. There was a striking maintenance of the overall subpopulation balance during active disease and six months following treatment. These findings could help understand the balance between CD4+ T cell subpopulations and their maintenance over time after disease resolution.

1850

DEVELOPMENT OF A CANDIDATE LEISHMANIASIS VACCINE LEISH-F3 + GLA-SE

Rhea N. Coler[1], Malcolm S. Duthie[1], Kimberly A. Hofmeyer[1], Lakshmi Jayashankar[1], Jill Ashman[1], Randall F. Howard[1], Anna Marie Beckmann[1], Dinesh Mondal[2], Steven G. Reed[1]

[1]Infectious Disease Research Institute, Seattle, WA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Key antigens of ***Leishmania*** species identified in the context of host responses in ***Leishmania***-exposed individuals were prioritized for the development of a subunit vaccine against visceral leishmaniasis (VL). Two ***Leishmania*** proteins – nucleoside hydrolase (NH) and a sterol 24-c-methyltransferase (SMT), each of which are protective in animal models of VL when properly adjuvanted – were produced as a single recombinant fusion protein NS (LEISH-F3) for ease of antigen production and broad coverage of a heterogeneous MHC population. When formulated with GLA-SE, a TLR4 TH1-promoting adjuvant, the LEISH-F3 polyprotein induced potent protection against both L. donovani and L. infantum in mice. A robust immune response to each component of the vaccine with polyfunctional CD4 TH1 cell responses, characterized by production of antigen-specific IFN, TNF, and IL-2, and low levels of IL-5 and IL-10, was induced in immunized mice. Based on the sum of pre-clinical data, we prepared GMP materials and performed a Phase 1 clinical study with LEISH-F3 + GLA-SE in healthy, uninfected adults in the United States. The vaccine candidate was shown to be safe and induced a strong antigen-specific immune response, as evidenced by cytokine and immunoglobulin subclass data. These data provide a strong rationale for additional trials in ***Leishmania***-endemic countries.

1851

EVALUATION OF *TRYPANOSOMA CRUZI*-SPECIFIC HUMORAL TO T CELL RESPONSES AFTER THERAPY WITH BENZNIDAZOLE IN CHILDREN IN THE EARLY CHRONIC PHASE OF CHAGAS DISEASE

Maria C. Albareda[1], Ana María De Rissio[1], Marisa Fernandez[1], Alicia Serjan[2], Gretchen Colley[3], Maria G. Alvarez[4], Laura Fichera[1], Rodolfo Viotti[4], Rick L. Tarleton[3], Susana A. Laucella[1]

[1]Instituto Nacional de Parasitologia Dr M Fatala Chaben, Buenos Aires, Argentina, [2]Hospital Fernandez, Buenos Aires, Argentina, [3]University of Georgia, Athens, GA, United States, [4]Hospital General Interzonal de Agudos Eva Peron, Buenos Aires, Argentina

We have previously shown that children in the indeterminate phase of Chagas disease have polifunctional T cells specific for ***T. cruzi***, while the overall T cell compartment already shows signs of persistent antigen stimulation. In this study, the effect of treatment with benznidazole on humoral and cellular T cell responses specific for ***T. cruzi***, as well as on the phenotype of the overall T cell compartment was evaluated in 21 ***T. cruzi***-infected children. Treatment with benznidazole induced an early decline in the total frequencies of activated (HLA-DR+) and highly differentiated memory (CD45RA-CD27-CD28-) and effector (CD45RA+CCR7-CD62L-) T cells along with a decrease in ***T. cruzi***-specific IFN-γ- and IL-2-producing T cells. A significant fall in antibody levels specific for ***T. cruzi***, as measured by the conventional serological tests, ELISA, immunofluorescence and hemagglutination, after 36 months following treatment with benznidazole was found. The non-conventional multiplex assay also detected a significant impact on humoral responses by 6 months post-treatment. The early decline in antibody levels found in children is in contrast with that observed in adults in which the fall in antibody levels is very slow. Our results show a significant impact on humoral and T cell responses after treatment with benznidazole which might be indicative of a reduction in parasite load.

1852

SMALL RNA SIGNATURES OF A MIDGUT ESCAPE BARRIER IN *CULEX QUINQUEFASCIATUS* MOSQUITOES INFECTED BY WEST NILE VIRUS

Abhishek Prasad[1], Doug Brackney[1], Claudia Rueckert[1], Darci Smith[1], Selene Garcia-Luna[1], Corey Campbell[1], Jennifer Beane[2], **Gregory D. Ebel**[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Boston University, Boston, MA, United States

Small RNA regulatory pathways (SRRPs) are important regulators of endogenous pre- and post-transcriptional control in metazoans. The role of SRRPs such as the exogenous small-interfering RNA (exo-siRNA), PIWI-interacting RNA (piRNA) and microRNA (miRNA) pathways in controlling arbovirus infection in insects has been the subject of intense study in recent years. The role of any of these pathways in vector competence, however, is poorly understood. To evaluate how SRRPs may contribute to vector competence, we identified ***Cx. quinquefasciatus*** mosquitoes that were susceptible to WNV but did not permit virus escape from the midgut into peripheral compartments after 14 days of extrinsic incubation. We then compared sRNA expression from these "elite controllers" of WNV to those that permitted virus dissemination. In particular we compared the intensity of sRNA targeting of the WNV genome, differential production of virus-derived small interfering RNAs (viRNAs) reads, and miRNA expression among these two groups of mosquitoes. We found that viRNAs differentially target 1,519 positions of the WNV genome, and that 177 reads are differentially produced between groups. The most significantly differentially targeted positions and expressed viRNA reads targeted conserved structures in the 3'utr of the WNV genome. Similar results were obtained from analysis of sRNA reads corresponding to a larger size class (24-30nt in length). 1076 WNV genome positions were differentially targeted, but only 3 sRNA reads were differentially produced. These reads also tended to target conserved structures in the WNV 3'utr. A miRNA signature associated with the elite controller phenotype was also detected. These results indicate that SRRPs contribute to the formation of a midgut escape barrier in ***Cx. quinquefasciatus*** mosquitoes and provide novel insights into the molecular mechanisms that underpin vector competence in the Culex-WNV system.

1853

AVIAN INNATE IMMUNE RESPONSES TO WEST NILE VIRUS INFECTION

Nisha Duggal, Aaron C. Brault

Centers for Disease Control and Prevention, Fort Collins, CO, United States

Since the first reports of West Nile virus (WNV) in the U.S. in 1999, WNV has been maintained in North America in an enzootic cycle between highly susceptible passerine birds and mosquitoes. However, the mortality of passerine birds in response to WNV infection and the capacity for viral replication vary dramatically between viral strains and avian species. For example, American crows (AMCRs) inoculated with the North American strain of WNV (NY99) manifest high viremias with concomitantly high mortality rates. However, AMCRs inoculated with an African strain of WNV (KEN98) exhibit significantly lower viremias and mortality rates. In contrast, the viremias and mortality rates of NY99 and KEN98 are not significantly different in inoculated house sparrows (HOSPs). In order to understand these viral- and host-specific differences in WNV replication and mortality, the expression levels of avian interferon genes and other innate immune factors potentially involved in regulating WNV replication were measured by qRT-PCR in samples taken from AMCRs inoculated with NY99 or KEN98. To further probe the avian interferon response to WNV infection, AMCRs and HOSPs were inoculated with a WNV mutant lacking 2'-methyltransferase activity (NS5-E218A) that has been shown to be susceptible to restriction by the interferon-stimulated gene family IFIT in mammals. Replication of the NS5-E218A mutant virus was severely retarded in both avian species, suggesting that AMCR and HOSP antiviral responses are robust. However, ***in vitro*** WNV infectivity assays in cells overexpressing avian IFIT genes show that the avian IFIT homolog does not restrict the NS5-E218A mutant virus. Further studies of infected birds, including sequencing of the avian transcriptome, will help to define the passerine innate immune response to WNV infection.

1854

DECONSTRUCTING THE NEUTRALIZING ANTIBODY RESPONSE ELICITED BY A WEST NILE VIRUS VACCINE CANDIDATE

Leslie Goo, Julie E. Ledgerwood, Ted C. Pierson

National Institutes of Health, Bethesda, MD, United States

There is no licensed vaccine or therapy to protect humans against West Nile virus (WNV), a mosquito-borne encephalitic flavivirus. Although neutralizing antibodies (NAbs) are a correlate of protection for existing flavivirus vaccines, the epitopes recognized by anti-WNV NAbs are unknown. The main target of flavivirus NAbs is the E protein, which contains three structural domains (DI, DII, DIII). Two recent studies showed that, despite low sequence conservation, a flexible hinge between DI and DII is a primary target of NAbs against multiple DENV serotypes, raising the possibility that this region is a functionally important target of flavivirus NAbs. To explore the role of the hinge as a target of WNV NAbs, we created a library of E variants containing 31 mutations in surface-accessible hinge residues. Reporter virus particles incorporating each variant were tested for infectivity and characterized using a panel of well-characterized monoclonal antibodies (mAbs) to identify confounding changes in virion conformational integrity. An unexpectedly large fraction (18/31) of the hinge region variants displayed altered sensitivity to mAbs targeting poorly accessible distal epitopes. Preliminary characterization of one of these variants suggests that the overall changes in antigenicity were due to altered virion conformational dynamics, which allows the transient exposure of otherwise inaccessible epitopes. The remaining hinge mutations that did not alter overall antigenicity were tested for neutralization sensitivity to sera from recipients of a candidate WNV vaccine. We identified a combination of two mutations at proximal residues on the E protein that reduced neutralization potency of sera from multiple donors, suggesting a significant contribution of NAbs against the hinge to the overall neutralizing activity of polyclonal sera. Overall, these results will provide insight into the importance of DI-DII hinge in eliciting protective NAb responses against flaviviruses, and in regulating virion conformational changes.

1855

INFECTION, DISSEMINATION TO TRANSMISSION OF JAPANESE ENCEPHALITIS VIRUS IN NORTH AMERICAN *CULEX* MOSQUITOES

Yan-Jang S. Huang[1], Susan M. Hettenbach[1], Julie N. Harbin[1], Stephen Higgs[1], Alan D. Barrett[2], Elin Maki[3], Lee W. Cohnstaedt[3], Dana L. Vanlandingham[1]

[1]Kansas State University, Manhattan, KS, United States, [2]University of Texas Medical Branch, Galveston, TX, United States, [3]United States Department of Agriculture, Manhattan, KS, United States

Japanese encephalitis virus (JEV) is a flavivirus transmitted by ***Culex*** species mosquitoes in Asia and sporadically Australia and Western Pacific. Because of the variation in surveillance and diagnostic methods, the true global incidence of Japanese encephalitis virus remains unknown with an estimated annual case number greater than 55,000. The geographic distribution of JEV has changed significantly in the last 30 years as JEV has expanded its geographic range. More recently, the detection of JEV viral nucleic acids was reported in ***Cx. pipiens***in Italy and subsequently raised the concern of the emergence of JEV in Europe. With the presence of several species of ***Culex*** mosquitoes that are vectors in JEV endemic areas, susceptible vertebrate hosts present and no vaccination program implemented, the continuous threat of introduction of JEV into

North America remains a human and veterinary public health concern. Studies to determine the vector competence of North American ***Culex*** populations for the transmission of JEV are currently lacking. In this study, selected ***Culex*** species mosquitoes were orally challenged with JEV and characterized for viral infection and dissemination by the detection of infectious virions of JEV. Transmission of JEV was also evaluated by RT-PCR of viral nucleic acids in mosquito saliva.

1856

POTENTIAL FOR CO-INFECTION OF A NOVEL MOSQUITO-SPECIFIC FLAVIVIRUS TO BLOCK HUMAN FLAVIVIRAL DISEASE AGENT INFECTION AND/OR TRANSMISSION IN MOSQUITOES

Silvina Goenaga[1], Joan L. Kenney[2], Nisha K. Duggal[2], S. Levis[1], Delia Enria[1], **Aaron C. Brault**[2]

[1]Instituto Nacional de Enfermedades Virales Humanas, Pergamino, Argentina, [2]Centers for Disease Control and Prevention, Fort Collins, CO, United States

Nhumirim virus (NHUV) represents an example of a unique subset of apparently insect-specific viruses that phylogenetically affiliate with dual-host mosquito-borne flaviviruses. Previous ***in vitro*** co-infection experiments indicated that prior or concurrent infection of mosquito cells with NHUV resulted in a 10,000-fold reduction in viral production of West Nile virus (WNV). In order to assess the potential for ***in vivo*** blockage of medically important flaviviruses in mosquitoes by NHUV, ***Cx. quinquefasciatus*** mosquitoes were intrathoracically inoculated with approximately 1,000 PFU of NHUV and 100 PFU of WNV or solely with WNV as a control. Mosquitoes were allowed to extrinsically incubate the viruses for 3, 5, 7 or 9 days prior to saliva collection by capillary tubes and subsequent trituration of the bodies for assessment of transmissibility and relative replication of the viruses, respectively. Results demonstrated 100% WNV infection of mosquitoes at all four time points in the control groups. Similarly, NHUV and WNV experimental co-infection groups exhibited 100% WNV infection at dpi 5,7 and 9 with 90% infection rates in the co-inoculated group at dpi 3. No significant differences in the mean viral titer from triturated bodies were observed at any time point between the dual and control WNV inoculation groups. Although there was an observed trend for the WNV titers in saliva to be higher in the control group compared to the dual infection group, this difference was not significant. Nevertheless, the proportion of mosquitoes (≥ 21 mosquitoes/ sampling) that were capable of transmitting WNV was significantly lower for the WNV/NHUV group than the WNV control at dpi 3, 7 and 9. By dpi 9, a 40% reduction in transmissibility in mosquitoes from the dual inoculation group was observed compared to the WNV control. These data indicate the potential that infection of ***Culex*** vectors with NHUV could serve as a barrier for efficient transmissibility of flaviviruses associated with human morbidity/mortality.

1857

A THREE-DIMENSIONAL, MULTICELLULAR LIVER MODEL TO STUDY TRANSCRIPTIONAL ACTIVATION OF INNATE IMMUNE RESPONSE TO HEPATIC METABOLISM FOLLOWING INFECTION WITH WILD-TYPE OR ATTENUATED YELLOW FEVER VIRUS

Nicolas Masse-Deragon[1], Nathalie Mantel[2], Catherine Legras-Lachuer[1], **Veronique Barban**[2]

[1]Université Lyon 1, Lyon, France, [2]Sanofi Pasteur, Marcy-L'Etoile, France

Most commercial Yellow Fever (YF) vaccines are based on the attenuated YF17D-204 strain derived by serial cultivation of wild-type YF Asibi virus. YF virus is highly hepatotropic ***in vivo*** and can replicate ***in vitro*** in human hepatocytes. No restriction of YF17D-204 replication, compared to YF Asibi, was observed in these cells. However, other liver cells populations like endothelial and macrophage cells were previously shown to be affected by YF virus infection, ***in vivo*** and ***in vitro***, and could play a role in infection control. We have used a cell-spheroid liver model (InSphero™) including major human liver primary cells (hepatocytes, Kupffer and liver endothelial cells) to study transcriptional regulations following infection with YF viruses. Spheroids composed of primary hepatocytes only were used as controls. About 400 genes related to innate immunity and hepatic metabolism were analyzed by PCR array at different times post-infection. No difference in transcriptional regulation of apoptosis-related genes (TNF-α, FASL, TRADD) was seen between the 2 viruses. YF17D-204 infection was shown to induce earlier and stronger activation than YFAsibi infection (p-value<0.05) of type III (IFNλ1 and IFNλ2) and type I β (but not α) interferons, as well as a larger panel of ISGs. YF17D-204 infection also generated distinct JAK/STAT pathway regulations in liver spheroids and in hepatospheroids, suggesting that liver spheroids may respond hierarchically to infection, the non-parenchymal cells response shaping the hepatocytes one. Whole transcriptome analysis was also carried out by RNA-Seq at 11h post-infection. Analysis of upstream transcription regulators (Ingenuity® Pathway Analysis) confirmed the establishment of a strong, early antiviral profile after YF17D-204 infection (z-scores: 2.7-5.0, p-values<10-10) and predicted transcription regulation of liver metabolism-related genes after YFAsibi infection(|z-score|≥2.3, p-value<10-3). Ongoing RNA-Seq studies at later infection times will provide more information on the ability of this liver model to mimic metabolic changes following wt Asibi infection ***in vivo***.

1858

COMPREHENSIVE MUTAGENESIS OF HCV E1/E2 ENVELOPE TO EPITOPE MAP ANTI-ENV ANTIBODIES TO FUNCTIONAL RESIDUES CRITICAL FOR HCV INFECTIVITY

Jennifer M. Pfaff, Trevor Barnes, Edgar Davidson, Benjamin J. Doranz

Integral Molecular, Inc., Philadelphia, PA, United States

To obtain epitope maps for anti-HCV Envelope (E1/E2) monoclonal antibodies (MAbs), we individually mutated 552 residues of HCV (H77 strain) E1/E2 to alanine. Each mutant was expressed in human cells and analyzed for its effects on MAb reactivity. This 'Shotgun Mutagenesis' approach offers the capability of mapping both linear and conformational epitopes, even for structurally complex proteins such as the oligomeric and glycosylated HCV Envelope protein. This approach identified critical amino acids required for the binding of dozens of MAbs, and has also been used to propose E2 disulfide bond cysteine pairs that are not resolved by the available E2 crystal structures. This approach has helped define the range of immunodominant structures on HCV E1/E2 and identify novel neutralizing antibody epitopes that can be used for the development of improved therapeutics, diagnostics, and vaccine candidates. In addition, to identify residues important for HCV infectivity we produced infectious HCV pseudoviruses from each mutant Env clone in the library. These pseudoviruses were used to evaluate each Env clone for infectivity on target cells. This allowed us to identify critical E1/E2 residues whose mutation eliminated HCV infectivity, identifying crucial HCV E1/E2 structural components that enable HCV infectivity.

1859

UNDERSTANDING THE DISTRIBUTION OF CHOLERA BURDEN TO RISK IN AFRICA: SPATIAL MODELING TO GUIDE PREVENTION TO CONTROL EFFORTS

Sean M. Moore, Andrew A. Azman, Justin Lessler

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

There are an estimated 2.8 million cholera cases per year globally, but the majority of these cases are not detected or reported. Because of inadequate surveillance and reporting the global distribution of cholera risk and its public health burden are poorly known. Previous attempts to determine the burden of cholera globally, and specifically in Africa, have

relied on a limited number of case studies that do not capture the broad range of settings and environmental conditions where cholera occurs. Here we assemble a large database of cholera surveillance and incidence reports from a variety of government, scientific, and non-governmental agency sources, with a particular focus on sub-Saharan Africa where a majority of cholera cases have been reported in the past several decades but where the distribution of risk and burden is still poorly understood. We develop a hierarchical Bayesian modelling framework to estimate the cholera incidence and risk at a 5km scale across the entire African Continent. Our method allows us to synthesize environmental and socioeconomic variables with cholera incidence reports at different spatial and temporal scales and estimate cholera incidence at a high spatial resolution. Preliminary results for 10 countries in West Africa indicate a cumulative cholera incidence rate of 3.3 per 100,000 since 2009 with local incidence rates as high as nearly 8,000 per 100,000. Over four million people in these countries live in area with an annual incidence rate >100 per 100,000. The resulting maps can be used to identify areas of high or low incidence (and risk) at finer spatial scales than the country-level, such as the province, district, or city-level. Work is ongoing to expand the model globally and incorporate additional explanatory variables. Improving our understanding of the spatial distribution of cholera and associating incidence with climate, environmental and socioeconomic factors will provide a basis for planning public health preventions to reduce cholera transmission.

1860

LABORATORY EVALUATION OF IMMUNOCHROMATOGRAPHIC RAPID DIAGNOSTIC TESTS FOR CHOLERA IN HAITI

Wilfredo R. Matias[1], Abelard Cademil[2], Fabrice E. Julceus[2], Leslie M. Mayo-Smith[3], Molly F. Franke[1], Jason B. Harris[3], Louise C. Ivers[4]

[1]Harvard Medical School, Boston, MA, United States, [2]Zanmi Lasante, Saint Marc, Haiti, [3]Massachusetts General Hospital, Boston, MA, United States, [4]Brigham & Women's Hospital, Boston, MA, United States

Rapid diagnostic tests (RDTs) for cholera play a key role in responding to cholera epidemics. Because microbiological culture capacity is often non-existent in resource-poor settings where most cholera epidemics occurs, RDTs can allow early identification of ***Vibrio cholerae*** as the causative agent in outbreaks, facilitating the deployment of rapid public health measures. Despite their importance, evidence on the performance characteristics of the many available RDTs for cholera is scarce. This study evaluated the performance characteristics of two cholera RDTs: Span Diagnostic's Crystal VC O1/O139 RDT, and Standard Diagnostic's SD Bioline Cholera O1/O139 RDT, in a regional laboratory in Haiti, where a protracted cholera epidemic is now in its fifth year. We retrospectively reviewed de-identified records from May 2014 to January 2015 of a laboratory-based surveillance program for ***Vibrio cholerae*** at Hôpital Saint-Nicolas in Saint-Marc, Haiti. We analyzed 189 Crystal VC RDT results and 233 SD Bioline RDT results and compared these to culture results as the gold standard. Of 236 cultures, 125 were positive for O1, 15 were positive for non-O1, and 96 were negative for ***V. cholerae***. Crystal VC demonstrated a sensitivity of 98.8% (95% CI: 96.5%-100%) and specificity of 72.1% (95% CI: 63.5%-80.7%). Notably, we documented a high percentage of ***V. cholerae*** O139 positive results, with 39% of all tests showing positive results for O139. Given the absence of ***V. cholerae*** O139 in Haiti, these are likely a result of cross-reactivity. SD Bioline demonstrated a sensitivity of 77.7% (95% CI: 70.3%-85.1%) and specificity of 93.7% (95% CI: 89.2%-98.2%). SD Bioline did not demonstrate the O139 cross-reactivity seen with Crystal VC, as no O139 positive results were documented. This study highlights the suboptimal specificity of Crystal VC, and brings attention to a high rate of O139 cross reactivity, a characteristic that may adversely impact its interpretation in the field. Additionally, it is the first study to document the performance characteristics of the SD Bioline RDT that unlike other available cholera RDTs, shows high specificity but low sensitivity.

1861

'O ANTIGENIC' POLYSACCHARIDE SPECIFIC MEMORY B CELL RESPONSES IN YOUNG CHILDREN, OLDER CHILDREN TO ADULTS INFECTED WITH *VIBRIO CHOLERAE* O1 OGAWA IN BANGLADESH

Amena Aktar[1], M. Arifur Rahman[1], Sadia Afrin[1], Aklima Akter[1], Taher Uddin[1], Omar Faruk[1], Israk Nur Sami[1], Tahirah Yasmin[1], Fahima Chowdhury[1], Ashraful I. Khan[1], Daniel T. Leung[2], Pavol Kovac[3], Peng Xu[3], Stephen B. Calderwood[2], Jason B. Harris[2], Firdausi Qadri[1], Edward T. Ryan[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, [3]National Institutes of Health, Bethesda, MD, United States

Infection with ***Vibrio cholerae*** O1 causes the cholera, which can be life threatening if quick and proper treatment is not given especially in severe dehydrating cases. It has been considered that long term protection against cholera may be mediated by anamnestic memory B cell responses after natural infection with ***V. cholerae*** O1. Protection against cholera is serogroup specific, and serogrouping is defined by the O-specific polysaccharide (OSP) of lipopolysaccharide (LPS). We determined Ogawa O-specific polysaccharide (OSP) and Lipopolysaccharide (LPS) specific memory B cell responses as well as other immune responses in Bangladesh in patients with cholera. They included young children (2 to 5 years of age; n= 11), older children (6 to 17 years of age; n=21) and adults (18 to 55 years of age; n=28). Patients were studied after hospitalization (day 2) as well as at convalescence at day 7, day 30, day 90 and day 180. We observed vibriocidal antibody responses that lasted up to the follow up periods ($P<0.05$) in both older children and adults while responses decreased to the baseline levels by 3 months in younger children. Patients of all age groups developed OSP and LPS specific plasma IgA, IgG and IgM antibody responses within 7 days ($P<0.01$) of onset of disease which decreased to baseline values at convalescence at 6 months; adults showed higher OSP and LPS specific antibody responses than children. We also found that in all age groups OSP specific IgA and IgG memory B cell responses developed within 30 days of illness, which persisted throughout the follow-up period. In addition, they also developed LPS specific IgA memory B cell by day 30 ($P <0.02$). All age groups had comparable memory B cell responses to OSP and LPS while children had higher OSP IgA memory B cell responses than adults ($P <0.05$) on days 30 and 180. We describe for the first time OSP-specific memory B cell responses in all age groups of cholera patients and show that the responses persist over the study period, which suggest that OSP-specific memory B cell may play a role in mediating long term immunity against cholera.

1862

CHARACTERIZATION OF DUODENAL MUCOSAL ASSOCIATED INVARIANT T (MAIT) CELLS IN *VIBRIO CHOLERAE* INFECTION

M. Arif Rahman[1], Taufiq R. Bhuiyan[1], Mohammad Rubel Hoq[1], Rasheduzzaman Rashu[1], Mohammad Ikhtear Uddin[1], Amena Aktar[1], Ashraful I. Khan[1], Fahima Chowdhury[1], Jason B. Harris[2], Stephen B. Calderwood[2], Edward T. Ryan[2], Firdausi Qadri[1], **Daniel T. Leung**[3]

[1]Centre for Vaccine Science, International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Division of Infectious Diseases, Massachusetts General Hospital, Boston, MA, United States, [3]Division of Infectious Diseases, University of Utah, Salt Lake City, UT, United States

Cholera is an acute dehydrating diarrheal disease caused by ***Vibrio cholerae*** O1 infection. The mechanisms of protection against cholera are not well known. MAIT cells are recently described innate-like T cells with adaptive capacity. We have previously shown that circulating MAIT cells are activated during cholera and associated with ***V. cholerae*** LPS-specific antibody responses. The objective of this study was to characterize MAIT

cells in the intestinal mucosa during cholera. We collected peripheral blood and duodenal biopsy specimens by endoscopy from adults with confirmed ***V. cholerae*** O1 infection at days 2 and 30 after onset of disease. Preliminary data using multispectral fluorescence microscopy suggest that MAIT cells are mostly present in the crypt of the duodenal lamina propria and are more abundant at day 2 post illness compared with day 30. Using flow cytometry, we found that a greater percentage of duodenal MAIT cells are activated (CD38+) than those in the periphery at both time points. Stool alpha-1-antitrypsin, a marker of intestinal permeability, was correlated with a decrease in % of activated MAITs between days 2 and 30. More complete results, including analysis of corresponding LPS-specific antibody responses, will be available at time of presentation.

1863

SMALL INTESTINE BACTERIAL OVERGROWTH IN BANGLADESHI TWO YEAR OLDS

Jeffrey Donowitz[1], Rashidul Haque[2], Beth Kirkpatrick[3], Jennie Ma[4], Masud Alam[2], Miao Lu[4], Ross Colgate[3], William Petri[4]

[1]Virginia Commonwealth University, Richmond, VA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of Vermont, Burlington, VT, United States, [4]University of Virginia, Charlottesville, VA, United States

Small intestine bacterial overgrowth (SIBO) has been associated with adverse nutritional outcomes, intestinal inflammation, and increased intestinal permeability when overgrowth is secondary to preexisting intestinal pathology. Children living in unsanitary conditions have high rates of SIBO despite having no predisposing condition. Limited information is known about the detrimental effects of SIBO when overgrowth develops in the setting of poor sanitation. We tested for SIBO via glucose hydrogen breath testing at 2 years of age in a cohort of 90 Bangladeshi infants. Children had C-reactive protein (CRP), endotoxin core- antibody (endocab), fecal Reg 1β, Lactulose:Mannitol ratio (L:M), and anthropometric indices measured. All children were previously enrolled in the PROVIDE study, a longitudinal birth cohort designed to investigate oral vaccination failure and environmental enteropathy. As part of PROVIDE, an extensive collection of biomarkers for enteropathy as was available. This data was analyzed via multivariate logistic regression and smoothly clipped absolute deviation (SCAD) to identify possible predictors of SIBO from a set of 50 biomarkers collected during the first 24 weeks of life. The incidence of SIBO was 16.7% (15/90). Children with SIBO had a greater mean loss in height-for-age Z score from birth to 2 years than those without (-.86 versus -.35, p value 0.03). Mean Reg 1β was higher in the children with overgrowth (116.75 µg/ml versus 65.62 µg/ml, p value .022). CRP, L:M, and endocab, were not statistically different in children with SIBO. Serum zinc level and fecal calprotectin were identified via both logistic regression and SCAD as possible predictors of SIBO. This data shows that SIBO due to unsanitary living conditions is associated with intestinal epithelial cell damage but not increased systemic inflammation. An increased rate of stunting in the first 2 years is associated with the development of SIBO which, along with increased fecal calprotectin and serum zinc levels in infancy, may represent a phenotypic predisposition to development of SIBO in the developing world setting.

1864

A COMPARISON OF DIARRHEAL SEVERITY SCORES IN A MULTISITE COMMUNITY BASED STUDY

Gwenyth Lee[1], Stephanie Richard[2], Gagandeep Kang[3], Eric Houpt[4], Jessica Seidman[2], Laura Pendergast[5], Richard L. Guerrant[4], Laura E. Caulfield[1], Robert E. Black[1], Margaret Kosek[1]

[1]Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]Fogarty International Center, National Institutes of Health, Bethesda, MD, United States, [3]Christian Medical College, Vellore, India, [4]University of Virginia, Charlottesville, VA, United States, [5]Temple University, Philadelphia, PA, United States

There is a lack of consensus on how best to measure diarrheal severity. Several severity scores based on caregiver-reported symptoms have been published, but the performance of these in relation to child health outcomes is unclear. The MAL-ED study is a multi-site, prospective birth cohort. In this report, we describe a modified Vesikari score (MAL-ED score), as well as two previously published severity scores, one by Clark and colleagues, and one derived from a Peruvian cohort study (Community Diarrheal Severity (CODA) score). The association between these scores and the risk of hospitalization was tested by means of receiver operating characteristic analysis, and each score was also related to short-term weight gain, illness etiology, and moderate-to-severe diarrhea (MSD) as defined by dysentery, health-care worker diagnosed dehydration, or hospitalization. A total of 9,803 episodes of non-persistent diarrhea from 1681 unique children were considered. There were 135 cases of hospitalization and 1,147 episodes (11.7%) met the definition of MSD. The area under the curve of each score as a predictor of hospitalization was 0.82 (Clark), 0.84 (MAL-ED), and 0.87 (CODA). Agreement with MSD diarrhea was lower (AUC= 0.65, 0.68, 0.70 for Clark, MAL-ED, and CODA respectively). Relative to enteropathogen-negative episodes, mean scores were higher during rotavirus- and adenovirus-positive diarrhea and lower during campylobacter- and giardia-positive diarrhea; and the mean MAL-ED or CODA scores were also significantly higher during astrovirus-, ETEC-, norovirus- and cryptosporidium-positive illness. Although families were more likely to seek care for severe diarrhea across all sites, our results also suggest that a large percentage of these cases never reached the health care system. Diarrhea severity scores based on maternal report are able to predict relevant child health related outcomes. They may therefore be useful in estimating the burden of disease, and the impact of disease control interventions, in community-based studies where not all episodes will necessarily reach the health care system.

1865

ASSOCIATION BETWEEN ENTEROPATHOGENS TO MODERATE-TO-SEVERE MALNUTRITION IN CHILDREN AGED 6-24 MONTHS IN DHAKA, BANGLADESH (MAL-ED): A CASE-CONTROL STUDY

James A. Platts-Mills[1], Mami Taniuchi[1], Md. Jashim Uddin[2], Shihab U. Sobuz[2], Mustafa Mahfuz[2], Md. Abdul Gaffar[2], Dinesh Mondal[2], Md. Iqbal Hossain[2], Munirul Islam[2], William A. Petri[1], Rashidul Haque[2], Eric R. Houpt[1], Tahmeed Ahmed[2]

[1]University of Virginia, Charlottesville, VA, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

The association between individual enteropathogens or cumulative pathogen burden and malnutrition in the absence of diarrheal disease remains poorly understood. As part of the MAL-ED study, we sought to identify pathogens associated with malnutrition by performing a case-control study of children presenting to a nutrition clinic in Dhaka, Bangladesh. Moderate to severely underweight children [weight for age Z score (WAZ) <-2] aged 6-24 months were enrolled as cases, and better nourished children aged 6-24 months (WAZ > -1) were enrolled as controls. All stools (500 cases and 480 controls) were tested using conventional bacterial culture as well as PCR for diarrheagenic E. coli

subtypes and by enzyme immunoassay (EIA) for rotavirus, adenovirus, astrovirus, ***Entamoeba histolytica, Giardia***, and ***Cryptosporidium***. A random subset of 202 cases and controls were also tested for a broader range of pathogens with arrayed, singleplex quantitative PCR using TaqMan Array Cards (TAC). The association between pathogens and malnutrition was estimated using age- and sex-adjusted logistic regression. By conventional culture, only detection in stool of ***Campylobacter*** was associated with malnutrition. In the subset tested by TAC, ***Campylobacter***, LT-ETEC, Aar-negative EAEC, Shigella, Norovirus GII and Giardia detection were associated with malnutrition. This set of pathogens was used to define a pathogen burden score. In a multivariate model, age, drinking water outside of the home and pathogen burden were associated with malnutrition, and higher income was associated with better nourished children. In this exploratory analysis, a subset of pathogens were identified for incorporation into a metric of pathogen burden, which could be validated in other studies of early childhood growth. Pathogen burden was an independent risk factor for malnutrition.

1866

URBAN MALARIA RISK CHARACTERISTICS FROM MULTIPLE METRICS OF THE URBAN-TO-RURAL CONTINUUM: RELATIONSHIPS WITH *ANOPHELES* VECTOR ABUNDANCES IN BLANTYRE, MALAWI

Mark L. Wilson[1], Nicole F. Dear[1], Themba Mzilahowa[2], Don P. Mathanga[3], Terrie E. Taylor[4], Edward D. Walker[4]

[1]University of Michigan School of Public Health, Ann Arbor, MI, United States, [2]Malaria Alert Centre, College of Medicine, University of Malawi, Blantyre, Malawi, [3]College of Medicine, University of Malawi, Blantyre, Malawi, [4]Michigan State University, East Lansing, MI, United States

Malaria risk in urban, peri-urban, and urban slum settings is becoming a major concern as urbanization swells in malaria endemic countries. Analysis of such malaria risk is complicated by multiple definitions of what is "urban," but also by uncertainty in where transmission occurs. We analyzed household-level Anopheles mosquito abundance patterns across an urban-to-rural continuum in and around the city of Blantyre, Malawi. As the country's "commercial capital," Blantyre (~1.1M pop.) has highly diverse land use/land cover (LU/LC) inside its ~225 sq km city limits. Mosquito abundance was sampled during the rainy and dry seasons of 2015 with light-traps and aspiration at 320 houses in 64 locations situated ~2.5km equidistant along 8 transects radiating outward from the city center. Using household geolocations, GIS-based data on geographical features, and satellite-image derived LU/LC, the urban-rural status of each household was classified by various metrics, including census population, house density, peri-domestic vegetation/agriculture, proximity to roads/infrastructure and a PCA-derived "urbanicity score." Multi-level statistics (e.g. households, locations, census areas) and spatial statistics (e.g. clustering, autocorrelation, interaction) were used to evaluate mosquito abundance in relation to traditional and derived urban-rural classifications. Results indicated that Anopheles indoor abundance generally increased with distance from the city center, but this explained less than one-third of the variation, making this designation of urban-rural was not strongly predictive of Anopheles abundance. LU/LC classifications that accounted for urban agriculture and topography improved predictability, regardless of geographic location. This association remained after controlling for clustering. Our findings have important implications for understanding household- and community-level "urban" malaria risk, and for identifying locations where malaria prevention and control efforts might be most effective.

1867

CHARACTERIZING THE SPATIAL DISTRIBUTION OF MALARIA VECTORS IN AN AREA OF HIGH TRANSMISSION IN NORTHERN ZAMBIA: EVIDENCE OF SPATIAL-TEMPORAL VARIATION IN THE DISTRIBUTION OF *ANOPHELES FUNESTUS* TO *ANOPHELES GAMBIAE* TO IMPLICATIONS FOR TARGETED INTERVENTIONS

Jessie Pinchoff[1], Jennifer Stevenson[1], Douglas E. Norris[1], Mbanga Muleba[2], Mike Chaponda[2], Modest Mulenga[2], William J. Moss[1], Frank C. Curriero[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Tropical Disease Research Centre, Ndola, Zambia

Characterizing the spatial distribution of malaria vectors is critical to understanding transmission dynamics, with implications for the effectiveness of targeted control interventions. Active entomological surveillance was conducted at randomly selected households in Nchelenge District in Zambia from April 2012 to December 2014. At each visit, a questionnaire was administered and a CDC light trap left overnight for indoor mosquito collections. A total of 4,591 ***Anopheles funestus*** s.s. and 548 ***An. gambiae*** s.s. were captured at 461 households. Counts of ***An. funestus*** and ***An. gambiae*** were modeled using zero-inflated Poisson regression models as a function of environmental variables. Both species were significantly associated with closer proximity to category 1, 2, and 3 streams and with increasing degree of topographical slope. Both species had higher abundances inland compared to along the banks of Lake Mweru. Overall, ***An. funestus*** did not display seasonal variation, but the abundance of ***An. gambiae*** was four times higher in the rainy season as compared with the dry season (RR=4.1; 95% confidence intervals: 2.9, 6.0). In the rainy season, ***An. funestus*** abundance increased 10% in proximity to category 2 streams (RR=1.1; 95% CI: 1.0, 1.1) and 10% per increased degree of topographical slope (RR=1.1; 95% CI: 1.0, 1.3). While ***An. funestus*** abundance was higher in proximity to roads in the dry season, this association reversed in the rainy season when ***An. funestus*** abundance decreased 50% with proximity to roads (RR=0.5; 95% CI: 0.4, 0.6). ***An. gambiae*** abundance was not associated with proximity to roads but decreased in proximity to roads in the rainy season (RR=0.3; 95% CI: 0.2, 0.5). These findings suggest differences in breeding site preferences between these species. Regression models expressing the significant spatial and seasonal variation in the abundance of ***An. funestus*** and ***An. gambiae*** mosquitoes, modeled as a function of identified environmental features, were used to generate maps of species-specific predictive abundance. These maps can be used to maximize the impact of targeted vector control interventions such as IRS or larviciding.

SPATIO-TEMPORAL VARIATION IN MALARIA TRANSMISSION INTENSITY IN RWANDA

Corine K. Karema[1], Emmanuel Hakizimana[1], Dunia Munyakanage[1], Alphonse Mutabazi[1], Alphonse Rukundo[1], Jean Baptiste Mazarati[2], Agnes Binagwaho[3]

[1]Malaria and Other Parasitic Diseases Division, Kigali, Rwanda, [2]National Reference Laboratory, Biomedical Services Department-RBC, Kigali, Rwanda, [3]Ministry of Health, Kigali, Rwanda

Knowledge of vector distribution and bionomics is critical for vector borne diseases control program strategy. Rwanda made steady progress in the control of malaria over the past decade by scaling up malaria control prevention, treatment, community case management, and behavior change communication. The use of long-lasting insecticidal nets (LLINs) and insecticide indoor residual spraying (IRS) has altered vector bionomics in Africa. This is the first report from Rwanda that determined the abundance, species composition, and infectivity of mosquitoes collected from entomological monitoring in seven sentinel sites by pyrethrum spray collection (PSC) and human landing catches (HLC). The monthly collections

between 2010 and 2013 identified 340,684 mosquitoes to species level using morphological characteristics and grouped into anophelines (26.2%) and culicines (73.8%). The species composition comprised of ***An. gambiae*** s.l, and ***An. funestus*** as the major malaria vectors and six other anophelines. The culicines comprised of Culex, Mansonia, Coquellittidia and Aedes mosquitoes. For ***Anopheles gambiae*** s.l. (n = 84,189), the proportion of mosquitoes host-seeking indoors and outdoors was assessed as well as infection the rates. The mosquitoes collected indoors dropped from an average of 51.3% (95% CI = 44.7, 51.0) in 2010 to 44.9% (95% CI = 43.1, 49.8) in 2013 ($p < 0.005$). We also calculated mean densities and entomological inoculation rates (EIR). The mean resting density for ***An. gambiae*** s.l was 0.3 mosquitoes/house/night with the highest resting density reported in Mashesha (1.0 ***An. gambiae*** /h/n). The average annual EIR 99.5 (range 1.0 - 329.8) with Mashesha showing the highest EIR of 329.8 (a rice growing area) followed by Busoro and Kicukiro with 107.5 and 103.6 infective bites per person per year respectively. We plan to collect and analyze mosquitoes from additional sentinel sites to provide a comprehensive database on vector bionomics which will be the critical data informing vector borne diseases control policies in Rwanda.

IMPROVED MONITORING OF IRS COVERAGE ON BIOKO ISLAND THROUGH THE USE OF A GIS-BASED CAMPAIGN INFORMATION MANAGEMENT SYSTEM

Wonder Philip Phiri[1], Guillermo Garcia[1], Liberato Motobe Vaz[1], Lucas Ondo Nze Nchama[1], Diosdado Olo Motu[1], Jose Osa Osa Nfumu[1], Telesforo Eyegue Abuy[1], Restituto Mangue Avue[1], Jeremias Nzamio Mba Eyono[1], Teobaldo Babo[1], Marcos Mbulito Ivanga[1], Rosa Patricia Richard Ateme[1], John Bradley[2], Immo Kleinshmidt[2], Christopher Schwabe[3], Dianna B. Hergott[1]

[1]Medical Care Development International, Malabo, Equatorial Guinea, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Medical Care Development International, Silver Spring, MD, United States

Starting in 2014, the Bioko Island Malaria Control Project (BIMCP) has used a GIS-based Campaign Information Management System (CIMS) to plan, implement and monitor Indoor Residual Spraying (IRS). The CIMS uniquely identifies each household based on geographical location. The maps can be easily updated to reflect changes due to new houses, or destroyed or burnt down houses, thus enhancing the accuracy of the house count that is used as the denominator for IRS coverage rates, and eliminating the ability of Spray Operators to report fictitious houses. High resolution maps that clearly identify households, enable Supervisors to track and verify that spraying has occurred in houses reported by Spray Operators. This has virtually eliminated the ability of Spray Operators to falsify spray records, thus inflating the numerator in IRS coverage rates. The CIMS also permits identification of non-compliant households, thus enabling focalized intervention where Spray Operators and community leaders return to low-compliance areas for mobilization in an effort to increase spray coverage. Prior to 2014, Spray Operator data obtained from SP1 cards suggested that spray coverage was consistently at least 80%, while retrospective 6-month recall data from annual Malaria Indicator Surveys (MIS) suggested that IRS coverage was no higher than 65% (95% CI = 61-69%) in 2010 and as low as 47% (95% CI = 41%-54%) in 2013. Without the CIMS it was impossible to discern whether the discrepancy was due to errors in the housing count and/or falsification of IRS spray data or to poor recall by MIS respondents. In 2014, using the CIMS, the spray data revealed 57% coverage during the spray round, while the MIS reported that 60% (95% CI= 51- 68%) of surveyed households were sprayed in the previous 6 months. By linking the CIMS and MIS data it was determined that MIS data were 85% accurate compared to CIMS spray data, confirming a high level of sprayer falsification and under reporting of the number of houses to be sprayed in previous years. The CIMS has improved coverage monitoring for IRS and confirmed that a high refusal rate exists in Bioko Island,undermining coverage and program performance.

EVALUATION OF A NOVEL LONG LASTING INSECTICIDAL NET TO INDOOR RESIDUAL SPRAY PRODUCT, SEPARATELY TO TOGETHER, AGAINST MALARIA TRANSMITTED BY PYRETHROID RESISTANT MOSQUITOES IN NORTHWEST TANZANIA: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Natacha Protopopoff[1], Derek Charlwood[1], Jacklin Mosha[2], Alexandra Wright[1], William Kisinza[3], Franklin Mosha[4], Immo Kleinschmidt[1], Mark Rowland[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]NIMR Mwanza, Mwanza, United Republic of Tanzania, [3]NIMR Amani, Muheza, United Republic of Tanzania, [4]KCM College, Moshi, United Republic of Tanzania

The scaling up of the primary malaria vector control interventions - long lasting insecticidal nets (LLIN) and indoor residual spraying (IRS) - are responsible for the major reduction in malaria burden in Africa. We need to develop a more rational approach to deployment of chemical control, one which reduces selection pressure for resistance but continues the present gains in malaria control. To help define future strategy of LLIN and IRS deployment in East Africa we are conducting a 4 arm cluster randomised controlled trial (CRT) in North-West Tanzania where the initial prevalence of malaria infection was 65% and resistance to pyrethroids in the predominant vector ***Anopheles gambiae*** exceeded 90% and consisted of at least two resistance mechanisms. The base arm of the trial is universal coverage of Olyset LN, the pyrethroid LLIN which constitutes the current standard of care. The second arm is universal coverage with Olyset Plus, a LLIN which combines pyrethroid and the synergist PBO that in bioassay can overcome pyrethroid resistance mediated by mixed function oxidases; this intervention is a potential future standard of care. The third arm combines Olyset LLIN and IRS with Actellic CS, a long lasting organophosphate insecticide for IRS. The fourth arm combines the LLIN with the synergist PBO and the IRS with the long lasting OP - and is the combination intervention most likely to control malaria transmitted by highly pyrethroid resistant vector populations. The study area comprises 48 clusters and population 150,000 inhabitants, allocated into 12 clusters per arm using restricted randomisation to ensure balance between study arms. The interventions were rolled out in January 2015 and achieved the required coverage to achieve community impact ahead of the long transmission season. Analysis of mosquito population surveillance and malaria infection prevalence in children in the four arms will be presented. The findings will help to define context-specific interventions and their potential to maintain or accelerate present progress and prevent further selection of insecticide resistance.

1871

IMPACT OF SEASONAL PATTERNS TO PARASITE ASEXUAL STAGE ON *ANOPHELES GAMBIAE* SUSCEPTIBILITY TO *PLASMODIUM FALCIPARUM* INFECTION IN BURKINA FASO

Awa Gneme[1], Wamdaogo M. Guelbeogo[2], Michelle M. Riehle[3], Gustave B. Kabre[1], N'Falé Sagnon[2], Kenneth D. Vernick[4]

[1]Université de Ouagadougou, Ouagadougou, Burkina Faso, [2]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [3]Department of Microbiology, University of Minnesota, Minnesota, MN, United States, [4]Unit of Insect Vector Genetics and Genomics, Department of Parasites and Insect Vectors, Institut Pasteur, CNRS Unit of Hosts, Vectors and Pathogens (URA3012), Paris, France

Transmission reduction is a key component of global efforts to control and eliminate malaria. A wide range of novel transmission-reducing drugs and vaccines are currently under development. Currently, it is unclear how the densities of the parasite stages or the season influence the infection rate and its intensity. Here, we highlighted the importance of the ***Plasmodium falciparum*** stages seasonal pattern in ***Anopheles gambiae*** infections success. Parasitological data were obtained by blood slide processing from

child volunteers with parental consent. Larvae were sampled from natural pools, reared to adulthood before experiment. Gametocytes carriers' infectiousness to mosquitoes was determined at the peak and end of wet season and dry season via membrane feeding assay. Infection prevalence and intensity were determined one week after feeding by midgut dissection. About 28062 mosquitoes offered blood meal and 29.6% fed and survived until dissection, seven days later. The average number of dissected mosquitoes 75 (range 18 - 207) was quite the same according to the assays period. In 71.8% (79/110) of feeding experiments, at least one mosquito was infected. The median percentage of infected mosquitoes per infectious experiment was 15.7% (IQR: 07.3- 89.2 %) with a median oocyst number of 2 (range 1 - 101). The prevalence of infected blood meal was similar across season (70.0%, 72.7% to 70.1% at the dry, the peak, and the end of the wet season. Mosquitoes' infection rate also did not show any significant variation within season. The infection success was higher for asexual parasites carriers (91%) than non carriers (9%). However, mosquitoes' infection rate and oocyst load did not significantly vary according to the asexual forms carriage. This highlights the need to carefully interpret evaluations, regarding asexual parasites and transmission season for malaria control program.

1872

QUANTIFYING BIAS TO OVERESTIMATION IN SELF-REPORTED ITN USE: A SYSTEMATIC REVIEW TO META-ANALYSIS

Paul Joseph Krezanoski

Massachusetts General Hospital, Cambridge, MA, United States

Insecticide-treated bednets (ITNs) are one of the most cost effective malaria prevention measures. In 2013, the WHO recommended universal coverage with ITNs for all 3 billion individuals at risk of malaria world-wide. Evidence for this recommendation is based on robust evidence of an 18-23% reduction in child mortality among households using ITNs. However, these studies used self-reported ITN use as a proxy for actual ITN use. We hypothesized that self-reports would overestimate actual ITN use, because self-reported ITN use may be subject to recall and social desirability bias. We performed a systematic review of the literature to identify studies which included both self-reports and another more objective measure of ITN use (surprise sleeping visits, visual confirmation of mounted ITNs, etc) in the same population in order to determine the magnitude of overestimation. We searched for relevant terms in Pubmed and Embase, reviewing 464 titles and abstracts. We performed full article reviews of 193 studies and eventually included 19 studies for analysis. The studies examined were published from 1989 through 2013, including countries from Southeast Asia and sub-Saharan Africa. Six of 19 studies used surprise night visits to confirm self-reported use, while the rest used visual confirmation of a mounted ITN. Self-reported ITN use over-estimated actual ITN use ranging from -2.9% to 32.1%, with a mean of 9.1%. This 9.1% mean difference between self-reported and observed ITN use represents a 23.5% overestimation of actual ITN use. The significant and consistent overestimation of ITN use reported by self-reports suggests that 1) ITNs may be more effective than currently thought, i.e. the accepted relationship between ITN use and malaria outcomes may be based on an overestimate of their actual use, and 2) self-reported ITN use may not be an appropriate measure of actual ITN use, indicating the need to shift from self-reports towards more valid measures of ITN use in malaria prevention studies, most especially related to adherence behaviors and cost-effectiveness modeling.

1873

TARGETING THE CELL STRESS RESPONSE OF *PLASMODIUM FALCIPARUM* TO OVERCOME ARTEMISININ RESISTANCE

Leann Tilley[1], Stanley C. Xie[1], Con Dogovski[1], Shannon Kenny[1], Jess Bridgford[1], Gaetan Burgio[2], Simon Foote[2], David A. Fidock[3], Sachel Mok[4], Zbynek Bozdech[4], Kesinee Chotivanich[5], Nick Klonis[1], Arjen M. Dondorp[6]

[1]University of Melbourne, Parkville, Australia, [2]Australian National University, A.C.T., Australia, [3]Columbia University Medical Center, New York, NY, United States, [4]Nanyang Technological University, Singapore, Singapore, [5]Mahidol University, Bangkok, Thailand, [6]Mahidol-Oxford Research Unit, Bangkok, Thailand

Artemisinin derivatives (ARTs) are recommended, in combination regimens, as first line antimalarials in most countries where malaria is endemic. However their mechanism of action is poorly understood and their usefulness is threatened by the emergence of drug resistance. We undertook a detailed kinetic analysis of the drug responses of K13 wildtype (sensitive) and mutant (resistant) isolates of ***Plasmodium falciparum*** sourced from a region in Cambodia (Pailin). We demonstrate that ART treatment induces growth retardation and an accumulation of ubiquitinated proteins, indicative of a cellular stress response that engages the ubiquitin/ proteasome system. We show that resistant parasites exhibit lower levels of ubiquitinated proteins and delayed on-set of cell death, indicating an enhanced cell stress response. We found that the stress response can be targeted by inhibiting the proteasome. Accordingly, clinically-used proteasome inhibitors strongly synergize ART activity against both sensitive and resistant parasites, including isogenic lines expressing mutant or wildtype K13. Synergy is also observed against ***P. berghei in vivo***. Our work provides a rationale for improving the detection of ART resistance in the field and for treatment strategies that can be employed in areas with ART resistance.

1874

ROLE OF CELL CYCLE REGULATORS IN ARTEMISININ INDUCED DORMANCY IN *PLASMODIUM FALCIPARUM IN VITRO*

Karen-Ann Gray[1], Karryn J. Gresty[1], Nanhua Chen[1], Christopher Peatey[1], Veronica Zhang[2], Marina Chavchich[1], Norman C. Waters[3], **Qin Cheng**[1]

[1]Australian Army Malaria Institute, Brisbane, Australia, [2]University of Queensland, Brisbane, Australia, [3]Walter Reed Army Institute of Research, Silver Spring, MD, United States

Artemisinin-induced dormancy provides a plausible explanation for the variable rates of recrudescence reported in the field following artemisinin monotherapy. This phenomenon is reminiscent of cell cycle arrest in mammalian cells where cell cycle regulators, such as cyclin dependent kinases (CDKs) and cyclins play an important role. We investigated the transcription dynamics of 6 ***P. falciparum*** CDKs and 4 cyclins as well as protein expression and kinase activity of selected CDKs before and after dihydroartemisinin (DHA) treatment. The role of CDKs in dormancy was further investigated by evaluating the effect of 3 CDK inhibitors on the induction of and parasite recovery from dormancy. Transcription analysis revealed an up-regulation of two plasmodial CDKs throughout the dormancy period, and a down-regulation of genes encoding the remaining 4 CDKs and cyclins. The 3 inhibitors demonstrated different effect on parasite recovery from dormancy, one of these inhibitors completely blocked the parasite recovery from dormancy when it was added at the early stage of dormancy. The results suggest that plasmodial CDKs play an essential role in artemisinin induced dormancy, most likely control of parasite entry into S phase and mitosis. These findings provide new insights of cell cycle regulation in ***P. falciparum*** and in artemisinin induced dormancy.

1875

ARTESUNATE/AMODIAQUINE VERSUS ARTEMETHER/LUMEFANTRINE FOR THE TREATMENT OF UNCOMPLICATED MALARIA IN UGANDA: CHANGING EFFICACY PATTERNS CONSISTENT WITH CHANGES IN TREATMENT PRACTICES TO DRUG SENSITIVITIES

Melissa D. Conrad[1], Adoke Yeka[2], Ruth Kigozi[3], Myers Lugemwa[4], Peter Okui[4], Charles Katureebe[5], Kassahun Belay[6], B.K. Kapella[6], Michelle A. Chang[7], Moses R. Kamya[8], Sarah G. Staedke[9], Grant Dorsey[1], Philip J. Rosenthal[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Makerere University School of Public Health, College of Health Sciences, Kampala, Uganda, [3]Infectious Diseases Research Collaboration, Kampala, Uganda, [4]National Malaria Control Program, Ministry of Health, Kampala, Uganda, [5]World Health Organzation, Kampala, Uganda, [6]US President's Malaria Initiative, Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [8]Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda, [9]London School of Hygiene & Tropical Medicine, London, United Kingdom

With older therapies limited by widespread drug resistance, standard treatment for uncomplicated falciparum malaria is now artemisinin-based combination therapy, with nearly all endemic countries in sub-Saharan Africa recommending either artemether/lumefantrine (AL) or artesunate/amodiaquine (AS/AQ). In Uganda, AL has shown superior efficacy compared to AS/AQ and is the first-line regimen. However, recent changes in treatment practices and evidence of shifting drug sensitivities prompted a reassessment of the relative efficacies of these regimens. We enrolled 602 patients aged 6-59 months from health centers in the Apac, Mubende, and Kanungu Districts of Uganda in 2013-14. Children with uncomplicated falciparum malaria were randomly assigned treatment with AL or AS/AQ, and 594 (98.7%) of those enrolled were followed for 28 days. Recurrent infections were genotyped to distinguish recrudescence from new infection, and ***Plasmodium falciparum*** resistance-mediating polymorphisms were characterized for all infections. At each site the risk of recurrent parasitemia was lower in children treated with AS/AQ compared to those treated with AL (overall 28.6% vs. 44.6%; p <0.001). Recrudescences were uncommon, but all occurred in the AL treatment arm (0% vs. 2.5%; p = 0.006). Recovery in hemoglobin was greater in the AS/AQ arm (1.73 vs. 1.39 g/dl, p = 0.04). Both regimens were well tolerated; serious adverse events were uncommon (1.7% for AS/AQ and 1.0% for AL). In new infections after therapy the two regimens selected for opposite polymorphisms in pfcrt and pfmdr1, with each selecting for polymorphisms associated with decreased sensitivity to the partner drug. Polymorphisms in the K13 propeller domain, which have been associated with artemisinin resistance in Asia, were uncommon (1/76) and not associated with recurrent parasitemia. Although both regimens were highly efficacious, AS/AQ showed superior efficacy, contrasting with older data, and consistent with recent changes in parasite drug sensitivity. Malaria treatment guidelines should consider multiple or rotating regimens to maintain the efficacies of leading treatments.

1876

PARASITE CLEARANCE IN CHILDREN UNDER FIVE YEARS OF AGE WITH UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA AFTER TREATMENT WITH ARTEMETHER-LUMEFANTRINE IN NCHELENGE DISTRICT, ZAMBIA

Mwiche Siame[1], Mike Chaponda[2], Geoffrey Chansa[3], Danver Hamayobe[4], Natasha Laban[1], Philip E. Thuma[1]

[1]Macha Research Trust, Choma, Zambia, [2]Tropical Diseases Research Centre, Ndola, Zambia, [3]Kabuta Rural Health Centre, Nchelenge, Zambia, [4]St. Paul's Mission Hospital, Nchelenge, Zambia

Artemether-lumefantrine (AL) has been used in Zambia as first line treatment since 2002. The World Health Organization (WHO) reported a decline in malaria prevalence of over 60% in Zambia and this has been partly attributed to prompt and effective treatment with AL. While efficacy of AL remains high, there have anecdotal reports of delayed clearance of parasites after treatment with the drug combination. Countries in South-east Asia, including Thailand, Cambodia and Myanmar, have reported artemisinin drug resistance, manifested by delayed parasite clearance and rare cases of treatment failure. Therefore, there is need to examine the efficacy of AL in Zambia and document whether or not some patients experience delayed parasite clearance despite adequate treatment with the drug. This study aimed to examine the efficacy of AL and delayed parasite clearance in children in Nchelenge District, Zambia. Febrile children aged 6 to 59 months, with uncomplicated ***Plasmodium falciparum*** infection, were enrolled into the study beginning in December 2014. The children were treated for three days with directly observed therapy of AL based on weight according to the WHO protocol and followed-up 35 days to evaluate drug efficacy by monitoring clinical and parasitological parameters with Giemsa-stained blood smears and PCR. The study results showing parasite clearance times, parasite slope half-life (using the WWARN Parasite Clearance Estimator) and associated clinical parameters, as well as the presence of K13 propeller mutations, will be presented. Preliminary analysis of the first 20 participants who have complete data sets (of a planned total of 100), revealed that all study participants cleared parasites within 48 hours, with 60% of the children having a lag phase before parasite clearance began, and a subsequent median clearance half-life of 2.69 hrs (IQR 1.64, 3.13).

1877

EFFICACY OF CHLOROQUINE TO PRIMAQUINE IN THE TREATMENT OF UNCOMPLICATED *PLASMODIUM VIVAX* MALARIA, CRUZEIRO DO SUL, ACRE, BRAZIL, 2014

Suiane Negreiros[1], Samela Farias[1], Thayna M. Souza[1], Giselle R. Vianna[2], Sheila Akinyi-Okoth[3], Paola Marchesini[4], Venkatachalam Udhayakumar[3], Marinete M. Povoa[2], Ana Carolina Santelli[4], **Alexandre Macedo de Oliveira**[3]

[1]Secretaria de Saude do Acre, Cruzeiro do Sul, Brazil, [2]Instituto Evandro Chagas, Belem, Brazil, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Ministerio da Saude, Brasilia, Brazil

The World Health Organization recommends the regular monitoring of antimalarial treatment policies. We evaluated the ***in vivo*** efficacy of chloroquine and primaquine for the treatment of uncomplicated ***P. vivax*** malaria in Brazil. The study was conducted in Cruzeiro do Sul from February to December 2014. We enrolled patients ≥5 years of age with parasitologically confirmed ***P. vivax*** monoinfection (parasitemia between 250 and 100,000 parasites/uL) and no evidence of severe disease. Patients were treated under direct observation with chloroquine for 3 days (daily dose of 25 mg/Kg). After laboratory confirmation of normal glucose-6-phosphate dehydrogenase (G6PD) activity levels, primaquine (daily dose of 0.5mg/Kg) was administered, also under direct observation, for 7 days. We monitored patients clinically and parasitologically on Days 1, 2, 3, 7, 14, 21, 28 and then every 4 weeks until Day 168. Seven neutral microsatellites were used to differentiate genetic profile of parasites detected at the time

of enrollment and recurrent infection. We enrolled 132 patients, 13 were excluded (nine with G6PD deficiency, and four with either low-density parasitemia or ***P. falciparum*** infection). Among the 119 valid patients, 65 (54.6%) were male and the median age was 24 years. The geometric mean of asexual parasitemia at admission was 3,373 per uL. At Day 28, no patient, among 110 patients to reach this time point, presented with recurrent ***P. vivax*** parasitemia; while at Day 168, 28 (30.1%; 95% CI: 21.0-40.5%) presented with recurrent ***P. vivax*** infection. Microsatellite typing demonstrated that 13 of those infections were due to a different strain (i.e., reinfection), while 15 were caused by a genetically identical strain compared to Day 0 and were most likely relapses. This finding brings the corrected rate of relapse to 18.8% (95% CI: 10.2-27.3%). Treatment with chloroquine and primaquine appears to remain efficacious to treat ***P. vivax*** malaria and prevent recrudescence, but it is likely associated with relapses 6 months after acute disease. Revision of the primaquine regimen with possible increase in total dose or use over 14 days should be considered.

1878

DISSECTING THE MUTATIONAL ACQUISITION OF PFCRT-MEDIATED ANTIMALARIAL DRUG RESISTANCE

Stanislaw J. Gabryszewski[1], Thanat Chookajorn[2], David A. Fidock[1]

[1]Department of Microbiology and Immunology, Columbia University College of Physicians and Surgeons, New York, NY, United States, [2]Department of Biochemistry and Center for Excellence in Malaria, Mahidol University, Bangkok, Thailand

Named for its primary role in mediating resistance to chloroquine (CQ), the ***Plasmodium falciparum*** Chloroquine Resistance Transporter (PfCRT) is increasingly recognized as a multi-drug resistance transporter with pleiotropic effects on parasite susceptibility to our present arsenal of antimalarials. Field studies of drug selective forces on the pfcrt locus have historically centered on the single-nucleotide polymorphism (SNP) K76T, a critical determinant of CQ resistance that is always accompanied by at least three mutations in all CQ-resistant isolates. The impact of these mutations on parasite drug resistance, fitness, and the mutational paths accessible to parasites as they acquire resistance remains unclear. To explore this, we used pfcrt-specific Zinc-Finger Nucleases (ZFNs) to dissect the mutational trajectories leading to the evolution of the Ecuadorian pfcrt allele Ecu1110, which harbors the fewest polymorphisms in a CQ-resistant parasite (namely K76T, A220S, N326D, I356L). We generated a collection of otherwise isogenic asexual blood-stage parasites expressing the wild-type (CQ-sensitive) PfCRT haplotype as well as each possible single-, double-, triple-, and quadruple-SNP combination of the four SNPs that comprise Ecu1110 PfCRT. We also generated isogenic parasites expressing the related quintuple-SNP 7G8 PfCRT variant (C72S, K76T, A220S, N326D, I356L) that is highly prevalent throughout South America and the Western Pacific. Parasite susceptibility to a panel of clinically employed antimalarials was determined via standard IC50 assays and was complemented with data from flow cytometry-based ***in vitro*** growth competition assays to model the mutational paths of PfCRT-mediated drug resistance. Our studies indicate that multiple PfCRT SNPs have a direct impact on parasite susceptibility to various antimalarial compounds, define mutational pathways that likely led to CQ resistance, and delineate growth rate constraints imposed on parasites as they evolve resistance.

1879

MUTATION OF THE MU-SUBUNIT OF THE *PLASMODIUM FALCIPARUM* CLATHRIN-ASSOCIATED AP2 ADAPTOR PROTEIN COMPLEX (PFAP2-MU) TO ITS EFFECT ON PARASITE SUSCEPTIBILITY TO ANTIMALARIAL AGENTS

Donelly A. van Schalkwyk[1], Gisela Henriques[1], Christian Flueck[2], David A. Baker[2], David A. Fidock[3], Colin J. Sutherland[1]

[1]Department of Immunology and Infection, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Department of Pathogen Molecular Biology, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Department of Microbiology and Immunology, Columbia University Medical Center, New York, NY, United States

Reports of ***Plasmodium falciparum*** infections with reduced susceptibility to artemisinin are now widespread throughout the Greater Mekong sub-region and threaten to undermine Artemisinin-based Combination Therapies (ACTs), currently the first-line WHO recommendation for malaria treatment. While the genetic basis for this reduced sensitivity to artemisinin in Asia has been associated with mutations in kelch13 (PF3D7_1343700), other candidate genes are thought to be involved in resistance developing independently elsewhere. Selection for parasites surviving artemisinin exposure in the murine malaria P. chabaudi uncovered a novel locus associated with antimalarial resistance, pcap2-mu. This gene encodes the mu chain of an adaptor protein complex that functions in clathrin-mediated endocytosis. Sequencing of submicroscopic parasites surviving ACT treatment in Kenyan children revealed an increased survival of parasites harbouring the Ser160Asn polymorphisms in the ***P. falciparum*** homologue, pfap2-mu. We have recently reported that the episomal expression of the mutant form of pfap2-mu (160Asn) in Dd2 parasites resulted in a significantly reduced susceptibility to dihydroartemisinin using the standard 48 hour ***in vitro*** growth inhibition assay. Furthermore, expression of the mutant pfap2-mu also resulted in reduced susceptibility to quinine. No differences in susceptibility to dihydroartemisinin were observed when comparing wild type with mutant parasites using the ring stage assay (RSA0-6h). We seek to expand on our previous findings by using gene editing CRISPR-Cas9 and Zinc Finger Nuclease approaches to replace the endogenous wild type Ser160 pfap2-mu gene with the mutant 160Asn gene associated with residual parasitemia after ACT treatment in Kenya. We will report the effects of this mutation on the ***in vitro*** parasite drug sensitivity to a range of antimalarial agents assessed with growth inhibition assays employing both the standard 48 hour exposure and newer 6 hour pulse assays.

IMMUNOMODULATION BY *LITOMOSOIDES SIGMODONTIS* INFECTION TO FILARIAL ANTIGEN ADMINISTRATION IMPROVES GLUCOSE TOLERANCE IN DIET-INDUCED OBESITY MICE

Afiat Berbudi, Jesuthas Ajendra, David Schmidt, Fabian Gondorf, Anna-Lena Neumann, Achim Hoerauf, **Marc P. Hübner**

University Hospital of Bonn, Bonn, Germany

Adipocyte necrosis in obesity causes pro-inflammatory macrophages to infiltrate into the adipose tissue and results in chronic inflammation and insulin resistance. Since filariae induce a regulatory immune response in their hosts and trigger type 2 immune responses that counter regulate type 1 immune responses, we investigated whether immunomodulation by ***Litomosoides sigmodontis*** (L.s.) improves glucose tolerance in diet-induced obesity (DIO) mice. After 10 and 16 weeks on high fat diet, respectively, L.s.-infected and L.s. antigen (LsAg)-treated mice were tested for glucose tolerance and immunological analysis was performed. Both L.s. infection and LsAg administration in DIO mice increased eosinophil and alternatively activated macrophage frequencies within the epididymal

adipose tissue and improved glucose tolerance, suggesting enhanced insulin sensitivity. This improved glucose tolerance by L.s. infection was dependent on eosinophils, as was shown with eosinophil deficient dblGATA mice. Total epididymal adipose tissue B-cell numbers were further reduced in L.s.-infected DIO mice and consisted substantially of B1-cells, whereas uninfected DIO controls had increased numbers of B2-cells. Consistently, L.s.-infected DIO-animals produced less IgG2a, which was previously shown to contribute to insulin resistance. qPCR arrays of epididymal adipose tissue further suggested a suppressed adipogenesis in L.s.-infected DIO mice. Accordingly, the differentiation of 3T3-L1 preadipose cells to mature adipocytes was suppressed by LsAg treatment ***in vitro***. However, two weeks of LsAg treatment did not suffice to reduce adipose tissue weight and adipocyte size in DIO mice. In conclusion our investigation indicates that L.s. infection and LsAg treatment restores a cellular composition within the adipose tissue of DIO mice that is dominated by eosinophils and alternatively activated macrophages and improves glucose tolerance in an eosinophil dependent manner. Additional protective mechanisms may include a suppressed adipogenesis and the induction of regulatory responses and are currently further investigated.

CHEMOKINES TO THE REGULATION OF EOSINOPHILIA IN LOIASIS

Senbagavalli Prakash Babu, Pryscilla Yoon, Michelle Makiya, Joseph Kubofcik, Thomas B. Nutman, Amy D. Klion

National Institutes of Health, Bethesda, MD, United States

Although eosinophilia is considered a hallmark of human helminth infection, the degree of blood eosinophilia varies considerably among infected individuals. Whereas some of this variation is likely due to differences in parasite burden, the host immune response to parasite antigens clearly plays an important role. To explore the role of chemokines in the regulation of blood eosinophilia in patients with microfilaremic loiasis, patients with loiasis were divided into low and high eosinophil groups based on the median absolute eosinophil count (AEC). Chemokines were measured by multiparameter immunoassays in antigen (***Brugia malayi*** antigen [BMA])- or mitogen (PMA/ionomycin ([PI])-sitmulated PBMC supernatants from 11 patients with loiasis. Chemokine levels in unstimulated supernatants were comparable between the two groups with the exception of IL-8, that was significantly increased in the low eosinophil group (GM 9.4 vs. 3.8 mcg/ml in the high eosinophil group, $p<0.01$) and showed a negative correlation with AEC overall ($r = -0.75$, $p = 0.001$). No significant differences were detected in BMA-stimulated chemokine levels between the two groups, although eotaxin 1, RANTES and MCP-4 showed significant negative correlations with AEC overall ($r= -0.77$, $p=0.007$ for eotaxin-1 and $r= -0.65$, $p=0.37$ for RANTES and MCP-4). TARC levels were increased in PI stimulated supernatants in the high eosinophil group ($p=0.056$). Microarray analysis was performed using PBMC from a separate group of 24 patients with loiasis divided into high and low eosinophil groups. Preliminary analysis of chemokine expression reveals upregulation of TARC and eotaxin-2 in the high eosinophil group and upregulation of RANTES in the low eosinophil group. Although IL-5 expression is comparable between the two groups, genes associated with Th1 and inflammatory responses appear to be upregulated in the low eosinophil group. Taken together these data suggest that differences in chemokine secretion by PBMC may contribute to the regulation of blood eosinophilia in loiasis.

TISSUE-SPECIFIC TRANSCRIPTOMICS TO PROTEOMICS OF *DIROFILARIA IMMITIS* TO ITS WOLBACHIA ENDOSYMBIONT

Ashley N. Luck[1], Kathryn G. Anderson[2], Colleen M. McClung[1], Nathan C. VerBerkmoes[1], Jeremy M. Foster[1], **Shelly Michalski**[2], Barton E. Slatko[1]

[1]New England Biolabs, Ipswich, MA, United States, [2]University of Wisconsin Oshkosh, Oshkosh, WI, United States

Recent evidence for the development of drug resistance among parasitic nematodes has accentuated the need for development of new treatment modalities. Although transcriptomic and proteomic characterization of filarial nematode life cycles using whole worms have greatly enhanced our knowledge of the biology of these organisms, it is clear that tissue-level approaches are needed to provide spatial resolution of gene expression that can aid drug discovery and vaccine studies. Here, we describe the first concurrent tissue-specific transcriptomic and proteomic profiling of a filarial nematode (***D. immitis***) and its Wolbachia endosymbiont (wDi) in order to better understand tissue functions and identify tissue-specific antigens that may be used for the development of new diagnostic and therapeutic tools. Hierarchical clustering of the ***D. immitis*** tissue transcriptomes, along with the recently published whole-worm adult male and female ***D. immitis*** transcriptomes, revealed that the whole-worm transcriptome is typically dominated by transcripts originating from the gonads (testis and uterus). The uterus appears to have the most variable transcriptome, and may reflect variance in worm age and fecundity. Although many functions are shared between the reproductive tissues, the most significant differences in gene expression were observed between the uterus and testis. Interestingly, wDi gene expression in the male and female body wall is fairly similar, yet slightly different to that of Wolbachia gene expression in the uterus. Proteomic methods verified 32% of the predicted ***D. immitis*** proteome, including over 700 hypothetical proteins of ***D. immitis***. Of note, hypothetical proteins were among some of the most abundant Wolbachia proteins identified, which may fulfill some important yet still uncharacterized biological function. The spatial resolution gained from this parallel transcriptomic and proteomic analysis adds to our understanding of filarial biology and serves as a resource with which to develop future therapeutic strategies against filarial nematodes and their Wolbachia endosymbionts.

1883

GENETIC VARIATION IN *ONCHOCERCA VOLVULUS* TO WOLBACHIA ENDOSYMBIONT REVEALS STRUCTURED PHYLOGEOGRAPHY IN RELATION TO PHENOTYPIC DIVERGENCE OF PATHOGENICITY

Young-Jun Choi[1], Samantha N. McNulty[1], Rahul Tyagi[1], Philip Ozersky[1], Thomas R. Unnasch[2], Carmelle T. Norice[3], Thomas B. Nutman[3], Gary J. Weil[1], Peter U. Fischer[1], Makedonka Mitreva[1]

[1]Washington University in St. Louis, St. Louis, MO, United States, [2]University of South Florida, Tampa, FL, United States, [3]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Onchocerca volvulus, the filarial nematode that causes onchocerciasis, is widely endemic in sub-Saharan Africa and in parts of Latin America. The pathology ranges from sub-clinical symptoms to dermatitis and ocular disease, and epidemiological studies have shown that blinding onchocerciasis is much more common in dry savannah regions than in rain forest regions of West Africa. To develop a comprehensive understanding of the population genetics and structure of ***O. volvulus***, we investigated the genomic diversity within and between ***O. volvulus*** populations by analyzing whole-genome (nuclear, mitochondrial and Wolbachia) sequences of >30 clinical parasite samples. Of these, 20 were collected from seven countries in Africa (forest or savanna) and 10 from Ecuador in South America. At a mean depth of 60x coverage per sample, we identified and annotated ~1 million segregating SNPs and small indels

(including 65k missense and 1k nonsense variants, together affecting 9k genes), as well as ~300 genomic regions (with a combined total length of >5Mb) displaying copy number variations. Admixture analysis of the inter- and intra-continental patterns of nuclear, mitochondrial and Wolbachia sequence variations provided genetic insights regarding the phylogeography of the parasite at an unprecedented resolution. Signatures of differential selection, identified through genomic markers of both the nuclear genome of the parasite and the Wolbachia endosymbiont, provided evidence of local adaption underpinning the phenotypic divergence of pathogenicity between the forest and the savanna strains. The study also provides new information on the genetic variability of potential vaccine, drug, and diagnostic targets.

1884

HELMINTH PARASITES TO CANCER-CAUSING TUMORS CONDITION HUMAN MONOCYTES SIMILARLY: INSIGHTS INTO PARALLEL MECHANISMS OF IMMUNE EVASION

Prakash Babu Narasimhan[1], Naureen Huda[1], Helen Sabzevari[2], Robert Hofmeister[2], Thomas B Nutman[1], Roshanak Tolouei Semnani[1]

[1]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [2]EMD Serono Research and Development Institute, Billerica, MA, United States

A number of features of the host-parasite interface are reminiscent of those that are also observed at the host-cancer interface. In particular, both cancer cells and parasites establish a tissue microenvironment that leads to immune evasion and likely reflects an alteration of the function of various antigen-presenting cells. The present study investigated how the phenotype and function of circulating human monocytes is altered by exposure to live filarial parasites and if these functional and phenotypic alterations parallel those induced by exposure to tumors. Thus, human monocytes were exposed either to live microfilariae (mf) of ***Brugia malayi*** - a causative agent of lymphatic filariasis - or to three different cancer cell lines MDA-MB-231 (breast cancer), OVCAR (ovarian cancer), or U-87 (glioblastoma). After 2 to 7 days of culture, cells were harvested, flow-sorted and assessed for mRNA expression, phenotype and function. To our great interest, following exposure to either mf or any of the 3 cell lines, the cell surface expression of the inhibitory ligands PDL1 and PDL2 were highly induced. Furthermore, monocytes exposed to tumor cell lines for even 2 days showed markedly upregulated expression of M1-associated (TNF-α, PDL1; > 6-fold), M2-associated (PDL2, MRC1; >5 fold) and Mreg-associated (IL-10, IDO, TGF-β; > 4–10–fold) genes, as well the expression of MMP-9 and VEGF, both known to be pro-angiogenic. The expression of these markers was also elevated in mf-exposed monocytes but most profoundly only after 7 days of exposure. Conditioning the human monocytes with either mf or tumor cell lines clearly altered their function as shown by a diminution of production of IP10, TNF-α, CCL22, and IL-10 in response to TLR3 and TLR7 agonists. Collectively, our data suggest that helminth parasites and tumor cell lines share similar abilities to alter the phenotype and function of human monocytes and may provide common insights into immune evasion.

1885

A MULTI-OMICS APPROACH FOR DEVELOPING IMPROVED DIAGNOSTIC TOOLS FOR ONCHOCERCIASIS

Samantha N. McNulty[1], Bruce A. Rosa[1], Peter U. Fischer[2], Reid Townsend[2], Kurt C. Curtis[2], Sabine Specht[3], Gary J. Weil[2], Makedonka Mitreva[1]

[1]The Genome Institute, St. Louis, MO, United States, [2]Washington University School of Medicine, St. Louis, MO, United States, [3]Institute for Medical Microbiology, Immunology and Pathology, University Hospital of Bonn, Bonn, Germany

Onchocerciasis is a neglected tropical disease that is responsible for significant morbidity (blindness and severe skin disease) in sub-Saharan Africa and parts of Latin America. Large-scale public health programs based on mass distribution of ivermectin have reduced ***Onchocerca volvulus*** infection rates in many areas, and plans are being developed to scale up activities to eliminate the disease. Improved diagnostic methods are needed for identifying hypoendemic areas that were excluded from prior control programs and for determining when transmission has been interrupted. The recently introduced Ov-16 antibody test is a major step forward, but it has only moderate sensitivity in subjects with microfiladermia. We have used a multi-omics approach to identify novel diagnostic antigens with high levels of sensitivity and specificity that may be useful for immunoassays to support the onchocerciasis elimination program. The approach included: i) development of a relational database that includes the annotated genome, developmental transcriptome (including MF, L3, adult male and adult female), and adult female proteome of ***O. volvulus***; ii) affinity purification ***O. volvulus*** antigens using IgG from onchocerciasis patients for identification via mass spectrometry. A total of 180 immundominant proteins showed favorable interactions with patient and control sera. These included many of the major diagnostic antigens that have been identified over the past 25 years (e.g., Ov16, Ov3.6, Ov7) plus many new candidates. The immunodominant proteins were characterized based on their conservation with orthologs in relevant species, expression pattern across the life cycle, and expression among eight individual female worms, and 19 candidates were prioritized for recombinant expression and laboratory testing in serodiagnostic assays. These candidate proteins, as well as our extensive genomic, transcriptomic, and proteomic datasets, are offered to the community (http://nematode.net) to further basic and translational onchocerciasis research in diagnostics and other areas.

1886

FURTHER CHARACTERIZATION OF A CARBOHYDRATE-RICH CIRCULATING *WUCHERERIA BANCROFTI* ANTIGEN AS A MEMBER OF THE JUV-P120 GENE FAMILY

Philip J. Budge, Jeanne Rumsey, Samantha McNulty, Reid Townsend, Peter U. Fischer, Gary J. Weil

Washington University in St. Louis, St. Louis, MO, United States

Rapid diagnostic tests (RDTs) used in the Global Programme to Eliminate Lymphatic Filariasis detect a 200 kD circulating filarial antigen (Wb-CFA) in blood and serum samples from humans infected with ***W. bancrofti***. Prior studies have shown that Wb-CFA is an adult worm excretory-secretory (E-S) product that is recognized by monoclonal antibodies AD12.1 and DH6.5. These antibodies bind to a single repeated epitope that is not specific to ***W. bancrofti*** and is likely responsible for false positive RDT results seen in some persons with loiasis. The exact nature of the epitope is unknown, but its immunoreactivity is destroyed by metaperiodate and is not affected by pronase B. In the present study, the Consortium for Functional Glycomics (Emory University) assessed the binding specificity of AD12.1. The antibody bound strongly to only 2 of 609 targets in their mammalian glycan array (GlcAß1-3GlcNAc and GlcAß1-3Gal). These disaccharides have been detected in O-linked carbohydrate side chains in glycoproteins from other nematodes including C. elegans. To identify the protein associated with the glycan moiety, we used tandem mass spectroscopy to analyze a tryptic digest of Wb-CFA that had been immunoaffinity-purified from pooled patient sera using antibody DH6.5. Three peptide sequences were identified in sequences encoded by two predicted ORFs situated adjacent to each other on a single 5,762 base pair contig in the ***W. bancrofti*** draft genome assembly (GenBank accession LM003610.1). These peptide sequences were not observed in human or common contaminant proteins. Although there is some ambiguity in the contig assembly in the vicinity of these ORFs, comparisons with ***Brugia*** sequences suggest that the two predicted ORFs actually combine to form a single ORF encoding protein of ~550 amino acids with high homology (66% identity, E score 1e-164) to a ***B. malayi*** protein (GenBank accession AHB87099.1) that is an orthologue of the ***L. sigmodontis*** E-S protein

Juv-p120 (GenBank accession AAS92593.1). Work in progress may provide insights regarding the function of Wb-CFA and lead to a more specific assay for the antigen.

1887

NEW EVIDENCE THAT *ANOPHELES GAMBIAE SENSU LATO* DISCRIMINATE AQUATIC HABITATS FOR OVIPOSITION: COULD THIS LIFE TRAIT BE EXPLOITED TO CONTROL RESIDUAL MALARIA TRANSMISSION?

Manuela Herrera[1], Michael N. Okal[1], Steve W. Lindsay[2], Ulrike Fillinger[1]

[1]International Centre of Insect Physiology and Ecology/London School of Hygiene & Tropical Medicine, Mbita, Kenya, [2]School of Biological and Biomedical Sciences, Durham University, Durham, United Kingdom

Residual malaria transmission in Africa is sustained by vector populations that resist insecticides and bite outdoors. These could be conceivably controlled by targeting gravid ***Anopheles gambiae*** s.l. searching for oviposition sites. Thus the aim of this study was to investigate if ***An. gambiae*** s.l. make informed choices when selecting egg-laying sites and to identify physical, chemical and biological parameters associated with this choices. Egg-count bioassays were used to evaluate oviposition responses to habitat water and test if bacterial volatiles affect the selection of the aquatic habitat. A cross-sectional case–control study of aquatic habitats was done on Rusinga Island in Lake Victoria, Western Kenya to compare the characteristics of habitats colonised and not colonized by early instar Anopheles larvae. Factors evaluated included biological characteristics of the sites, zooplankton, invertebrate fauna, physical parameters, nutrients, bacteria communities and volatile chemicals released from the water. Experiments showed that wild and caged ***An. gambiae*** s.l. discriminate between potential aquatic habitats using chemical cues. In the field no evidence was found that bacteria from natural habitat water influence habitat selection. Although chemical cues were highly diverse analysis suggests that cases and control habitats differ in the headspace volatile profiles. High turbidity >200 NTU was the only environmental factor strongly associated with cases. Other risk factors were higher grass coverage (positive association), and the abundance of creeping water bugs of the family Naucoridae and fish (negative associations). This study demonstrates that gravid ***An. gambiae*** choose suitable habitats for oviposition using a complex system of chemical and visual cues from water bodies. Habitats preferred by ***An. gambiae*** exhibited distinct and measurable characteristics that can be potentially exploited to attract and kill gravid mosquitoes. Such strategies would additionally target insecticide resistant and outdoor vector improving vector monitoring and control.

1888

QUANTIFYING DISPERSAL BEHAVIOR FOR *CULEX QUINQUEFASCIATUS* TO *AEDES ALBOPICTUS IN* COLLEGE STATION, TEXAS

Emily Boothe[1], Mark Johnsen[2], Brendan Roark[1], **Gabriel L. Hamer**[1]

[1]Texas A&M University, College Station, TX, United States, [2]Brazos County Health Department, Bryan, TX, United States

To better control populations of mosquitoes and break the transmission cycle of vector-borne diseases, it is crucial to understand the dispersal of adult mosquitoes. We performed a stable isotope mark-capture study, focusing on ***Culex quinquefasciatus*** and Aedes albopictus, to characterize dispersal distance and behavior. We enriched (i.e. marked) naturally occurring larval mosquitoes in container habitats with ^{13}C-glucose or ^{15}N-potassium nitrate at two different locations (~0.5km apart) in College Station, Texas in 2013. We used 32 CDC light trap, 32 gravid trap, and 16 BG Sentinel at different trap locations within a two-kilometer radius of the enriched larval habitats. Each location was trapped once per week and all mosquitoes collected were identified and numerated. ***Cx. quinquefasciatus*** and ***Ae. albopictus*** were pooled and tested for West Nile virus (WNV) by RT-PCR or tested by stable isotope analysis. In total, 720 trap nights were completed from July to August 2013 yielding a total of 32,140 ***Cx. quinquefasciatus*** and 7,722 Ae. albopictus. Overall, 69 marked female mosquitoes (n=2,758) and 24 marked male mosquitoes (n=350) were captured throughout the study period. Mean distance traveled (MDT) was calculated by sex and species. Female ***Cx. quinquefasciatus*** have a MDT of 0.94km, female ***Ae. albopictus*** of 0.38km, male ***Cx. quinquefasciatus*** of 1.16km, and male ***Ae. albopictus*** of 1.04km. This study provides a greater understanding of the dispersal of two important mosquito vectors capable of transmitting diseases in urban environments. We also confirm the ability to use stable isotope enrichment as a means to study the biology of mosquitoes.

1889

MINIMUM INFECTIOUS TIME 50: A METRIC NOVEL FOR STANDARDIZED COMPARISONS OF VECTOR COMPETENCE

Rebecca Christofferson[1], Helen Wearing[2], Christopher Mores[1]

[1]Louisiana State University, Baton Rouge, LA, United States, [2]University of New Mexico, Albuquerque, NM, United States

Chikungunya (CHIKV) virus has seen an increase in its transmission intensity and geographic range. Two particular events - the Indian Ocean and the ongoing outbreak in the Caribbean, each resulting in hundreds of thousands of cases - have been caused by different lineages of the virus. It has been reported that phenotypic differences between lineages of CHIKV are critical to understanding the scope of outbreaks. After the emergence of East Central South African sublineage in the Indian Ocean (ECSA-V), laboratory studies indicated increased efficiency of this viral type in a historically secondary vector, Ae. albopictus. Since then, this combination of lineage-vector has been the focus of most of the CHIKV vector competence studies. However, the ongoing outbreak in the Caribbean has been attributed to a strain belonging to the Southeast Asian genotype and ***Ae. aegypti***, suggesting that this focus might be short-sighted. There is a paucity of data directly comparing the vector competence of these two lineages in ***Ae. aegypti***. Further, mathematical models of transmission, used often to predict and forecast outbreak trajectories, rely on vector competence studies to parameterize their models by extrapolating the extrinsic incubation period (EIP) of the virus within the mosquito vector(s). These two measures- vector competence and EIP- are parts of a single process, but are rarely considered together either for the design of experimental investigations or for interpretation of vector competence to parameterize models. To bridge these gaps, we directly compare experimental vector competence results of these two lineages and subsequently propose the MIT50, the mosquito infectious time 50 (the time it takes post-exposure for 50% of exposed mosquitoes to become infectious). We show that the phenotypic differences detected between the two lineages are more directly comparable and more likely to be appropriately interpreted for model parameterization with the MIT50. We demonstrate the effect of mosquito mortality on transmission by calculating the mortality reduced transmission rate as the probability that a mosquito survives to transmit at MIT50.

1890

NATURAL *WOLBACHIA* INFECTIONS IN *ANOPHELES GAMBIAE SENSU LATO*

Robert Shaw[1], Perrine Marcenac[1], Abdoulaye Diabaté[2], Flaminia Catteruccia[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Institut de Recherche en Sciences de la Santé/Centre Muraz, Bobo-Dioulasso, Burkina Faso

Wolbachia is an intracellular bacterial endosymbiont that infects the germlines of many arthropod species. It has been proposed as a tool to control malaria transmission in Anopheles mosquitoes for two key

properties. First, Wolbachia can spread through natural populations due to reproductive phenotypes induced in the host insect, principally cytoplasmic incompatibility (CI). In CI, Wolbachia-uninfected females produce no fertile progeny with Wolbachia-infected males, while Wolbachia-infected females produce fertile progeny with any male, thus driving the infection into the population. Second, Wolbachia infection can block human pathogen development in several insects, recently extended to include the inhibition of *Plasmodium* development in female Anopheles mosquitoes. Central to the future of using Wolbachia in malaria control, our laboratory has identified for the first time strong evidence of natural Wolbachia infections in field populations of ***An. gambiae*** sensu lato in Burkina Faso, Africa. Whole-genome shotgun metagenomic sequencing has placed this strain in a novel phylogenetic group – wAnga – distinct from, but related to, other dipteran Wolbachia strains. Infection persisted at low frequency (20-40%) over four years despite imperfect vertical transmission to progeny. We have successfully colonized mosquitoes harboring this infection and have examined whether these bacteria affect the reproductive success of their mosquito host. Moreover, fluorescent in situ hybridization targeting 16S rRNA sequences localizes wAnga within the female germline, consistent with vertical transmission. Our results suggest a role for Wolbachia in modulating aspects of mosquito biology that are highly relevant to vectorial capacity.

1891

REGULATION OF THE MOSQUITO MIDGUT BACTERIA BY THE STEROID HORMONE 20-HYDROXYECDYSONE

Sarah D. Sneed, Letitia K. Thompson, Michael Povelones

Department of Pathobiology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA, United States

Anopheles gambiae and ***Aedes aegypti*** are mosquito species that cause high morbidity and mortality by spreading pathogens such as *Plasmodium* parasites and arboviruses. As the midgut of the mosquito is the main barrier to dissemination of pathogens from a bloodmeal into the hemolymph, understanding midgut immune mechanisms and their regulation is critical. Blood feeding triggers signaling pathways required for successful egg development. We hypothesized that these pathways may play additional roles in modulating immunity. The steroid hormone 20-hydroxyecdysone (20E) signaling cascade plays an important role in egg development. 20E is rapidly produced in the ovaries in response to blood feeding and is released into the hemolymph where it can signal to peripheral organs. Previously, studies of the relationship between 20E and mosquito immunity have been focused on 20E's effect on the fat body. To date, no studies have examined the midgut as a potential target of 20E signaling. We found that directly injecting 20E into non-blood fed ***Ae. aegypti*** and ***An. gambiae*** resulted in a significant increase in midgut bacteria measured by colony counting and 16S qPCR. The increase in bacteria parallels what is observed after blood feeding. Metagenomic, transcriptomic, and functional analyses of 20E treated mosquitoes are underway to explore mechanisms leading to expansion of midgut bacteria. Our work provides evidence that 20E signaling influences midgut bacteria levels and that this mechanism is conserved across diverse mosquito species. Understanding regulation of the mosquito commensal population is crucial as their abundance and species composition have been implicated in disease transmission.

1892

GENOMIC DIVERGENCE TO LOCAL ADAPTATION IN CRYPTIC SUBGROUPS OF *ANOPHELES FUNESTUS*

Caroline Fouet, Colince Kamdem, Stephanie Gamez, Bradley J. White

University of California Riverside, Riverside, CA, United States

Anopheles funestus, the second most important vector of human malaria in Sub-Saharan Africa, is splitting into multiple cryptic species and subgroups, which have yet to be fully delineated. We used high-throughput sequencing to explore the genomic patterns of divergence and local adaptation in wild-caught ***An. funestus*** from Cameroon. Genotyping of 6605 SNPs across 101 individuals confirmed the presence of cryptic ecotypes differentially adapted to the savannah and rainforest. Genomic regions of high differentiation between the two ecotypes are clustered on the 3R chromosome, particularly within the 3Ra and 3Rb chromosomal inversions. Comparative mapping of chromosomal arms showed that several outlier regions of genetic differentiation within the 3Rb inversion of ***An. funestus*** map to the 2La inversion of ***An. gambiae***, which is also associated with adaptation to aridity. Despite 50 million years of divergence, it appears that ***An. funestus*** and ***An. gambiae*** utilize the same repertoire of genes to adapt to contrasting environment - a truly remarkable case of convergent evolution. Further functional analyses of genes within the overlapping chromosomal regions of ***An. funestus*** and ***An. gambiae*** will provide a deeper understanding of the direct mechanisms underlying parallel adaptation in these two rapidly evolving species.

1893

EFFICACY OF SISAL STRIPS IMPREGNATED WITH TRANSFLUTHRIN SPATIAL REPELLENT DISPENSED AT ROOM TEMPERATURE TO PROTECT AGAINST OUTDOOR BITING MALARIA VECTORS

Sheila O. Barasa, Arnold Mmbando, Johnson Kyeba, Hasan Ngonyani, Mohammed Kitumbukile, Gerald F. Killeen

Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania

In most African settings, people spend time outside houses in the early evening before they are under the protection of long lasting insecticide treated nets thus are exposed to infectious mosquito bites. An ideal spatial repellent is likely to provide long range repellency outdoors and reduce mosquito bites. The objectives of this study were to determine protective efficacy of sisal strips treated with Transfluthrin and to determine protection to non-users, as well as degree of diversion of mosquitoes from users of Transfluthrin sisal strips to the non-users. Experiments were conducted in a rural village, southeastern Tanzania. The main malaria vectors are Anopheles arabiensis mosquitoes that bite both indoors and outdoors. Efficacy of Transfluthrin sisal strips was determined by measuring the biting rate of mosquitoes of human landing catchers with treated Transfluthrin sisal compared to untreated sisal. Durability of efficacy of treated sisal was determined as well as protection of treated to non-user at different distances (10m, 20m, 30m, 40m and 60m) from the user of treated sisal. Over 8000 persons hours of human catches were conducted. Treated strips prevented more than 80% bites for a period of 30 weeks and at least 50% bites were prevented 90 weeks after the strips had been treated. Treated strips provided 40% relative protection to non-users at 5m and no evidence of increased risk to non-users beyond that distance was obvious. Analysis of all 4032 person hours of human landing catches from the dose-response reveal that; 0.01ml Transfluthrin provided 80% protection against mosquito bites, 1ml Transfluthrin provided 70% protection, 2ml provided 70% protection and 5ml Transfluthrin provided 70% protection. Sisal fibers are excellent substrates for dispensing vapour active spatial repellents, including Transfluthrin without the need of external sources of heat. This study shows that treated sisal strips reduced bites of outdoor biting An. arabiensis hence are likely to protect against malaria occurring outdoors LLINs may not be sufficient.

1894

NORTH AMERICAN PARAGONIMIASIS: IDENTIFICATION OF A NOVEL INTERMEDIATE SNAIL HOST FROM MISSOURI

Melanie Lloyd[1], Stephen E. McMurray[2], Peter U. Fischer[1]

[1]*Washington University School of Medicine, St. Louis, MO, United States,* [2]*Missouri Department of Conservation, Columbia, MO, United States*

Paragonimiasis is a foodborne trematode infection that affects 23 million people mainly in Asia. The infection is locally of great public health

importance and can cause a serious lung disease that is often misdiagnosed as tuberculosis or cancer. In North America, paragonimiasis is caused by ***Paragonimus kellicotti***. Infection is rarely seen in humans but is common is the animal definitive host in some states. After a small outbreak of human paragonimiasis in southern Missouri, the second intermediate host and source of human infection was identified as common crayfish species ***Orconectes punctimanus, O. luteus*** and ***O. virilis***. Although the infection rates in crayfish were locally very high (>60%), the first intermediate host remained unknown. Only the walker snails ***Pomatiopsis lapidaria*** and ***P. cincinnatiensis*** (family Hydrobiidae) have been reported as first intermediate hosts for ***P. kellicotti***. These snail species have not been observed in areas with high infection rates in crayfish. In order to identify the snail host of ***P. kellicotti*** in our study area, we collected more than 2,000 snails of the three most common species and screened them by light exposure/cercariae shedding and dissection for developmental stages of ***P. kellicotti***. We detected cerariae and rediae of ***P. kellicotti*** in the endemic ***species Elimia potosiensis*** (family Pleuroceridae). Trematode identity was confirmed by PCR and DNA sequencing. ***E. potosiensis*** is also the first intermediate host to at least two undescribed trematode species. According to ITS-2 sequence, these appear similar to ***Lecithodendrium spathulatum***, a parasite of bats, and ***Collyriclum faba***, a parasite of birds. Our findings indicate that ***P. kellicotti*** has a wider first intermediate host range than previously assumed, and can use high abundance snail species of different families for development. The flexibility of the host range of all developmental stages of ***P. kellicotti*** may explain why this parasite species can be locally so abundant.

1895

ASSESSING THE EFFECT OF WATER QUALITY MARKERS ON THE VIABILITY OF SCHISTOSOME-BEARING SNAILS

Amsul Khanal, Yi-Ju Hsieh, Margaret Mentink-Kane, Grace Cheung, Michael H. Hsieh

Biomedical Research Institute, Rockville, MD, United States

Schistosomiasis, infection by ***Schistosoma*** worms, is a disease that affects over 200 million people worldwide, mostly in developing areas in Africa and Asia. ***Biomphalaria, Bulinus***, and ***Oncomelania*** snails are the intermediate hosts for ***Schistosoma***, which emerge from these snails as cercaria, the larval stage which infects humans. At the Biomedical Research Institute (BRI), we maintain the life cycle for multiple species of schistosomes and provide these parasites for researchers around the world. Given the importance of optimizing viability of lab-cultivated snails to our mission, we are investigating the effects of water quality markers on the growth and viability ***of Biomphalaria, Bulinus***, and ***Oncomelania*** snails. We have determined the baseline values for various water quality markers such as pH, chlorine content, conductivity, total dissolved solids, salinity, hardness and surface tension. Adjustment of multiple water quality markers affects the viability of schistosome-bearing snails. Our work has implications for not only optimal laboratory cultivation of snails, but may also help identify novel means by which water properties can be manipulated in order to reduce infestation by schistosome-bearing snails.

1896

SPATIAL ANALYSIS TO HUMAN FECAL WATER CONTAMINATION BY MICROBIAL SOURCE TRACKING: ASSOCIATION WITH RISK OF SCHISTOSOMIASIS FOLLOWING TREATMENT IN BRAZIL

Rafael Ponce-Terashima[1], Ronald Blanton[2], Mitermayer G. Reis[3]

[1]Mercer University, Macon, GA, United States, [2]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States, [3]Laboratory of Pathology and Molecular Biology, Gonçalo Moniz Research Center, Oswaldo Cruz Foundation, Salvador, Brazil

Schistosomiasis is to a degree a disease of contact with fecally contaminated surface waters, rather than ingestion. In a community in rural Bahia, Brazil that straddles a shallow river, we previously developed a model which showed that proximity from a person's home to the nearest water contact site and concentration of human fecal contamination at this point explained ~50% of the risk of infection. This result was for data obtained during a community survey prior to treatment when prevalence of infection was 45%. We also observed that human fecal contamination increased considerably in the downstream portion of the village. Human fecal contamination was assessed by determination of a widely used Lachnospiraceae marker, which we validated by pyrosequencing and qPCR of local stool samples. In this opportunity, we used QGIS to test our model in this same village following treatment. All individuals who tested positive were treated in 2009 and at follow up in 2012, prevalence had declined by 48% and intensity by 44%. Those infected were again treated in 2012 and the village was re examined in 2013 when prevalence declined by 32% and intensity by 30%. Re infection rates were 33.7 and 18.4% in 2012 and 2013, respectively. Incidence was 22.0 and 12.9%. Our model explained 73% and 81% of the risk of infection in 2012 and 2013, respectively. Improvement in identification of risk by the model over time can be explained by the effect of treatment. People who live closer to water with high human fecal contamination are more likely to be re infected and people who live in proximity to water with low contamination are likely to remain infection free. This is further supported by spatial analysis which showed that over time, new infections clustered downstream. Our findings give more insight into the importance of human fecal water contamination for schistosome transmission. Models of schistosome transmission and spatial analysis may aid in identifying areas at risk of re infection in communities with high prevalence of infection undergoing treatment.

1897

DETERMINANTS OF *SCHISTOSOMA JAPONICUM* INTERMEDIATE HOST MIGRATION IN SICHUAN, CHINA

Jennifer R. Head[1], Howard H. Chang[2], Justin V. Remais[1]

[1]Department of Environmental Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, GA, United States

Schistosomiasis is targeted for elimination in China, and monitoring for re-emergence in previously controlled areas in this country has become a major public health priority. Host and vector dispersal can facilitate the spread and re-emergence of infectious diseases, but little is known about the movement of ***Oncomelania hupensis***, the intermediate host for ***Schistosoma japonicum***. This study characterized intermediate host snail movement between villages in Western China and examined environmental factors that affect host dispersal in this setting. Snail migration rates between 32 sites in Sichuan Province, China, were estimated using Bayesian assignment tests conducted on genotypes of 833 ***O. hupensis*** snails. Bi-directional effective geographic distances (EGD) between each site pair were estimated based on geographic weightings representing nine environmental models: Euclidean, topography, incline, wetness, land use, distance from watershed, stream use, streams and channels, and stream velocity. Median, first quartile and minimum EGD values were analyzed as to their ability to explain estimated paired migration rates using mixed effects models. Among sites, 7.8% to 32.7% of sampled snails were identified as migrants, with 20 sites containing over 20% migrants. Migration rates were generally low between sites; however, for 12 sites, as much as 80% of the migrant population and over 10% of the overall snail population originated from a proximal site. EGD was found to be a significant predictor of migration rate, with the log of the minimum EGD emerging as the best predictor across all environmental models. Odds of migration decreased as EGD increased (OR from Euclidean model: 0.70, 95% CI: 0.63, 0.78). Models accounting for topography and wetness explained a significantly larger proportion of the variance in migration between sites as compared to the Euclidean model. Random intercept models suggest nearly 50% of the variation in migration rate can be attributed to site-specific factors, and roughly 10% can be attributed to EGD. Our findings have important implications for controlling the geographic spread of schistosomiasis in China.

1898

DOES FLOODING DETERMINE THE DISTRIBUTION OF SCHISTOSOME-TRANSMITTING SNAILS IN MIDDLE TO LOWER REACHES OF THE YANGTZE RIVER, CHINA?

Sheng-Bang Zheng[1], Song Liang[2], Yi-Biao Zhou[1], Jin-Yi Wu[1], Jian-Chuan Gao[1], Lin-Han Li[1], Guang-Hui Ren[3], Xiu-Xia Song[1], Zhong He[4], Qing-Wu Jiang[1]

[1]Fudan University, Shanghai, China, [2]University of Florida, Gainesville, FL, United States, [3]Hunan Station for Schistosomiasis Control, Changsha, China, [4]Junshan Office of Leading Group for Schistosomiasis Control, Yueyang, China

Schistosomiasis, caused by blood fluke genus ***Schistosoma***, is one of the most devastating tropical diseases in the world. ***Oncomelania hupensis*** is the only intermediate host of schistosoma and its growth and development are sensitive to environmental factors. In China, these snails are only found in the 12 Provinces located along the Yangtze River and south of it. Hunan Province, located in the southeastern hinterland of China, along the middle and lower reaches of the Yangtze River, is one of the schistosomiasis endemic areas in China, and ***Oncomelania*** snails are mainly distributed in the vast floodplains of Dongting Lake region, the northeastern part of Hunan Province, while no snail is found in the southwestern part of Hunan Province, where the altitude is much higher. In this study, we focused on the influence of extreme low air temperature, annual precipitation and time of flooding on the distribution of ***Oncomelania*** snails in Hunan Province, China. The distribution areas of snails in Hunan Province were marked and the data of annual extreme low air temperature, annual precipitation and the time of flooding from 1995 to 2002 was collected or calculated. Nonparametric tests suggest that in Hunan Province, the extreme low air temperature and precipitation are not the main factors that impact the distribution of ***Oncomelania*** snails, while the time of flooding is a crucial factor that influences the distribution of ***Oncomelania*** snails in Hunan Province, and the favorable time for the snail's survival ranges from about 2 to 7 months.

1899

THE *SCHISTOSOMA MANSONI* CYTOCHROME P450 (CYP450) IS ESSENTIAL FOR WORM SURVIVAL

Peter D. Ziniel[1], Ethan Fisher[2], Andrew Barnard[1], Larissa M. Podust[3], **David Williams**[1]

[1]Rush University Medical Center, Chicago, IL, United States, [2]Illinois Mathematics and Science Academy, Aurora, IL, United States, [3]Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California San Diego, La Jolla, CA, United States

Schistosomiasis affects millions of people in developing countries and is responsible for over 200,000 deaths annually. There is only one drug, praziquantel, available for its treatment. Recent data suggest that drug resistance could soon be a problem. There is therefore the need to identify new drug targets and develop drugs for the treatment of schistosomiasis. Unlike many other organisms, e.g., humans have 57 CYP450 genes and C. elegans has 83 CYP450 genes, ***Schistosoma mansoni*** has only one CYP450 gene encoded in its genome. Analysis shows that the predicted 1452 bp open reading frame encodes a characteristic heme-binding region in its catalytic domain and a hydrophobic sequence that is usually present as the membrane interacting region in other CYP450s. The highest identity to human CYP450s is 22%. Using 5' RACE and analysis of cDNAs from worm populations and different developmental stages, we found no evidence that the schistosome CYP450 mRNA is differentially spliced or processed, suggesting that a single CYP450 protein is present in worms. Analysis of CYP450 mRNA abundance indicates that it is differentially regulated with the egg and schistosomula having the highest levels. Additionally, adult female worms have higher message levels than adult male worms. We used reverse genetic and chemical tools in order to determine if the CYP450 is essential for parasite survival. RNA interference caused large reductions in CYP450 mRNA and resulted in schistosomula death. CYP450s are targets of many antifungal and cancer therapies. Antifungal azoles target 14α-demethylase (CYP51A1), a vital CYP450 enzyme for sterol metabolism and cell membrane stability in fungi. We found that imidazole antifungal agents related to miconazole targeted CYP450 and resulted in larval and adult worm death at low micromolar concentrations. In addition, combined sub-lethal concentrations of both CYP450-specific dsRNA and miconazole showed an additive effect on larval worm death indicating that the effect of miconazole is CYP450 specific. Our results indicate that the schistosome CYP450 is essential for worm survival and could be an ideal drug target.

1900

SCHISTOSOME ABC TRANSPORTERS: ROLES IN DRUG SUSCEPTIBILITY TO PARASITE PHYSIOLOGY

Swarna Bais, Yue Ning, Ravi S. Kasinathan, **Robert M. Greenberg**

University of Pennsylvania, Philadelphia, PA, United States

Praziquantel (PZQ) is essentially the only drug available for the treatment of schistosomiasis, a disease affecting hundreds of millions. Although invaluable, PZQ has significant limitations. It is largely ineffective against juvenile schistosomes, and there are several reports of treatment failures in the field. Clearly, there is an urgent need for new therapeutics. ATP binding cassette (ABC) transporters such as P-glycoprotein (Pgp) mediate efflux of toxins and xenobiotics from cells and are associated with drug resistance in many organisms, including parasitic helminths. They show broad substrate specificity and are inhibited by several drugs currently in clinical use. ABC transporters are also implicated in a variety of normal physiological activities and transport many potent signaling molecules with high affinity, including several with immunomodulatory activity. We hypothesize that schistosome ABC transporters offer attractive candidate targets for new or repurposed drugs that act either as antischistosomals on their own or as adjuncts that enhance parasite susceptibility to PZQ. Schistosomes with reduced PZQ sensitivity show higher basal expression of ABC transporters such as Pgp (SMDR2) and multidrug resistance associated protein (SmMRP1). ABC transporters are also upregulated in response to sub-lethal concentrations of PZQ. PZQ is both an inhibitor and likely substrate of schistosome Pgp. Disruption of transporter function (by inhibition) or expression (by RNAi) increases the activity of PZQ against adult parasites, and results in PZQ-refractory juvenile worms becoming susceptible to the drug. ABC transporters also appear to play a role in parasite egg production. We are currently investigating the role of schistosome ABC transporters in PZQ susceptibility of the parasite within the host. We are also assessing the role of these transporters in the parasite's modulation of host immune responses. These studies should provide important insights into the role of ABC transporters in PZQ susceptibility and parasite physiology, and may offer targets for novel or repurposed therapeutics.

1901

EBOLA EPIDEMIC IMPEDES MALARIA CARE DELIVERY IN GUINEA

Mateusz Plucinski[1], Timothée Guilavogui[2], Sidibe Sidikiba[3], Nouman Diakité[2], Souleymane Diakité[2], Mohamed Dioubaté[2], Ibrahima Bah[4], Ian Hennessee[5], Jessica K. Butts[1], Eric S. Halsey[1], Peter D. McElroy[1], S. Patrick Kachur[1], Jamila Aboulhab[1], Richard James[6], Moussa Keita[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]National Malaria Control Program, Conakry, Guinea, [3]Mafèrinyah Rural Health Research Center, Mafèrinyah, Guinea, [4]Catholic Relief Services, Conakry, Guinea, [5]Emory Rollins School of Public Health, Atlanta, GA, United States, [6]Division of Prevention and Disease Control, Ministry of Health, Conakry, Guinea

The current Ebola epidemic has had significant impact on the overall functioning of the healthcare system in affected countries. Due to the overlap of symptoms of Ebola virus disease and malaria, and malaria's position as the leading cause of health facility visits, malaria care delivery is

particularly sensitive to healthcare system perturbations due to the Ebola epidemic. A survey of 60 randomly-selected health facilities in prefectures highly affected by Ebola and 60 randomly-selected health facilities in Ebola-unaffected prefectures was performed in Guinea in December 2014. Study teams abstracted malaria case management indicators from registers for January-November for 2013 and 2014 and interviewed healthcare workers and community health workers. Nationwide weekly surveillance data on suspected malaria cases reported for 2011-2014 were also analyzed. The expected number of cases in 2014, estimated from the trends in 2011-2013, was compared to the observed surveillance data for 2014. There were substantial reductions in all-cause patient visits (-42%), fever cases (-46%), and patients treated with oral and injectable antimalarials (-58% and -69%) in adults and children >5 in Ebola-affected prefectures, with smaller but still substantial reductions in other age groups and in Ebola-unaffected prefectures. In Ebola-affected prefectures, only 74% of community health workers were operational, and only 48% of those working reported actively treating malaria cases, compared to 66% before the Ebola epidemic (p-value <0.01). Nationwide, the Ebola epidemic was estimated to have resulted in 74,000 (95% CI: 71,000-77,000) fewer malaria cases seen at health facilities from the start of the Ebola epidemic to the end of 2014. The decrease in malaria care delivery at the health facility and community level due to the Ebola epidemic threatens malaria control in Guinea. Untreated and inappropriately treated malaria cases lead to excess malaria morbidity and mortality, and thus more fever cases in the community. This makes identification of suspect Ebola cases more difficult, potentially hampering an effective Ebola outbreak response.

1902

DEATHS DUE TO *PLASMODIUM KNOWLESI* MALARIA IN SABAH, MALAYSIA, 2012-2014: REDUCED FATALITY RATE WITH IMPROVED USE OF INTRAVENOUS ARTESUNATE

Giri Rajahram[1], **Bridget E. Barber**[2], Timothy William[1], Matthew J. Grigg[2], Jenarun Jelip[3], Jayaram Menon[4], Tsin W. Yeo[2], Nicholas M. Anstey[2]

[1]Department of Infectious Diseases, Queen Elizabeth Hospital, Kota Kinabalu, Malaysia, [2]Menzies School of Health Research, Darwin, Northern Territory, Australia, [3]Sabah Department of Health, Kota Kinabalu, Malaysia, [4]Department of Medicine, Queen Elizabeth Hospital, Kota Kinabalu, Malaysia

Plasmodium knowlesi is the most common cause of malaria in Malaysia, and an important cause of fatal malaria in Sabah. In a review of malaria deaths in Sabah during 2010-2011, fatal outcomes were associated with misdiagnosis of knowlesi malaria as ***P. malariae*** and consequent delayed initiation of parenteral therapy. In Malaysia intravenous artesunate is now the recommended firstline treatment of severe malaria of any species. We reviewed malaria notification data and case notes of mandatorily-reported malaria deaths in Sabah 2012-2014, to describe clinical details of ***P. knowlesi*** deaths and to assess for trends in ***P. knowlesi*** case fatality. Sixteen malaria deaths were reported: 7 ***P. knowlesi***, 7 ***P. falciparum***, and 1 ***P. vivax*** (all PCR-confirmed), and one microscopy-diagnosed "***P. malariae***". Median age of fatal ***P. knowlesi*** cases was 61 years, and four were female. Complications of PCR-confirmed ***P. knowlesi*** cases included jaundice (N=5), metabolic acidosis (N=5), acute kidney injury (N=3), shock (N=6), and respiratory distress (N=7). Four ***P. knowlesi*** cases were diagnosed by microscopy as ***P. malariae***, 1 as ***P. falciparum***, 1 as ***P. vivax*** and 1 as ***P. knowlesi***. All recognised to have severe malaria on admission received intravenous artesunate. A total of 3138 cases of microscopy-diagnosed ***P. malariae/P. knowlesi*** were notified in Sabah during 2012-2014, giving a fatality rate of 2.23 per 1000 notifications, compared to a fatality rate of 5.5 per 1000 notifications during 2010-2011 (1087 notifications with 6 ***P. knowlesi*** deaths). Despite ongoing microscopic misdiagnosis of ***P. knowlesi***, management of severe malaria in Sabah appears to have improved. Although the study demonstrates the ability of ***P. knowlesi*** to cause fatal disease despite optimal therapy, increased use of artesunate has been associated with a reduction in ***P. knowlesi*** fatality-rates.

1903

CLUSTERING OF IMPORTED MALARIA CASES IN A SETTING OF VERY-LOW MALARIA INCIDENCE IN NORTHERN SENEGAL

Yakou Dieye[1], Adama Tall[1], Gnagna Dieng Sow[1], Algaye Ngom[2], Mady Ba[3], Badara Cisse[1], Farba Faye[1], Balla M. Mboup[4], Michael Hainsworth[5], Philippe Guinot[1], Duncan Earle[6], Rick W. Steketee[5]

[1]PATH MACEPA, Dakar, Senegal, [2]Richard-Toll District Medical Office, Richard-Toll, Senegal, [3]Senegal National Malaria Program (NMCP), Dakar, Senegal, [4]Saint-Louis Regional Medical Office, Saint-Louis, Senegal, [5]PATH MACEPA, Seattle, WA, United States, [6]PATH MACEPA, Lusaka, Zambia

Richard-Toll district (pop. 157,915) in northern Senegal is home to industrial activities among which are sugar cane harvesting and refining, with about 2,000 seasonal and 3,000 permanent workers. Recognizing very low transmission and numbers of infected residents in the district, a malaria case investigation strategy was initiated in Richard-Toll by the NMCP in 2012 and has continued as a routine district-wide intervention. RDT or microscopy-confirmed cases presenting to health facilities are followed to their homes and all members of the index case household and the 5 nearest households are tested for malaria and given treatment if positive. In 2013, 234 passively detected cases of malaria were investigated and 10,071 contacts were tested, with 42 positive secondary cases. Of the 276 total positive cases, 175 (63%) had recent travel history. In 2014, 134 passively detected cases of malaria were investigated and 5,751 contacts were tested, with 14 positive secondary cases. Of the 148 total positive cases, 104 (70%) had recent travel history. Travel appears to play an important role in malaria transmission and there appears to be clustering of travel-related cases around Richard-Toll city during October-November: in 2013 and 2014, 79% and 80% of cases had recent travel (53% and 62% of total imported cases in district) and 51% and 57% occurred in October and November. In 2014, 82% of cases with recent travel were concentrated in 4 neighborhoods. This period coincides with the beginning of the school year and the sugar cane harvest, as well as a major religious holiday in 2014. These results suggest that opportunities exist to improve targeting of malaria elimination strategies within the district, including focused screening of higher-risk populations such as seasonal workers, pupils and travelers. During 2012-2014, 478 cases were passively identified in health facilities and 72% were associated with travel and likely imported, suggesting that local transmission within the district is extremely low (average of 0.28/1000 pop./year) and with attention to reducing the risk of imported infections, the district could rapidly become malaria-free.

1904

TOLERABILITY TO SAFETY OF WEEKLY PRIMAQUINE AGAINST RELAPSE OF *PLASMODIUM VIVAX* IN GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENT TO NORMAL CAMBODIANS

Walter R. Taylor[1], Sim Kheng[2], Muth Sinoun[2], Narann Tops[3], Khem Kosal[4], Khon Sothea[4], Phum Souy[5], Saorin Kim[6], Chuor Char[2], Chan Vanna[7], Po Ly[2], Pascal Ringwald[8], Virak Khieu[2], Alexandra Kerleguer[6], Pety Tor[6], John K. Baird[9], Steven Bjorge[3], Didier Menard[6], Eva Christophel[10]

[1]MORU, Bangkok, Thailand, [2]CNM, Phnom Penh, Cambodia, [3]World Health Organization, Phnom Penh, Cambodia, [4]Pailin Referral Hospital, Pailin, Cambodia, [5]Aning Venh Referral Hospital, Oddar Meanchey, Cambodia, [6]Pasteur Institute, Phnom Penh, Cambodia, [7]Pramong Health Centre, Pursat, Cambodia, [8]World Health Organization, Geneva, Switzerland, [9]Eijkman Oxford Clinical Research Unit, Jakarta, Indonesia, [10]WHO WPRO, Manila, Philippines

Primaquine (PQ) is not implemented in many malaria endemic countries, including Cambodia, to prevent ***Plasmodium vivax*** relapse for fear of precipitating PQ-induced acute haemolytic anaemia (AHA) in patients with glucose-6-phosphate dehydrogenase deficient (G6PDd). Reluctance to

use primaquine is reinforced by a lack of quality safety data. From January 2013-January 2014, Cambodians with acute vivax malaria were treated with dihydroartemisinin-piperaquine on Days (D) 0, 1 and 2 plus weekly primaquine 0.75 mg/kg x 8 doses (D0, 7, 14 to D49) and follow to Day 56. G6PD genotype and measured G6PD activity confirmed G6PD status. The primary outcome was treatment completion without primaquine toxicity defined as any one of: (i) severe anaemia (Hb<7 g/dL), (ii) a fractional fall in Hb >25% vs. D0, (iii) blood transfusion, (iv) haemoglobinuria, (v) acute kidney injury (AKI, an increase in baseline serum creatinine > 50%), or (vi) methaemoglobinaemia (metHb) > 20%. The Trial registration number is ACTRN12613000003774. 75 patients were enrolled with a median (range) age of 24 (5-63) years; 63 (84%) patients were males. D0 G6PD activity ranged from 0.1-1.5 U/g Hb (median 0.85 U/g Hb) in 18 G6PDd patients (17/18 had the Viangchan variant) and 6.9-18.5 U/g Hb (12 U/g Hb) in 57 G6PD normals (G6PDn). Median (range) D0 Hb concentrations were similar (p=0.46) between G6PDd vs. G6PDn: 13 g/dL (9.6-16) vs. 13.5 g/dL (9-16.3) and nadired on D2 in both groups: 10.8 g/dL (8.2-15.3) vs. 12.4 (8.8-15.2) g/dL (p=0.006), respectively. By D7, five G6PDd patients (27.7%) had > 25% fall in Hb vs. 0/57 in G6PDn (p=0.00049), including one G6PDd male who required a blood transfusion (D0-D5 Hb 10.0-7.2 g/dL). No patient developed severe anaemia, haemoglobinuria, metHb concentration > 4.9% or AKI. In conclusion, vivax infected, G6PDd patients suffered significant, mostly transient, falls in Hb and one was transfused. Weekly primaquine in G6PDd patients mandates medical supervision and pretreatment screening for G6PD status. The feasibility of implementing a package of G6PDd testing and supervised primaquine should be explored.

1905

IMPROVING MALARIA DATA QUALITY TO USE IN HEALTH MANAGEMENT INFORMATION SYSTEM, TANZANIA

Ritha A. Willilo[1], Franky Chacky[2], Renata Mandike[2], Enock Mhehe[3], Naomi Kaspar[4], George Greer[4], Ramsan Mahdi[1], Jeremiah Ngondi[1]

[1]RTI International, Dar es Salaam, United Republic of Tanzania, [2]National Malaria Control Program, Dar es Salaam, United Republic of Tanzania, [3]Ministry of Health and Social Welfare, Dar es Salaam, United Republic of Tanzania, [4]United States Agency for International Development, Dar es Salaam, United Republic of Tanzania

Malaria data is an important aspect for monitoring malaria burden and intervention coverage to inform evidence-based programmatic decisions. Anecdotal evidence suggests that the quality of malaria data from routine health management information system (HMIS) is poor which made it difficult to analyze, interpret and ultimately the use of these data is limited. The situation analysis was conducted to assess, identify gaps, and setting up priorities of malaria data quality and use in Tanzania's HMIS. Desk reviews and field-based data collection was conducted to gather information that describes current practice, barriers and needs for malaria data quality improvement. A stakeholder's workshop was convened to triangulate data, identify gaps, propose solutions, prioritize activities and develop a work plan to improve data quality and use. The findings suggest that malaria data quality in Tanzania is poor. The main issues reported at the facility level were data inconsistencies (in the registers, tally sheets and summary forms), data collection tools not being available and not being filled out. The findings also showed that most of health facilities do not complete the tally sheets. At the district and regional levels, the main challenge encountered was unreliable internet connectivity that hindered timely processing of data into the DHIS2 system. The stakeholders proposed priorities for improving data quality and use, including: 1) data quality and use of data to be introduced as permanent agenda item in Health Management teams at district and regional level; 2) develop guidelines on data quality and use; and 3) supporting CHMTs to conduct regular, comprehensive and effective supportive supervision and, including data quality assessments. HMIS that produce complete, timely, reliable, and valid data are needed by national malaria control programs to monitor malaria burden and intervention coverage at national and sub-national levels to inform evidence-based programmatic decisions. The challenges appear to be behavioral and organizational, relating to how staff value and use data in their everyday work.

1906

SEASONAL MALARIA CHEMOPREVENTION, THREE YEARS OF IMPLEMENTATION

Estrella Lasry[1], Matthew Coldiron[2], Alena Koscalova[3], Francesco Grandesso[2], Paul Milligan[4], Ma Angeles Lima[5], Jorgen Stassjins[6], Esther Sterk[3], Greg Elder[7], Martin de Smet[6]

[1]Medecins Sans Frontieres/Doctors Without Borders, New York, NY, United States, [2]Epicentre, Paris, France, [3]Medecins Sans Frontieres/Doctors Without Borders, Geneva, Switzerland, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]Medecins Sans Frontieres/Doctors Without Borders, Barcelona, Spain, [6]Medecins Sans Frontieres/Doctors Without Borders, Brussels, Belgium, [7]Medecins Sans Frontieres/Doctors Without Borders, Paris, France

In 2012, Médecins Sans Frontières (MSF) started implementing seasonal malaria chemoprevention (SMC), following WHO recommendation for children in areas with high seasonal transmission using sulphadoxine-pyrimethamine and amodiaquine. MSF works in southern Mali, Chad and Niger where children suffer 2-3 episodes of malaria/year and where the malaria season is accompanied by a malnutrition peak causing an increase in admissions. SMC started in 2012 in MSF projects in Mali and Chad, and in 2013 in Niger. Monthly contacts with families at SMC delivery, give opportunities to provide other health interventions. In 2013 SMC was combined with screening for malnutrition, and in 2014, in Chad, with Pentavalent vaccination for children under 2. In Niger we included SMC in a preventive package (PP) which includes nutrition screening and prevention and EPI. Programs were evaluated through surveys to determine coverage, adherence and acceptability of SMC. We assessed the impact of the programs on incidence of simple and severe malaria, hospital mortality, all-cause hospitalizations and admissions with severe malarial anaemia, using program data. Estimates of SMC efficacy were made from the proportion of malaria cases who had received SMC and SMC coverage, using the screening method. Side-effects where monitored through re-inforced national pharmacovigilance systems. The prevalence of molecular markers of resistance to SMC drugs was assessed through surveys before and after SMC implementation. There has been a high level of acceptability of SMC in the communities. Monthly coverage of SMC exceeded 85% in rural areas but was lower in an urban area. When combined with a PP and delivered at the health center, coverage was similar to SMC alone. Pentavalent vaccine coverage increaased when combined with SMC in Chad. SMC led to substantial reductions of both simple and severe malaria cases in Mali, Chad and Niger. We observed a reduction in cases of severe malarial anaemia, but no reduction in the number of cases of cerebral malaria. Integration with other interventions is feasible and can prevent missed opportunities in the child health package.

1907

MALARIA INDICATORS IN THE DEMOCRATIC REPUBLIC OF THE CONGO, 2014

Filiberto Hernandez

Centers for Disease Control and Prevention, Atlanta, GA, United States

Malaria continues to be a major health problem in DRC, accounting for an estimated 40% of outpatient visits by children under five and 19% of the overall mortality in the same age group. The implementation of large scale malaria interventions in the country continues to face serious challenges. The USG funding for malaria activities in the Democratic Republic of Congo (DRC) has increased from $18 million in FY 2010, to 50 million in FY 2014, a substantial increase which has allowed the DRC to obtain the successful results seen in the last Demographic and Health Survey (2013). Results have shown: a) the increase in the use of mosquito nets by children under five, from 38% to 56%; b) the increase in their use by pregnant

women, from 43% to 60%; and c) the malaria prevalence in children under five, with a rate of 30.8% obtained by RTDs, and 22.6% obtained through microscopy tests. The aim of this study is to review malaria cases throughout ten years, and describe the different malaria interventions carried out during those same years and their impact. The NMCP is reviewing this data to define its new country malaria strategy 2015-2020. Additionally, data will be presented from the 5 provinces supported by PMI to show the impact of five years of interventions in those provinces. The US President's Malaria Initiative in the Democratic Republic of Congo has been supporting the majority of interventions in five provinces, and together, with the support of the Global Fund, the World Bank, and the Department for International Development of the British Government (DFID), the coverage of the country has reached all the health zones, even those with very difficult access.

DEVELOPMENT OF EFFECTOR MOLECULES TO BLOCK *LEISHMANIA* TRANSMISSION UTILIZING THE PARATRANSGENIC APPROACH

Ivy Hurwitz, Annabeth Fieck, Ravi Durvasula

University of New Mexico, Albuquerque, NM, United States

Leishmaniasis is a neglected tropical disease that affects 13 million people worldwide. This disease is caused by the protozoan parasite Leishmania, and is transmitted by the bite of an infected female phlebotomine sand fly. Our laboratory utilizes the paratransgenic approach to control parasite transmission by host vectors. In this approach, symbiotic or commensal bacteria residing within the gut of the vector are genetically modified to express molecules that target the parasite. In previous work, we had reported on the toxicity of honey bee melittin against ***Leishmania*** spp. Leishmaniacidal activities of human histones H2A and H2B has been shown by others. In this study, we are examining the combined toxicity of these two antimicrobial peptides (AMP's) on ***Leishmania major*** promastigotes in an effort to develop a broader panel of effector molecules for use in the paratransgenic strategy. In experiments measuring live/dead ratios of cultured promastigotes by flow cytometry and fluorescent plate assays, the IC100 for melittin and H2B are observed at 5 uM and 7 uM, respectively. Synergistic toxicity is observed when the AMP's are used in combination treatments, decreasing the calculated IC100 values by more than half. There results were further verified by con-focal microscopy. Similar experiments are underway to characterize the activity of these two AMP's against other strains of ***Leishmania*** as well as ***Trypanosoma cruzi***, the causative agent of Chagas disease. The addition of a second AMP to paratransgenic systems that result in more efficient parasite killing has multiple advantages. Specifically, it decreases the absolute expression levels required from the transformed commensal bacteria within the gut of the sand fly. Additionally, the use of multiple AMP's drastically reduces the incidence of acquired resistance by the parasite

1909

EVOLUTIONARY COMPARISON OF THE GENOME OF *LEISHMANIA DONOVANI* CLINICAL ISOLATES FROM INDIA WITH ITS ANCESTOR *LEPTOMONAS*

Neeloo Singh[1], Surendra Chikara[2]

[1]CSIR Central Drug Research Institute, Lucknow, India, [2]Xcelris Genomics, Ahmedabad, India

Flagellates of the family Trypanosomatidae fall into two natural groups. The ancestral genera is ***Leptomonas*** which is confined to invertebrates, the more evolved genera is ***Leishmania*** which uses both vertebrate and invertebrate hosts. Utilizing next generation sequencing technology we explore the genomes of the two clinical isolates, ***Leishmania*** and ***Leptomonas*** to answer a wide range of evolutionary and pathological questions. We find that the genome of ***Leishmania*** donovani was similar to size and coding capacity with other ***Leishmania*** genomes. However, genome of ***Leptomonas*** is much smaller but contains in contrast more protein coding genes. It was seen that this genome expansion is mostly due to larger number of repetitive sequences and analysis of SNPs showed that the core genome was more variable in this isolate. Aneuploidy indicated there is significant opportunity for generation of SNPs that may have many applications in molecular epidemiology. Transposable elements (TEs) provided a source of genetic variation in ***Leptomonas***. Variation in the Ras protein superfamily between ***Leishmania*** donovani and ***Leptomonas*** was observed. Absence of urea cycle in ***Leptomonas*** was found to be an ancestral feature. Our whole-genome sequence data reveals genetic structural differences between ***Leishmania*** and it's ancestral species ***Leptomonas***, which cannot be identified by using multilocus typing alone. Our research finding has immense potential for creating renewed impact of the parasite genome on biomedical research, contributing to a paradigm shift in research activities that will lead to new diagnosis and treatment.

1910

ELECTRONIC VOLUMETRIC ASSESSMENT DURING SODIUM STIBOGLUCONATE THERAPY IN PATIENTS WITH CUTANEOUS LEISHMANIASIS: A PROMISING TECHNIQUE USING DIGITAL 3D MODELS

Braulio M. Valencia[1], Fernando Zvietcovich[2], Roberto J. Lavarello[2], Andrea K. Boggild[3], Benjamin Castañeda[2], Alejandro Llanos-Cuentas[1]

[1]Institute of Tropical Medicine Alexander von Humboldt, Lima, Peru, [2]Pontificia Universidad Católica del Peru, Lima, Peru, [3]University of Toronto, Toronto, ON, Canada

Cutaneous Leishmaniasis (CL) is susceptible to bias and subjectivity during assessment of treatment response and follow-up. As a part of standard of care, methods to estimate the extent of lesions are usually performed through manual or visual methods which are non-uniform and difficult to standardize in low-income settings. This work shows a novel, non-invasive method to obtain metrics of depth and volume by creating digital models of CL lesions. Digital models of CL lesions were created by acquisition of point-clouds with a commercial 3D scanner. The data were exported using the .XYZ file format that provided the point coordinates to recreate 3D mesh models. After IRB approval, patients with CL were enrolled, and lesions were digitalized: twenty-six before treatment, and 8 at the end of treatment. Two volumes were considered from each lesion: inflammatory volume (IV, a volume between an imaginary line following normal skin surface and an imaginary surface located at the top of raised edges) and an ulcerative volume (UV, a volume between an imaginary line following normal skin surface and the deepest point of the ulcer). Three metrics (in mm3) and one coefficient were obtained for each lesion: global volume (GV: IV+UV), IV, UV, and the volume coefficient (VC: IV/UV proportion). Mean duration of disease was 2.2 ± 0.89 months. 12 of 26 (46%) were classified as ulcer-predominant (if UV was higher than IV), and 14 (54%) as inflammatory-predominant (if IV was higher than UV). Median metrics at baseline evaluation were: 221.6 for GV, 143.14 for IV, 36.6 for UV, and 1.66 for VC. According treatment outcome, there were no significant differences in these metrics at baseline evaluation. In patients with volumetric evaluations after treatment, GV was higher in those classified as treatment failure compared to those classified as cured after 1-3 months of follow-up (2218.5 vs. 224, p=0.04). As a proof of concept, this study represents initial evidence to support the utility of electronic volumetric assessment of treatment response and follow-up of CL, with future possible extension to other transmissible and non-transmissible dermal diseases.

1911

THE DILEMMAS OF CONGENITAL CHAGAS DISEASE SCREENING IN AN ENDEMIC SETTING

Louisa A. Messenger[1], Gerson Galdos-Cardenas[2], Victoria R. Rendell[3], Malasa Jois[4], Vishal Shah[5], Edward Valencia[6], Leny Sanchez[6], Janet Acosta[6], Manuela Verastegui[6], Herado Sanchez[6], Remo Gonza[6], Robert H. Gilman[2], Caryn Bern[7]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Duke University, Durham, NC, United States, [4]Brown University, Providence, RI, United States, [5]St. Louis University School of Medicine, St. Louis, MO, United States, [6]Universidad Peruana Cayetano Heredia, Lima, Peru, [7]University of California San Francisco, San Francisco, CA, United States

Concomitant with successful trans-national disease control programs across Latin America, Chagas disease has shifted from a neglected, endemic parasitic infection of the rural poor to an urbanized chronic disease and now a potentially emergent global health problem. Congenital transmission has become proportionately more important, estimated to account for 22% of new Trypanosoma cruzi infections in 2015. Treatment during infancy is significantly more efficacious and better tolerated than later, but current diagnostic methods, even when optimally executed, fail to detect over half of infected neonates and <20% of infants complete 9-months of follow-up. We recruited pregnant women presenting for delivery in two urban hospitals in Santa Cruz department, Bolivia and monitored infants of infected women at birth, 1, 6 and 9 months to evaluate the performance of quantitative PCR (qPCR), IgM Western blots (using trypomastigote excreted-secreted antigen; TESA-blots) and micromethod (microscopic observation of trypomastigotes) for newborn screening for congenital Chagas disease. Of 518 at-risk infants from 507 seropositive women, unequivocal congenital transmission was identified in 32 infants of 29 mothers, including 3 sets of concordantly infected twins (5.7% transmission rate); 6 additional neonates were diagnosed at 6 months or later and vectorial or intrapartum transmission could not be excluded. In cord blood, qPCR, TESA-blot and micromethod displayed sensitivity/specificity of 82.8%/97.3% (median of 7143.6 parasites/ml; interquartile range of 5.0-187788.9 parasites/ml), 71.4%/99.5% and 20.7%/100%, respectively. When birth and 1 month results were combined, cumulative sensitivity reached 96.9%, 89.7% and 38.7% for qPCR, TESA-blot and micromethod, respectively. qPCR has the potential to facilitate earlier diagnosis and circumvent loss to follow-up. We critically discuss the technical, logistical and economic obstacles of implementing routine molecular screening for congenital Chagas disease in resource-limited settings and describe the future prospects for improvement.

1912

GALECTIN 3 IS ASSOCIATED WITH THE MORE SEVERE FORM OF CHAGAS CARDIOMYOPATHY

Fabio Fernandes[1], Carlos H. Moreira[2], Léa C. Oliveira[3], Marcela Souza[4], Charles Mady[1], Barbara M. Ianni[1], Erika Manuli[4], Ester C. Sabino[4]

[1]Heart Institute, Hospital das Clínicas de São Paulo, School of Medicine, University of São Paulo, São Paulo, Brazil, [2]Institute of Infectology Emilio Ribas; Laboratory of Parasitology (LIM46), Tropical Medicine Institute of São Paulo, University of São Paulo, São Paulo, Brazil, [3]Laboratory of Medicine Laboratorial (LIM03), Hospital das Clínicas de São Paulo, School of Medicine, University of São Paulo, São Paulo, Brazil, [4]Laboratory of Parasitology (LIM46), Tropical Medicine Institute of São Paulo, University of São Paulo, São Paulo, Brazil

Chagas Chronic Cardiomyopathy (CC) is characterized by a diffuse myocarditis with intense myocardial remodeling, fibrosis, cardiomyocyte hypertrophy and damage. Gal-3 is involved into two pathophysiological mechanisms (fibrosis and inflammation), hence GAL-3 levels maybe a good biomarker to stratify Chagas Disease patients and identify those who could benefit from early treatment strategies. The objective of this study was to evaluate if Gal-3 level in plasma is associate with the development of the severe form of CC and prognosis. We have used samples collected in a previous retrospective cohort that enrolled ***T cruzi*** seropositive, and seronegative blood donors (BD) in São Paulo and Montes Claros, Brazil. This cohort was supplemented with CC patients from a tertiary hospital (Heart Institute). All subjects underwent a health clinical evaluation, ECG, and echocardiogram (Echo). ECG and Echo were reviewed blindly by centralized reading centers. The subjects were classified as with or without signs of CC by a blinded panel of 3 cardiologists. Gal-3 (VIDAS® galectin 3 France - bioMerieux Inc.) was available to test 441 samples: 101 negative controls, 190 BD without CC, 60 BD with CC, and 90 patients with CC. The median level of GAL-3 was 13.1ng/mL for negative controls, 12.ng/mL for BD without CC, 13.1ng/mL for BD and 15.4ng/mL for CC patients. The proportion of individuals with Gal-3 level > 17.8 was significantly higher ($p<0.0001$) among the CC patients (37.8%) as compared to negative controls (14.8%), BD without CC(11.1%) and BD with CC (16.7%). Ejection fraction <50 was also associated with higher levels of Gal3 ($p=0.0001$). The Gal3 showed correlation with lCAM-1, MPO, PAI-1, CRP, IL6, TNFα, IL8, VEGF, Troponin and NT-proBNP, with p values <0,01. Follow up date on mortality was available for the CC patients. In this group, we could detect an association of Gal-3 level and subsequent death in the follow up 5 years. ($p=0.0004$). In conclusion, our data suggest that Gal-3 is associated with the more severe form of CC and risk of death.

1913

A FIELD-APPLICABLE MOLECULAR TOOL TO DIAGNOSE AMERICAN CUTANEOUS LEISHMANIASIS

Bruno L. Travi[1], Omar A. Saldarriaga[1], Alejandro Castellanos[1], Gerald C. Baldeviano[2], Maxy De los Santos[2], Peter C. Melby[1], Andres G. Lescano[2]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]US Naval Medical Research Unit - 6, Lima, Peru

Dermal and mucosal leishmaniasis is widely distributed in Central and South America affecting an estimated 190,000- 300,000 people annually. Microscopy is the most common diagnostic method used in endemic regions but its sensitivity is low (≤70%) and tends to decrease further with disease chronicity. Serology is variable and does not distinguish between current and past infections. Conventional or quantitative PCR from dermal or mucosal samples have high sensitivity (≈87-98%) and specificity (≥87%) but require expensive equipment, trained personnel and lab facilities beyond the possibilities of resource-limited health infrastructure of endemic areas. We developed a novel point of care molecular test to diagnose dermal and mucosal leishmaniasis produced by ***Leishmania Viannia*** spp., which are responsible for the majority of cases. We designed primers and probes that targeted the kinetoplast DNA minicircles. ***Leishmania*** DNA was extracted using the Qiagen® kit and detected by isothermal Recombinase Polymerase Amplification coupled with a lateral flow immunochromatographic strip (RPA-LF). The test has sensitivity similar to real time PCR (gold standard) detecting as few as 0.1 parasites per reaction. It does not require expensive equipment and the results are read with the naked eye in < 1 hour. The RPA-LF specificity for the L. Viannia subgenus was confirmed by the amplification of ***L. braziliensis, L. panamensis, L. guyanensis, L. peruviana*** and ***L. lainsoni***. There was no cross amplification with ***L. chagasi, L. major, L. mexicana, L. amazonensis*** or ***T. cruzi***. Preliminary data indicated that RPA-LF has an excellent agreement with PCR as determined in patient samples from endemic areas of Peru. We are evaluating additional primer sets capable of amplifying the ***Leishmania*** subgenus with the goal of developing an RPA- multiplex lateral flow test that encompasses all species that produce cutaneous leishmaniasis. This novel method could fill the need for a field applicable diagnostic tool critical to cutaneous and mucosal leishmaniasis management and control.

1914

ACTIVATION OF BICYCLIC NITRO DRUGS BY A NOVEL NITROREDUCTASE (NTR2) IN *LEISHMANIA*

Susan Wyllie, Adam Roberts, Suzanne Norval, Stephen Patterson, Alan Fairlamb

University of Dundee, Dundee, United Kingdom

The novel nitroimidazopyran agent, (***S***)-PA-824, has potent antibacterial activity against ***Mycobacterium tuberculosis in vitro*** and ***in vivo*** and is currently in Phase II clinical trials for TB. In contrast to ***M. tuberculosis***, where the (***R***) enantiomer is inactive, our previous studies demonstrated that (***R***)-PA-824 shows potent cidal acitivity against ***Leishmania donovani***, the causative agent of visceral leishmaniasis (VL). In the murine model of VL, (***R***)-PA-824 led to >99% suppression of parasite burden when administered orally at 100 mg kg^{-1}, twice daily for 5 days. Defining the mechanism of action of this promising anti-leishmanial has now become the focus of our current studies. In general, nitro drugs are believed to function as pro drugs requiring enzyme mediated reduction before becoming cytotoxic. In trypanosomatids, a type I nitroreductase (NTR) has been demonstrated as catalysing the bio-activation of the bicyclic nitro drugs nifurtimox, benznidazole and fexinidazole. However, transgenic ***L. donovani*** promastigotes overexpressing ***L. major*** NTR do not show an increased sensitivity to (***R***)-PA-824 suggesting that this nitroimidazopyran is not activated by NTR. (***R***)-des-nitro-PA-824 is inactive against ***L. donovani in vitro***, confirming that the nitro group is important for the anti-leishmanial activity of PA-824. Thus, if the mechanism of action of PA-824 does involve bio-activation, then this putative reduction is mediated by an as-yet unidentified enzyme(s). Here, we describe our use of genome-wide sequencing, proteomics and genetic approaches to identify NTR2, a novel nitroreductase involved in the bio-activation of (***R***)-PA-824 and several other bicyclic nitro drugs.

1915

METABOLIC REGULATION OF MACROPHAGE FATE: THE ROLE OF MTORC2 SIGNALING IN ALTERNATIVELY ACTIVATED MACROPHAGES

Stanley Ching-Cheng Huang, Amber M. Smith, Bart Everts, Erika L. Pearce, Joel D. Schilling, Edward J. Pearce

Washington University School of Medicine, Department of Pathology and Immunology, St. Louis, MO, United States

The mammalian target of rapamycin complexes, mTORC1 and mTORC2 have emerged as important regulators of environmental cues for development of immune cells. mTORC1, the most well studied mTOR complex whose activity is highly responsive to changes in cellular glucose and amino acid levels. Intriguingly, however, it has been shown that the constitutive activation of mTORC1 negatively regulates the alternative (M2) macrophage activation. In contrast, it is still unknown that the role of mTORC2 in macrophage activation. Here we report that myeloid lineage specific deletion of Rictor, a critical adaptor protein of mTORC2 in macrophages, they failed to fully become M2 macrophages during the ***Heligmosomoides polygyrus*** infection and have protective immunity to the parasite. Also, importantly, we observed that level of IRF4 expression and glycolytic/mitochondrial metabolism was markedly decreased from Rictor-deficient M2 cells during the infection. Since IRF4 is required for aerobic glycolysis and development of CD8 T cells, we found that expression of IRF4 was elevated in IL-4 stimulated macrophages, and conditional IRF4 deletion in macrophages affected neither mTORC2 activity nor the phosphorylation of Stat6, but led to a significant reduction of glucose metabolism and polarization of M2 macrophages. Taken together, our finding suggests that mTORC2-IRF4 signaling links to metabolic reprogramming and activation of macrophages.

1916

EXPORTED EPOXIDE HYDROLASES MODULATE ERYTHROCYTE SIGNALLING LIPIDS DURING PLASMODIUM FALCIPARUM INFECTION

Natalie J. Spillman, Daniel E. Goldberg

Department of Internal Medicine (Infectious Diseases), Washington University School of Medicine, St. Louis, MO, United States

Erythrocytes are storage reservoirs for epoxide-containing lipid signalling molecules, including epoxyeicosatrienoic acids (EETs) and epoxy octadecenoic acids (EpOMEs). EETs/EpOMEs function as vasodilators and anti-inflammatory modulators in the blood stream. These bioactive epoxides are hydrolysed by epoxide hydrolases, converting them into less active diols. We have identified and characterized two epoxide hydrolases (EH) of ***Plasmodium falciparum***, PfEH1 and PfEH2. Both proteins are exported to the periphery of infected erythrocytes. Recombinantly expressed PfEH1 can hydrolyze a non-physiological reporter epoxide, and both enzymes convert several EET regioisomers to the corresponding diols. Overexpression of PfEH1 or PfEH2 in parasites results in a significant alteration in the epoxide fatty acids stored in the infected erythrocyte phospholipids. Although we were able to knock out PfEH1 and 2 ***in vitro***, we propose they may have an increased importance ***in vivo***. ***P. berghei ANKA*** has no predicted exported EHs, but chemical inhibition of the host EH enzyme reduced the percentage of mice that developed severe, cerebral malaria, without reducing parasitemia. We hypothesize that the parasite disruption of EETs/EpOMEs leads to perturbed vascular function, and favorable conditions for binding and sequestration of infected erythrocytes to the microvascular endothelium.

1917

A *PLASMODIUM* SPECIFIC KINASE IS AN ESSENTIAL S PHASE PROMOTING FACTOR DURING BLOOD-STAGE SCHIZOGONY

Markus Ganter[1], Jonathan M. Goldberg[1], Jeffrey D. Dvorin[2], Joao A. Paulo[3], Jonas King[4], Aditya S. Paul[1], Isabelle Coppens[4], Rays H. Jiang[5], Jing Yang[1], David A. Baker[6], Steven P. Gygi[3], Rhoel R. Dinglasan[4], Manoj T. Duraisingh[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Boston Children's Hospital, Boston, MA, United States, [3]Harvard Medical School, Boston, MA, United States, [4]Johns Hopkins Malaria Research Institute, Baltimore, MD, United States, [5]University of South Florida, Tampa, FL, United States, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom

Like invasion and host cell remodeling, ***Plasmodium*** schizogony is a parasite specific process, offering an attractive route for intervention. During schizogony a multinucleated cell is formed after which daughter parasites bud off the mother cell. In search of potential new drug targets, we assessed all schizont-stage kinases for their essentiality in ***Plasmodium falciparum***, employing the inducible destabilization domain system in a loss-of-function knockdown screen. We identified the ***P. falciparum*** cdc2-related protein kinase (CRK) 4 as essential for proliferation in the blood-stage and for transmission to anopheline mosquitoes. Knockdown of ***P. falciparum*** CRK4 led to a complete block of DNA replication at the onset of schizogony. Organellar development, however, was not impaired in mutant parasites. This suggests that the regulation of nuclear and organellar development is independent. By quantitative phosphoproteomic profiling, we identified key effects for ***P. falciparum*** CRK4 on pathways that co-ordinate cell cycle events including the initiation of DNA replication, histone modifications, and regulation of gene transcription. ***P. falciparum*** CRK4 was also found to be required for subsequent rounds of DNA replication, which characterize schizogony. Together our data indicate that chemotherapeutic targeting of ***P. falciparum*** CRK4 would be possible throughout schizogony, which in addition to blocking transmission, are attractive features for drug development.

1918

SCHISTOSOMA MANSONI INFECTION INDUCES ANTI-ATHEROGENIC TRANSCRIPTIONAL CHANGES IN HEPATIC MACROPHAGES

Keke C. Fairfax[1], Andrew Elvington[3], Andrew Ready[2], Edward J. Pearce[3], Gwendalyn J. Randolph[3]

[1]Purdue University, West Lafayette, IN, United States, [2]Washington University, St. Louis, MO, United States

Hepatic macrophages play an essential role in the granulomatous response to infection with the parasitic helminth ***Schistosoma Mansoni***, but the transcriptional changes that underlie this participation are poorly understood. To explore this, we sorted the two previously recognized hepatic macrophage populations (perivascular and Kupffer) from naïve and ***S. mansoni*** infected mice and performed microarray analysis as part of the Immunological Genome Project. Consistent with the pattern of great diversity identified in other organ macrophages, the two hepatic macrophage populations displayed signatures distinct from all other macrophages, with the two populations exhibiting remarkable differences between them. However, this diversity was greatly reduced following infection with ***S. mansoni***, and in fact, many of the transcripts identified as uniquely perivascular or Kupffer cell specific were lost following infection, raising the possibility that both populations may be replenished by monocytes following infection. Our analysis showed a profound alteration in phospholipid and cholesterol metabolic pathways, including prostaglandin signaling, in addition to alterations in M2 markers. These changes suggested a possible mechanism for the previously reported atheroprotective effects of ***S. mansoni*** infection. Indeed we find that ApoE null mice fed a high fat diet in combination with ***S. mansoni*** infection have reduced body mass and increased glucose tolerance in addition to reduced plaque area as compared to control mice.

1919

A GENOME-WIDE CRISPR/CAS9 SCREEN REVEALS GENES THAT ARE CRITICAL FOR *TOXOPLASMA GONDII* GROWTH IN HUMAN FIBROBLASTS

Diego Huet, Saima Sidik, Sebastian Lourido

Whitehead Institute for Biomedical Research, Cambridge, MA, United States

Despite recent advances in apicomplexan genetics, the available tools have remained low-throughput. Although RNAi can be used to elucidate gene function in ***Trypanosoma brucei***, differences in the underlying machinery have precluded its use in apicomplexans. Recently, we and others used CRISPR/Cas9 to generate double-stranded DNA breaks and efficiently induce precise mutations in ***Toxoplasma.*** We have now used CRISPR/Cas9 to perform pooled genetic screens. By transfecting a ***Toxoplasma*** strain that constitutively expresses Cas9 with a library comprised of ten different sgRNAs against each gene, we mutated every gene in the ***Toxoplasma*** genome, in multiple ways, in seven days. Quantifying the fold-change in abundance of each sgRNA over the course of this experiment using next-generation sequencing allowed us to identify genes that contribute to the fitness of ***Toxoplasma*** when grown in human fibroblasts. The power of having ten independent mutations per gene allowed us to identify a set of genes that we can confidently say are critical under these conditions. In a CRISPR/Cas9 screen performed in the presence of a toxic uracil analog, sgRNAs against a component of the uracil scavenging pathway were enriched by approximately 1000-fold, demonstrating that our platform yields expected results and holds potential for identifying mechanisms of drug resistance. These results give us insight into ***Toxoplasma's*** large set of uncharacterized genes on an unprecedented scale. Our work now focuses on characterizing a set of 58 hypothetical genes that are conserved within Apicomplexa and confer significant fitness defects when mutated.

1920

GENETIC MODIFICATION OF THE DIARRHEAL PATHOGEN *CRYPTOSPORIDIUM PARVUM*

Sumiti Vinayak, Mattie C. Pawlowic, Adam Sateriale, Carrie F. Brooks, Caleb J. Studstill, Yael Bar-Peled, Michael Cipriano, Boris Striepen

Center for Tropical and Emerging Global Diseases, University of Georgia, Athens, GA, United States

Cryptosporidium is the second most important pathogen after rotavirus to cause diarrhea in young children. ***Cryptosporidium*** is also an opportunistic pathogen and causes severe disease in HIV/AIDS patients and organ transplant recipients. Currently, there are no fully effective drugs or vaccines to treat or prevent cryptosporidiosis. The main roadblock in the development of drugs and vaccines is the overall poor tractability of ***Cryptosporidium*** due to lack of continuous culture system, poor animal models, and lack of genetic tools. We report here a robust approach to genetically modify this important human pathogen. We demonstrate the transfection of ***Cryptosporidium parvum*** sporozoites in tissue culture and optimization of regulatory sequences and electroporation conditions to drive expression of a luciferase reporter gene. We developed a mouse model for ***C. parvum*** infection to inject electroporated sporozoites directly into the small intestine of IFN-γknockout mice. We used the CRISPR/Cas9 system to knockout the parasite's thymidine kinase (***tk***) gene and replaced it with a cassette expressing the luciferase reporter fused to a neomycin resistance gene that conferred paromomycin resistance ***in vivo***. Quantitative PCR and luminescence measurements were used to monitor infection in mice, and development of paromomycin-resistant transgenic parasites. We confirmed loss of ***tk*** gene in the stable transgenics, and evaluated the use of transgenic oocysts for performing drug assays. Using this powerful approach, we have generated stable transgenic parasite lines that express other reporters such as fluorescent protein and red-shifted luciferase. We used the red-shifted luciferase transgenic to monitor and quantify the real-time dynamics of ***C. parvum*** infection in mice using ***in vivo*** bioluminescence imaging. Ongoing efforts are directed towards testing the efficacy of potential anti-cryptosporidial compounds in mice using this transgenic parasite. Our ability to genetically engineer ***C. parvum*** will help to answer key questions related to parasite biology and accelerate the development of novel therapeutics for disease intervention.

1921

TRYPANOSOMA BRUCEI INFECTION ACCELERATES THE MOUSE CIRCADIAN CLOCK

Filipa Rijo-Ferreira[1], Joseph S. Takahashi[2], Luisa M. Figueiredo[1]

[1]Instituto de Medicina Molecular, Biology of Parasitism Lab, Lisbon, Portugal, [2]UT Southwestern, Department of Neuroscience, Howard Hughes Medical Institute, Dallas, TX, United States

By living in a 24-hour world, organisms are subjected to daily environmental changes. Many organisms have evolved molecular mechanisms to anticipate such changes. In humans, the internal circadian clock regulates many physiological functions, including sleep/wake cycle and metabolism. Although the internal clock is controlled by the brain, all cells have an intrinsic clock. Patients with sleeping sickness show alterations of sleep/wake cycle, body temperature and endocrine secretion, which have led to the hypothesis that sleeping sickness may be a circadian rhythm disorder. We first infected mice with ***T. brucei*** and we recorded the circadian behavior using a running-wheel assay. We observed that infected animals run 2-fold less during the active phase and are 7-fold more active in the rest phase than healthy mice, confirming the changes in circadian behavior observed in patients. When we infected circadian reporter mice and measured the circadian parameters of several organs ***ex vivo,*** we observed that, although all organs have a robust circadian rhythm, those with higher parasite load have an internal clock that runs two hours faster than non-infected organs. These alterations were reproduced ***in vitro,*** when parasites were directly co-cultured with isolated

fibroblasts, suggesting that parasites may have a direct effect on the host cell circadian clock. Finally we observed that expression of clock genes ***in vivo*** is significantly affected in peripheral tissues, especially in those with the highest parasite load. These results show that (i) ***T. brucei*** mouse infection reproduces circadian behavior changes observed in humans; (ii) ***T. brucei*** infection accelerates the mouse circadian rhythm by two hours; (iii) this effect may be partly caused by a direct interaction with the parasite.

1922

THE INOSITOL PHOSPHATE PATHWAY CONTROLS TRANSCRIPTION OF TELOMERIC EXPRESSION SITES IN TRYPANOSOMES

Igor Cestari, Kenneth Stuart

Center for Infectious Disease Research, Seattle, WA, United States

African trypanosomes evade host antibody clearance by periodically changing their variant surface glycoprotein (VSG) coat. They transcribe only one VSG gene at a time from one of about 20 telomeric expression sites (ESs), and they undergo antigenic variation either by switching transcription between telomeric ESs or by recombination of the VSG gene expressed. We found that the inositol phosphate/phosphatidylinositol (IP) pathway controls both transcription of telomeric ESs and VSG antigenic switching in ***Trypanosoma brucei***. Conditional knockdown of phosphatidylinositol 5-kinase (PIP5K), phosphatidylinositol 5-phosphatase (PIP5Pase) or overexpression of phospholipase C (PLC) derepresses numerous silent telomeric ESs in ***T. brucei*** bloodstream forms. This derepression is specific to telomeric ESs and coincides with an increase in the number of telomeric and RNA polymerase I foci that colocalize outside of the nucleolus. Monoallelic VSG transcription resumes after re-expression of PIP5K; however, most of the resultant cells switch the VSG gene expressed. PIP5K, PLC, their metabolic substrates and products localize to the plasma membrane, whereas PIP5Pase localizes in the nucleus proximal to telomeres. PIP5Pase associates with repressor/activator protein 1 (RAP1), and their telomeric silencing function is altered by PIP5K knockdown. The results show that the IP pathway controls ES transcription and antigenic switching in ***T. brucei*** by epigenetic regulation of telomere silencing, which likely involve a signal transduction process.

1923

EXPLORING UNKNOWN GENES IN MALARIA PARASITES BY A ROBUST GENE REGULATORY SYSTEM

Suresh Maddur Ganesan, Alejandra Falla, Sebastian Nasamu, Jacquin C. Niles

Massachusetts Institute of Technology, Cambridge, MA, United States

Malaria is a major health problem in tropical and subtropical countries. The most severe form of malaria is caused by the parasite, Plasmodium falciparum. A limited set of antimalarial drugs is used to treat the disease, but drug resistance is spreading at alarming rate. Hence, there is an urgent need for identification of novel anti-malarial drugs. A major challenge in new antimalarial drug development is identification and prioritization of potential targets for drug discovery. This is mainly due to lack of reliable functional genetics tools for investigating parasite genes. To address this need, we have developed a RNA-protein interaction system that facilitates robust and inducible regulation of target gene translation in eukaryotic organisms, including Plasmodium. Here, we present the application of protein engineering approaches to integrate our synthetic control system with native Plasmodium translational regulatory mechanisms. In so doing, we have achieved substantially increased regulatory dynamic ranges (up to 200-fold) compared to a 5-10 fold range of the original system. As a proof-of-concept, we have successfully used this system to generate parasite lines in which various proteins of interest can be knocked down to reveal clear growth phenotypes. In addition, we have successfully combined this approach with CRISPR/Cas9 genome editing technology to rapidly validate essential genes. We are currently applying these genetic tools to broadly study parasite genes of unknown function. Since ~60% of the encoded P. falciparum genes have no known homologs in other eukaryotes, we believe that understanding their functions will aid in identifying potential targets for novel antimalarial drug development.

A NETWORK OF PROTEIN INTERACTIONS REQUIRED FOR TRAFFICKING OF *PF*EMP1 IN *P. FALCIPARUM*-INFECTED ERYTHROCYTES

Steven Batinovic[1], Emma McHugh[1], Aishwarya Kulkarni[1], Joseph D. Smith[2], Matthew W. Dixon[1], Leann Tilley[1]

[1]Department of Biochemistry and Molecular Biology, Bio21 Institute, The University of Melbourne, Parkville, VIC, Australia, [2]Center for Infectious Disease Research, Seattle, WA, United States

Plasmodium falciparum is the most virulent human malaria parasite. Parasites invade red blood cells (RBCs) and extensively modify the structure and morphology of their host cell - including the generation of virulence complexes on the surface of the erythrocyte. These complexes comprise of a collection of exported parasite proteins that assemble at knob-like structures under the surface of the erythrocyte membrane and allow infected RBCs to cytoadhere and sequester within the microvasculature of the host. One key parasite protein, ***P. falciparum*** Erythrocyte Membrane Protein-1 (PfEMP1), is largely responsible for this adhesion. It is becoming clear that PfEMP1 is trafficked with the aid of a complement of host and parasite-structures and compartments that are generated ***de novo*** during the approximate 48-hour lifecycle of the parasite inside its host RBC. In this work, we have made use of mini-PfEMP1 constructs to examine this complex export process. We have delineated discrete trafficking compartments that these virulence proteins associate with during export and used immunoprecipitation followed by mass spectrometry to identify the 'interactome' of virulence proteins in these compartments. Known and novel interacting-proteins were identified across multiple parasite and host compartments, consistent with our current knowledge of the ***Pf***EMP1 trafficking pathway. This includes parasite proteins localized to the parasite secretory pathway, parasitophorous vacuole (such as PTEX) and exported proteins found in the host RBC compartment. We also present the identification of a number of human chaperone-type proteins that may represent a mechanism for parasite recruitment of host factors in the export of parasite proteins such as ***Pf***EMP1. Using inducible knockdown systems we show that depletion of these identified proteins results in the reduction of ***Pf***EMP1 export to the surface of the RBC. Ultimately, understanding and targeting the export of parasite virulence proteins may ultimately allow us to ablate parasite virulence ***in vivo***.

PROGRAMMATIC USE OF MOLECULAR XENOMONITORING AT THE LEVEL OF EVALUATION UNITS TO ASSESS PERSISTENCE OF LYMPHATIC FILARIASIS IN SRI LANKA

Ramakrishna U. Rao[1], Sandhya D. Samarasekera[2], Kumara C. Nagodavithana[2], Udaya S. Ranasinghe[2], Manjula W. Punchihewa[3], Ralph H. Henderson[4], Gary J. Weil[1]

[1]Washington University School of Medicine, St. Louis, MO, United States, [2]Ministry of Health, Anti-Filariasis Campaign, Colombo, Sri Lanka, [3]Ministry of Health, Regional Anti-Filariasis Unit, Galle, Sri Lanka, [4]The Task Force for Global Health, Decatur, GA, United States

Sri Lanka's Anti Filariasis Campaign (AFC) distributed 5 annual rounds of MDA with DEC plus Alb. to all LF endemic regions in the country from 2002-2006. Post-MDA surveillance has consistently documented microfilaremia rates <1% in all sentinel and spot check sites, and all implementation units easily satisfied WHO TAS targets in 2013. However, recent studies have shown that Sri Lanka has low level persistence of LF in some areas based on several criteria, especially molecular xenomonitoring (MX, detection of filarial DNA in mosquitoes). Some of the highest signals for persistence of LF were observed in sentinel sites in Galle district. The purpose of this study was to demonstrate the use of MX at the program

level and to field test different sampling methods. Galle district (population 1.1 million) was divided into two evaluation units (EUs). These included a coastal EU with persistent LF and a low risk inland EU. Mosquitoes were systematically sampled from ~300 trap sites in 30 randomly selected clusters (lower health administrative units) per EU. Approximately 28,000 blood fed, gravid or semigravid Culex quinquefasciatus mosquitoes were collected with CDC gravid traps, sorted into pools, and tested for filarial DNA by qPCR. 92/620 pools (14.8%) from the coastal EU and 8/583 pools (1.4%) from the inland EU were positive for filarial DNA. 16/30 clusters in the coastal EU had one or more positive pools compared to 3/30 in the inland EU. Maximum likelihood estimates (MLE) for filarial DNA rates calculated by Poolscreen2 were essentially the same when the same number of pools were collected and tested from 75, 150, or 300 trap sites. The range of filarial DNA rates calculated in the coastal EU with the different samples was 0.61-0.72%, and the range in the inland EU was 0.04-0.06%. The ability to use a smaller number of trap sites reduces the cost and time required for mosquito sampling. The MX results suggest there is widespread, low-level persistence of LF in coastal Galle district 8 years after the last round of MDA. This study has shown MX can be used by national programs to assess and map the persistence of LF at the level of large EUs in regions with Culex transmission.

1926

EPIDEMIOLOGICAL, CLINICAL, AND LABORATORY EVALUATION OF ONCHOCERCIASIS IN AN AREA OF HIGH PREVALENCE -TSHOPO PROJECT AREA, DEMOCRATIC REPUBLIC OF THE CONGO, 2014

Nana Wilson[1], Paul T. Cantey[2], Josias Likwela[3], Karla Feeser[4], Nestor Ndakala Gyamba[5], Jacques Muzinga wa Muzinga[5], Nicholas Ayebazibwe[6], Yassa D. Ndjakani[7], Naomi Awaca Pitchouna[8], Dieudonné Mumba Ngoyi[9], Antoinette K. Tshefu[10], Vitaliano Cama[1]

[1]Division of Parasitic Diseases and Malaria and Epidemic Intelligence Service, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Programme National de la Lutte contre l'Onchocercose, Kisangani, Democratic Republic of the Congo, [4]Oak Ridge Institute for Science and Education, Oak Ridge, TN, United States, [5]Field Epidemiology and Laboratory Training Program, Kinshasa, Democratic Republic of the Congo, [6]African Field Epidemiology Network, Kampala, Uganda, [7]Division of Global Health Protection, Centers for Disease Control and Prevention, Kinshasa, Democratic Republic of the Congo, [8]Programme Nationale de la Lutte contre l'Onchocercose, Kinshasa, Democratic Republic of the Congo, [9]Institut National de Recherche Biomédicale, Kinshasa, Congo, Democratic Republic of the, [10]Ecole de Santé Publique, Kinshasa, Democratic Republic of the Congo,

Onchocerciasis, a neglected parasitic disease caused by Onchocerca volvulus, affects at least 37 million people globally. Efforts to eliminate this disease are based on mass drug administration of ivermectin (IVM MDA). As part of a study to evaluate tools for measuring the impact of elimination efforts, we evaluated different diagnostic tests for O. volvulus. We performed convenience sampling in Tshopo Project area in the Democratic Republic of Congo, where there was a baseline nodule prevalence of 50-70%, and IVM MDA had been ongoing for 1-5 years before the study. Risk factor and clinical data were collected for 500 people. Blood smears for Loa loa and Mansonella perstans, immunochromatographic card tests for lymphatic filariasis (LF), and skin snips for onchocerciasis were evaluated on-site. Plasma, serum, blood smears, dried blood spots, and preserved skin snips were sent to CDC-Atlanta for further testing. Median participant age was 50 years (range: 6-88 years); 193 (39%) were female. Past-year ivermectin use was reported by 60 (12%), though 117 (34%) reported having taken it at least once before. At least one nodule was present in 253 (51%) people, with a median of three (range 1-11) nodules. Onchocercal eye disease was present in five (1%) people; one (0.2%) had microfilaria (MF) in the anterior chamber of the eye. The skin snip was positive for O. volvulus in 205 (41%) people. Among those with at least one positive snip, the mean MF load per snip, determined by averaging the number in both snips, was 27.5 (range: 0.5-341.5). On-site tests for other filariae showed 273 (55%) people were infected with M. perstans, 108 (22%) with L. loa, and 25 (5%) with LF. Six (1%) people were infected with all four filarial parasites, 51 (10%) with three, and 135 (27%) with two. The OV-16 antibody test for O. volvulus was positive in 333 (67%) people. Additional laboratory testing is pending to define OV-16 test sensitivity and specificity in this setting. A better understanding of the performance of the OV-16 antibody test in the African context, particularly in the setting of co-endemic filarial infections, is needed to ensure proper usage by elimination programs.

1927

TOWARDS THE ELIMINATION OF LYMPHATIC FILARIASIS IN MALAWI: CESSATION OF MASS DRUG ADMINISTRATION NATIONWIDE AFTER TRANSMISSION ASSESSMENT SURVEYS

Square Mkwanda[1], Bagrey Ngwira[2], Brent Thomas[3], Joan Fahy[3], Maria Rebollo[4], Louise Kelly-Hope[3], **Moses Bockarie**[3]

[1]Ministry of Health, Lilongwe, Malawi, [2]College of Medicine, Lilongwe, Malawi, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]NTD Support Center, Task Force for Global Health, Atlanta, GA, United States

Malawi, a small land-locked country in south-eastern Africa was shown to be highly endemic for lymphatic filariasis (LF) when disease mapping at national scale was completed in 2008. LF is a debilitating mosquito-borne parasitic infection that is endemic in 34 countries in Africa. Mapping delineated 26 LF endemic districts out of 28 and mass drug administration (MDA) to eliminate the disease started in 9 districts in 2008. In 2009, MDA was scaled up to 100% geographic coverage for the target population of 13 million people at risk. Between 2008 and 2014, treatment coverage surpassed 80% for each MDA round. In 2014, after 6 consecutive rounds of MDA, Malawi met all the criteria to conduct transmission assessment surveys (TAS) to determine if transmission of LF has been interrupted. Pre-TAS sentinel site surveys involving >300 parsons, five years or older, per site were conducted at 48 sites. None of the sentinel sites was shown to have a microfilaria (MF) prevalence rate of 1% or greater. In 2014, TAS was conducted in 11 evaluation units (EUs) following WHO guidelines and infection status determined using a point of care ICT method. The survey was conducted in 30 randomly selected schools per EU and altogether 18,337 children, about 6 and 7 years old were enrolled from 330 schools. A total of 34 (0.19%) children from all 11 EUs were found to be ICT positive. The LF infection rate for each EU was below the critical cut-off level suggesting that all EUs met the criteria to stop MDA. The NTD Regional Programme Review Group (RPRG) for the WHO African Region reviewed and approved the TAS results in 2015 indicating that MDA could be stopped in Malawi. However Malawi is endemic for two other debilitating neglected tropical diseases targeted with the same drugs as LF: onchocerciasis and soil transmitted helminthiasis. The endemicity status of these two diseases should be taken in to consideration before any decision to stop distribution of ivermectin and albendazole can be made. The RPRG report singled out Malawi for a special commendation as a success story. Stopping MDA in Malawi represents a big step forward for the global LF elimination programme as we approach the 2020 target.

1928

SUCCESSFUL FINAL TRANSMISSION ASSESSMENT SURVEY FOR LYMPHATIC FILARIASIS USING ICT AND STRIP TEST SIX YEARS AFTER STOPPING MDA IN TOGO

Améyo M. Dorkenoo[1], Rachel N. Bronzan[2], Kossi G. Yakpa[1], Efoé Sossou[1], Poukpessi Adjeloh[1], Menssah Teko[1], Anders Seim[3], Yao Sodahlon[4]

[1]Ministry of Health, Lomé, Togo, [2]HDI, Seattle, WA, United States, [3]HDI, Oslo, Norway, [4]Mectizan Donation Program, Atlanta, GA, United States

Lymphatic filariasis (LF) was once endemic in 8 of the 40 districts in Togo. From 2000 to 2009, the National Lymphatic Filariasis Control Program of Togo conducted between seven and nine rounds of mass drug administration (MDA) with albendazole and ivermectin in these 8 districts. In 2010, based on consistently high MDA coverage and low prevalence of nocturnal microfilaremia (<1%) at sentinel and spot-check sites, MDA for LF was stopped following a successful Transmission Assessment Survey (TAS). According to World Health Organization (WHO) recommendations, two TAS should be conducted 2 to 3 and 5 to 6 years after stopping MDA. Togo conducted and passed its first post-MDA TAS in 2012, and its second, final post-MDA TAS in January 2015, to reconfirm that there is no transmission of Wuchereria bancrofti. We report on this latter survey here. The survey was conducted according to WHO recommendations. The 8 endemic districts were grouped into 4 evaluation units (EU); in the north, Tone, Cinkassé and Kpendjal districts comprise EU1; in the northeast, Binah and Doufelgou districts make EU2; Kozah district in central eastern Togo is EU3; and Amou and Haho districts in the south are EU4. School-going children aged 6 to 7 years old were selected for testing using cluster sampling. Children were tested for LF filarial antigen using both an immunochromatographic test (ICT) and an LF test strip in EU1 and EU2, and ICT alone in EU3 and EU4. Test results were scored 0 for negative tests and 1 to 4 according to the intensity of a positive result. An EU was considered to have successfully passed the TAS when the number of positive cases found was inferior to a critical cut-off number, which varied from 18 to 20 among the EUs. Of the children tested – 1701 in EU1, 1547 in EU2, 1542 in EU3, and 1564 in EU4 – there were, respectively, 6 (0.35%), 0 (0%), 0 (0%) and 0 (0%) positive cases found, well below the critical threshold in every EU. All six cases were positive by both test methods. The risk of recrudescence of LF remains very low in these 8 previously endemic districts more than six years after stopping MDA for LF in Togo. Togo is preparing a dossier to submit to WHO for validation of elimination of LF.

1929

SHRINKING THE LYMPHATIC FILARIASIS MAP: DOES GABON NEED TREATMENT TO ELIMINATE LYMPHATIC FILARIASIS?

Maria Rebollo Polo[1], Julienne Atsame[2], Vitaliano Cama[3], Moses John Bockarie[4]

[1]Task Force for Global Health, Decatur, GA, United States, [2]Ministry of Health Gabon, Libreville, Gabon, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Historical records suggest that lymphatic filariasis (LF), was found in Gabon, but there is little information on its presence. MDA has never been conducted. Establishing the endemicity of LF is challenging using traditional parasitological and serological methods because of the limited skills for microscopy and coendemicity with Loa loa (loa). Loa and Wb microfilaria are difficult to distinguish microscopically and Loa antigens have been shown to cross react with Wb antigens in individuals with high Loa microfilaria counts who are negative for Wb test positive by ICT. We conducted a nationwide integrated survey of LF, onchocerciasis and loiasis. For LF, 114 villages were surveyed across the 9 provinces. Individuals aged 15 years or above were tested using ICT cards. A total of 28 ICT positive individuals were found in 22 communities, from 18 different districts. To further investigate if the ICT positives found during the survey were truly due to Wb and not a cross reaction due to Loa infection, we collected dried blood spots (DBS) to perform multiplex assays for Wb123 and Bm14, two antigens for filarial parasites. Antibody based assays to detect Wb123 has been shown to be sensitive and specific for LF infection while Bm14 has lower specificity and is recognized by a proportion of individual with other filarial infections. DNA was extracted from each DBS and amplified by PCR and qPCR using pan filarial primers. Only one sample had borderline positive responses to Wb123, but 13 had positive serology to Bm14, suggesting that ICT positivity was related to Loa and not Wb. All 28 samples had positive results for Loa by both PCR approaches. Our inability to confirm that ICT positivity was related to Wb suggests that LF is no longer present and therefore no intervention is required against LF. More robust epidemiological methods may be required to confirm that transmission of LF has been interrupted. These results would represent a tremendous step forward for the Global Program to Eliminate Lymphatic filariasis, shrinking the LF map by one more country and helping to cross the bridge towards the achievement of the ultimate goal of worldwide elimination of LF by 2020.

1930

PROGRESS TOWARDS LYMPHATIC FILARIASIS ELIMINATION IN SIERRA LEONE

Santigie Sesay[1], Jusufu Paye[2], Mohamed S. Bah[2], Florence M. McCarthy[1], Abdulai Conteh[1], **Mustapha Sonnie**[2], Mary H. Hodges[2], Joseph B. Koroma[3], Yaobi Zhang[4]

[1]Neglected Tropical Disease Program, Ministry of Health and Sanitation, Freetown, Sierra Leone, [2]Helen Keller International - Sierra Leone, Freetown, Sierra Leone, [3]Family Health International (FHI 360), Accra, Ghana, [4]Helen Keller International Regional Office for Africa, Dakar, Senegal

Lymphatic filariasis (LF) is endemic across Sierra Leone, and mass drug administration (MDA) with ivermectin and albendazole started in 2007, reaching 100% geographical coverage in 2010 with effective epidemiological coverage. Baseline microfilaraemia (mf) level was assessed before the first MDA. Mid-term assessment (after the 3rd MDA) and pre-TAS (after the 5th MDA) was conducted in 12 rural health districts (HDs) at sentinel sites (SS) and spot check sites (SC), using midnight blood samples from at least 300 people at each site. Two HDs were paired into each group (6 groups) according to population size and epidemiological characteristics, sharing SS and SC. At baseline (14 sites), the mean mf prevalence in 12 HDs was 2.6% (95% CI: 2.3-3.0%), ranging 0-6.9%. The mean mf density was 1.3mf/ml (95% CI: 1.0-1.7). Ten HDs had mf prevalence ≥1% at SS. At mid-term (6 SS and 6 SC), the mean mf prevalence was 0.3% (95% CI: 0.2-0.5%), ranging 0-1.6%. The mean mf density was 0.1mf/ml (95% CI: 0.0-0.1). Eleven HDs showed mf prevalence <1% at SS and SC. In 2013 a pre-TAS was conducted in 6 SS and 7 SC. Overall mf prevalence was 0.5% (95% CI: 0.4%-0.8%), ranging 0-2.7%. The mean mf density was 1.0mf/ml (95% CI: 0.30-1.8). Nine HDs showed mf prevalence <1%, persistent from the mid-term. Compared to baseline there was significant decrease in mf prevalence and mf density ($p<0.001$). Eight districts qualified for and will be subject to transmission assessment survey (TAS). Three HDs (Bombali, Kailahun, and Koinadugu) that showed mf prevalence ≥1% had baseline mf prevalence 6.9%, 5.7% and 2.6% respectively, and, together with Kenema (though mf prevalence <1% at pre-TAS), share borders with Guinea and/or Liberia where 100% geographical coverage of MDA has not been reached. These 4 HDs will continue MDA for additional 2 years, while the cross border issues are addressed. Significant increase in mf density from the mid-term was mainly due to a SC in hard to reach areas in Bombali. This highlights the importance of SC in identifying hot spot of LF prior to TAS.
