THE ZMAPP, ZMAB, AND MB-003 COCKTAIL ANTIBODIES INHIBIT EBOLA VIRUS BY BINDING TO NON-IDENTICAL EPITOPES ON THREE DOMAINS OF THE GLYCOPROTEIN

Edgar Davidson, Christopher Bryan, Rachel H. Fong, Trevor Barnes, Benjamin J. Doranz

Integral Molecular, Inc., Philadelphia, PA, United States

Cocktails of monoclonal antibodies (MAbs) that target the Ebola virus (EBOV) surface glycoprotein (GP) have been used under emergency compassionate treatment protocols in fifteen patients. However, the detailed epitope binding sites for the MAbs in ZMapp, ZMAb, as well as the related MB-003 cocktail, have not been fully elucidated. In this study we resolved the amino acid epitopes of all six MAbs in these cocktails, as well as the commonly used reference MAb KZ52. Comprehensive alanine scanning (shotgun mutagenesis) was used to create 641 EBOV GP variants that were individually expressed in human cells to enable identification of the most energetically important GP residues required for the binding of each MAb. Identification of epitope residues for these MAbs helps explain their breadth of reactivity against different EBOV species, predict viral evasion against these MAbs, and design new cocktails of MAbs that may offer improved complementarity.

HETEROGENEITIES IN THE CASE FATALITY RATE IN THE EBOLA OUTBREAK IN WEST AFRICA

Tini Garske[1], WHO Ebola Response Team[2]

[1]MRC Centre for Outbreak Analysis and Modelling, London, United Kingdom, [2]World Health Organization, Geneva, Switzerland

The ongoing Ebola outbreak in West Africa is the largest on record with over 24,000 case and 10,000 deaths officially recorded by April 2015, the true burden likely considerably higher - a humanitarian catastrophe for which we were not adequately prepared. The case fatality ratio (CFR, proportion of cases that are fatal) is a key indicator of disease severity useful for gauging the appropriate public health response or for evaluating treatment benefits if estimated accurately.We analysed the VHF databases of the three most heavily affected countries Guinea, Liberia and Sierra Leone. The overall CFR in was 68.4% (95% CI: 67.4% - 69.5%) in confirmed and probable cases, with age the most important modifier of survival probabilities: the CFR decreased throughout childhood with a minimum around 15 years of age, then increasing monotonically with age.We classified Treatment Centers (TCs) into 6 types. The CFR varied significantly between TC types: it was higher among cases who were not hospitalized or whose hospitalization status was unknown than that of hospitalized patients ($p<0.001$). Furthermore, the CFR varied between districts and between TCs more than would be expected by chance. We developed a statistical analysis to detect outliers in CFR between districts ($n=41$) and TCs ($n=32$) with 10 or more cases, adjusting for known factors influencing survival and identified twelve districts - eight (two in Liberia and three each in Guinea and Sierra Leone) with significantly higher and four (two in Sierra Leone and one each in Guinea and Liberia) with significantly lower CFR than the average, while there were two TCs with significantly higher and two TCs with significantly lower CFR than average. From the current dataset we cannot determine whether the observed variation in CFR seen by district or TC reflects real (perhaps care-related) differences in survival or was caused by differences in reporting practices or case ascertainment. We will update these results with the latest dataset available in October 2015.

3

PRECLINICAL DEVELOPMENT OF AN EBOLA VIRUS VACCINE BASED ON RECOMBINANT SUBUNITS EXPRESSED IN INSECT CELLS

Axel T. Lehrer[1], Michael M. Lieberman[1], Teri-Ann S. Wong[1], Heinz Feldmann[2], Andrea Marzi[2]

[1]University of Hawaii, Honolulu, HI, United States, [2]National Institute of Allergy and Infectious Diseases, Laboratory of Virology, Hamilton, MT, United States

Soluble recombinant Ebola virus glycoproteins (GP) and matrix proteins (VP24 and VP40) were generated in the Drosophila S2 cell expression system and purified by immunoaffinity chromatography. The immunogenicity of recombinant subunits and admixtures formulated with or without clinically relevant adjuvants was evaluated in mice, guinea pigs and macaques. Strong antigen-specific IgG titers as well as virus neutralizing titers were observed after administering two or three doses of adjuvanted formulations. In mice and non-human primates subunit proteins were also shown to elicit cell mediated immune responses. Analysis of secreted cytokines in batch-cultured, antigen-stimulated splenocytes or PBMC's demonstrated antigen-induced Th1 and Th2 type responses.Recombinant vaccine candidates were tested in mice for protection against challenge with mouse-adapted EBOV. All vaccine formulations containing EBOV GP generated protective responses and serum transfer from such animals into naïve mice demonstrated that humoral immunity alone can be fully protective. Furthermore, the transfer of immune splenocytes into naïve mice showed that recombinant GP and VP24 subunits elicit functional T cell responses that lead to protection against live virus challenge.Immunogenicity and efficacy studies in guinea pigs were focused on optimized antigen dosing, antigenic balance and adjuvantation. Multiple formulations consistently produced strong antibody responses and demonstrated 100% protective efficacy in the EBOV guinea pig model.Results from studies in two species of non-human primates suggest that vaccination with GP+VP40+VP24 and an emulsion-based adjuvant consistently produces high anti-EBOV IgG and virus neutralizing titers. This prevents viremia subsequent to live virus challenge and protects animals from terminal EBOV disease. These studies suggest that we have defined a viable Ebola virus vaccine candidate based on non-replicating viral subunits.

4

PROTEIN-LEVEL SPECIFICITY OF ANTIBODY RESPONSES TO EBOLA AND MARBURG VIRUSES BY HUMAN SURVIVORS OF INFECTION

Mohan Natesan, Teddy Kamata, Sarah Keasey, John M. Dye, Robert G. Ulrich

U.S. Army Medical Research Institute for Infectious Diseases, Fort Detrick, MD, United States

The lack of approved Ebola vaccines or therapeutics has contributed to the high mortality rate of the current outbreak. Clinical evidence suggests that serum from recovered individuals may be effective in the treatment of active cases. The epidemic caused by ***Zaire ebolavirus*** has infected >20,000 people, yet previous outbreaks involving other species of filoviruses also resulted in many fatalities. It follows that variability in human responses to infection can influence the therapeutic effects of antibody products. We examined antibody specificity with sera collected from survivors of outbreaks that were caused by ***Marburg marburgvirus***(MARV), ***Bundibugyo ebolavirus*** (BDBV), or ***Sudan ebolavirus*** (SUDV). To measure antibody responses, we used a protein microarray that displayed NP,VP40, and GP antigens from isolates of the six species of filoviruses that are primate pathogens. Analysis of the microarray data by hierarchical clustering revealed clear separation of positive signals from negative controls. The control samples clustered according to geographical region, with non-infected US subjects exhibiting

the lowest background levels of antibodies. Statistically significant antibody responses to autologous antigens were observed for all three outbreak cohorts. Consistent with amino acid sequence similarities, NP was most cross-reactive and exhibited the highest level of antibody responses, while antibody responses to GP were the most specific. Antibodies to GP, NP and VP40 were also long-lived, as observed for Gulu SUDV survivors 14 years after infection. While most sera were not monospecific, antibodies from MARV survivors presented the lowest level of cross-reactivity with heterologous antigens. Our results suggest that there is a considerable amount of variability in human responses to Ebola and Marburg viruses. The observed anti-GP antibodies, which are important for blocking virus entry into cells, were primarily directed towards the infecting species, whereas antibodies to VP40 and NP may also serve as biomarkers of infection.

5

COMPARISON OF RIFT VALLEY FEVER VIRUS PREVALENCE AMONG COMMUNITY MEMBERS AND SLAUGHTERHOUSE WORKERS IN WESTERN KENYA

Elysse N. Grossi-Soyster[1], Elizabeth A. Cooke[2], William A. de Glanville[2], Lian F. Thomas[2], Njeri C. Wamae[3], Sam Kariuki[3], Eric M. Fèvre[4], A. Desiree LaBeaud[1]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Center for Infection, Immunity and Evolution, University of Edinburgh, Edinburgh, United Kingdom, [3]Center for Microbiology Research, Kenya Medical Research Institute, Nairobi, Kenya, [4]International Livestock Research Institute, Nairobi, Kenya

Rift Valley fever virus (RVFV) is a virus of the Bunyaviridae family that infects both domesticated animals, primarily livestock, and humans. The spread of RVFV and the occurrence of zoonotic infections are both considered to be related to the handling and trading of infected livestock. RVFV is also transmitted by mosquitoes, yet determining the contribution of mosquito-borne transmission towards RVFV infection in humans is difficult, mainly due to limited surveillance. The goal of this study was to measure the seroprevalence of RVFV in a rural community that may have exposure to livestock through animal herding and husbandry (n=2071), and compare this to the seroprevalence of RVFV in persons employed in slaughterhouses in the study area in western Kenya (n=720). Samples were screened in-house for anti-RVFV IgG by indirect ELISA. Of the community samples, 16 samples (0.77%, CI95 0.44 to 1.25) were positive for RVFV IgG, whereas 19 of 720 samples (2.64%, CI95 1.6 to 4.1) from slaughterhouse workers were positive for RVFV IgG (p=0.0003). Anti-RVFV IgG concentrations in positive samples were higher overall in the slaughterhouse worker samples than those of the community samples (geometric mean concentrations of 5.583 AU/ml (p=0.0292) versus 3.522 AU/ml (p=0.0003), respectively). Variation in anti-RVFV antibody concentrations between the two groups may reflect inherent differences in the nature of the exposure to RVFV and inoculum size. Risk factors for the community samples include occupation as a farmer (OR 4.8, CI95 1.1 to 21.2, p=0.040) and age of >36 years (OR 8.2, CI95 2.0 to 34.2, p=0.004). Risk factors associated with the slaughterhouse samples include age of >36 years (OR 2.8, CI95 0.8 to 10.2, p=0.12), position as a slaughterman compared to other occupations in the slaughterhouse (OR 3.3, CI95 1.0 to 11.2, p=0.06), and working with only cattle (OR 3.9, CI95 0.8 to 18.0, p=0.08) instead of in a mixed-ruminant slaughterhouse. These results confirm the presence of RVFV in western Kenya, of which direct contact with livestock may increase risk for RVFV transmission, and suggest that mode of transmission influences host immune response to RVFV.

6

CO-CIRCULATION OF HUMAN MONKEYPOX VIRUS AND VARICELLA-ZOSTER VIRUS (CHICKENPOX) IN THE SANKURU DISTRICT, DEMOCRATIC REPUBLIC OF CONGO

Chelsea L. McMullen[1], Nicole A. Hoff[2], Reena H. Doshi[2], Patrick Mukadi[3], Benoit Kebela-Illunga[4], Robert Shongo[3], Emile Okitolonda[5], Jean-Jacques Muyembe[3], Anne W. Rimoin[2]

[1]Duke University, Mooresville, NC, United States, [2]University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, [3]National Institute of Biomedical Research, Kinshasa, Democratic Republic of the Congo, [4]DRC Ministry of Health, Kinshasa, Democratic Republic of the Congo, [5]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Monkeypox virus (MPXV) is considered the most important virus in the orthopoxvirus genus since the eradication of smallpox (variola). MPXV causes similar clinical features to chickenpox, caused by varicella zoster virus (VZV). There have been reports of the co-circulation of MPXV and VZV in Central Africa. However, a sustained outbreak of both viruses has never been confirmed. Here, we use data from a 2005-2007 active surveillance program for human MPX in Kasai Oriental province, Democratic Republic of Congo (DRC) to show that co-circulation is occurring in 9 health zones of the Sankuru District. Demographic and contact tracing information was collected as well as samples of vesicles, crusts, or fluid from active lesions. . Samples were tested for both MPXV and VZV by PCR and test results were aggregated into the following categories: -MPXV/-VZV, +MPXV/-VZV, -MPXV/+VZV, and +MPXV/+VZV. Proportions were compared across the 9 health zones to determine which zones had the highest incidence of co-circulation. Cases with GPS coordinates were plotted geographically by time period to assess the spatiotemporal spread of the outbreaks. Additionally, an adjacency matrix of contacts was used to create a graph of the contact network. All analyses were completed using R and Excel. Of the 1115 cases investigated during the active surveillance period that were tested for MPX V and VZV, 53% tested positive for MPXV only, while 24% were only VZV positive. Approximately 8% of cases were negative for both viruses and 14% had evidence of MPX/VZV co-infection. At least one +MPXV/+VZV case was detected in each of the health zones, with Lodja and neighboring Djalo Ndjeka containing the most significant amount of both +MPXV/+VZV and +MPXV/-VZV.Although MPXV and VZV have been confirmed to co-infect humans, their co-circulation within the same outbreaks has never been confirmed, and its epidemiological significance is little understood. Here, we show the chains of transmission where MPXV and VZV both thrived, as well as potential geographical factors involved in co-circulation success.

7

OUTBREAK INVESTIGATION OF KAYSANUR FOREST DISEASE (KFD) IN WAYANAD DISTRICT, KERALA, INDIA 2015

Preeti Padda[1], Aakash Srivastava[1], Samir V. Sodha[2], N. Balakrishnan[3], Vidhya N[4], Anil Kumar[1], S. Venkatesh[1], Neeta Vijayan[4]

[1]National Centre for Disease Control, New Delhi, India, [2]Centre for Disease Control and Prevention, New Delhi, India, [3]National Centre for Disease Control, Bangalore, India, [4]Government Health Services, Wayanad, India

Kyasanur Forest disease (KFD), a tickborne viral hemorrhagic fever, is endemic to Karnataka State but has been reported spreading to bordering states of Tamil Nadu and Kerala. Infected ticks transmit infection to monkeys, the amplifying host, which disseminate infection (hotspots). Vaccination of high risk populations is the primary strategy for controlling KFD along with use of personal protection measures. On February 6, 2015, Kerala reported its first KFD outbreak in an area adjoining Chikenji forest range of Wayanad district. The outbreak was investigated to assess its extent and identify risk factors. Residents of Sulthan Bathery taluk (sub-district) who during 25 December 2014 - 13 March 2015 presented with sudden onset of fever, headache, and myalgia were defined as

cases. For each case we selected two healthy controls matched for age, sex and place of residence and they were interviewed regarding recent exposures using a structured questionnaire. Entomological and monkey death investigations were also conducted. We identified 113 cases (attack rate 6.9 cases/10,000 persons) with a case fatality rate of 5.3%. Most cases (96%) were over 14 years of age and 62% were females. None had received vaccination prior to this outbreak. Of 81 cases laboratory tested, 43 (53%) confirmed for KFD virus (KFDV) by reverse transcription polymerase chain reaction (RT-PCR). Among the enrolled 59 cases and 118 controls, a recent visit to forest (OR=4.8, 95%CI=2.1-10.6), grazing animals in forest (OR=3.1, 95%CI=2.2-6.9), exposure to monkey death (OR=4.1, 95%CI=2.2-7.2) and collection of heaps of leaves around house (OR=1.9, 95%CI=1.09-2.8) were significantly associated with the disease. The tick vector (Hemophysalis spinigera) for KFD was found in abundance in the affected forest area. Out of 18 monkey deaths (Macaca radiate species) reported, 5 tested positive for KFDV by RT-PCR. The evidence suggests transmission of KFDV within the district as both the virus and the vector have been found. We recommended vector control, use of personal protective measures and an effective vaccination policy for prevention of KFD outbreaks in future.

8

FAILURE OF DIHYDROARTEMISININ-PIPERAQUINE IN NORTHERN CAMBODIA FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM*

Rithea Leang[1], Cesia Quintero[1], Sara E. Canavati[2], Bunkea Tol[1], Bunthai Leang[1], Didier Menard[3], Jack S. Richards[4], Pascal Ringwald[5], Rekol Huy[1]

[1]The National Center for Parasitology, Entomology and Malaria Control, Ministry of Health, Phnom Penh, Cambodia, [2]Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Malaria Molecular Epidemiology Unit, Institut Pasteur in Cambodia, Phnom Penh, Cambodia, [4]Centre for Biomedical Research, Burnet Institute of Medical Research, Melbourne, Victoria, Australia, [5]Antimalarial Drug Resistance, Global Malaria Programme, World Health Organization, Geneva, Switzerland

Since artemisinin drug resistance was first observed in 2006, a series of artemisinin-based combination therapies (ACTs) have been selected for the treatment of ***Plasmodium falciparum*** malaria in Cambodia; partner drugs with favourable pharmacological properties are selected in order to minimise the impact of artemisinin resistance. Dihydroartemisinin-piperaquine (DHA-PQP), introduced as first-line treatment for ***P. falciparum*** in Cambodia in 2009, is the most recent of five artemisinin-based combination therapies (ACTs) to be recommended by World Health Organization (WHO). Although DHA-PQP initially demonstrated a high efficacy, there has been recent evidence of parasitological and clinical failure. This study presents the data collected in several 2014-15 therapeutic efficacy studies using DHA-PQP for the treatment of ***P. falciparum*** in Cambodia. This study utilised the standardized WHO protocol for assessment of antimalarial treatment efficacy. It was conducted in the northern Cambodian provinces of Siem Reap, Stung Treng and Mondulkiri between August 2014 and February 2015, during the malaria transmission season. A total of 120 patients infected with ***P. falciparum*** were included. Efficacy data and risk of PCR-adjusted recrudescence up to Day-42 (D42) were evaluated using intention-to-treat and Kaplan-Meier analysis. High DHA-PQP treatment failure rates were observed at D42: 62.5% in Siem Reap, 40% in Stung Treng and 10% in Mondulkiri. In the context of regional artemisinin resistance, these results are suggestive of ***P. falciparum*** resistance to Piperaquine. Piperaquine is a bisquinoline and is structurally similar to chloroquine, for which there is known resistance in Cambodia. This is the first time that the northern provinces of Cambodia have been found to have higher treatment failures and a higher proportion of D3-positive participants than the western provinces. It is concerning that western and northern Cambodia have a high volume of population movement, which is likely to contribute significantly to the spread of spread of multidrug resistance; this population movement is a considerable hindrance to the elimination of malaria. These findings demonstrate that it is becoming increasingly difficult to find a highly effective antimalarial treatment for ***P. falciparum*** in both western and northern Cambodia. There is an urgent need for new antimalarial regimens for these populations.

9

SAFETY AND EFFICACY OF PYRONARIDINE-ARTESUNATE AGAINST UNCOMPLICATED *PLASMODIUM FALCIPARUM* IN WESTERN CAMBODIA

Sara E. Canavati[1], Rithea Leang[2], Harrriet L. Lawford[2], Pisal Heng[2], Bunkea Tol[2], Mey Bouth Denis[3], Nimol Khim[4], Saorin Kim[4], Jack S. Richards[5], Lasse S. Vestergaard[6], Didier Menard[4], Rekol Huy[2], Arjen M. Dondorp[7], Pascal Ringwald[8]

[1]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University; Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]The National Centre for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [3]World Health Organization, Phnom Penh, Cambodia, [4]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [5]Burnet Institute of Medical Research; Department of Microbiology, Monash University, Melbourne, Victoria, Australia, [6]World Health Organization, Manila, Philippines, [7]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [8]World Health Organization, Geneva, Switzerland

The first signs of artemisinin resistance were reported from Pailin Province in western Cambodia. There are now increasing reports of parasitological and clinical failure following most widely used ACTs indicating resistance to both the artemisinin compound and the partner drugs. There is an urgent need for new malaria treatment options, including new ACT regimens, especially in areas of known multi-drug resistance. The combination of pyronaridine-artesunate could be an alternative option for the treatment of uncomplicated ***Plamodium falciparum*** malaria in western Cambodia. In an open-labelled, controlled clinical trial conducted in two sites in western Cambodia (Pailin and Pursat provinces), patients with ***P. falciparum*** mono-infection were treated with pyronaridine-artesunate and were followed up for 42 days. The primary endpoint was PCR-adjusted adequate clinical and parasitological response (ACPR) by day 42, and secondary endpoints included: PCR-adjusted ACPR on day 28, parasite positivity rate on day 3, liver function test and other safety outcomes, and prevalence of molecular markers of drug resistance. One hundred and twenty-three patients were enrolled and completed the full course of treatment and 42 days of follow-up. Fourteen (14/116=12.1%) patients had RT-PCR confirmed recrudescence, all of which carried the C580Y K13-propeller mutant allele associated to artemisinin resistance. Recrudescent infections at the Pailin site (n=8), all shared the same ***msp1***, ***msp2*** and ***glurp*** genotypes as well as 10-SNPs bar coding, but all occurred within a single village. Transient elevations of liver enzymes occurred in 15 (12%) patients but values returned to normal by day 28 in the majority patients. The WHO criterion for introducing a new first-line malaria treatment (i.e. an adequate clinical and parasitological response in more than 95% of patients at follow-up on day 28) was not met western in Cambodia. However, pyronaridine-artesunate was observed to be a safe drug and well tolerated with no reports of severe adverse effects including no indications of significant liver toxicity.

10

TRANSMISSION-BLOCKING EFFICACY OF SINGLE DOSE PRIMAQUINE ADDED TO ACT IN CAMBODIANS WITH UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA

Jessica Lin[1], Ratawan Ubalee[2], Worachet Kuntawunginn[2], Thay Kheang Heng[3], Sok Somethy[4], Soklyda Chann[3], Dav Vy[3], Nareth Kong[3], Sujata Balasubramanian[1], Montri Arsanok[5], Ponsa Chanudom[2], Piyaporn Saingam[2], Nitima Chanarat[2], Michele Spring[2], Char Meng Chuor[6], Panita Gosi[2], Chanthap Lon[3], David Saunders[2]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [4]Royal Cambodian Armed Forces, Phnom Penh, Cambodia, [5]Armed Forces Research Institute of Medical Sciences, Bangkok, Cambodia, [6]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

In low transmission areas, single dose primaquine is recommended by the WHO to be given alongside artemisinin-based combination therapy to ***Plasmodium falciparum*** patients to prevent transmission. While multiple studies have shown that this intervention reduces post-treatment gametocytemia, no clinical studies have directly measured its effect on infectiousness to mosquitoes in those already treated with ACT. We conducted an open-label clinical trial in 101 Cambodian patients with normal to moderately deficient G6PD-activity deficiency randomized to either 45mg single dose primaquine or no primaquine on Day 3 of dihydroartemisinin-piperaquine (DP) therapy. Human-to-mosquito infectivity was assessed using membrane feeding assays pre-treatment and at days 4, 7, and 14 on 300 ***Anopheles dirus*** mosquitoes. We examined 50 of the roughly 220 engorged mosquitoes per feed for the presence of midgut oocysts, saving the rest for PCR and genetic analyses. Only 6/101 (5.9%) patients were infectious to mosquitoes prior to DP treatment. On day 4 post-treatment, 3/6 remained infectious (1 of 3 had received primaquine 20hrs earlier) and 3 more patients became infectious (none of whom had received primaquine). By week 1 post-treatment, 4/6 patients remained infectious, none of whom had been treated with primaquine. This transmission-blocking effect was statistically significant (0/48 patients vs. 4/49 patients transmitted in the PQ vs no PQ group at week 1, p=0.043). There were no clinically significant adverse hematologic events. Details of mosquito infection, gametocyte, and PCR endpoints will be discussed. This study supports the transmission-blocking utility of a 45mg dose of primaquine in subjects without severe G6PD deficiency. We are currently studying the lower dose of primaquine (0.25mg/kg) recently recommended by the WHO for all patients without G6PD screening.

11

IMMUNITY TO MALARIA AND EMERGING ARTEMISININ RESISTANCE

Freya J. Fowkes[1], Ricardo Ataide[1], Elizabeth Ashley[2], Mehul Dorda[2], Rosanna Powell[1], Gaoqian Feng[1], Jo-anne Chan[1], Michael Malloy[3], Takafumi Tsuboi[4], Eizo Takashima[4], Katherine O'Flaherty[1], James Beeson[1], Francois Nosten[5], Julie A. Simpson[3], Nicholas J. White[2], On behalf of the Tracking Resistance to Artemisinin Collaboration (TRAC)[2]

[1]Burnet Institute, Melbourne, Australia, [2]Mahidol–Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Centre for Epidemiology and Biostatistics, University of Melbourne, Melbourne, Australia, [4]Division of Malaria Research, Proteo-Science Center, Ehime University, Ehime, Japan, [5]Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot, Thailand

Resistance to artemisinin, the first-line treatment against falciparum malaria, was first reported in Western Cambodia in 2009. Recently, the Tracking Resistance to Artemisinin Collaboration (TRAC) a unique multicentre artemisinin therapeutic efficacy study, including 15 sites of varying malaria transmission across Asia and Africa, confirmed that resistant falciparum malaria (defined by a slow clearing phenotype and the presence of the kelch13 molecular marker) is firmly established in Western Cambodia, Thailand, Eastern Myanmar, and Southern Vietnam, and is emerging in Northern Cambodia and Southern Laos. Naturally acquired immunity to malaria has the ability to clear parasites and is an important host factor to understand in the context of understanding the emergence of resistant parasites. To date, there have been no large multinational studies of malarial immunity or any investigations into how variations in population levels of immunity may impact on the geographical spread of artemisinin resistance. We aimed to quantify variations in ***Plasmodium falciparum*** antibody responses and their impact on parasite clearance time after artemisinin treatment across multiple populations experiencing varying levels of malaria transmission. We determined antibody levels and function to a panel of ***P. falciparum*** antigens representing various stages of the life-cycle to enable us to identify immune biomarkers that predict parasite clearance time in 16 sites and 9 countries participating in TRAC. We show that i) host-immunity to ***P. falciparum*** varies across populations and is lowest in areas where the prevalence of kelch13 mutations and the slow clearing phenotype is the highest; ii) ***P. falciparum*** antibodies are associated with faster ***P. falciparum*** clearance times, even in areas of relatively low immunity; iii) ***P. falciparum*** antibodies have the biggest impact on ***P. falciparum*** clearance in the presence of slower-clearing parasites carrying kelch13 mutations. We conclude that immunity is an important confounder in the assessment of emerging artemisinin resistance and may also contribute to the emergence of artemisinin resistance in the region.

12

METABOLIC PROPERTIES OF *PLASMODIUM FALCIPARUM* SUB-POPULATIONS ASSOCIATED TO ARTEMISININ RESISTANCE IN CAMBODIA

Ankit Dwivedi[1], Christelle Reynes[2], Nimol Khim[3], Frédéric Ariey[3], Didier Ménard[3], Emmanuel Cornillot[1]

[1]Institut de Biologie Computationelle, Montpellier, France, [2]Institut de Génétique Humaine, Montpellier, France, [3]Pasteur Institute in Cambodia, Phnom Penh, Cambodia

The undergoing WHO Malaria elimination program is threatened by emergence and the potential spread of the ***Plasmodium falciparum*** artemisinin resistant parasite. Artemisinin resistant parasites have emerged in the western part of Cambodia, where chloroquine and pyrimethamine drug resistance emerged in the past. Recent reports have shown (1) presence of several ***P. falciparum*** sub-populations in Cambodia and (2) evidence that mutations in the propeller domain of the K13 gene are major determinants of artemisinin resistance in Cambodian parasite population. To characterize the Cambodian parasite sub-population metabolic properties and identify genetic evidence associated to the acquisition and the transmission of artemisinin resistance, a reliable SNP variant calling pipeline based on analysis of signal parameters in comparison with 3D7 reference genome was applied to around 170 NGS Cambodian genome sequences recovered from ENA database. In addition, a barcode approach based on LUMINEX technology was used to screen for parasite population structure in Cambodia. Genome wide analysis revealed presence of major hot spots of variation and specific haplotypes among the Cambodian sub-populations. The annotation for sub-population specific gene set based on proteins and domain associated GO terms, pathways and networks (co-expression, metabolism, Y2H, ⋯) was determined. Distribution of K13 mutant alleles provide genetic evidence that acquisition and transmission of artemisinin resistance is related to parasite population structure in Cambodia. Presence of admixture parasite sub-population was found as a major risk for artemisinin resistance transmission. Based on the barcode analysis, a new sub-population located in south Cambodia, was associated with the most common C580Y K13 allele. Parasite sub-populations differed in metabolic capacities and specific genes in some sub-populations were associated to various housekeeping

functions including cytoskeleton and ubiquitination, likely involved in K13 protein interaction. Our findings question the origin and the persistence of the ***P. falciparum*** sub-populations in Cambodia.

13

COMPARISON OF TWO REGIMENS OF ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN PREGNANT WOMEN IN THE DEMOCRATIC REPUBLIC OF CONGO

Marie A. Onyamboko[1], Caterina I. Fanello[2], Gareth Turner[2], Nikki Jackson[2], Joel Tarning[2], Francois Nosten[3], Nick J. White[2], Antoinette K. Tshefu[4], Nick P. Day[2]

[1]Kinshasa School of Public Health/Centre for Tropical Medicine and Global Health, NDM, University of Oxford, Mahidol, Democratic Republic of the Congo, [2]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Centre for Tropical Medicine and Global Health, NDM, Mahidol, Thailand, [3]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Shoklo Malaria Research Unit, Mahidol, Thailand, [4]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Malaria in pregnancy is a major cause of maternal and newborn morbidity and mortality. Artemether-lumefantrine (AL) is an effective 3-day therapy, however its pharmacokinetic properties are altered in pregnancy resulting in reduced plasma concentrations. The aim of this study was to compare an extended regimen of AL to the standard one in a group of pregnant women (PG) and a control of non-pregnant women (NP) with uncomplicated falciparum malaria. Ninety-six patients were randomly allocated to 5-day (extended) or 3-day (standard) regimen. AL was administered DOT and with milk. Drug plasma concentrations were characterized for each patient. Therapeutic efficacy was assessed using the standard 42-days WHO protocol. Tolerability and safety (including pregnancy outcomes) were also assessed. The maximum concentrations (Cmax) were significantly higher in the PG-5d arm than the PG-3d arm: 75 ng/mL (range 29 to 118) vs. 52 ng/mL (27 to 130), p=0.008. Similarly the median day 7 lumefantrine plasma level was higher in the PG-5d arm, 1545 ng/mL (537 to 3650) vs. 597 ng/mL (216 to 928). The day-42 efficacy, PCR unadjusted, was similar in the PG-5d and PG-3d arm, 90% vs. 91%. The 4 pregnant women with a recurrent episode of malaria had a day-7 level of lumefantrine between 320 and 750 ng/mL. One patient only (PG-3d) had a value below 280 ng/mL, the critical cut-off predicting treatment failure. Results were comparable in the control group of non-pregnant women. There were no hematological or biochemical abnormalities but more patients in the 5-d regimen had GI symptoms. Active placental malaria at delivery was observed in 6 cases in the 3d arm and 3 in the 5d arm (p=0.02). Four neonatal deaths (unrelated to study treatment) were reported: 3 stillbirths in the 3d arm and 1 neonatal sepsis in the 5d arm. Thirty-nine babies (87%) were followed-up for 1 year and displayed a normal physical and neurological development. Further analyses are currently being performed. The extended regimen improved the exposure to lumefantrine in pregnancy with a good safety profile.

14

COMPARING ARTEMETHER-LUMEFANTRINE AND CHLOROQUINE--WITH AND WITHOUT PRIMAQUINE--FOR THE TREATMENT OF UNCOMPLICATED VIVAX MALARIA IN ETHIOPIA: A RANDOMIZED CLINICAL TRIAL

Tesfay Abreha[1], **Jimee Hwang**[2], Yehualashet Tadesse[1], Samuel Girma[1], Bereket H. Alemayehu[3], Ashenafi Assefa[4], Moges Kassa[4], Keren Z. Landman[5], Joseph L. Malone[6], S. Patrick Kachur[5], Venkatachalam Udhayakumar[5], Ya Ping Shi[5], Daddi Jima[4], Amha Kebede[4], Hiwot Solomon[7], Addis Mekasha[8], Zenebe Melaku[1], Hiwot Teka[9], Gunewardena Dissanayake[9], Sarah Auburn[10], Lorenz von Seidlein[10], Kamala Thriemer[10], Ric Price[10]

[1]Columbia University ICAP, Addis Ababa, Ethiopia, [2]President's Malaria Initiative/Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Columbia University ICAP, New York, NY, United States, [4]Ethiopia Public Health Institute, Addis Ababa, Ethiopia, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]President's Malaria Initiative/Centers for Disease Control and Prevention, Addis Ababa, Ethiopia, [7]Ethiopian Federal Ministry of Health, Addis Ababa, Ethiopia, [8]Oromia Regional Health Bureau, Addis Ababa, Ethiopia, [9]President's Malaria Initiative/United States Agency for International Development, Addis Ababa, Ethiopia, [10]Menzies School of Health Research, Darwin, Australia

Chloroquine (CQ) is currently the first line treatment for ***Plasmodium vivax*** monoinfections in Ethiopia and artemether-lumefantrine (AL) for those with mixed infections or ***P. falciparum***. Treatment of hypnozoite stages with primaquine (PQ) is not widely practiced due to G6PD deficiency-related safety concerns. To determine the safety and efficacy of primaquine radical cure and confirm the ***P. vivax*** schizontocidal efficacy of AL and CQ, we conducted a 4-armed randomized open label controlled trial comparing AL and CQ--with and without PQ (0.25mg/kg once daily x 14 days). The study was conducted in two sites in Oromia State: Bishoftu and Bulbula. Patients older than 1 year of age presenting with uncomplicated vivax malaria were randomly assigned to one of four treatments: AL alone, AL+PQ, CQ alone and CQ+PQ. Initial efficacy outcomes were measured for day 28 and 42, but follow up was continued for 12 months irrespective of recurrence. Patients with recurrent episodes after 42 days were treated with the same treatment as on enrolment. Between October 2012 and December 2014 a total of 399 patients were enrolled. Preliminary analyses revealed the uncorrected efficacy rate at day 42 was 81.2% (95% CI: 71.8-87.7) following CQ, 70% (95% CI: 59.5-78.4) after AL, 98.8% (95% CI: 91.9-99.8) after CQ+PQ, and 93.3% (95% CI: 85.3-96.8) after AL+PQ. The risk of recurrence at 12 months was 60% (96% CI: 43.6-74.4) in the CQ arm, 66.6% (95% CI: 50.3-97.8) in the AL arm, 20.5% (95% CI: 10.8-35.5) in the CQ+PQ arm and 37.8% (95% CI: 15.4-43.0) in the AL+PQ arm. The full analysis of the completed study including additional laboratory testing results will be presented. The high risk of recurrence at day 42 likely reflects emerging resistance in the CQ arm and lower post treatment prophylaxis following AL. The addition of the standard 14-day dose PQ was well tolerated and reduced recurrences, but the risk of recurrence at 12 months was significantly higher when combined with AL compared to CQ.

15

THE CONTRIBUTION OF HUMORAL IMMUNITY TO CLINICAL OUTCOMES IN AN AREA OF MULTIDRUG-RESISTANT *PLASMODIUM FALCIPARUM* IN CAMBODIA

Michele Spring[1], Chanthap Lon[2], Sathit Pichyangkul[3], Kosol Yongvanitchit[3], Thay Kheang Heng[4], Sok Somethy[5], Soklyda Chann[2], Soch Va[4], Mok My[4], Savoeun San[4], Davy Taing[2], Samon Nou[2], Utaiwan Srichairatanakul[3], Amporn Limsalakpeth[3], Montri Arsanok[3], Rathvicheth Bun[4], Sut Thang Phann[4], Sheetij Dutta[1], Worachet Kuntawunginn[3], Satharath Prom[5], Char Meng Chuor[4], Jessica Lin[6], Evelina Angov[1], David Saunders[3]

[1]US Military Malaria Vaccine Program, Silver Spring, MD, United States, [2]Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, [3]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [4]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [5]Royal Cambodian Armed Forces, Phnom Penh, Cambodia, [6]University of North Carolina, Chapel Hill, NC, United States

Mutations in the kelch 13 propeller gene of ***Plasmodium falciparum*** have been implicated as molecular markers of artemisinin resistance associated with prolonged parasite clearance times. We recently reported that Cambodian patients with the k13 C580Y mutation were 5.4 times more likely to fail dihydroartemisinin-piperaquine (DP) therapy for uncomplicated ***P. falciparum*** infection than those with non-C580Y mutations. However, 47% of those with C580Y mutation did not recrudesce, suggesting other factors involved in cure, particularly pre-existing immunity. We compared clinical outcomes among 93 evaluable patients with antibody levels by median fluorescent intensity (MFI) and seropositivity rates to 4 ***P. falciparum*** antigens (MSP1, AMA1, CelTOS, CSP) using a multiplexed bead array (Luminex®). Approximately 90% of patients were seropositive for MSP1, AMA1 and CelTOS while 56% were seropositive for CSP. Volunteers who were seropositive for AMA were more likely to have complete cure (ACPR) at 42 days compared to those with malaria recurrence (53% vs 8% p=0.003). Seropositivity for AMA was also associated with ACPR versus recrudescence in those with the C580Y k13 mutation (p=0.04) but not the R539T mutation (p=0.1). PfMSP1 titers at admission in those who went on to ACPR were higher versus those who had recrudescence (unpaired t-test p=0.025). Neither MFI nor seropositivity for any antigen was predictive of parasite clearance half-life or day 3 positivity. Humoral immunity, particularly the presence of AMA1 antibodies, appeared to contribute to the cure of malaria infection in populations residing in areas of multi-drug resistance, suggesting efficacious vaccine could play an important adjunctive role in malaria elimination in the region.

16

DISSECTING THE FUNCTIONAL DIFFERENCES AMONG SPECIFIC HUMAN IGG SUBCLASSES AGAINST *PLASMODIUM FALCIPARUM* MEROZOITES

Vashti Irani[1], Peck Szee Tan[1], Andrew J. Guy[1], Dean Andrew[1], Catherine F. Latham[1], Paul Sanders[1], Gaoqian Feng[1], Linda Reilling[1], Kathirvel Alagesan[2], Daniel Kolarich[2], Peter Siba[3], Ivo Mueller[4], James G. Beeson[1], Paul A. Ramsland[1], Jack S. Richards[1]

[1]Burnet Institute, Melbourne, Australia, [2]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany, [3]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [4]Walter and Eliza Hall Institute, Melbourne, Australia

Individuals living in malaria endemic areas develop natural immunity that protects them from symptomatic malarial disease, and antibody responses against blood stage antigens play a major role. Some antibodies target the invasive form of the parasite, the merozoite, and are able to inhibit erythrocyte invasion. Antibodies targeting ***Plasmodium falciparum*** erythrocyte binding antigen 175 (EBA-175) have been shown to inhibit binding to its erythrocyte receptor, glycophorin A. Interestingly, naturally acquired antibodies to EBA-175 and other merozoite antigens are typically skewed towards either IgG1 or IgG3, and the IgG3 responses are generally more strongly associated with protection. It remains unclear how the important differences in the functional effector responses between IgG subclasses impact malaria immunity. To assess this, we used a well-characterised invasion inhibitory monoclonal antibody (mAb) to EBA-175 (R217). We determined that Papua New Guinean children, following natural infection, acquire antibodies that target the same EBA-175 epitope as the mAb R217. We then expressed this R217 mAb as recombinant chimeric human IgG1, IgG2, IgG3 and IgG4 and examined potential functional differences in a series of ***in vitro*** functional assays. These chimeric antibodies contained the same Fv region as R217 but had different human IgG backbones. These chimeric human mAbs showed similar epitope-specificity, affinity, glycosylation patterns and the ability to inhibit parasite growth and EBA175-glycophorin A binding interactions. Subclass specific differences were observed for other functional effector responses including complement deposition and opsonic phagocytosis. These findings suggest that human IgG subclasses do mediate differences in functional immunity and have important implications for assessing outcomes from vaccine studies.

17

FCRL5 EXPRESSION IS ASSOCIATED WITH *PLASMODIUM FALCIPARUM* EXPOSURE AND DEFINES A FUNCTIONALLY DISTINCT SUBSET OF ATYPICAL MEMORY B CELLS

Richard T. Sullivan[1], Charles C. Kim[1], Mary F. Fontana[1], Margaret E. Feeney[1], Prasanna Jagannathan[1], Michelle J. Boyle[1], Chris J. Drakeley[2], Isaac Ssewanyana[2], Harriet Mayanja[3], Grant Dorsey[1], Bryan Greenhouse[1]

[1]University of California, San Francisco, San Francsico, CA, United States, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Makerere University, Kampala, Uganda

Atypical memory B cells (MBCs) are associated with ***Plasmodium falciparum*** (Pf) exposure, and have been hypothesized to be functionally exhausted due to long-term Pf exposure. Recent reports by our group and others have found that a majority of atypical MBCs express FCRL5, not FCRL4 as previously thought, however, the functional relevance of FCRL5 expression has not been assessed. We tested the hypothesis that poor antibody recall was associated with FCRL5 expression, and that FCRL5 expression relates to Pf exposure. When we stimulated FCRL5+ and FCRL5- atypical and classical MBCs ***in vitro*** with the poly-clonal B cell mitogen CpG, we found that FCRL5+ MBCs, either classical or atypical, had decreased antibody recall responses compared to their FCRL5- counterparts (mean of 1.7 and 33.7 antibody secreting cells per 1000 atypical MBCs, FCRL5+ and FCRL5- respectively, p=0.03). We also assessed the frequency of FCRL5+ atypical MBCs from individuals living in an area of intense Pf exposure compare to age matched individuals with more moderate exposure, and found that frequencies of FCRL5+ atypical MBCs were increased in individuals with higher Pf exposure. Since FCRL5 expression was functionally important and associated with Pf exposure, we tested whether Pf infected red blood cells could directly induce expression of FCRL5 on B cells. Preliminary findings indicate that infected red blood cells can induce FCRL5 expression on class-switched B cells from non-Pf exposed individuals in a dose dependent fashion (MFI of 500 to 1400 with iRBC), and this FCRL5 induction was augmented with the addition of CpG (MFi of 2500 with CpG and 6000 with CpG + iRBC). These findings suggest that induction of FCRL5 on B cells may be, at least in part, non-specific or innate-like since these B cells were unlikely to have memory responses, but we are also currently testing the hypothesis that FCRL5 expression may be antigen-specific in people highly exposed to Pf. In summary, our findings suggest that FCRL5 expression is strongly associated with B cell exhaustion and exposure to Pf, and may be driven, at least in part, through non-specific or innate-like mechanism(s) during infection.

18

CHARACTERIZATION OF IMMUNE RESPONSES TO *PLASMODIUM FALCIPARUM* GAMETOCYTES

Kathleen W. Dantzler[1], Karl Seydel[2], Miriam Laufer[3], Terrie Taylor[2], Matthias Marti[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States, [3]Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States

Drugs and vaccines targeting ***Plasmodium falciparum*** transmission stages have recently gained prominence as necessary tools for malaria elimination and eradication. Current transmission-blocking vaccine strategies target the stages in the mosquito while the developing sexual stages in the human host, or gametocytes, have so far been neglected. However, we would argue that targeting these stages has tremendous potential to decrease the global burden of malaria. As in asexual sequestration, the recently described gametocyte sequestration process in human bone marrow is likely mediated by interactions between specific host receptors and adhesins on the surface of infected red blood cells (iRBCs). Antibodies recognizing early-stage gametocytes could confer protection by 1) inhibiting binding necessary for entry and/or development in the bone marrow, 2) increasing killing by effector cells, and/or 3) inducing phagocytosis by macrophages and neutrophils. Hypothesizing that early-stage gametocytes entering into or developing inside the bone marrow are targets of host antibody responses, we performed the first systematic characterization of immune responses targeting gametocytes. After establishing a flow cytometry assay to screen Malawian patient sera for antibody recognition of gametocyte-iRBCs, we were able to identify samples that are significantly positive for the gametocyte-iRBC surface. Some of these positive sera also recognize asexual-iRBCs while others uniquely recognize gametocyte-iRBCs, particularly early gametocyte-iRBCs. Immunofluorescence microscopy confirms that early gametocytes are recognized more than later gametocytes. We are currently further defining the stage specificity of the response, using qRT-PCR to correlate gametocyte densities with immune responses, and using proteomics to identify the corresponding target antigens. Understanding the human immune response elicited by ***Plasmodium*** gametocytes and the target antigens involved is essential for understanding host-pathogen interactions and designing transmission-blocking vaccine strategies.

19

COMPLEMENT AND ANTIBODY-MEDIATED ENHANCEMENT OF RED BLOOD CELL INVASION BY *PLASMODIUM FALCIPARUM*

Sergei Biryukov[1], Evelina Angov[2], Mary E. Landmesser[1], Michele D. Spring[2], Christian F. Ockenhouse[3], Jose A. Stoute[1]

[1]Pennsylvania State College of Medicine, Hershey, PA, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]PATH, Washington, DC, United States

Plasmodium falciparum malaria results in close to one million deaths worldwide each year due to repeated cycles of red blood cell (RBC) invasion and destruction. Attempts to develop a vaccine to block RBC invasion have failed. Although antibodies induced against merozoite vaccine antigens show inhibition of invasion ***in vitro*** in the presence of heat-inactivated (HI) serum (to remove complement), there is poor efficacy ***in vivo***. The reasons for this discrepancy are unknown. We hypothesized that complement activation and opsonization of merozoites actually enhances complement receptor 1 (CR1)-mediated invasion of RBCs. We tested this hypothesis by studying the effect of mouse monoclonal anti-merozoite surface protein 1 (MSP-1) antibody 5.2 (mAb5.2) and antibodies from recipients of a merozoite vaccine (MSP-1_{42}) for their ability to enhance or inhibit invasion in the presence or absence of complement. Invasion of RBCs was enhanced by fresh serum relative to 3 min, 5 min, or 30 min HI serum. Furthermore, addition of mAb5.2 to fresh serum increased the enhancement effect. Addition of C2 and Factor B to 3 min HI serum, but not to 30 min, rescued the enhancement of invasion in the presence of mAb5.2. Likewise, Compstatin, a C3 specific inhibitor, and soluble CR1 w(sCR1) ere able to negate the enhancing affects of mAb5.2 in fresh serum but not that of fresh serum alone. Purified antibodies from MSP-1 vaccinees showed inhibitory activity in C3/C4-inactivated serum, but inhibition was drastically reduced in C3/C4 reconstituted serum. Our results demonstrate that anti-merozoite antibodies in the presence of complement can enhance RBC invasion via CR1 constituting a novel mechanism of immune evasion by ***P. falciparum***. These findings are of great importance to the efforts to develop a merozoite blocking vaccine since understanding the mechanisms of parasite immune evasion will aid in the development of more effective vaccines. Further studies will be needed to understand the relevance of our findings to ***in vivo*** models.

20

PLASMODIUM FALCIPARUM INDUCES DIFFERENTIAL CHANGES ON DENDRITIC CELLS IN SYMPTOMATIC AND ASYMPTOMATIC PATIENTS FROM THE AMAZON REGION

Katherine Torres[1], Pamela Rodriguez[1], Katherine Garro[1], Dionicia Gamboa[1], Joseph Vinetz[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]University of California San Diego, San Diego, CA, United States

Dendritic cells (DCs) play an important role in the induction and regulation of immune responses via antigen-presentation, co-stimulation and production of cytokines and chemokines. Circulating circulating DCs are essential for adequate immunity as they continually replenish the pool of tissue-residing DCs. In malaria, the functionality of DCs remains elusive because of immunomodulatory properties of the ***Plasmodium falciparum*** parasite. Changes in peripheral populations of DCs during acute ***P. falciparum*** malaria were characterized in other setting transmission, but no data are available for ***P. falciparum*** infections in the Peruvian Amazon. We characterized peripheral populations of DCs in uncomplicated malaria patients infected with ***P. falciparum*** and in healthy controls living in the same area of endemicity and exposed to relatively low levels of malaria transmission. Cryopreserved PBMCs from ***P. falciparum*** infected patients (symptomatic and asymptomatic) and endemic controls were stained with an antibody mixture containing lineage-specific mAbs to CD3, CD14, CD16, CD19, CD20, and CD56 conjugated with FITC (lin-FITC), antibodies to CD11c conjugated with APC and CD123 conjugated with PE, and antibodies to HLA-DR conjugated with PerCP. 50000 events were analyzed in a C6 Accury flow cytometer (BD). HLA-DR+CD123+lin–cells were defined as plasmocytoid dendritic cells (PDC) and HLADR+CD11c+lin– as myeloid dendritic cells (MDC). The results showed that the absolute number of PDC and MDC increased in both symptomatic (3,48 x10e7 cells/L) and asymptomatic (2,96 x10e7 cells/L) ***P. falciparum*** patients compared to control individuals (1,83 x10e7 cells/L). Furthermore, it was found a greater absolute number of PDC but not MDC in symptomatic patients versus asymptomatic patients and controls. Here, we also observe the relationship between increased levels of plasma IL-10 and numbers of DC in patients with clinical Pf infections. In conclusion, ***Plasmodium falciparum*** is associated with a clear increase in the absolute number of plasmacytoid DCs (CD123+) phenotype in symptomatic patients.

21

MONOCYTE SUBSET PHENOTYPES AND FUNCTIONS IN KENYAN CHILDREN WITH UNCOMPLICATED MALARIA

Katherine Dobbs[1], Paula Embury[1], John Vulule[2], Peter Odada Sumba[2], James Kazura[1], Arlene Dent[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya

Monocytes/macrophages play an important role in innate and adaptive immunity to malaria. Human blood monocytes are classified into 3 subsets according to levels of expression of CD14 and CD16, surface molecules

functionally significant to tissue migration, and inflammatory cytokine production. Cryopreserved PBMC were obtained from 23 children at presentation with acute uncomplicated malaria and at 6 weeks following recovery, 17 healthy child controls, and 14 healthy adult controls in western Kenya. We determined the proportions of monocyte subsets and levels of TLR2, TLR4, CD36, PD-L1, CD86, and BAFF expression. Children with acute malaria had an increased proportion of intermediate "inflammatory" monocytes (CD14hiCD16+) compared to 6 week recovery samples and healthy children and adults (p values <0.03). Compared to 6 week recovery samples and healthy child controls, acute malaria was associated with increased TLR2,TLR4, BAFF, and PD-L1 expression on intermediate monocytes and decreased CD36 and CD86 expression on classical and nonclassical monocytes (p values <0.05). An increased PD-L1/CD86 ratio was seen on all 3 monocyte subsets during acute malaria compared to 6 week recovery and healthy child controls (p values <0.001). Functional assays of these subsets, including phagocytosis and cytokine production, are in progress, and results will be correlated with phenotypic data. These data indicate that monocyte surface expression phenotypes are altered with acute malaria, and these changes are subset-specific.

22

I GET HEIGHT WITH A LITTLE HELP FROM MY FRIENDS: HERD PROTECTION FROM SANITATION IN RURAL ECUADOR

James A. Fuller[1], Eduardo Villamor[1], William Cevallos[2], Joseph N. Eisenberg[1]

[1]The University of Michigan, Ann Arbor, MI, United States, [2]Universidad Central de Quito, Quito, Ecuador

Infectious disease interventions, such as vaccines and bednets, have the potential to provide herd protection to non-recipients. Similarly, improved sanitation in one household may provide community-wide benefits if it reduces contamination in the shared environment. Sanitation at the household-level is an important predictor of child growth, but less is known about the effect of sanitation coverage in the community. From 2008 to 2013, we took repeated anthropometric measurements on 1,314 children under five years of age in 24 rural Ecuadorian villages. Using mixed effects regression, we estimate the household and neighborhood effects of sanitation on child growth.Sanitation coverage at the neighborhood level was strongly associated with child height, as those with 100% coverage in their neighborhood had a 5 fold reduction in the odds of being stunted (OR 0.21, 95%CL 0.05-0.84) compared to those with 0% coverage. Children from households with improved sanitation had a slightly lower odds of being stunted (OR 0.70, 95%CL 0.43-1.15). This protective effect of neighborhood sanitation is manifested primarily among girls during the second year of life, the time at which growth faltering is most likely to occur. Discussion-Our study highlights that a household's sanitation practices can provide herd protection to overall community. Studies which fail to account for the positive externalities that sanitation provides will underestimate the overall protective effect. Future studies could seek to identify a threshold of sanitation coverage, similar to a herd immunity threshold, above which increases in coverage have no marginal benefit.

23

SCALE-UP OF MOBILE-TO-WEB COMMUNITY-LED SANITATION ACROSS 13,000 RURAL VILLAGES IN ZAMBIA: CHALLENGES AND OPPORTUNITIES

Laurie Markle[1], Amy Tiwari[1], Alexandra Hoehne[2], David A. Larsen[3], Chinyama Lukama[4], Sharon Mazimba[1], Engervell Musonda[4], Anne Mutunda[1], Nicolas Osbert[2], John Pinfold[2], Scott Russpatrick[1], Anna Winters[1], Benjamin Winters[1]

[1]Akros, Lusaka, Zambia, [2]UNICEF Zambia Country Office, Lusaka, Zambia, [3]Syracuse University, Syracuse, NY, United States, [4]Ministry of Local Government and Housing, Lusaka, Zambia

The Ministry of Local Government and Housing in Lusaka has adopted community-led total sanitation (CLTS) as its intervention of choice for driving progress toward an open defecation free (ODF) Zambia. CLTS is a behavior-change intervention that generates community engagement and impetus to achieve ODF. As with all public health interventions, accurate targeting and timely monitoring are critical for sustainable, efficient uptake, however the traditional, paper-based systems used to monitor CLTS and other community-based interventions are slow, unwieldy and expensive. We instituted a mobile-to-web monitoring system in 29 districts to target intervention efforts and track community progress toward ODF. Community-level sanitation action groups collect household-level hygiene and sanitation information on paper forms, aggregate to the community-level and submit via mobile phone into the DHIS2 decision support platform. Automated data validations, dashboards and reports are then fed back to community, district, traditional leadership and central level stakeholders. Monthly reporting rates in the system exceed 85% thanks to the dedication of community volunteers and traditional leaders, further reinforced by informed, timely feedback provided by districts using DHIS2. National progress toward ODF is substantial. Over 1,500,000 new users of improved sanitation have been produced in less than 2 years. Further one full district is already certified as ODF, the first documented instance of its kind in southern Africa and more likely to be certified later in 2015. Cost savings have been substantial. Districts implementing CLTS through the mobile-to-web platform save, on average, 34% in total implementation costs compared to districts implementing CLTS without mobile-to-web. Zambia is now scaling mobile-to-web CLTS to 46 districts and the system is being augmented to include indicators measuring village-level access to safe, clean drinking water. We will discuss challenges, solutions and opportunities in developing and sustaining real-time monthly monitoring across thousands of villages in resource-deprived settings.

24

PROGRESS TOWARD COMMUNITY ACHIEVEMENT OF OPEN-DEFECATION FREE BEFORE AND AFTER INVOLVEMENT OF TRADITIONAL LEADERS IN ZAMBIA

Amy Tiwari[1], Scott Russpatrick[1], Chinyama Lukama[2], Paul Mboshya[2], Tumba Mupongo[1], Engervell Musonda[2], Anne Mutunda[1], Joseph Ngambi[3], Ilenga Nkhata[1], Nicolas Osbert[3], Goeffrey Saloka[4], Rabson Zimba[1], Benjamin Winters[1], David A. Larsen[5]

[1]Akros, Lusaka, Zambia, [2]Ministry of Local Government and Housing, Lusaka, Zambia, [3]UNICEF Zambia Country Office, Lusaka, Zambia, [4]Ministry of Chiefs and Traditional Affairs, Lusaka, Zambia, [5]Syracuse University, Syracuse, NY, United States

Community-led total sanitation (CLTS) is a behavior change intervention intended to cease the practice of open defecation, a leading risk factor for the transmission of diarrheal disease and soil-transmitted helminths. CLTS engages district and sub-district agents who 'trigger' communities by clearly illustrating fecal transmission between open-defecation piles and common food sources, rousing the collective disgust and pride of residents; households are subsequently encouraged to build latrines in effort to become open defecation free (ODF). The Zambia Ministry of

Local Government and Housing implements CLTS through community champions who use mobile phones to transmit monthly data on latrine coverage and adequate sanitation for each of roughly 13,000 villages in rural districts. These data post to an instance of DHIS2, a web-based decision management system, which then pushes feedback to various stakeholders. We devised one such automatic feedback loop - a mechanism for routing intervention impact data - for traditional leaders who are outfitted with tablet computers which display DHIS2 data for the relevant chiefdom. The mobile-to-web CLTS system has been rolled out in 14,020 villages across 29 districts in Zambia, with plans to scale nationwide. A total of 47 out of 71 chiefdoms have been oriented into the system. Before chiefdom orientation only 12.8% of triggered villages achieved ODF; after chiefdom orientation mean progress was doubled with 25.6% of remaining villages achieving ODF. Further nine Chiefdoms are verified as ODF. The engagement of traditional leaders is an important consideration for interventions requiring community engagement, though there are certain limitations. Some of the chiefs in Zambia are less engaged in the push toward ODF and some chiefdoms are in dispute limiting their effectiveness in engaging the community. In Zambia feedback of data empowers traditional leaders and is likely to have impact in other sectors beyond sanitation. In areas without traditional leaders feedback to community-level stakeholders may elicit a similar response in the community.

25

SOIL-TRANSMITTED HELMINTH CONTAMINATION OF SOIL IN RURAL KENYAN HOUSEHOLDS

Lauren E. Steinbaum[1], Kara Nelson[2], Ayse Ercumen[2], Laura Kwong[1], Jimmy Kihara[3], Sammy Njenga[3], Alexandria Boehm[1], Jenna Davis[1], Clair Null[4], Amy Pickering[1]

[1]Stanford University, Stanford, CA, United States, [2]University of California, Berkeley, Berkeley, CA, United States, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Emory University, Atlanta, GA, United States

Globally, about 1.5 billion people are infected with at least one species of soil-transmitted helminth (STH). We developed a method to test for STH in soil and conducted a pilot study to determine the prevalence of STH in soil among rural households in Kenya. We adapted the US EPA method for detecting and enumerating ***Ascaris*** in biosolids via microscopy to identify STH eggs in soil. Soil was seeded with a known number of ***Ascaris suum*** eggs and then processed to determine a recovery efficiency of 73%. Viability of the eggs was not determined, although an incubation step could easily be added to allow determination of viability. We conducted a pilot study from June to September 2014 in Kakamega, Kenya to characterize the prevalence of soil-transmitted helminth contamination of household soils using a version of the method described above. Field staff collected soil samples from the household entrance and the latrine entrance (if present) from each household. We found that 27% of households (N=67) had at least one type of STH egg in the soil. ***Ascaris*** was the most common STH detected at the household-level (19%), followed by ***Trichuris*** (9%), and hookworm (1%). Prevalence of any STH egg in soil was slightly higher at the household entrance (19%, N=67) compared to the latrine entrance (11%, N=62), but the difference was not statistically significant (p=0.31). Among positive samples, the median STH concentration was 0.7 eggs/g dry soil. Detection of soil-transmitted helminth eggs in soil at almost one-third of households suggests that child exposure to soil may be a substantial health risk. Contamination of the soil at both the house and latrine entrances could indicate that there are multiple sites of helminth transmission and exposure within the home. The results from this study will inform soil sampling methods in a large randomized controlled trial to assess the impact of improved sanitation on levels of STH in household soil.

26

WASH FOR WORMS: A CLUSTER RANDOMIZED CONTROLLED TRIAL OF THE IMPACT OF A COMMUNITY-BASED WASH PROGRAM ON SOIL-TRANSMITTED HELMINTH INFECTIONS IN TIMOR-LESTE - MID-POINT RESULTS AT SIX MONTHS FOLLOW-UP

Susana V. Nery[1], Suzy Campbell[1], Stacey Llewllyn[2], Ross Andrews[3], Darren Gray[1], Rebecca Traub[4], James S. McCarthy[2], Archie Clements[1]

Soil-Transmitted Helminths (STH) are most prevalent in communities lacking adequate clean water, sanitation and hygiene (WASH). Deworming programmes with anthelminthic drugs are highly effective in reducing morbidity but rapid reinfection occurs if there is no reduction in environmental contamination with infective stages, impeding the sustainability of STH control programmes based on deworming alone. "WASH for Worms" is a cluster randomised controlled trial (RCT) assessing the impact of a community-based WASH intervention, implemented by WaterAid Australia, on infection with intestinal parasites following mass albendazole (ALB) chemotherapy in villages in Timor-Leste. In this trial, initiated in 2012, twelve intervention villages receive the WASH programme and ALB treatments every six months. Twelve control villages receive only the six-monthly ALB. All villages are followed-up for two years after the first ALB distribution. Infection prevalence and intensity is measured by a modified qPCR. An overview of the study design and implementation progress will be presented. Additionally, the prevalence and intensity of STH infections at baseline and after the first (6-monthly) follow-up will be discussed and compared across trial arms. At baseline the prevalence of STH in the 24 villages was high, with more than 70% of the 2225 participants who provided stools infected with at least one STH, mostly comprising Necator americanus (62.3%) followed by Ascaris lumbricoides (30.4%). At the first follow-up the overall prevalence of STH infection decreased to 46.3%, with 34.6% of the 1630 participants who provided stools infected with N. americanus and 21.0% infected with A. lumbricoides. In the intervention arm, N. americanus decreased from 62.8% to 32.2% whereas A. lumbricoides decreased from 31.6% to 22.0%. In the control group, N. americanus decreased from 61.8% to 36.9% whereas A. lumbricoides decreased from 29.2% to 20.1%.This trial is the first reported RCT evaluating the impact of integrated WASH and deworming programmes on infection with STHs; and will provide essential evidence for scaling up integrated programmes for STH control.

27

FECAL MARKERS OF ENVIRONMENTAL ENTEROPATHY ARE ASSOCIATED WITH ANIMAL EXPOSURE AND CAREGIVER HYGIENE IN RURAL BANGLADESH

Christine M. George[1], Lauren Oldja[1], Shwapon Biswas[2], Jamie Perin[1], Gwenyth O. Lee[1], Shahnawaz Ahmed[2], Rashidul Haque[2], R. Bradley Sack[1], Tahmina Parvin[2], Ishrat J. Azmi[2], Sazzadul Islam Bhuyian[2], Kaisar A. Talukder[2], Abu G. Faruque[2]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]International Center for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Recent estimates by the World Health Organization (WHO) report that a quarter of children under five years of age are stunted globally. There is a growing body of literature indicating an association between stunting and environmental enteropathy (EE), a disorder defined by abnormal intestinal morphology, reduced intestinal barrier function, and increased inflammation. To determine if household unsanitary environmental conditions were significantly associated with environmental enteropathy and stunting in children, we conducted a cross-sectional study of 216 children(<30 months) in rural Bangladesh. Stool was analyzed

for fecal markers of environmental enteropathy: alpha-1-antitrypsin, myeloperoxidase, and neopterin combined to form an environmental enteropathy disease activity(EE) score, and calprotectin. We observed a significant association between having an animal corral in a child's sleeping room and elevated EE scores (1.0 point difference, 95% confidence interval (CI): 0.13,1.88) and stunting(height for age z-score <-2) (Odds Ratio(OR): 2.53, 95% CI: 1.08,5.43), after adjusting for potential confounders. In addition, children of caregivers with visibly dirty hands had significantly elevated fecal calprotectin(µg/g)(384.1, 95% CI: 152.37, 615.83). These findings suggest that close contact with animals and caregiver hygiene are potential risk factors for environmental enteropathy in young children. These findings are consistent with the hypothesis that unsanitary environmental conditions can potentially lead to environmental enteropathy in susceptible pediatric populations.

28

HOUSEHOLD SANITATION AND HYGIENE INDICATORS OF ENTERIC PATHOGEN TRANSMISSION AND CHILDHOOD DIARRHEAL EXPOSURE RISK IN MIRZAPUR, BANGLADESH

Kurt Z. Long[1], Shamsir Ahmed[2], Abul S. Faruque[2], Tahmeed Ahmed[2], Inong Gunanti[1], Mohammad E. Hoque[2], Sumon K. Das[2], Shahnawaz Ahmed[2], Dilruba Nasrin[3], James P. Nataro[4], Karen Kotloff[3], Myron M. Levine[3]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]University of Maryland Medical School, Baltimore, MD, United States, [4]University of Virginia Medical School, Charlottesville, VA, United States

The effectiveness of water quality, sanitation and hygiene (WASH) interventions in reducing diarrheal disease can be strengthened through the identification of enteric pathogen transmission pathways. Our aim was to determine associations between significant diarrheal pathogens among rural Bangladeshi children and potential pathogen sources and household risk factors that may make up such transmission pathways. Stools collected from children aged < 59 months with moderate-to-severe diarrhea (MSD) and matched healthy controls enrolled in the Bangladeshi component of the Global Enteric Multicenter Study (GEMS) were screened for enteric pathogens. Multinomial logistic regression was used to determine associations of ***Shigella flexneri, Cryptosporidium*** spp**,** enterotoxigenic ***Escherichia coli*** (ETEC), rotavirus and ***Aeromonas*** outcomes with WASH measures. Children from households with improved sanitation facilities and disposed children's feces had lower ***S. flexneri*** and ***Cryptosporidium*** diarrhea risk. ***Cryptosporidium*** diarrhea risk was higher when cow dung was used as fuel and mothers did not wash hands before eating. Children from households with toilets and that disposed children's feces had lower ETEC infection risk when no handwashing was practiced after cleaning a child, following defecation and before cooking, respectively. Rotavirus diarrhea was lower among children from households with deep tube wells when no hand washing was practiced after handling of animals. Finally, children from households with improved sanitation facilities and whose mothers washed hands before nursing had lower ***Aeromonas*** diarrhea. We have identified household sources and factors that are critical points in pathogen transmission pathways and children's exposure to selected enteric pathogens and shown how distinct hygiene behaviors may modify these pathways. These findings have important implications for the development of more cost-effective intervention that reduce pathogen exposure risk and overall diarrheal burden through targeted interventions that focus on critical points in pathogen-specific transmission pathways.

29

HIGH RATES OF CHAGAS DISEASE CO-INFECTION IN HIV-INFECTED BOLIVIANS

Natalie M. Bowman[1], Daniel Clark[2], Jeong Choi[3], Mauricio Dorn[4], Enzo Fortuny[5], Omar Gandarilla[5], Roxana Bravo Nevarro[4], Clare Sepping[6], Jorge Flores[4], Roni Colanzi[7], Leny Sanchez[8], Lisbeth Ferrufino[5], Anne Palumbo[5], Gerson Galdos Cardenas[9], Maritza Ramirez Jaldin[8], Eliana Saenza Vasquez[5], Janeth Acosta[8], Manuela Verastegui[8], Caryn Bern[10], Robert H. Gilman[9]

[1]University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, [2]Vanderbilt University, Nashville, TN, United States, [3]University of California, Davis, Davis, CA, United States, [4]Hospital San Juan de Dios, Santa Cruz, Plurinational State of Bolivia, [5]AB PRISMA, Santa Cruz, Plurinational State of Bolivia, [6]London School of Tropical Medicine & Hygiene, London, United Kingdom, [7]Universidad Catolica Boliviana, Santa Cruz, Plurinational State of Bolivia, [8]Universidad Peruana Cayetano Heredia, Lima, Peru, [9]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [10]University of California, San Francisco, San Francisco, CA, United States

Chagas disease, caused by protozoa ***Trypanosoma cruzi***, affects 8-12 million Latin Americans. Reactivation Chagas disease with microscopy-positive parasitemia can manifest with severe neurological and cardiac symptoms in patients with advanced HIV, but there are few systematic studies of the syndromes of coinfection. We recruited hospitalized HIV-infected patients from the emergency or inpatient departments of Hospital San Juan de Dios in Santa Cruz, Bolivia to better characterize the epidemiology and clinical spectrum of HIV/***T. cruzi*** coinfection. All subjects underwent interview, physical examination, and laboratory testing. Parasitemia was quantified using RT-PCR. ***T. cruzi*** infection was defined as a positive result by 2 serological tests or parasites detected by microscopy or PCR. CD4 counts and HIV viral loads were performed by the Bolivian government agency CENETROP. 157 HIV-infected subjects (54 women, 103 men) were recruited, and 37 of 150 (25%) were infected with ***T. cruzi***. 28 subjects (80% of ***T. cruzi***-infected subjects) had PCR-detectable parasitemia ranging from 0.71-556,726 parasites/ml. Sex was not related to ***T. cruzi*** infection, but coinfected subjects were almost 6 years older (p=0.01). ***T. cruzi*** infected subjects had higher CD4 counts (median 307 vs. 134, p=0.03); among coinfected subjects, CD4 counts were lower in subjects with PCR-detectable parasitemia (median 161 vs. 563, p=0.09) and HIV viral loads were higher (median 597 vs. 65,357.5 p=0.01). Prevalence of ***T. cruzi*** infection in HIV-positive people in our study was high, reflective of the high burden of disease in Bolivia. Parasites were detectable by RT-PCR in most coinfected subjects and were more prevalent in those with advanced HIV. A more refined definition of reactivation Chagas disease is needed that incorporates the increased sensitivity of PCR technology and characteristic clinical manifestations in order to define the epidemiology of HIV/***T. cruzi*** coinfection and guide studies of treatment and prophylaxis of these patients.

30

A PROSPECTIVE COHORT STUDY TO ASSESS THE EFFECT OF COTRIMOXAZOLE PROPHYLAXIS IN HIV-EXPOSED CHILDREN ON MALARIA IN SOUTHERN MALAWI

Nyanyiwe M. Mbeye[1], Zinenani Truwah[1], Misho Chibwe[1], Thandile Nkosi[1], Ndamiwe Mweso[1], Feiko O. ter Kuile[2], Kamija S. Phiri[1]

[1]Malawi College of Medicine, Blantyre, Malawi, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

A number of studies on the use of malaria chemoprophylaxis have reported an increase in episodes of malaria and other morbidities in the year following termination of prophylaxis. Cotrimoxazole prophylaxis (CPT) is given to HIV exposed but not infected children until HIV infection can be excluded and the child is no longer exposed through breastfeeding. CPT may provide effective prophylaxis against malaria, and may modulate

the development of malaria-specific immunity. It is unclear if cessation of chemoprophylaxis in these circumstances is associated with a rebound in malaria disease. We have studied the protective efficacy of CPT and determined if there was an increased risk of malaria after cessation. We recruited a birth cohort at 6 weeks of age of HIV exposed (HIV-exp) children who were prescribed CPT for 12 months at the PMCT clinic in Zomba, Malawi. Simultaneously age and residency-matched non-HIV exposed children who were not on CPT were recruited from the community. Both cohorts were systematically followed until their second birthday. HIV-exp children who stopped breastfeeding (usually at 12 months) were tested for HIV and those who tested negative had CPT stopped. All children were encouraged to come to the research clinic at anytime for all morbidities. Data on malaria-related and all-cause OPD visits, admissions and deaths was collected over the 2 years of follow-up. We recruited 500 HIV exposed and 500 HIV non-exposed children. Recruitment and follow-up is now complete and analysis is on going. Results will be presented at the conference and will enhance an understanding of the implications of this HIV prevention strategy on malaria and hence directly inform the policies on HIV and malaria control in areas where both diseases are endemic.

31

RISK FACTORS, SEXUAL BEHAVIOR AND HIV PREVALENCE AMONG MEN WHO HAVE SEX WITH MEN (MSM) IN LOME, TOGO

Horacio Ruisenor-Escudero[1], Vincent Pitche[2], Simplice Anato[3], Dometo Sodji[4], Jules Tchalla[4], Ashley Grosso[5], Sosthenes Kathende[5], Stefan Baral[5]

[1]Michigan State University, East Lansing, MI, United States, [2]Conseil National de Lutte contre le SIDA et les IST, Lome, Togo, [3]Arc-en-ciel, Lome, Togo, [4]Famme, Lome, Togo, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Men who have sex with other men (MSM) have been consistently identified to be at higher risk of HIV infection and transmission. In Togo, there is limited epidemiological information about HIV prevalence, risk factors and behaviors that render them at higher risk of infection. Three hundred and fifty four MSM ≥18 years of age were recruited using respondent driven sampling (RDS) for a cross-sectional survey in Lome, Togo. Participants completed a structured questionnaire. Participants were tested for HIV and syphilis. Statistical analysis included RDS-weighted proportions, bootstrapped confidence intervals and logistic regression models. Mean age was 22 years; 71.5% were between 18 and 24 years. Ever having anal sex without a condom was reported by 155 (43.8%) MSM. In the final RDS-weighted multiple logistic regression model, higher risk of HIV infection was observed among MSM who were 25 years or older (RDS aOR=7.4, 95% CI=2.3-23.6) and among those reporting community/social stigma and discrimination (RDS aOR=2.1,95%CI=1.2-3.9). MSM who reported having sex with another man for the first time when they were 18 years of age or older had lower risk of HIV infection (RDS aOR=0.03, 95% CI=0.0-0.03). RDS weighted HIV prevalence was 9.2% (5.4%-13.2%) and syphilis RDS weighted prevalence was 1.3% (0.0-2.9%). Results indicate that HIV prevalence in MSM is approximately three times that of the general population, making it a priority group for HIV prevention, care and treatment services in Togo. Individual level, social, community and public policy factors might all be affecting the HIV epidemic within this key population and should be seen as targets for interventions. Multilevel approach is required to address risk of HIV infection. Community and social interventions to address stigma and policy change should be key to fight the epidemic in Lome.

32

INTRA-VAGINAL PRACTICES AND STRETCHING OF THE *LABIA MINORA* MAY CONTRIBUTE TO AN INCREASED RISK OF STI/HIV INFECTION IN MOZAMBIQUE

Carolyn M. Audet, Charlotte Buehler, Meridith Belvins, Ann Green, Troy D. Moon

Vanderbilt University, Nashville, TN, United States

The magnitude of risk for HIV and sexually transmitted infection (STI) acquisition among women in sub Saharan Africa (SSA) is unparalleled. In 2011, HIV prevalence among pregnant women in Mozambique was estimated to be 16%. Intra-vaginal drying/ tightening and stretching of the ***labia minora*** may contribute to an increased risk of STI/HIV infection. We sought to describe the intra-vaginal and labia stretching practices of women in Zambézia Province, Mozambique. A 2014 population-based survey gathered information from 3892 female heads of household from 255 enumeration areas across 14 districts. Kriging analyses using Geographic Information Systems (GIS) were used to map spatial patterns of traditional vaginal practice prevalence in three heavily sampled districts, and statistical analyses were conducted to estimate associations of covariates with vaginal practices. To determine if specific vaginal practices were associated with HIV infection, we modeled the probability of HIV diagnosis at last pregnancy among 810 women who reported HIV test receipt at ANC using multivariable logistic regression with robust covariance estimates. Among all women surveyed, 56% were planning to use intra-vaginal substances for drying/ tightening in the next year. Almost 100% of women who had heard of labia stretching reported they either had or planned to undergo labia stretching in the coming year. From inspection of GIS maps, both practices varied remarkably intra- and inter-district. There was a bivariate association between women who planned to use intra-vaginal substances and HIV infection (p=0.049), but this relationship was not detected in our multivariable model (p=0.21). Given the association between intra-vaginal agent use and STIs/ bacterial vaginosis and the potential link between vaginal infections and HIV acquisition, understanding local practices may be an essential first step to addressing high rates of HIV in young women.

33

A CLINICAL SNAPSHOT OF HOSPITALIZED, NEWLY DIAGNOSED, HIV-POSITIVE MALAWIAN CHILDREN REVEALS OPPORTUNITIES FOR IMPROVED HIV HEALTHCARE DELIVERY

Theresa Madaline[1], Sarah Hochman[1], Karl Seydel[2], Terrie Taylor[2], Alice Liomba[3], Alex Saidi[3], Grace Matebule[4], Lario Chigaru[4], Bernadette O'Hare[3], Dan Milner[5], Kami Kim[1]

[1]Albert Einstein College of Medicine, Bronx, NY, United States, [2]Michigan State University, East Lansing, MI, United States, [3]University of Malawi College of Medicine, Blantyre, Malawi, [4]Queen Elizabeth Central Hospital, Blantyre, Malawi, [5]Harvard Medical School, Boston, MA, United States

In Malawi, all HIV-positive children under 5 years old qualify for antiretroviral treatment (ART), but CD4+ T cell quantification (CD4 count), when available, or WHO clinical staging of HIV severity is used to determine ART eligibility for children ≥5 years old. Few studies have examined the clinical or immunological status of older children with newly diagnosed HIV infection. We studied children ≥ 18 months of age admitted to Queen Elizabeth Central Hospital in Blantyre, Malawi, from May 2013-June 2014. Initial HIV testing followed the WHO-recommended serial testing algorithm using HIV rapid diagnostic tests (RDT) Determine and Uni-Gold. Guardians of 222 children with positive HIV RDT consented to CD4 count and HIV-1 RNA PCR (HIV VL) while in hospital. We examined age, discharge diagnosis, total and percent CD4 count, HIV VL, and clinical HIV stage using 2013 WHO guidelines. Median age of the children was 48 months (range 18-192 months) and median absolute CD4+ T-cell count was 541 cells/mm3 (range 1-3888 cells/mm3). Of the 182 subjects with HIV VL results, 16 had low (<1000 copies/ml) or undetectable HIV

VL, prompting confirmatory HIV Western Blot and Enzyme Immunoassay. Ten out of 16 patients had positive confirmatory HIV serological testing, consistent with elite-controller status, while 6 had negative confirmatory test results, indicating that 3.3% of children incorrectly reported to have positive HIV RDTs were not HIV seropositive. The most common reasons for hospitalization were sepsis (n=43, 19%), pneumonia (n=42, 19%), malaria (n=38, 17%), malnutrition (n=36, 16%), and meningitis (n=14, 6%). There was poor correlation between clinical and immunologic staging. Of patients aged ≥5 years (n=106), 33% (n=35) qualified for ART by CD4 count but would have been ineligible by WHO clinical stage alone. These findings highlight the importance of regular quality assessment and need for confirmatory testing prior to initiating ART, and support the current WHO algorithm of routine staging of all children, initiation of ART in children who are WHO stage III or IV, and obtaining CD4 count in children who are stage I or II.

34

MENTAL HEALTH OF HIV+ FEMALE CAREGIVERS IN RURAL UGANDA. IMPLICATIONS FOR RESEARCH AND PROGRAMMING

Itziar Familiar-Lopez[1], Horacio Ruisenor-Escudero[1], Michael J. Boivin[1], Neoline Nakasujja[2], Robert Opoka[2], Judith K. Bass[3]

[1]Michigan State University, East Lansing, MI, United States, [2]Makerere University, Kampala, Uganda, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

In Sub-Saharan Africa the intersection of mental health and HIV/AIDS frequently constitutes a double burden for HIV+ caregivers. The physiological and psychological effects of HIV disease, the effect of antiretroviral therapies, social stressors (including stigma and discrimination), and financial strains associated all inform the mental health status of women living this the disease. Findings from three studies in rural eastern Uganda assessing mental health of HIV+ caregivers of HIV infected and affected children showcase potential research and clinical implications for global health. In our first two studies, results suggest that caregiver's depression can significantly bias parent-reported ratings. First, caregivers (N=150) with greater depressive symptoms (as measured by the Hopkins Symptom Checklist-HSCL) reported their children as having more behavioral problems related to executive functioning (as measured by the Behavior Rating Inventory of Executive Function-BRIEF) (b=11.0, t(150)=3.97, p<0.01), with the association being stronger in HIV-infected as opposed to HIV-exposed children. Caregivers (N=118) from a second study with higher depressive symptoms in the HSCL reported more Internalizing (b=.25, t(118)=2.29; p=.02) and Total Problems (b=.22, t(118)=2.23; p=.03) in the Child Behavior Check List (CBCL) evaluating their children. Finally, a third study including 288 HIV-positive women; most of who were the biological mothers (98%) of HIV affected children, we found that lower family support was significantly associated with higher depressive symptoms (b= -.10, t (286)= -2.61, p= .01), while higher socio-economic status predicted less depression (b= -.16 t (34)= -.47, p=.01). Findings highlight the relevance of maternal mental health and on identifying and addressing the mental health concerns of HIV infected mothers, which can allow for research design and adjustment, for planning community-level programs aimed at identifying and treating depression, and enhanced child development through maternal well-being.

35

TRACKING DEVELOPMENT ASSISTANCE FOR THE PREVENTION AND TREATMENT OF HIV/AIDS, 1990-2014

Joseph Dieleman, Lavanya Singh, Elizabeth Johnson, Casey Graves, Annie Haakenstad

Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States

Millennium Development Goal (MDG) six focuses on halting the spread of HIV/AIDS. Since this goal was established, more resources have been devoted to combat HIV/AIDS in low- and middle-income countries than any other cause of illness. This presentation will cover findings related to tracking the development assistance for health (DAH) disbursed for the prevention and treatment of HIV/AIDS. We extract data from the Institute for Health Metrics and Evaluation's Financing Global Health 2014 report. This report systematically tracks DAH from 1990 to 2014, splits disbursed DAH into 15 health focus areas, and draws data from all the major international development agencies engaged in combating HIV/AIDS. The sources of the funds, primary channels of delivery, and country recipients of DAH are reported. Since 2000, $100.4 billion of DAH has been provided for HIV/AIDS. In 2014 alone, $10.9 billion was disbursed. Between 2000 and 2010, DAH for HIV/AIDS grew at an annualized rate of 22.5%. Since 2010, the annualized rate of growth has only been 0.7%. The United States government was the largest source of DAH for HIV/AIDS during this period, proving $56.5 billion, or 56.3% of the total, since 2000. 81.0% of the DAH for HIV/AIDS from the US was channeled through US government agencies, while 9.2% was channeled through the Global Fund to Fight AIDS, Tuberculosis, and Malaria. The Bill & Melinda Gates Foundation was the largest private organization providing DAH targeting HIV/AIDS, furnishing $3.3 billion since 2000. Of DAH for HIV/AIDS that could be tracked to a single recipient country, 38.6% was disbursed to sub-Saharan Africa. Across all recipient countries, an average of $3,600 of HIV/AIDS DAH per HIV/AIDS disability-adjusted life-year (DALY) was disbursed between 2000 and 2014. With the post-MDG era in sight, these estimates and trends hold lessons for future global health ambitions and the unfinished agenda of the MDGs.

36

THE ABILITY OF CHIKUNGUNYA TO REEMERGE IN A PREVIOUSLY EXPOSED POPULATION

Henrik Salje[1], Simon Cauchemez[2], Isabel Rodriguez-Barraquer[1], Maria Theresa Alera[3], Butsaya Thaisomboonsuk[4], Anon Srikiatkhachorn[5], Catherine B. Lago[3], Daisy Villa[6], Chonticha Klungthong[4], Stefan Fernandez[4], John M. Velasco[3], Vito G. Roque Jr[7], Ananda Nisalak[4], Louis Macareo[4], Jens W. Levy[4], Derek Cummings[1], In-Kyu Yoon[4]

[1]Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]Institut Pasteur, Paris, France, [3]Philippines-Armed Forces Research Institute of Medical Sciences, Cebu, Philippines, [4]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [5]University of Massachusetts, Worcester, MA, United States, [6]Cebu City Health Department, Cebu, Philippines, [7]National Epidemiology Center, Manilla, Philippines

Chikungunya is a mosquito-transmitted alphavirus, causing potentially severe disease manifestations that can last for many months or even years. There have been a number of large-scale outbreaks in recent years. However, it is unclear if the virus will become established in these populations. This knowledge gap is unsurprising as the locations of chikungunya outbreaks are often unpredictable and local immunity levels at the start of an epidemic are usually unknown. In addition, many surveillance systems have not historically recorded cases. To help address this gap, we used data from two studies conducted in the same community in Cebu, Philippines 39 years apart (in 1973 and 2012). In both studies, individuals of all ages (N=150 in the 1973 study, N=854 in the 2012 study) were tested for evidence of historic exposure using neutralization tests. The proportion of seropositive individuals varied

greatly by age in both studies. In particular, no one under the age of 14 in the 2012 study had been exposed (out of 316 tested) compared to 28% overall, suggesting an absence of chikungunya since before 2000. We used the age of individuals and serostatus to estimate the proportion of the population that was infected in each year between 1950 and 2012. We used historical census records to estimate the proportion of the population that remained susceptible to infection at any time point. Overall our models identified four short-lived outbreaks since 1950 (in 1968, 1986, 1993 and 1999), with an average of 24% of the susceptible population infected following each introduction (range: 16% to 37%). These dates are consistent with historical case reports from the area. We estimated that at least half of the population remained susceptible in any year with an average of 56% unexposed, suggesting there existed a significant pool of people capable of becoming infected at any time point. These findings are consistent with occasional introductions resulting in brief but rapid dispersal of the virus, followed by long absences. Local environment, in particular climactic factors and regional human movement patterns may drive these observations.

37

CLINICOPATHOLOGIC CHARACTERISTICS AND IMMUNOLOCALIZATION OF VIRAL ANTIGENS IN CHIKUNGUNYA-ASSOCIATED FATAL CASES- PUERTO RICO, 2014

Tyler M. Sharp[1], Wun-Ju Shieh[2], Rebecca Levine[2], Dianna M. Blau[2], Jose V. Torres[3], Aidsa Rivera[1], Janice Perez-Padilla[1], Dana Thomas[4], Julu Bhatnagar[2], Dianna Ng[2], M. Kelly Keating[2], Elizabeth Hunsperger[1], Jorge Munoz-Jordan[1], Dario Sanabria[3], Brenda Rivera Garcia[4], Harold S. Margolis[1], Sherif R. Zaki[2]

[1]Centers for Disease Control and Prevention, San Juan, PR, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Insituto de Ciencias Forenses de Puerto Rico, San Juan, PR, United States, [4]Puerto Rico Department of Health, San Juan, PR, United States

Chikungunya virus (CHIKV)-related deaths are uncommon and usually occur in neonates exposed intrapartum, older adults, or people with underlying medical conditions. We describe the epidemiology and histopathologic findings for people that died and had evidence of acute CHIKV infection during an outbreak in Puerto Rico in 2014. We identified patients who died following an acute febrile illness and had CHIKV RNA detected by RT-PCR in a pre-mortem serum specimen, or in serum or tissue specimens collected at autopsies. Immunohistochemical staining for CHIKV antigen was performed on post-mortem tissue specimens. Data from medical records, autopsy findings, family interviews, and diagnostic test results were compiled. We identified 26 people who died in Puerto Rico during May-December 2014 and had laboratory evidence of acute CHIKV infection. Median age was 61 years (range: 6 days-85 years) and 16 (62%) were male. All had ≥1 underlying medical condition, most frequently hypertension (54%), diabetes (46%), and obesity (35%). Seven (27%) people died at home without seeking medical care. Median day of death post-illness onset was 6 (range: 1-28) for the 18 (69%) cases where these data were available. Of 21 cases with post-mortem tissue available for evaluation, CHIKV antigen was detected in 10 (48%). Common histopathologic findings included intraalveolar hemorrhage and edema. Viral antigen was detected in multiple organs, predominantly in mesenchymal tissues and cells of the mononuclear phagocytic system. CHIKV RNA was detected in the serum or tissue of 26 people who died during a chikungunya outbreak in Puerto Rico. All had comorbid conditions and most were older adults. Half of the patients evaluated had viral antigen detected in post-mortem tissue. Evaluation of autopsy tissue from patients infected with CHIKV provides evidence on the pathologic consequences of the disease that cannot be gained by diagnostic laboratory testing alone. This underscores the importance of enhanced surveillance, autopsies, and tissue-based diagnostic testing in understanding mortality associated with an emerging infectious disease.

38

EXPOSURE OF EPITOPE RESIDUES ON THE OUTER FACE OF THE CHIKUNGUNYA VIRUS ENVELOPE TRIMER DETERMINES ANTIBODY NEUTRALIZING EFFICACY

Rachel H. Fong[1], Soma S. Banik[1], Kimberl-Anne Mattia[1], Trevor Barnes[1], David Tucker[1], Nathan Liss[2], Kai Lu[2], Suganya Selvarajah[2], Surabhi Srinivasan[1], Manu Mabila[1], Adam Miller[1], Marcus O. Muench[3], Alain Michault[4], Joseph B. Rucker[1], Cheryl Paes[1], Graham Simmons[2], Kristen M. Kahle[1], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]Blood Systems Research Institute, San Francisco, CA, United States, [3]Blood Systems Research Institute; Department of Laboratory Medicine, University of California, San Francisco, CA, United States, [4]Centre Hospitalier, Groupe Hospitalier Sud-Reunion, La Réunion, France

Chikungunya virus (CHIKV) is a reemerging alphavirus that causes a debilitating arthritic disease and infects millions of people and for which no specific treatment is available. Like many alphaviruses, the structural targets on CHIKV that elicit a protective humoral immune response in humans are poorly defined. Here we used phage display against virus-like particles (VLPs) to isolate seven human monoclonal antibodies (MAbs) against the CHIKV envelope glycoproteins E2 and E1. One MAb, IM-CKV063, was highly neutralizing (50% inhibitory concentration, 7.4 ng/ml), demonstrated high-affinity binding (320 pM), and was capable of therapeutic and prophylactic protection in multiple animal models up to 24 h post-exposure. Epitope mapping using a comprehensive shotgun mutagenesis library of 910 E2/E1 mutants with alanine mutations demonstrated that IM-CKV063 binds to an intersubunit conformational epitope on domain A, a functionally important region of E2. MAbs against the highly conserved fusion loop have not previously been reported but were also isolated in our studies. The fusion loop MAbs were broadly cross-reactive against diverse alphaviruses but were non-neutralizing. Fusion loop MAb reactivity was affected by temperature and reactivity conditions, suggesting that the fusion loop is hidden in infectious virions. Visualization of the binding sites of 15 different MAbs on the structure of E2/E1 revealed that all epitopes are located at the membrane-distal region of the E2/E1 spike. Interestingly, epitopes on the exposed topmost and outer surfaces of the E2/E1 trimer structure were neutralizing, whereas epitopes facing the interior of the trimer were not, providing a rationale for vaccine design and therapeutic MAb development using the intact CHIKV E2/E1 trimer.

39

ARTHRITIS PATHOGENESIS IN TWO MOUSE MODELS OF CHIKUNGUNYA VIRUS INFECTION

Brad A. Goupil, Margaret A. McNulty, Michael K. McCracken, Rebecca C. Christofferson, Christopher N. Mores

Louisiana State University, Baton Rouge, LA, United States

Chikungunya virus (CHIKV) is an alphavirus spread by ***Aedes aegypti*** and ***Ae. albopictus*** mosquitoes. Currently, an outbreak affecting more than 1 million people is occurring in the Caribbean and the Americas, representing a significant emerging threat to the United States. Generally, infection results in high fever and arthralgia, with resolution of symptoms in a few weeks. However, in 20-60% of cases, people develop a painful chronic relapsing arthritis lasting months to years. Currently there are no commercially available vaccines for CHIKV and treatment is mainly supportive. While persistent arthritis can be a significant and debilitating component of the disease, little is known about the pathogenesis. We hypothesize that CHIKV-induced arthritis is an erosive and inflammatory arthritis exhibiting articular degeneration and osteoclastic bone resorption. To investigate this, two mouse models exhibiting a wide spectrum of disease severity were employed: IRF $3/7^{-/-}$ mice and wild-type C57Bl/6 mice. Mice were intradermally or subcutaneously inoculated with 10^5 pfu of virus [Southeast Asian strain SVO 476-96] in the hind footpad or adjacent to the stifle; control mice were inoculated with a sterile PBS solution.

IRF 3/7$^{-/-}$ mice were sacrificed at various timepoints post inoculation and analyzed by micro-computed tomography to assess for changes in bone volume, density and morphometry and by histopathology to determine the pathogenesis of arthritis. Additionally, various serological parameters will be evaluated to assess for correlation with disease severity and potential utility as novel prognostic markers. Virus inoculated mice developed significant swelling associated with the inoculation site by 2 days post inoculation (dpi) and at 6 dpi had a mild pleocellular tenosynovitis and moderate to marked cellulitis and myonecrosis of adjacent tissues. Control mice had no significant gross or histological lesions. The C57Bl/6 mouse experiment is currently ongoing. Detailed characterization of the pathogenesis of CHIKV-induced arthritis could provide novel targets for disease prevention or alternative treatment modalities.

40

CENTRAL NERVOUS SYSTEM ENTRY OF NEUROINVASIVE ALPHAVIRUSES IN MICE FOLLOWING PERIPHERAL ROUTE OF INFECTION

Amber B. Rico, Aaron T. Phillips, Charles B. Stauft, Tawfik A. Aboellail, Ken E. Olson

Colorado State University, Fort Collins, CO, United States

Alphaviruses most often associated with neuroinvasive disease include EEEV, VEEV, and WEEV. Alphavirus entry into the CNS of infected vertebrates after peripheral challenge is associated with hematogenous spread of virus although the precise entry sites are not well described. We determined the site of CNS entry following footpad inoculation of CD-1 mice using a combination of ***in vivo/ex vivo*** bioluminescence imaging, CLARITY, and traditional histological examination methods. We found a consistent pattern of virus entry among imaged brains that implicated circumventricular organs as the initial site for neuroinvasion. Confirmatory histological analyses of the imaged tissues, led to the finding that CNS entry by EEEV, VEEV, and WEEV likely occurs in areas of the CNS where the blood-brain barrier is naturally absent. These areas include the hypothalamus, the subfornical organ, the pineal gland, and the area postrema. Importantly, these results reveal a previously unrecognized method of alphavirus entry into the CNS.

41

SRC FAMILY KINASE INHIBITORS BLOCK ALPHAVIRUS STRUCTURAL AND NONSTRUCTURAL PROTEIN TRANSLATION *IN VITRO*

Rebecca Broeckel[1], Jennifer Vomaske[1], Craig Kreklywich[1], Patricia Smith[1], Michael Diamond[2], Thomas Morrison[3], Mark Heise[4], Victor DeFilippis[1], Daniel Streblow[1]

[1]Oregon Health and Science University, Beaverton, OR, United States, [2]Washington University School of Medicine, St. Louis, MO, United States, [3]University of Colorado, Aurora, CO, United States, [4]The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Alphaviruses are arthropod-transmitted positive-sense single-stranded RNA viruses that derive evolutionarily from the New World [e.g. Eastern (EEEV), Venezuelan (VEEV), and Western Equine Encephalitis (WEEV) viruses] and Old World [e.g. Chikungunya (CHIKV), Ross River (RRV), Semliki Forest (SFV), and Sindbis (SINV) viruses]. Two distinctive virus-dependent pathologies are manifest during Alphavirus infection. Neurological disease including encephalitis is primarily associated with New World species and can present high mortality rates especially in hosts with weakened or immature immune systems as well as the young and aged populations. Arthralgia and inflammatory syndromes are typically associated with Old World species and while these are uncommonly fatal they can elicit incapacitating effects that persist long after viral clearance. Currently no FDA approved vaccines or antiviral therapeutics are available to prevent Alphavirus infection or treat Alphavirus-associated disease. Importantly, Alphavirus genomes mutate rapidly, greatly facilitating spontaneous changes in their host and vector ranges and virulence, and escape from prior immunity. However, all viruses intimately rely on host cellular machinery for crucial components of their replication cycles. Herein we screened inhibitors of host kinases using a CHIKV replication assay. We have identified a number of kinases as playing essential roles in CHIKV replication. Specifically, we found that inhibition of host Src family kinases blocks Alphavirus replication. Src family kinase inhibition blocked late events of virus replication reducing the release of infectious particles. While viral RNA amplification was unaffected by kinase inhibitor treatment, we saw a reduction in viral protein expression and reduction in titer and genomic copy number in the supernatant. Targeting host factors involved in Alphavirus replication represents an innovative, perhaps paradigm-shifting strategy for antiviral therapeutic development.

42

A ROLE FOR THE INTERFERON-STIMULATED EXONUCLEASE, ISG20, AND ITS REGULATED GENES IN THE RESTRICTION OF CHIKUNGUNYA VIRUS

Christopher M. Weiss[1], Hanqi Tang[2], William B. Klimstra[1], Kate D. Ryman[1]

[1]University of Pittsburgh, Pittsburgh, PA, United States, [2]Tsinghua University, Beijing, China

Chikungunya virus (CHIKV) is an arthritogenic alphavirus that has spread globally, causing a pandemic of acute febrile disease and viral arthritis across Asia, Europe and the Americas. CHIKV and related alphaviruses are controlled to varying degrees by the activity of effector proteins induced by type I interferon (IFN). We previously used a systems biology approach to identify interferon-stimulated genes with potential roles in controlling alphavirus infection. This analysis identified ISG20, a 3'-5' interferon-induced exonuclease with specificity for RNA substrates, as having a potent antiviral effect against CHIKV and other alphaviruses. In the current studies, ISG20 restricted CHIKV replication immediately after entry through a disruption of early viral gene translation. This restriction appeared to be independent of direct exonuclease activity on the viral RNA. RNA deep sequencing analysis of cells overexpressing ISG20 revealed cell-wide changes in gene transcription. Notably, ISG20 overexpression induced a number of other known antiviral genes, including IFIT1, independent of IFN production. We further examined the role of IFIT1 as a potential mediator of ISG20 restriction of CHIKV due to its related function in translation inhibition. Using overexpression of mouse IFIT1 in murine fibroblasts, we demonstrated a similarly potent restriction of CHIKV as seen with ISG20. Our findings demonstrate a role for IFIT1 in the restriction of CHIKV replication and provide a possible mechanism by which ISG20 may indirectly inhibit translation of incoming CHIKV genomes. Continuing work is aimed at determining the importance of these two antiviral proteins using knockout mice in an established mouse model for CHIKV pathogenesis coupled with ***in vivo*** imaging (IVIS) for longitudinal monitoring of disease progression in individual mice.

43

MINIMAL TISSUE FACTOR EXPRESSION REDUCES BLOOD BRAIN BARRIER PERMEABILITY AND SUSCEPTIBILITY TO NEUROLOGICAL SYMPTOMS IN EXPERIMENTAL CEREBRAL MALARIA

Tara C. Bracken, Catherine Smith, Caitlin Cooper, Demba Sarr, Julie M. Moore

University of Georgia, Athens, GA, United States

Sequestration of ***Plasmodium falciparum***-infected erythrocytes in the brain results in a severe neurological syndrome, cerebral malaria (CM). Although the extent to which coagulation is responsible for severe disease is incompletely understood, thrombosis and endothelial disruption likely play a significant role in CM pathogenesis and may provide useful diagnostic and therapeutic targets. To assess the role of Tissue Factor (TF) in CM-induced blood brain barrier (BBB) disruption and neurological

symptoms, mice with a null mutation in TF that are transgenic for human TF expressed at 1% of the normal level (low TF; LTF), mTF heterozygous littermates (LTF+/-) and TF-intact C57BL/6J (B6) mice were infected with ***P. berghei*** ANKA, a CM-inducing malaria strain, and were serially sacrificed between days 4 (ED4) and 6 (ED6) post-infection. TF procoagulant activity was assessed in homogenized brain samples using a one-step clotting assay. To assess the extent of BBB permeability, mice were injected with Evans blue dye and intensity of staining in the brain was quantified. Brain pathology was assessed in H&E-stained histological sections. Pro-inflammatory cytokines were measured in plasma and tissue by ELISA. The strains exhibited varying susceptibility to CM; 47% (B6), 100% (LTF+/-), or 30% (LTF) of mice succumbed to CM on ED5, and 75% (B6) or 0% (LTF) succumbed on ED6. TF activity was increased in brains of CM-positive (CM+) B6 (100-fold, ED5; 10-fold, ED6), LTF +/- (1000-fold, ED5) and LTF (100-fold, ED5) mice versus those with uncomplicated malaria. Though extensive hemorrhage was seen in histological sections from CM+ B6 and LTF+/- mice, minimal to no hemorrhage was seen in brains of CM+ LTF mice. Extensive Evan's blue staining was seen in brains of CM+ B6 and LTF+/- mice; however, LTF mice that exhibited neurological symptoms showed minimal, focal Evan's blue staining. Increased TF activity in brains of CM+ mice and reduced BBB permeability of LTF mice together suggest TF is playing a significant role in the pathogenesis of CM. Ongoing studies are assessing the mechanisms by which this occurs, with emphasis on thrombin-dependent PAR1 signaling.

44

TCR USAGE IN PATHOGENIC CD4+ AND CD8+ T CELLS DURING EXPERIMENTAL CEREBRAL MALARIA

Joanna Chorazeczewski, Victoria Majam, Mark Kukuruga, Adovi D. Akue, Sanjai Kumar, Miranda S. Oakley

Food and Drug Administration, Silver Spring, MD, United States

T cells are major mediators of the pathogenesis of experimental cerebral malaria (ECM) in mice. While $CD4^+$ T cells exert their pathogenic effect during the induction phase of disease, brain sequestered $CD8^+$ T cells target endothelial cells of the blood brain barrier for destruction during the effector phase of disease contributing to the symptoms of ECM. Although it is understood that T cells play a critical role in the pathogenesis of ECM, the biology and diversity of the T cells that are expanded during ECM are poorly understood. Specifically, it is unclear whether a dominant clone of pathogenic T cells is expanded during ECM or whether a rare population is sufficient to induce ECM. To determine T cell receptor (TCR) usage by pathogenic T cells in ECM, we isolated highly pure populations of $CD4^+$ and $CD8^+$ T cells during the induction phase (day 3 post-infection) from spleen and during the effector phase (day 6 post-infection) from brain and spleen of ***P. berghei*** ANKA-infected C57BL/6 mice by fluorescence activated cell sorting (FACS). We then sequenced the complementarity-determining region 3 (CDR3) of the TCRβ gene by template-switch anchored RT-PCR on RNA isolated from sorted cells. Analysis is currently being performed using the IMGT/V-QUEST alignment tool for TCR nucleotide sequences. The T cell populations under investigation are malaria specific ($CD49b^+CD11a^+$) $CD4^+$ and $CD8^+$ T cells. TCR sequences analysis and their association with ECM will be presented. A better understanding of the antigen repertoire recognized by these pathogenic T cells may facilitate the design of an anti-disease vaccine that could prevent the activation and migration of pathogenic T cells during a severe malaria episode.

45

IMMUNOPATHOLOGY ASSESSMENT OF CENTRAL NERVOUS SYSTEM IN *PLASMODIUM COATNEYI*-INFECTED RHESUS MACAQUE AS A CEREBRAL MALARIA MODEL

Piyanate Sunyakumthorn[1], Sujitra Tayamun[1], Laksanee Inamnuay[1], Rawiwan Im-erbsin[1], Robin L. Burke[1], Arthur E. Brown[1], Gareth D. Turner[2], Eric D. Lombardini[1]

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand

Cerebral malaria (CM) is one of the major manifestations of severe falciparum malaria causing not only significant numbers of deaths but also neuro-disability in surviving patients. Relevant animal models represent an important way of investigating the pathogenesis of falciparum malaria and potential adjuvant neuroprotective treatments. ***Plasmodium coatneyi***-infected rhesus macaques (Macaca mulatta) have been proposed as a suitable non-human primate model for human CM; however, the pathogenesis of disease in the model has not been well characterized. Here we investigated the immunohistochemical changes of the central nervous system (CNS) in ***P. coatneyi***-infected rhesus macaques. Animals were splenectomized and infected with ***P. coatneyi*** which progressed to high levels of parasitemia (32-39%). All infected monkeys developed severe lethargy, markedly decreased mentation without coma, anemia, mild to moderate thrombocytopenia, and signs of hepatic and renal dysfunction. After euthanasia and necropsy, sections of the cerebrum, cerebellum, brain stem, and spinal cord were immunostained with glial fibrillary acidic protein (GFAP) as a marker of astroglial activation, and β-Amyloid precursor protein (βAPP) to detect axonal injury, both of which have been demonstrated in brain from human cases of CM. Staining patterns of fibrinogen were also examined to detect blood-brain barrier leakage. Generalized astrogial activation was not seen, whereas significant axonal injury was detected most predominantly in the brainstem and spinal cord. In addition, we evaluated cytokine expression levels in cerebrospinal fluid (CSF) from malaria-infected animals in comparison to controls. These demonstrated increases in inflammatory biomarkers including IL-8, IL-15, MCP-1, and TGF-ο, which may be involved in the immunopathology of CM. A better understanding of CM pathogenesis and pathophysiological processes will facilitate research into therapeutics in the treatment of severe falciparum malaria.

46

PROTEOMIC ANALYSIS OF *PLASMODIUM FALCIPARUM* 3-DAY LIVER STAGE PARASITES

Patricia A. Gonzales Hurtado[1], Sumana Chakravarty[2], Minglin Li[3], Yun Wu[3], Abraham Eappen[2], Tao Li[2], B. Kim Lee Sim[2], Stephen Hoffman[2], Michal Fried[1]

[1]National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, [2]Sanaria Inc., Rockville, MD, United States, [3]Protein Potential, Rockville, MD, United States

Malaria caused by the ***Plasmodium falciparum*** parasite is one of the most deadly diseases in the world causing over 600,000 deaths. Developing a vaccine that targets the pre-erythrocytic stage of ***Plasmodium falciparum*** (Pf) would be facilitated by identification of antigens that are the targets of protective immune responses. The goal of this study was to describe the proteome of Pf liver-stage parasites cultured in cell-free environment for three days and compared it to previously identified sporozoite and other parasite's stages proteomes. The first proteomics analysis of a 3-day axenic cultured sporozoites identified 1,517 Pf proteins with 175,481 peptide spectrum matches and 65% of the proteins were identified with multiple peptides. These 3 days liver-stage parasites were grown in an axenic culture with a final count of 9E7 of which 72% transformed into liver-stage mimicking parasites based on morphology and expression of new liver stage proteins. The sample was electrophoresed followed by in-gel digestion with trypsin. Peptide samples were analyzed by LC-MS/MS with exclusion runs using the LTQ Orbitrap

Velos. 7% of the proteins identified were unique. They previously have not been identified in Pf sporozoites, or asexual or sexual stages erythrocytic stages, and include proteins which are members of the VAR gene family. We will present data describing the molecular function of the proteins uniquely expressed during the parasite's liver-stage development.

47

UIS2, A UNIQUE PHOSPHATASE REQUIRED FOR THE DEVELOPMENT OF *PLASMODIUM* LIVER STAGES

Min Zhang[1], Satish Mishra, Victor Nussenzweig[2]

[1]New York University Medical Center, New York, NY, United States, [2]New York University School of Medicine, New York, NY, United States

Plasmodium salivary sporozoites, the infectious form of the malaria parasite, are dormant while inside salivary glands of *Anopheles* mosquitoes. During dormancy, protein translation is inhibited by the kinase UIS1 that phosphorylates serine 59 in eIF2α. De-phosphorylation of eIF2α-P is required for the transformation of sporozoites into liver stages. In mammalian cells the de-phosphorylation of eIF2α-P is mediated by protein phosphatase 1 (PP1). Instead, we report here that in malaria sporozoites the eIF2α-P phosphatase is UIS2. Both ***uis1*** and ***uis2*** are highly transcribed in salivary gland sporozoites, but the translation of ***uis2*** is inhibited by the Pumilio protein Puf2. The translational repression of ***uis2*** is alleviated when sporozoites developed into liver stages. UIS2 belongs to the PP2C/PPM phosphatase family. While most eukaryotic phosphatases attach transiently to their substrates, UIS2 binds tightly to phosphorylated eIF2α, but does not recognize unphosphorylated eIF2α, raising the possibility that high throughput searches may identify chemicals that disrupt the interaction and prevent malaria infection.

48

CHARACTERIZATION OF THE EXPANDED ACYL CO-A SYNTHETASE GENE FAMILY

Selina Bopp[1], Allison Demas[1], Pamela Magistrado[1], Sarah Volkman[1], Ulf Ribacke[2], Dyann F. Wirth[1]

[1]Harvard School of Public Health, Boston, MA, United States, [2]Uppsala University, Uppsala, Sweden

Plasmodium falciparum has the ability to quickly adapt its genome to selective pressures encountered in the human host by acquiring single nucleotide polymorphisms, recombination or gene duplications. The acyl Co-A synthetase (ACS) gene family is one example of such duplication and recent positive selection. In ***P. falciparum*** and ***P. reichenowi*** four conserved orthologs of ACS are predicted to perform classical ACS function while nine paralogs have expanded and diverged from the ***Pf***ACS9 ortholog. ACSs activate fatty acids (FA) scavenged from the host, which can then be used for protein modification, phospholipid biosynthesis, FA elongation, and beta-oxidation. To characterize the function of individual family members, we tagged single genes and observed different subcellular localization and protein abundance throughout the asexual lifecycle. Using different protein extraction methods, we also observed distinct membrane associations for individual family members. Taken together, these results suggest different roles for individual ACSs and potential neo-functionalization. The CRISPR/CAS system allowed us to generate knock out parasites lines for ***Pf***ACS5, ***Pf***ACS8, ***Pf***ACS9 and ***Pf***ACS12. None of the knock out lines showed a major growth defect in complete media when compared to the parental line. We are currently testing different growth conditions to further characterize the biological function of the individual ACSs. We hypothesize that the expansion and recent positive selection of the ***Pf***ACS gene family are the consequence of metabolic pressures driving parasite evolution, and understanding FA metabolism will give us insight into key metabolic pathways that might serve as potential targets for novel antimalarials.

49

PLASMODIUM SPP. PREFERENCE FOR IMMATURE RED BLOOD CELLS: THE MISSING RECEPTOR?

Richard Thomson-Luque[1], Francis Ntumngia[1], Amy Taylor[2], Karoly Szekeres[3], Kenneth Udenze[1], Suzanne Li[1], Wanlapa Roobsoong[4], Samantha Barnes[1], John H Adams[1]

[1]University of South Florida Global Health, Tampa, FL, United States, [2]DRAPER, Tampa, FL, United States, [3]University of South Florida, Tampa, FL, United States, [4]Mahidol Vivax Research Center, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Plasmodium vivax is the predominant form of malaria outside of Africa and is an important public health and economic development problem in many countries. The blood stages of ***P. vivax***, which cause the disease, have a strong preference to infect immature red blood cells, or reticulocytes. In contrast, the other major human malaria parasite, ***P. falciparum***, can infect mature and immature red blood cells. Understanding unique mechanisms regulating ***P. vivax***-specific host cell preferences is fundamental for basic research of this parasite, limiting our ability to maintain long term continuous cultures of ***P. vivax***, and consequently hinders development of more effective drugs and vaccines to prevent vivax malaria. In this study we have investigated surface receptors present subpopulation of reticulocytes (CD71neg/CD71low/CD71med/CD71high) preferentially infected by clinical isolates of ***P. vivax***. We discovered ***P. vivax*** had better invasion rates into CD71med/CD71high reticulocytes, which occurred also with laboratory lines of ***P. falciparum***, suggesting that there may be a common receptor on immature reticulocytes for all ***Plasmodium*** species. Further characterization of these subpopulations revealed that cell surface markers CD49d-alfa4 integrin, CD44, as well as mitochondria were more abundant on the CD71med/CD71high reticulocytes. Nevertheless we could not find positivity for CD49d, CD44 as well as CD36 for any red blood cells hosting the four ***P. vivax*** ring stage's frozen isolates from Thailand that we tested. Binding assays with PvSal1 DBP into different population of reticulocytes confirmed a better binding to CD71med/CD71high reticulocytes consequently to the higher expression of DARC in reticulocytes compared to mature erythrocytes. Consistent with the preferred invasion patterns, ***in vitro*** binding assays with ***P. vivax*** recombinant RBP1 showed a sharp increase in binding into CD71med/CD71high. These results reveal new insights into the molecular basis for the preference of ***P. vivax*** to invade very immature reticulocytes.

50

EFFECT OF DEWORMING ON NUTRITIONAL INDICATORS, COGNITIVE ABILITIES AND SCHOOL PERFORMANCE AMONG SCHOOLCHILDREN IN RURAL CHINA: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

Louise Lu[1], Chengfang Liu[2], Alexis Medina[3], D. Scott Smith[4], Linxiu Zhang[2], Scott Rozelle[3]

[1]Yale University School of Medicine, New Haven, CT, United States, [2]Chinese Academy of Sciences, Beijing, China, [3]Stanford University, Freeman Spogli Institute for International Studies, Stanford, CA, United States, [4]Stanford University School of Medicine, Stanford, CA, United States

Chronic infection with soil-transmitted helminths (STH) among school-aged children has been correlated with nutritional deficiencies, cognitive impairment, and lower rates of school attendance, but the effectiveness of deworming in improving these outcomes is unclear. This aim of this cluster-randomized controlled trial was to examine the impact of a deworming intervention on STH infection prevalence, infection intensity, nutritional indicators, cognitive abilities, and school performance among 2,028 school-aged children in rural Guizhou Province, China, where STH prevalence is over 40 percent. The intervention involved biannual administration of a 400 mg dose albendazole accompanied by cartoon

pamphlets about STH infection, treatment, and prevention. Specific outcomes measured at baseline and follow-up were STH infection prevalence, infection intensity (fecal egg count), anemia prevalence (Hb < 115 g/L), stunting prevalence (HAZ < -2), underweight prevalence (WAZ < -2), processing speed index (PSI), working memory index (WMI), school attendance rates, and normalized scores on the Trends in International Mathematics and Science Study (TIMSS). Follow-up evaluation after 12 months found that in this population with light-intensity infection, deworming significantly reduced both infection prevalence and infection intensity in the intervention group (n=1000) relative to the control group (n=1028). However, our results found no evidence that the deworming intervention improved outcomes of nutritional indicators, cognitive abilities, or school performance. Main implications of this trial for future studies are two-fold: (1) researchers should quantify and report infection intensity (fecal egg counts) for accurate epidemiological characterization of the sample population; and (2) evidence from future randomized-controlled trials is needed to assess the effect of deworming on key outcomes in populations with moderate and high-intensity infections.

51

PERFORMANCE AND COST-EFFECTIVENESS OF STOOL-BASED MULTIPLEX REAL-TIME PCR FOR THE DETECTION OF HUMAN SOIL-TRANSMITTED HELMINTHS ACROSS DIFFERENT STUDY SETTINGS

Birgit Nikolay[1], Eric Brienen[2], Washington Benitez Ortiz[3], Michael Boele- Van Hensbroek[4], Felisberto Mendes[5], Taniawati Supali[6], Judd L. Walson[7], Liya Assefa[1], Simon J. Brooker[1], Lisette van Lieshout[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Leiden University Medical Centre, Leiden, Netherlands, [3]Central University of Ecuador, Quito, Ecuador, [4]Academic Medical Center Amsterdam, Amsterdam, Netherlands, [5]Catholic University of Mozambique, Beira, Mozambique, [6]University of Indonesia, Jakarta, Indonesia, [7]University of Washington, Seattle, WA, United States

The sensitivity of currently used copromicroscopic tests for the diagnosis of soil-transmitted helminths (STH) can vary markedly among studies and is especially low for the detection of individuals with light infections. With the current effort to control NTDs, including STHs, infection intensities will decrease substantially and infections may be missed. The sensitivity of copromicroscopic diagnosis across settings may also be variable due to difficulties in standardising diagnostic procedures. To overcome these limitations, new sensitive molecular diagnostic tools have been developed to allow the simultaneous species specific detection of DNA of ***Ancylostoma duodenale, Necator Americanus, Ascaris lumbricoides*** and ***Strongyloides stercoralis*** (ANAS) in human stool. To evaluate whether STH diagnosis based on the ANAS real-time PCR allows a more accurate and standardised assessment of infections, we compared its qualitative and quantitative performance to standard copromicroscopic methods across five different study settings in Ecuador, Indonesia, Kenya, Malawi and Mozambique. Sensitivities of diagnostic tests were estimated based on a Bayesian latent class analysis approach. The cost-effectiveness of real-time PCR and copromicroscopic methods was compared across the settings. Our study showed that the sensitivity of the ANAS real-time PCR for the detection of hookworms, A. lumbricoides and S. stercoralis was high across all study settings (72.5- 99.6%) while sensitivity of copromicroscopic methods varied dramatically (8.2- 95.3%). DNA loads and egg counts were correlated; however, the agreement in the identification of moderate and heavy infections was fair to poor. In conclusion, real-time PCR based STH diagnosis is a sensitive tool for comparable assessment of hookworm, ***A. lumbricoides***, and ***S. stercoralis*** infections across different settings and its performance is less influenced by deviation from sample processing protocols than copromicroscopic methods. More research is needed to better understand the relationship between DNA load and observed egg counts for the assessment of infection intensities.

52

USE OF QUANTITATIVE REAL-TIME PCR TO MEASURE ACQUISITION OF ENTERIC PARASITIC INFECTIONS DURING THE FIRST 5 YEARS OF LIFE: OBSERVATIONS FROM A BIRTH COHORT IN RURAL ECUADOR

Andrea Arévalo Cortés[1], Yosselin Vicuña[1], Martha Loor[1], Pablo Espinosa[1], Martha Chico[1], Carlos Sandoval[1], Sophia Loor[1], Peter Hotez[2], Philip J. Cooper[1], Rojelio Mejia[2]

[1]Centro de Investigación en Enfermedades Infecciosas, Pontificia Universidad Católica del Ecuador, Quito, Ecuador, [2]National School of Tropical Medicine, Baylor College of Medicine, Houston, TX, United States

Over 2 billion humans are estimated to be infected with gastrointestinal parasites worldwide. These fecal-oral transmitted parasites are indicator infections of poverty and are associated with limited access to basic services. Standard microscopy of stool samples for detection of these parasites has a low diagnostic sensitivity compared to quantitative real-time PCR (qPCR). There are few data on the epidemiology of gastrointestinal infections from the rural tropics in pre-school children. We analyzed stool samples collected longitudinally during the first 5 years of life in a birth cohort, the ECUAVIDA cohort, set in a rural District of Quinindé, Esmeraldas Province, in tropical Ecuador using a random sample of 400 of 2,404 newborns recruited into the cohort. Stool samples collected at 1, 2, 3, and 5 years of age, were analyzed using a high throughput multi-parallel qPCR for the presence of intestinal helminths (***Ascaris lumbricoides, Ancylostoma duodenale, Necator americanus, Strongyloides stercoralis, Trichuris trichiura***) and protozoa (***Cryptosporidium spp., Entamoeba histolytica*** and ***Giardia lamblia***). ***Giardia*** and ***Ascaris*** were the most prevalent parasites in children at all ages: ***Giardia*** (31.5%, 45.6%, 52.1%, and 43.3%); ***Ascaris*** (6.8%, 12.9%, 16.4%, and 14.4%) at 1, 2, 3 and 5 years, respectively. The prevalence of most enteric parasites increased through 3 years of age after which the prevalence leveled off or fell, except for ***Cryptosporidium*** was most frequently detected during the first 2 years of life (5.3% at 1 and 5.9% at 2 years). Infections with ***E. histolytica*** and ***A. duodenale*** were of low prevalence (<4%) during the first 5 years of life in the cohort. Furthermore, the burden of infection increased comparing the 1 and 5 year olds, for ***Ascaris*** (0.72 fg/µl to 2.3 fg/µl, $p < 0.05$) and ***Giardia*** (0.84 fg/µl to 6.7 fg/µl, $p < 0.05$), respectively. Signifying increasing rates of parasitic infections and intensity of burden. Future analyses will determine the impact of these enteric parasites on growth and the development of the immune response during the first 5 years of life.

53

WHAT ARE THE BENEFITS OF COMMUNITY WIDE TREATMENT FOR THE CONTROL AND ELIMINATION OF HOOKWORM?

Hugo C. Turner, James E. Truscott, Alison A. Bettis, Roy M. Anderson

Imperial College, London, United Kingdom

The WHO treatment guidelines for soil-transmitted helminth (STH) infections focus on targeting children. However, unlike the other STH infections, the majority of hookworm infections are harboured by adults. This untreated burden may have important implications in controlling both hookworm's morbidity and transmission. This is particularly significant given recent increased interest in investigating STH elimination strategies. We used a deterministic model of the dynamics of STH transmission to evaluate the impact of child-targeted verses community-wide treatment against hookworm in terms of preventing heavy infections (a proxy for morbidity) and the timeframe for breaking transmission. Furthermore, we investigated how community-wide treatment may influence the long term programmatic costs of preventive chemotherapy for hookworm. We found that a large proportion of the overall prevalence of heavy infections is unaffected by the current targeted strategy. Furthermore,

biannual targeted treatment offered little additional benefit. Annual community-wide treatment was markedly more effective in controlling heavy infections, and was the only scenario in which breaking transmission was possible - reducing the required programme duration. Due to these reductions in programme duration it is possible for community-wide treatment to generate long term cost savings compared to using the current targeted strategy - even if it notably increases the distribution costs of the programme. In conclusion, community-wide treatment is notably more effective for controlling hookworm morbidity and transmission, and could even be cost saving in many settings. This shows that it is not optimum to treat the different STH infections in the same way, and highlights the need for further consideration of community-wide treatment for hookworm control.

54

MULTI-PARALLEL QPCR PROVIDES INCREASED SENSITIVITY AND DIAGNOSTIC BREADTH ALLOWING FOR IMPROVED EVALUATION OF THE IMPACT OF DEWORMING PROGRAMS FOR SOIL-TRANSMITTED HELMINTHS (STH)

Alice V. Easton[1], Rita G. Oliveira[2], Elise M. O'Connell[1], Stella Kepha[3], Cassian Mwatele[4], Simon J. Brooker[5], Jimmy H. Kihara[4], Charles Mwandawiro[4], Sammy M. Njenga[4], Maurice R. Odiere[6], Joanne P. Webster[7], Roy M. Anderson[2], Thomas B. Nutman[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [3]College of Health Sciences, Kampala, Uganda, [4]Eastern and Southern Africa Centre of International Parasite Control, Kenya Medical Research Institute, Nairobi, Kenya, [5]Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]Neglected Tropical Diseases Branch, Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [7]Pathology and Pathogen Biology, Royal Veterinary College, University of London, Hertfordshire, United Kingdom

Although chronic morbidity resulting from STH infections can be reduced by anthelmintic treatment, inconsistent diagnostic tools make it difficult to measure the impact of deworming programs. In order to quantify the variability in different STH diagnostic measures, we intensively screened 1671 people in four villages for helminth infections using the Kato-Katz (KK) method. We retrospectively screened these samples using multi-parallel qPCR. We treated everyone with albendazole, and collected ***Ascaris lumbricoides*** expelled post-treatment. Three months later, we re-screened and re-treated 1225 people and collected expelled worms. Between baseline and follow-up the prevalence by KK fell from 8 to 5% for ***A. lumbricoides***, and from 5 to 2% for hookworm. Expelled ***A. lumbricoides*** worms were highly aggregated, and there was a strong correlation (Spearman r=.64; p<0.0001) between the number of adult worms expelled and the intensity of infection pre-treatment. When compared to qPCR results, KK missed 20% of ***A. lumbricoides*** infections and 80% of ***N. americanus*** infections. While the limit of sensitivity for qPCR is such that a single ***A. lumbricoides*** egg is consistently detected, false negative results were common using KK at infection intensities below 2000 eggs per gram. Among a subsample of 246 individuals, 22% were found to be infected with ***Giardia lamblia***, and 16% with ***Entamoeba histolytica,*** based on qPCR. No infections with ***Trichuris trichiura, Ancylostoma duodenale, Strongyloides stercoralis*** or ***Cryptosporidium parvum*** were detected. Our data suggest that KK may be an inadequate tool for measuring worm burdens, especially in areas where hookworm and/or Strongyloides are common or where intensity of infection is low. As it becomes important for deworming programs to distinguish between populations where STH infection is controlled and those where further treatment pressure is required, multi-parallel qPCR (or similar high throughput molecular diagnostics) may offer new diagnostic tools for STH control programs.

55

INDIVIDUAL-BASED MODELLING OF HOOKWORM INFECTION: PREDICTED FEASIBILITY OF ACHIEVING CONTROL AND ELIMINATION BY 2020

Luc E. Coffeng, Roel Bakker, Sake J. de Vlas

Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

Globally, 440 million people are infected with hookworms, the majority living in developing countries. High parasite loads contribute to development of anaemia, particularly in children and women of childbearing age (WCBA). In recognition of the hookworm disease burden, the WHO has set the target to implement annual or semi-annual preventive chemotherapy (PCT) for pre-school and school-aged children and WCBA in endemic areas with an overall coverage of at least 75% by 2020. The associated parasitological goal is to achieve <1% prevalence of heavy hookworm infection in these PCT target populations (and thus prevent most morbidity). As part of the NTD Modelling Consortium, we evaluated the feasibility of achieving control (prevalence of heavy infection <1%) or even elimination of hookworm infection, given currently recommended intervention strategies. To this end, we developed an individual-based model for transmission and control of soil-transmitted helminths that synthesizes all relevant available information on hookworm biology, and captures heterogeneities in transmission and PCT participation. Model predictions were compared to longitudinal parasitological data spanning five years, collected pre-control and during PCT. In general, model predictions suggest that elimination of hookworm infection is not possible by means of PCT, unless a broader age group is targeted (e.g. including all adults). Controlling levels of heavy infection (<1%) is however very well possible through annual or semi-annual PCT (depending on pre-control endemicity) applied to current target populations at 90% coverage. Sensitivity analysis showed that individual systematic non-participation is a key determinant for achieving control, and in particular, elimination. In conclusion, we present the first individual-based model for hookworm infection and a first-time comparison of mathematical model predictions to longitudinal data. Model predictions suggest that hookworm infection can be controlled with PCT, but probably cannot be eliminated with the current strategy.

56

EVALUATION OF SEROPREVALENCE OF PARASITIC DISEASES IN U.S-BOUND REFUGEES FROM BURMA (MYANMAR)

Diana Martin[1], **Gretchen Cooley**[1], Tarissa Mitchell[1], William Stauffer[1], Paul Cantey[1], Kittisak Amornpaisarnloet[2], Valentina Parr[2], Valentina Parr[2], Deborah Lee[1], Michelle Weinberg[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]IOM, Bangkok, Thailand

The U.S. Refugee Resettlement Program resettles ~60-80,000 refugees to the United States annually. The Centers for Disease Control and Prevention provides guidance for pre-departure and post-arrival management of health conditions, including voluntary testing and presumptive treatment for parasites. There has been limited evaluation of the current program management strategies for parasitic diseases in refugees. A large cohort of refugees of Burmese origin has recently been resettling annually from Thailand. Serological testing for several parasitic diseases, including cysticercosis, lymphatic filariasis (LF), and strongyloidiasis, was undertaken from samples collected in camps in Thailand. Blood specimens were collected at the initial medical screen (approximately 3-6 months prior to departure for the U.S), before departure, and, when possible, after arrival in the U.S. All patients were offered presumptive parasitic treatment with albendazole and ivermectin at the initial medical screen and at departure. To date, 964 (48%) of the 2003 individuals enrolled have been tested for antibody responses against antigens from ***Strongyloides*** (NIE), cysticercosis (T24H), and LF (Bm14, Bm33 and Wb123) using the Luminex multiplex platform. At baseline, specimens from 5% of participants

reacted against T24H and none were positive against all three LF antigens. Seropositivity against NIE was 15%. After treatment, NIE-specific antibody levels decreased in 65% of reactive individuals with 14.5% of individuals converting to seronegative. Changes in titers as well as decreases in median fluorescent intensities (MFI) of the responses were observed in non-reverters. Especially noticeable were changes in individuals with high magnitude responses; 82% (18/22) showed decreases in the magnitude of the response (average of 88% decrease in MFI) and titers post treatment. The data suggest that presumptive treatment impacts strongyloides infection rates among U.S.-bound refugees from Thailand. Measuring the magnitude of the NIE antigen response may prove a useful tool in monitoring treatment efficacy.

57

DEVELOPMENT OF A PROOF-OF-CONCEPT *DE NOVO* BACTERIOPHAGE THERAPEUTIC AGAINST MULTIDRUG RESISTANT *ACINETOBACTER BAUMANNII* WOUND INFECTIONS

James M. Regeimbal[1], Anna Jacobs[2], Matthew Henry[1], Brendan Corey[2], Rae Heitkamp[2], Amy Zale[2], Rebecca Pavlicek[1], Daniel Zurawski[2], Tony Pierson[2], Nimfa Teneza-Mora[1], Biswajit Biswas[1], Eric Hall[1]

[1]Naval Medical Research Center, Silver Spring, MD, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States

Multidrug Resistant (MDR) bacterial infections have become a significant threat to civilian and military populations alike. Recently bacteriophage have remerged as a promising alternative therapeutic. Our objective was to develop a phage cocktail that could serve as an antibacterial therapy for MDR ***Acinetobacter baumannii*** wound infections. We isolated and purified 31 lytic phage capable of killing clinical isolates of MDR ***A. baumannii*** from DC metro area wastewater. From this modest library, we have assembled a proof-of-concept 5-member phage cocktail that is highly effective in treating mice harboring a full thickness wound infected with the model clinical isolate MDR ***A. baumannii*** 5075. Mice harboring a wound infected with 5075 were treated with our phage cocktail intraperitoneally and topically, and compared to untreated controls. In these experiments our cocktail: I) significantly reduced the ***A. baumannii*** bioburden in the wound-bed, II) prevented the invasion of ***A. baumannii*** into tissue surrounding the wound and thus promoted tissue preservation/vitality in adjacent areas, III) prevented the infection-associated increase in wound size seen in untreated controls, IV) decreased the morbidity of the wounded/infected mice as measured by a significant reduction in infection-associated weight-loss, and V) promoted rapid wound healing at a rate similar to that of uninfected controls. Based on the success of this initial cocktail our goal is to develop a broad-spectrum phage cocktail that kills at least 90% of ***A. baumannii*** clinical isolates. To do so, we have developed a 70-member MDR ***A. baumannii*** diversity set composed of divergent clinically relevant strains for improved phage isolation. We have also begun phage isolation from sites around the world, including: NAMRU6-Peru, NAMRU3-Egypt, NAMRU2-Cambodia, and FT Benning, GA. Thus, we are building a large and diverse phage library from which new cocktails can be compounded for the treatment of MDR ***A. baumannii*** wound infections.

58

A RANDOMIZED, CONTROLLED TREATMENT TRIAL FOR THE VERRUCOUS STAGE OF *BARTONELLA BACILLIFORMIS* INFECTION IN PERU

Joan M. Neyra, Ciro Maguiña, Enrique Canales, Bonnie Smoak, Larry Laughlin, David Blazes

Uniformed Services University of the Health Sciences, North Bethesda, MD, United States

There are no clinical trials that study the effect of alternative therapies for the verrucous stage of ***Bartonella bacilliformis*** infection. Our main objective was to compare the standard treatment with rifampin versus azithromycin in terms of time to resolution of the verrucous stage and time of resolution of the bacteremia. We conducted a randomized, controlled treatment trial. Participants were recruited in Caraz, Peru (northern Andean mountains) were randomly allocated in two groups of treatment (rifampin and azithromycin). At each arm, they received the treatment during two weeks, and they were followed up at 7, 14, 30, and 60 days. At each visit, we assessed the number of lesions, size of lesions, and number of body areas involved as well as the time to resolution of the verrucous rash of ***B. bacilliformis*** infection and the duration of the bacteremia associated with the verrucous rash. 125 participants were recruited (62 in the rifampin groups and 63 in the azithromycin group). We found that azithromycin reduced the time of resolution of baseline bacteremia (8.26 ± 1.79 days for rifampin vs. 7.60 ± 1.77 days for azithromycin, $p < 0.001$) and the time of reduction of verrucous lesions (16.15 ± 16.52 days for rifampin vs. 13.50 ± 11.25 days for azithromycin, $p = 0.786$). In addition, azithromycin reduced the average size of the lesions over time compared to rifampin. The results of the study showed that azithromycin had similar or better effects than those of rifampin for reducing the time of resolution of the verrucous rash and the time of resolution of initial bacteremia. Also, it had a similar effect in reducing the number of lesions, the average size of lesions and the number of body regions involved, becoming a valid alternative for the treatment of the verrucous stage of ***B. bacilliformis*** infection.

59

REGULATION OF B12 BIOSYNTHESIS BY PATHOGENIC *LEPTOSPIRA*

Michael A. Matthias[1], Carla Fernandez de Cuadros[1], Francois-Baptiste Halter[1], Jessica Ricaldi[2], Joseph Vinetz[1]

[1]University of California, San Diego, La Jolla, CA, United States, [2]Universidad Peruana Cayetano Heredia, Lima, Peru

To better understand Leptospira virulence and pathogenic mechanisms, we sequenced and annotated the genomes of two strains of a novel species ***Leptospira licerasiae*** prevalent in the Peruvian Amazon and then compared the gene content of these genomes with those of L. interrogans, ***L. borgpetersenii*** and ***L. biflexa***. These comparative genome studies revealed a 17-gene B12 biosynthesis gene cluster (cob I/III) restricted to infectious species and a non-coding RNA regulatory element in the 5′ un-translated region of the cluster. Because these genes and associated regulatory elements were present in infectious Leptospira, we hypothesized that, in contrast to current dogma, infectious Leptospira should grow in the absence of B12. Using bioinformatics approaches to determine the distribution of the previously identified cob I/III cluster amongst >300 recently sequenced and annotated high quality draft Leptospira genomes, we confirm that both the cluster and associated regulatory element are widely and uniquely distributed amongst infectious strains. Second, we tested whether infectious Leptospira synthesize B12 de novo. We created a chemically defined minimal medium and demonstrate that whereas ***L. interrogans*** and ***L. licerasiae*** grow indefinitely in the absence of B12, growth of the non-pathogen, L. biflexa, was inhibited in minimal medium without B12 supplementation. Finally, we confirmed by qRT-PCR that expression of cob I/III is modulated by exogenous B12. Because B12 is sequestered ***in vivo*** in mammals, this capacity of

infectious Leptospira to respond to diminishing levels of exogenous B12 and in response synthesize this essential nutrient could have important implications during Leptospira pathogenesis.

A MINIMAL EPITOPE COMBINATION VACCINE CAN PROTECT AGAINST ALL STRAINS OF *STREPTOCOCCUS PYOGENES* IRRESPECTIVE OF EMM TYPE AND VIRULENCE PHENOTYPE

Michael F. Good[1], Manisha Pandey[1], Rasmus Mortensen[2], Ainslie Calcutt[1], Jessica Powell[1], Emma Langshaw[1], Michael Batzloff[1], Jes Dietrich[2]

[1]Institute for Glycomics, Gold Coast, Australia, [2]Statens Serum Institut, Copenhagen, Denmark

Infections caused by ***Streptococcus pyogenes*** (group A ***Streptococcus***, GAS) and their sequelae are responsible for over 500,000 lives lost prematurely each year. A synthetic peptide, J8, from the conserved region of the M-protein combined with diphtheria toxoid (DT) has shown efficacy against disease that follows intraperitoneal inoculation of bacteria. By developing a murine model for infection that mimics human skin infection we show that the vaccine can also protect against pyoderma and bacteremia caused by multiple GAS strains. However, the vaccine was significantly less effective against hyper-virulent CovR/S mutant GAS strains and this correlated with up-regulation of SpyCEP and the strains' abilities to degrade CXC chemokines (IL8, MIP2, KC) thus preventing neutrophil chemotaxis. Chemokine proteolysis is mediated by bacterial SpyCEP. By combining J8-DT with an inactive form of recSpyCEP, we developed a vaccine that can block chemokine degradation thus permitting opsonic antibodies to kill the bacteria. Mice receiving the combination vaccine were strongly protected as evidenced by between a 100-fold to 1,000-fold reduction in bacterial burden following challenge. We then used a peptide array to identify the minimal epitope within SpyCEP. A twenty amino acid peptide ('S2') was one of several epitopes identified using serum from recSpyCEP-immunized mice; however, this epitope was the sole target for anti-SpyCEP antibodies that could protect IL8 from streptococcal SpyCEP-mediated proteolysis. It was of great interest that this epitope was also recognized by human serum from healthy individuals naturally exposed to GAS. Serum from mice immunized with S2-DT could completely protect IL8 from GAS-mediated proteolysis and human serum from healthy donors showed a partial ability to protect IL8. We then combined S2-DT with J8-DT to develop a minimal epitope vaccine and showed that the combination vaccine could protect mice against pyoderma and bacteremia due to all strains of GAS that we have tested irrespective of their emm type and independent of their CovR/S phenotype. This vaccine is now being prepared for a Phase I human trial.

61

INVESTIGATING THE ROLES OF T CELL-MEDIATED IMMUNITY DURING SCRUB TYPHUS WITH A NEWLY DEVELOPED MOUSE MODEL

Guang Xu, Thomas R. Shelite, Nicole L. Mendell, Lynn Soong, Donald H. Bouyer, David H. Walker

University of Texas Medical Branch, Galveston, TX, United States

Scrub typhus, a long neglected but important tropical disease, is caused by a Gram-negative obligately intracellular coccobacillus, ***Orientia tsutsugamushi***. Scrub typhus is a serious global public health problem that causes illness in one million people each year, the majority in the Asia-Pacific region. Without appropriate diagnosis and treatment, the disease can cause severe multiorgan failure with a mortality rate of 7-15%. However, the mechanisms behind the interactions between ***O. tsutsugamushi*** and host immunity are largely neglected and unknown. Using the newly developed intravenous (i.v.) mouse model, we discovered that host immunity was skewed towards T_h1 responses from 12 days post infection (dpi) until 3 months post infection. Our flow cytometry data determined that more $CD8^+$ T cells than $CD4^+$ T cells appeared in the spleen of infected mice after 12 dpi. We also found that T_{reg} cells and the proportion of T cell producing IL-10 levels in T cells were significantly increased from 6 dpi, which was in parallel with the body weight loss and increased bacterial loads. Our latest studies with $CD8^{-/-}$ mice and their wild type (WT) C57BL/6 control counterparts determined the important role of $CD8^+$ T cells. After being administered one LD_{50} of ***O. tsutsugamushi***, all $CD8^{-/-}$ mice expired by 11 dpi while half of the WT mice survived. Bacterial loads in the lung, kidney, liver and blood of $CD8^{-/-}$ mice were significantly higher than those in WT mice. IFN-γ mRNA levels in the lungs of $CD8^{-/-}$ mice were significantly higher than in WT mice. There was no statistically significant difference in the mRNA levels of IL-10 in the lung, liver, spleen, and kidney between $CD8^{-/-}$ and WT mice. We also found a greater pro-inflammatory immune response in the tissues of WT mice than in $CD8^{-/-}$ mice. More studies are necessary to better understand the role of host immunity during ***Orientia*** infection. This will benefit the control of scrub typhus as well as the development of a vaccine and improved therapy.

62

ACUTE GASTROINTESTINAL INFECTION AND OTHER HEALTH PROBLEMS ABOARD THE USNS COMFORT DURING CONTINUING PROMISE 2011: A HUMANITARIAN ASSISTANCE/DISASTER RESPONSE MISSION

Mark S. Riddle[1], Andy Chern[2], Andrea J. McCoy[1], Jessica M. Hameed[2], Ramona McCaffrey[3], Tracy A. Brannock[4], Krista Brooks[3], Gregory J. Martin[5], Shannon D. Putnam[3], Chad K. Porter[1], William T. Scouten[6]

[1]Naval Medical Research Center, Silver Spring, MD, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]Naval Health Research Center, San Diego, CA, United States, [4]Air Force Global Strike Command, Barksdale Air Force Base, LA, United States, [5]Department of State, Washington, DC, United States, [6]Naval Medical Center Portsmouth, Portsmouth, VA, United States

Disease and non-battle injuries (DNBI) can significantly impact operational missions and compromise readiness. No study to date has examined DNBI rates aboard hospital ships on humanitarian aid/disaster response (HADR) missions. Given their nature, these HADR training and operational missions utilize significantly different personnel and result in unique exposures compared to operational deployments. From April to September 2011, US military, partner nation military, non-governmental organization personnel, and merchant marines participated in Continuing Promise 2011, a HADR training mission aboard hospital ship USNS COMFORT (T-AH 20). We conducted health surveillance for the purpose of assessing DNBI trends and improving force health protection during the deployment. The data collected were from two sources: (1) weekly DNBI aggregate data from the medical treatment facility sick-call clinic; and (2) an enhanced weekly, self-reported, surveillance questionnaire (eDNBI). Additionally, a case series study of acute gastrointestinal illness (AGI) was conducted via culture-independent microbiology on stool specimens. Clinic-based DNBI were obtained from an average weekly force of around 900 personnel. In addition, 3,156 self-report surveys (~15% of personnel each week) were collected. The self-report survey respondents were a representative sampling of the entire ship's crew. The leading syndrome-specific cause of average weekly visits to the ship's clinic was AGI, followed by dermatological conditions and acute respiratory illness (ARI) (2.1, 1.9, 1.5 per 100 person-weeks, respectively). eDNBI rates were similarly represented in the top three, although in reverse order, with 11.2 ARI, 8.7 dermatological, and 7.4 AGI average cases per 100 person-weeks. AGI were responsible for a majority of duty days lost (201/325, 61.8%). Among 51 AGI cases, one or more pathogens were identified in 71% of cases, with ETEC and norovirus as leading causes. These data highlight important disease and injury burden on HADR missions and may be useful for future planning.

63

RISK FACTORS, GUT FUNCTION BIOMARKERS AND GROWTH DEFICIT ASSOCIATED WITH ENVIRONMENTAL ENTEROPATHY AND MALNUTRITION: THE CASE-CONTROL MAL-ED STUDY IN FORTALEZA, CEARÁ, BRAZIL

Aldo A. Lima[1], Álvaro M. Leite[1], Alessandra F. Moura[1], Noélia L. Lima[1], Reinaldo B. Oriá[1], Alberto M. Soares[1], José Q. Filho[1], Cláudia B. Abreu[1], Ila F. Lima[1], Alexandre Havt[1], Marjorie M. Guedes[1], Sean R. Moore[2], Jordi Mayneris-Perxachs[3], Jonathan R. Swann[3], Richard L. Guerrant[4]

[1]Federal University of Ceara, Fortaleza, Brazil, [2]University of Cincinnati, Cincinnati, OH, United States, [3]University of Reading, Reading, United Kingdom, [4]University of Virginia, Charlottesville, VA, United States

In Fortaleza, located in the poorest region of Brazil, there is a large socioeconomic and cultural disparity that maybe influences the prevalence of malnutrition and its serious consequences for growth and cognitive development in children. The aim of this study was to evaluate the variables related to the child and the mother, as well as environmental and socio-economic factors associated with environmental enteropathy (EE) and malnutrition (MN) in children from Fortaleza, Ceará, Brazil. The study design was a case-control prospective study. The protocol was approved by the local Internal Review Board (IRB) (Universidade Federal do Ceará), a national IRB (CONEPE) and IRB at University of Virgínia. The study period was from August/2010 to September/2013; Inclusion criteria for the case: z score weight-for-age (WAZ) -1; and all children aged 6-24 months. As for 30Nov2013 we screened 484 and enrolled 402 children in the study protocol. The results showed preliminary analysis on 244 children (126 controls and 118 cases) for risk association with EE and MN. The age mean ± standard deviations was 11.83 (5.2) for controls and 15.00 (5.5) for cases ($p<0.001$). Sex distribution was similar on both groups. The mean ± standard deviations for z-score on WAZ was 0.03 (0.97) for controls compared to -2.70 (0.78) on cases ($p<0.0001$). The multiple linear logistic regression and Wald test analysis showed three variables that hold significant results with <5%, which were increased in control for birth weight, head circumference and number of pregnancies compared to cases. Calprotectin (CAP) was increased on both (cases and control) and it was significantly higher on malnourished compared to nourished children. Higher myeloperoxidase (MPO) and alpha1-antitrypsin (A1AT) were associated with impaired "catch-up" growth. These data showed protective risk factors associated with nourished compared to malnourished children. Elevated CAP, MPO and A1AT are associated with gut inflammation and impaired growth in these children.

64

THE QUECHUA PEOPLE OF SOUTHERN PERU: A DESCRIPTIVE ANALYSIS OF CLINIC ATTENDEES

Matthew Belenchia[1], David Adams[2], Daniel Traylor[3], Cesar Fernandez[1], Ellen Robinson[4]

[1]ASU, Savannah, GA, United States, [2]ASU/Medical College of Georgia, Savannah, GA, United States, [3]Clemson University/ASU, Clemson, SC, United States, [4]Incarnate Word University, San Antonio, TX, United States

This project builds upon a 2014 study, "The Epidemiology of Disease among the Quechua People of Southern Peru: A Pilot Study". In this present research, we will analyze data (N = 839) related to common primary care issues among the Quechua People of southern Peru, e.g., diabetes, hypertension, anthropometric measures, etc. Up to this time, previous studies have focused their attention primarily on biogenetic issues such as hemoglobin variants. As such, day-to-day primary care issues have eluded the attention of researchers. Data concerning primary care complaints among the Quechua, an underserved, rural---and largely unstudied--population with regard to common medical issues were collected during a two week primary care clinic based in the remote town of Pampichiri in the Andahuaylas region of southern Peru. The findings in this study, one of the first of its kind, highlight primary care health issues among Quechua clinic attendees.

65

KNOWLEDGE AND PRACTICES OF VILLAGE HEALTH TEAM MEMBERS IN EARLY DETECTION AND CARE FOR CHILDREN WITH SEVERE ACUTE MALNUTRITION AT COMMUNITY LEVEL: A CASE STUDY OF A RURAL COMMUNITY IN UGANDA

Elizabeth Kemigisha[1], Rosemary Namayanja[2], Gad Agaba[3], Silvano Twinomujuni[2], Daniel Atwine[1], Francis Oriokot[4], Noni E MacDonald[5]

[1]Epicentre Mbarara Research Centre, Kampala, Uganda, [2]Mbarara University of Science and Technology, Kampala, Uganda, [3]Healthy Child Uganda, Kampala, Uganda, [4]Mbarara Regional Referral Hospital, Kampala, Uganda, [5]Dalhousie University/ Microresearch, Halifax, NS, Canada

Background Malnutrition remains a serious problem for young children in many developing countries. In Uganda, highest malnutrition rates are in the South West where 40% of children have chronic malnutrition; 5% acute malnutrition.The first level of government provided healthcare are community based Village Health Team (VHTS) with very basic health knowledge. The study determined how VHT members identified and managed children with early malnutrition in SW Uganda. Methods Cross sectional survey of VHTs in randomly selected parishes of Bushwere and Ryamiyonga in SW Uganda who attended two sessions in August and September 2013.A pretested malnutrition knowledge and management questionnaire was used.The project received ethical approval from MUST-REC and was funded by MicroResearch Results A total of 59 VHTS from the 2 parishes were interviewed. Their mean age was 37 ± 9y (range 22-60y); 75% were female. 95% had initial 5-day training for their VHT role;90% had served in their position for > 5 years.50% of VHT had mid upperarm circumference (MUAC)training for nutrition assessment, none had received a MUAC tape.83% could correctly classify the local food crops in their respective food groups. 88% identified body swelling, changes in skin or hair colour and having protuberant abdomen signs of malnutrition in children.However, only 8% of VHTs selected measuring MUAC as a method to identify malnutrition.Knowledge on feeding options when mother is HIV+ showed that 97% were only aware of outdated options; e.g no breastfeeding or for a short time only.. 89% reported offering feeding advice; 42% reported advising referral to health unit to parents when severe malnutrition was noted in their children. Conclusion VHTs had adequate knowledge of feeding of children and could correctly classify foods into three major food groups.They were able to describe late signs of malnutrition but unable to detect early signs possibly due to lack of MUAC tapes. VHTs would benefit from refresher courses on (a) recommended nutrition for infant and young children of HIV+ mothers,(b) training on MUAC use and measurement and should be given MUAC tapes and normal values for age.

66

EFFECT OF COOKING METHODS ON THE CONCENTRATION OF OXYTETRACYCLINE RESIDUES IN CHICKEN

Ekene Vivienne Ezenduka, John A. Nwanta, Steve I. Oboegbulem, Den-Chris N. Onah

University of Nigeria, Nsukka, Nigeria

Antibiotics are used in poultry industry to obviate disease, enhance growth and increase production. However, the use of these drugs often results in the accumulation of violative levels of residues in tissues. Consumption of such poultry meat would potentially adversely affect human health through the development of resistant pathogenic microorganisms and hypersensitivity reactions in sensitized individuals. Although meat is always heat treated before consumption, which should ordinarily render

the residues innocuous, some drugs are heat stable and therefore would persist at residue violative levels. Since tetracyclines are the most frequently used antibiotics in poultry production in Nigeria, this study was therefore embarked upon to find out the effect of cooking methods (boiling, microwaving and roasting) on the concentration of oxytetracyclines (OTC) in poultry meat and organs. Muscle and liver tissues were harvested from birds that were treated with OTC either by intramuscular injection or orally in drinking water and analysed for residues using the three plate test (TPT) and the enzyme-linked immunosorbent assay (ELISA). TPT at two different pH levels reduced the inhibition zones of raw muscles between 34-49%, 67-69.6% and 53-56% for microwaving, boiling and roasting respectively but the difference in the means was not statistically significant ($P > 0.05$). TPT however, significantly ($P < 0.05$) reduced the inhibition zones of raw liver between 79- 80.9%, 57-60.29% and 88-89.71% for microwaving, boiling and roasting respectively, at both pH levels. ELISA determined a slight increase in mean OTC concentration in microwaved (1.2%) and roasted (0.3%) muscle tissues with a slight decrease by boiling (3.5%) but the differences were not significant. Boiling and roasting however significantly ($P<0.05$) reduced OTC concentration in liver tissues by 2.83% and 3.17% respectively. The reduction of OTC concentrations by heating will give a ray of hope for those in developing countries who are exposed to violative levels of OTC residues due to non-enforcement of laws against antimicrobial use in livestock and poultry production.

67

EFFECTIVENESS OF LONG LASTING INSECTICIDE NETS ON UNCOMPLICATED CLINICAL MALARIA: A CASE-CONTROL STUDY FOR OPERATIONAL EVALUATION

Barikissou B. Damien[1], Armel Djenontin[2], Evelyne Chaffa[3], Sandra Yamadjako[1], Papa Makhtar Drame[4], Emmanuel Elanga[4], Marc Egrot[4], Marie-Claire Henry[1], Vincent Corbel[4], Franck Remoué[4], Christophe Rogier[5]

[1]Entomological Research Center at Cotonou, Cotonou, Benin, [2]Centre de Recherche Entomologique de Cotonou, Laboratoire Evolution, Biodiversité des Arthropodes et Assainissement, Faculté des Sciences et Techniques-Université d'Abomey-Calavi, Cotonou, Benin, [3]Health Ministry of Benin, Cotonou, Benin, [4]Maladies Infectieuses et Vecteurs, Ecologie, Génétique, Evolution et Contrôle/CREC, Cotonou, Benin, [5]Institut Pasteur de Madagascar, Institut de Recherche Biomédicale des Armées, Antananarivo, Madagascar

In a context of large scale implementation of malaria vector control interventions such as LLINs, it is an urgent need to monitor their effectiveness. Case-control study could be an alternative tool for this evaluation since this study design avoids many of the ethical issues inherent to longitudinal and experimental studies. The present study aimed to use the case-control approach to evaluate the post-deployment effectiveness of LLINs. A case-control study took place in two health districts in Benin; Ouidah-Kpomassè-Tori (OKT) in South and Djougou-Copargo-Ouaké (DCO) in North. Children aged 0-60 months recruited in populations were included. Cases were children with a high axillary temperature (≥37.5°C) or a reported history of fever during the last 48 hours with a positive RDT. Controls were children with neither fever nor signs evoking malaria with negative RDT. The necessary sample size was at least 396 cases/1,188 controls per area. The main exposure was "Sleeping all night under LLINs two weeks preceding the survey". The conditional logistic regression model taking into account clustering random effect was used for analysis. The protective effectiveness (PE) of LLINs was calculated as (PE=1-OR). The declared use of "LLINs all night since two weeks" ranged was 17.0% and 27.5%, respectively, in cases and controls in OKT area and 44.9% and 56.5% in cases and controls, respectively, in DCO area. The use of LLINs conferred 40.5% [95CI: 22.2%-54.5%] and 55.5% [95CI: 28.2%-72.4%] of PE in the OKT and the DCO area, respectively. Differences in PE were observed according to the education level of the mother. The case-control study appeared to be a relevant and suitable epidemiological tool for operational evaluation of LLINs effectiveness in the real condition after their deployment. In the context of a mass distribution of LLIN, the use of LLINs conferred protection up to 40% against the occurrence of uncomplicated malaria cases in children.

68

ASSOCIATION OF CAUSAL BELIEFS ABOUT SHOE WEARING TO PREVENT PODOCONIOSIS: A BASELINE STUDY

Desta A. Alembo[1], Abebayehu Tora[2], David Farrell[3], Getnet Tadele[1], Gail Davey[4], Colleen McBride[5]

[1]Addis Ababa University College of Social Science, Addis Ababa, Ethiopia, [2]Department of Sociology, Wolaita Sodo University, Sodo, Ethiopia, [3]People Designs Inc., Durham, NC, United States, [4]Brighton and Sussex Medical School, Falmer, Brighton, United Kingdom, [5]Behavioral Sciences and Health Education, Emory University, Atlanta, GA, United States

Podoconiosis is a neglected tropical disease caused by long term barefoot exposure to volcanic clay soil. Susceptibility to podoconiosis is hereditary but disease can be prevented if individuals at high risk consistently wear shoes. Our previous qualitative research identified various domains of beliefs about the causes of podoconiosis held by members of the community. This study aimed to quantitatively evaluate the prevalence of these beliefs and to assess their association with observed shoe-wearing behavior. A baseline study was conducted in 2013, in six communities endemic for podoconiosis in Wolaita zone, southern Ethiopia. A total of 1800 respondents (600 affected and 1200 unaffected parents of an index child aged between 3 and 6 years) took part in the study. The care-giver who spent the "most time with the [index child] and knew the child's daily habits the best" was asked to complete the baseline survey with the index child in mind. Two versions of the enumerator-administered survey were created with measures assessed in parallel for the affected and unaffected household respondents. Associations among measures were assessed using linear regression models. Respondents from affected families were significantly more likely to report that the index child wore shoes than respondents from unaffected families ($p<0.001$). Accuracy of understanding about podoconiosis was significantly lower among respondents from unaffected than affected households ($p<0.001$).Beliefs about heredity among affected respondents were negatively associated with reported shoe wearing of the index child (OR=0.67, 95% CI 0.55-0.83). Associations of causal beliefs with shoe wearing were moderated by risk perceptions for both groups. Interventions aimed at preventing podoconiosis and improving shoe wearing should consider family-oriented education on hereditary susceptibility targeting both affected and unaffected families in resource limited settings.

69

GLOBAL HEALTH WITHIN BORDERS: OUTLOOK OF HEALTH SCREENING AMONG IRAQI AND SUDANESE REFUGEE COMMUNITY AND THE IMPACT OF LANGUAGE BARRIER THE PATIENT SELF-ADVOCACY

Juliana D. da Silva[1], Pratibha Seshadri[2], Matthew Behme[2]

[1]Baylor College of Medicine, Houston, TX, United States, [2]Einstein Medical Center, Philadelphia, PA, United States

The CDC estimates that between 50 to 70 thousand refugees are resettled in US each year. Caring for this highly diverse population represents a unique opportunity and challenge to practice international health and community outreach within US borders. We report health screening finding among refugees at an urban clinic. We aim to review the immunization status of adult immigrants, identify missed opportunities for vaccination and analyze the impact of fluency in English have on compliance with recommended schedule A retrospective chart analysis was conducted in 101 patients seen at a refugee health reference center in Philadelphia from 2012 to 2014. Variables measured included demographic, medical and anthropometric data, vaccination statuses and fluency in English. For the purpose of this study, full vaccination encompassed influenza, MMR, Tdap and varicella. English fluency was

determined by provider documentation. Our demographically diverse population was originated from 16 different countries, largely young (median age 33.2), comprising mostly Iraqi (50%) and Sudanese (14.8 %) refugees. They had high burden of transmissible diseases: LTBI (19.8%), presumed parasitic infections (7.9), syphilis (4%). In regards to vaccination, 5.9% were susceptible to varicella and 1.9% had incomplete MMR vaccine. Among non English speakers, 58% had received full vaccination versus 71% of English speakers. Much like Americans, refugees exhibited high rates of or chronic diseases and mental illness. One in every three patients was smoker and obesity rates were 20.1% Mental health screening was positive in 10.9%. Length of stay > 1 year was not correlated to increase in BMI, contrary to previous literature reports. No differences in BMI, smoking rates, vaccinations rates were found among ethnic groups. In conclusion, ability to speak English represents a significant barrier to patient self-advocacy, despite availability of interpretation service and patient navigation resources. Targeted interventions of health English literacy are likely to improve vaccination compliance and health indicators among refugees

70

USING RAPID ETHICAL APPRAISAL (REA) TO DESIGN A CONTEXTUALIZED CONSENT PROCESS FOR BIOMEDICAL STUDIES THE ETHIOPIA

Tewodros T. Gebresilase[1], Zebene Andargie[1], Girmay Tsegay[2], Abraham Aseffa[1], Gail Davey[3], Melanie Newport[3], Fasil Tekola-Ayele[4], Adamu Addissie[5]

[1]Armauer Hansen Research Institute, Addis Ababa, Ethiopia, [2]Debre Markos University, Debre Markos, Ethiopia, [3]Brighton and Sussex Medical School, Brighton, United Kingdom, [4]Center for Research on Genomics and Global Health, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States, [5]Addis Ababa University, Addis Ababa, Ethiopia

Conducting biomedical studies in developing countries can be difficult partly due to poor knowledge about research process and research ethics. The situation is complicated when the disease of interest is thought to be familial and a reason for stigmatisation. We used a Rapid Ethical Appraisal tool to assess local factors that were barriers to getting genuine informed consent prior to conducting genetic study of podoconiosis (non-filarial elephantiasis) in two provinces in Ethiopia. The tool involves In-depth Interviews and Focus Group Discussions with patients, healthy community members, field workers, Institutional Review Board members, elders, religious leaders, and administrators who work closely with patients. We compared our findings with two earlier studies that employed this method in another part of Ethiopia and north western Cameroon. Most of the study participants did not differentiate research from routine clinical diagnosis. The decision to participate in a study was influenced by the presence of trusted community members during the consent process and the type of biological sample sought. Many believed podoconiosis to be hereditary; some also considered it to be a communicable disease that can be transmitted by wearing patients' shoes and washing with the same basin the patients have used. Participants better understood genetic susceptibility concepts when analogies drawn from their farming experience were used. Understanding the concerns of local people in areas where research is to be conducted will help to design contextualized consent processes appropriate for all parties and will ultimately result in getting genuine consent.

71

COMMUNITY-BASED LARVAL SOURCE MANAGEMENT WITH LARVIVOROUS FISH TO CONTAIN VECTORS OF JAPANESE ENCEPHALITIS THE DISTRICT GORAKHPUR, UTTAR PRADESH, INDIA

Susanta K. Ghosh

National Institute of Malaria Research, Bangalore, India

Community-based larval source management with larvivorous fish to contain vectors of Japanese Encephalitis in district Gorakhpur, Uttar Pradesh, India Susanta K Ghosh1, Vijay P Ojha2, Satyanarayan Tiwari1, Milind Gore2 and Neena Valecha2 1National Institute of Malaria Research, ICMR complex, Devanahalli, Bangalore 562110, India 2National Institute of Malaria Research, Sector 8, DWARKA, New Delhi 110077, India 3National Institute of Virology, Field Unit, BRD Medical College, Gorakhpur-273013, Uttar Pradesh, India Japanese Encephalitis (JE) is a mosquito-borne viral disease mostly prevalent in rice growing areas in the Asia-Pacific region. In India JE is endemic in 24 states and union territories. About 75% of Indian JE cases are reported Uttar Pradesh, and district Gorakhpur also contributed nearly 75% cases from Uttar Pradesh. We undertook a study to contain the JE vectors in three endemic blocks in district Gorakhpur using larvivorous fish involving the local administration and community. Baseline larval survey data in July-August 2013 revealed JE vectors Culex tritaneorynchus, Cx. vishnui, Cx. pseudo vishnui breed in ponds, wells, rice fields and borrow pits. During summer months only ponds and wells support the vector breeding. Based on our malaria vector control experience in Karnataka, we targeted ponds with mosquito fish Gambusia affinis and wells with Guppy fish (Poecilia reticulata). Geographical reconnaissance (GR) of all water sources were mapped at village level. Workshops were organized involving the staff of local health and Block Development Officers, Panchayat (Local self-government) members. Focused group meetings in each village were also organized. Monthly monitoring of vectors in the post fish-intervention data revealed a reduction of 78% on breeding indices. Here, rice fields have very limited role as they get dry up in the summer months, and no breeding of vector was observed in rice field post fish intervention period. Our study showed that larvivorous fish has a potential role to contain vectors of JE. Study is undergoing to expand this programme in other areas of the district and other JE endemic areas.

72

STIGMA TOWARDS A NEGLECTED TROPICAL DISEASE: FELT AND ENACTED STIGMA SCORES AMONG PODOCONIOSIS PATIENTS IN NORTHERN ETHIOPIA

Abreham T. Alemayehu[1], Kebede Deribe[2], Sara Tomczyk[3], Elizabeth Mousley[4], Gail Davey[4]

[1]International Orthodox Christian Charity, Debre Markos, Ethiopia, [2]Addis Ababa University, Addis Ababa, Ethiopia, [3]International Orthodox Christian Charity, Addis Ababa, Ethiopia, [4]Brighton and Sussex Medical School, Brighton, United Kingdom

Podoconiosis, or non-filarial elephantiasis, is a neglected tropical disease (NTD) characterised by swelling of the lower legs. When left untreated, this disfiguring condition has a significant social impact. This study aimed to describe the stigma experience among podoconiosis patients in Dembecha, Northern Ethiopia and assess potential associations between stigma and sociodemographic determinants. The study was conducted in May 2012 in Northern Ethiopia. A questionnaire-based cross-sectional study design was used and stigma was assessed using a validated podoconiosis stigma scale including 'felt' and 'enacted' stigma domains. Enacted stigma includes the experience of discrimination such as abuse, loss of employment or prejudicial attitudes, while felt stigma is the perceived fear of enacted stigma. A multivariable linear regression model was used to explore determinants that may be associated with stigma. A total of 346 clinically confirmed podoconiosis patients participated in

the study. The total mean score ofall stigma scale items was 30.7 (Range = 0 to 96). There was a higher mean score of scale items in domains of feltstigma (21.7; Range = 0 to 45) as compared to enacted stigma (9.0; Range = 0 to 51). The total mean score of all stigma scale items appeared to increase with disease stage. A final adjusted linear regression model found an association between stigma and factors including monthly income, duration lived in the current residence, and disease stage, after controlling for confounders. In conclusion, podoconiosis is a stigmatized disease with a clear social impact. This paper documented the burden of podoconiosis-related stigma and identified associated factors. Programs aimed at preventing and treating podoconiosis should incorporate interventions to mitigate both felt and enacted stigma.

73

PODOCONIOSIS PREVALENCE AND PREVENTION EDUCATION IN RWANDA AFRICA

Jean Paul Bikorimana

Imidido Project, Musanze, Rwanda

Non-filarial elephantiasis (also known as Podoconiosis), is a noninfectious neglected tropical disease caused by prolonged exposure of bare feet to irritant volcanic soils. The focus of our research has been to determine the number of individuals in the Northern Province with this condition in an attempt to treat those with the condition and to prevent any new cases from occurring through a focused prevention education program. The Imidido Project team began registering those with Podoconiosis in March of 2013 and to date we have 183 registered in Musanze with a population of 368,267. The Imidido Project expanded services to Kinoni in the Burera District with 72 registrants and a population of 339,200. Our preliminary results indicate that less than 1% of the population in the Northern Province is suffering from Podoconiosis. High risk individuals have been a focus for our prevention education team and our preliminary data indicates that of the 183 persons with Podoconiosis only 2 family members of the 183 registrants have signs and symptoms of Podoconiosis since the prevention education team began its work visiting families in their homes. Podoconiosis prevalence is less than 1% of the population in the Northern Province; however, the prevention education team focuses on building awareness in schools, churches, communities and healthcare centers throughout the Northern Province with hopes of eradicating this neglected tropical disease in Rwanda Africa.

74

PREVENTING MATERNAL MORTALITY THE THE DEMOCRATIC REPUBLIC OF THE CONGO: EFFECT OF THE ORGANIZATIONAL MODEL OF HEALTH CARE

Abel M. Ntambue[1], Françoise K. Malonga[1], Michèle Dramaix-Wilmet[2], Philippe Donnen[2]

[1]University of Lubumbashi, Lubumbashi, Democratic Republic of the Congo, [2]Université Libre de Bruxelles, Brussels, Belgium

The Democratic Republic of the Congo (DRC) has the third highest number of maternal deaths (MD) and one of the highest risks of MD (730/100,000live births) in the world. Reaching Millennium Development Goal 5 (≤138/100,000 live births) in 2015 is out of the question; appropriate care is often not accessible. This study aimed to determine the impact of differentorganizational models of mother-child health (MCH) services on maternal mortality (MM).Using data on the MM ratio, cause of MM, and MCH services use from the Multiple Indicator Cluster Survey 4 (MICS4), we modeled the reduction in MM as a function of the variation in the level of use of services for the period from 2010-2015. We evaluated scenarios based on the model of service provision: family-based or informal care, community-based care, and clinical care. For each model, the rate of MCH services use was progressively varied between 60 and 90%. This rate was not varied for services for which the use was already above the set threshold. In 2010, 16,390 MD occurred in DRC. If universal (>90%) coverage of all types of services, on the continuum, were assured to women over one year, more than 48.5% of these deaths could be avoided. Cost-effective MCH services are well-known. Universal coverage across the mother-child continuum constitutes the strategy most likely to significantly reduce MM in DRC. To achieve this level of performance, the entire health care system must be strengthened.

75

HOUSEHOLD CHARACTERISTICS ASSOCIATED WITH MALARIA-INTESTINAL HELMINTHS CO-INFECTIONS AMONG RURAL DWELLERS THE SOUTHWEST, NIGERIA

Chinenye Afonne, Ikeoluwapo O. Ajayi, Dada- Adegbola Hannah, Catherine O. Falade

University of Ibadan, Ibadan, Nigeria

Malaria and intestinal helminth infections occur concurrently in tropical regions due to similarity of favorable breeding conditions, the effects on morbidity outcomes cannot be over-emphasized. The household environment is a major determinant and influences the risk of infectious diseases. This study explored household related risk factors associated with the occurrence of both infections particularly among rural dwellers. A two stage sampling technique was employed to recruit 647 household representatives and/or head of households from 35 communities. At the household of the enrollees, data was collected using a pre-tested questionnaire and an observation checklist. About 47% of the respondents were males and mean age was 46.0 ± 1.3 years, 51.1% had no formal education. Farming (51.0%) and trading (31.8%) were the major occupations of the people. The Well was mentioned as the predominant source of water for domestic use (84.0%) and drinking (81.0%). About 85.8% defecated in the bush. Only 7.7% used bednet as malaria preventive material, 7.5% slept under the net the night before and only 9.7 had window/door screens. Very few (2.5%) had had an Indoor residual spray in the last 1 year preceding the study. Several (61.2%) managed malaria at home first before seeking any other provider. Of all respondents, 20% said the health facility was far from their house. A number of (33.7%) had passed out worms in the last one year, 49.3% dewormed once in the last one year while 35.3% said they never deworm. About 54.6% had overgrown vegetations, 49.3% had uncovered containers with water, 11.6% had stagnant water around the household environs. A number (26.5%) of the respondents recalled that they had fever two weeks before the study. Household characterististics and risky practices associated with malaria and intestinal helminths abound in most of the households and environs visited in the study.

76

EVALUATION OF A UNIVERSITY-NGO PARTNERSHIP TO ADVANCE EQUITY THROUGH NURSING EDUCATION

Emily Hall[1], Sharon Rose[1], Roodaline Valcourt[2], Kate Dieringer[3], Ellen Scarr[1], Brooke Finkmoore[1], Evan Brown[1], Beatrice Romelo[2]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]Zanmi Lasanté, Port-au-Prince, Haiti, [3]Partners in Health/Zanmi Lasanté, Port-au-Prince, Haiti

Nurses provide 90% of health care worldwide today, yet global health nursing is a field still in its infancy. There is growing recognition of the need to elevate the leadership role of nurses, especially in resource-limited settings. In Haiti, few public nursing schools, limited opportunities for continuing education and high levels of nurse migration weaken an already overburdened health system. In 2014, the University of California, San Francisco (University of California San Francisco) developed the University of California San Francisco Global Health Nursing Fellowship to advance nursing competency and leadership in Haiti, while also training US-based nurses in global health care delivery in resource-limited settings (RLS). Partnering with the non-profit Partners In Health, the fellowship aims to support PIH's Nursing Center for Excellence trainings and mentorship for the local nursing workforce. The 10-month fellowship is offered to US-based advanced practice nurses. Fellows

spend 50% of their time in Haiti creating educational opportunities and modeling team-based care, and the rest of their time at University of California San Francisco mentored as associate clinical faculty. This study was undertaken to address two interrelated, unmet needs in nursing education: clinical, didactic and leadership support for nurses in low-resource settings; and post-graduate global health training for US-based nurses. The collaboration has completed its inaugural year and offers an evaluation here. Successes include: 1) piloting a structured format for bed-side teaching; 2) modeling the role of a dedicated in-patient nurse educator; and 3) increasing fellows' understanding of local burden of disease, health inequities and barriers to care delivery. Challenges include: 1) engaging overburdened nursing staff and leadership; 2) aligning the learning needs of the fellows with the contextual realities of a hospital in a RLS; 3) reinforcing collaborative relationships with physicians to improve interprofessional rounding. These early results demonstrate a potential model for international university-NGO partnerships that can advance health equity, benefiting both US-based learners as well as the local nurse workforce.

77

ASSESSING THE COST-EFFECTIVENESS OF DIFFERENT VACCINATION STRATEGIES FOR CHILDREN IN THE DEMOCRATIC REPUBLIC OF CONGO

Reena H. Doshi[1], Calixte Shidi[2], Nicole A. Hoff[1], Patrick Mukadi[3], Audry Mulumba[2], Sue Gerber[4], Emile W. Okitolonda[5], Jean-Jacques Muyembe[3], Anne Rimoin[1]

[1]University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, [2]Expanded Programme on Immunization, Kinshasa, Democratic Republic of the Congo, [3]National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, [4]Bill & Melinda Gates Foundation, Seattle, WA, United States, [5]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

While measles mortality has been reduced more than 78%, the disease remains one of the major causes of childhood vaccine preventable diseases globally. Measles immunization requires a two-dose schedule and only countries with strong, stable immunization programs have been able to rely on routine services to deliver the second measles dose. In the Democratic Republic of Congo (DRC), the second dose of measles vaccine is administered via supplementary immunization activities (SIAs), due to inadequately low routine immunization coverage. We used a decision analysis with a Markov model based on published and unpublished data to compare the cost-effectiveness of two different strategies for the second dose of Measles Containing Vaccine (MCV) to one dose of MCV through routine immunization services over a 15-year time period for a hypothetical birth cohort of 3 million children. Compared to strategy 1, strategy 2 (MCV2 by SIA) would prevent a total of 279,110 measles cases and 6,795 deaths and save U.S. $2.26 million. Compared to strategy 1, strategy 3 (MCV2 by RI) would prevent a total of 207,996 measles cases and 5,074 measles-related deaths and save U.S. $0.71 million. Strategy 2 was both cost-saving and dominated the other two strategies, yielding the fewest deaths and the lowest total program costs over the 15-year time period for the hypothetical cohort. Vaccination recommendations should be tailored to each country, offering a framework where countries can adapt to local epidemiological and economical circumstances in the context of other health priorities. Our results reflect the synergistic effect of two doses of MCV and demonstrate that the most cost-effective approach to measles vaccination in DRC is to continue the administration of the second dose by mass campaign.

78

COMPARING ANTHROPOMETRIC MEASURES OF INDIGENOUS SCHOOL-AGED CHILDREN THE GUERRERO, MEXICO TO AVAILABLE INTERNATIONAL, NATIONAL AND LOCAL GROWTH REFERENCES

Deborah A. Lardner, Michael Passafaro, David T. Guernsey III, Min-Kyung Jung

NYIT-COM, Old Westbury, NY, United States

Malnutrition, both acute and chronic, continues to be a major health burden for children in resource poor countries. Nutritional surveillance studies in the form of anthropometric measures are useful screening tools to identify children at risk. Established international measures of wasting (< - 2SD weight-for-height, BMI-for age Z-score), being underweight (< - 2SD weight-for-age Z score), and stunting (< - 2SD height-for-age Z score) are now more commonly used in the field. The Comisión Nactional para el Desarrollo de los Pueblos Indígenas reports the indigenous population of Mexico lives in the poorest and most disadvantaged states. This cross-sectional study conducted in February 2013 examined the severity of nutritional deficiencies in the form of grown parameters for indigenous children in two communities in the state of Guerrero, Mexico. Anthropometric measures were collected for children in the communities of Buena Vista (n= 72) and Nuevo Zaragoza (n= 51). The data was entered into the World Health Organization (WHO) AnthroPlus program, and z-scores were generated for height-for-age (HAZ), weight-for-age (WAZ), and BMI-for-age (BAZ). Statistical analysis was performed using simple, independent t-test comparing the collected variables to published mean z-scores from the World Health Organization, Mexico, and the state of Guerrero. The sampled indigenous population had significantly lower z-scores for each t-test performed (All p-values < 0.001). This small study suggests nutritional disparities exist in this mostly indigenous region of Mexico. Specifically, children demonstrated evidence of stunting and are at risk for wasting and being underweight as indicated by their z-scores. The authors believe this information may be useful to public health, policy-makers, governmental and non-governmental organizations seeking to improve health parameters in this region through innovative partnerships addressing this disparity. Understanding the environmental and social influences on health and nutrition in these communities with future studies will allow for site appropriate interventions and stronger advocacy for children at risk.

79

DEVELOPMENT OF A COMMUNITY HEALTH WORKER PROGRAM FOR RURAL HAITI

Lisa Altieri[1], Aline Zorian[1], Susan Partovi[1], Ross Donaldson[2]

[1]David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States, [2]Harbor-University of California Los Angeles Department of Emergency Medicine, Los Angeles, CA, United States

Access to health care poses an essential challenge for Haiti. To bridge such gaps in health care access, rural communities in a number of countries have instituted a system of community health workers (CHWs). These CHWs are individuals selected from within the community who are trained to serve in both direct patient care and health education. In April 2015, a pilot study will be conducted to investigate (1) the current state of access to primary and emergency health services in the rural community of Mussotte, Haiti, (2) the attitudes of community members toward existing health services and health providers, and (3) the extent of interest in a community health worker program. A cluster sampling method will be used to select approximately 50 subjects for participation in a household survey. Data analysis will include a regression analysis for factors influencing knowledge, attitudes, and perceptions about need for community health workers. Our findings will not only further our understanding of the current health care needs in Mussotte but also allow

for interventions that will more effectively address the existing structural and cultural barriers to care. Ultimately, we hope that this research will create a platform for improvement in access to quality medical services in Mussotte, as well as other rural communities in Haiti which face similar barriers to care.

80

ADVOCACY AND TROPICAL DISEASES: ETHICAL RAMIFICATIONS OF THE WEST AFRICAN EBOLA VIRUS DISEASE PUBLIC HEALTH RESPONSE

Kata Chillag, Karen Meagher, Maneesha Sakhuja, Elizabeth Fenton, Lisa M. Lee

Presidential Commission for the Study of Bioethical Issues, Washington, DC, United States

As important as it is to devote significant resources to the west African Ebola virus disease (EVD) epidemic, against the backdrop of insufficient resources for public health, the scope and scale of the response has had and will continue to have consequences for other public health problems, including diseases such as malaria, responsible for greater morbidity and mortality. A highly visible public health problem like EVD, from which the U.S. public perceives themselves at risk, provides a rare opportunity for public health officials to advocate for resources for immediate and long-term public health investments, including in parts of the world that are often overlooked. However, there is no substitute for direct advocacy for less publicly compelling public health problems like neglected tropical diseases. This presentation critically examines policy and public health implications of defining public health crises in ways that garner substantial public and political attention. Public health officials often find themselves advocating for resources for the current emergency against a backdrop of political and budgetary constraints, including emphasis on national interest and short-term funding cycles. As a result, public health officials are often required to make difficult choices that might immediately set back other public health priorities, such as vaccine-preventable diseases. Short-term advocacy in the context of a public health emergency can have positive long-term implications, including increased funding and capacity of the public health workforce. Yet these longer term dividends are not automatic, do not always extend to the most intractable public health problems, and often do not obviate the short-term trade-offs that might result from prioritizing crisis response. We must acknowledge these tensions and explicitly engage with the ethical dimensions of tropical diseases and other persistent public health problems, including their social and economic determinants. It is sustained investment in health infrastructure that will better equip systems to manage and overcome public health crises.

81

DECREASING INEQUITY OF INSECTICIDE-TREATED NET (ITN) OWNERSHIP IN SUB-SAHARAN AFRICA COUNTRIES FROM 2003-2014

Cameron Taylor[1], Lia Florey[1], Yazoume Ye[2]

[1]DHS Program/ICF International, Rockville, MD, United States, [2]MEASURE Evaluation/ICF International, Rockville, MD, United States

The increase in funding for malaria control in the past decade resulted in an increase in ownership and use of insecticide treated nets (ITNs) in many countries in sub-Saharan Africa (SSA). However, with the shift in programmatic focus from high risk target groups to universal coverage there is a need to ensure equal access to ITNs for all sub-populations regardless of socioeconomic status. This study assessed change in disparity in ITN ownership among different socioeconomic groups using wealth quintiles in 19 malaria-endemic countries in SSA that had at least two national household surveys with ITN data between 2003 and 2014. One survey must have been published between years 2003-2008 (baseline) and the other survey published between years 2009-2014 (endline). The authors used Lorenz Concentration Curve and Index (C-Index) to assess equity in household ITN ownership between wealth quintiles. C-Index values range between -1 to 1. A value of 0 suggests no difference in outcomes among different socioeconomic groups. Across all countries ITN ownership significantly increased between baseline and endline with the greatest improvement in Tanzania and Rwanda where ownership increased by 68%. Equity in ITN ownership increased in 17 out of 19 countries particularly South and East African countries. In a pooled multi-country analysis a significant reduction in wealth inequality was seen in areas of medium/high malaria transmission (PfPR2-10≥5%) between baseline (C-Index 0.10, 95% CI: 0.09;0.18) and endline surveys (C-Index -0.01, 95% CI: -0.00;-0.02). These findings show the tremendous achievement of ITN ownership across sub-Saharan Africa in increasing ITN coverage and reducing inequity in the past 10 years.

82

MATHEMATICAL MODELLING APPROACHES TO ESTIMATING THE OPTIMUM STRATEGY FOR THE ERADICATION OF YAWS

Michael E. Marks[1], Sebastian Funk[1], Oriol Mitja[2], Christopher Fitzpatrick[3], Kingsley Asiedu[3], Anthony W. Solomon[1], David C. Mabey[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]ISGlobal, Barcelona, Spain, [3]Department of Control of Neglected Tropical Diseases, World Health Organization, Geneva, Switzerland

Yaws is a re-emerging endemic treponemal infection. The WHO aims to eradicate yaws by 2020 with a strategy that is based on mass treatment of the entire population with a single dose of oral azithromycin treatment. Previous mass treatment campaigns based on penicillin in the 1950's and 1960's failed due to inadequate coverage, in particular of latent cases, and failures of surveillance post the initial round of treatment. Subsequent successes in Ecuador and India have suggested that, with prolonged intervention and high coverage, disease elimination can be achieved. However, the number of rounds of treatment or the coverage that will be required to achieve eradication are currently unknown. This information will be vital if the aim of yaws eradication is to be achieved. Cost and time constraints limit the ability of traditional randomised studies to fully evaluate all possible control strategies but mathematical modelling approaches may allow a detailed exploration of the number of rounds and coverage that will be required to achieve the goal of yaws eradication. We developed a stochastic model of yaws transmission in an endemic setting. Baseline parameters were estimated using robust epidemiological data derived from study sites in Papua New Guinea and the Solomon Islands. We applied different control strategies varying both the coverage and number of rounds of treatment. We then used the model to assess the predicted impact of different control strategies including the probability of achieving eradication for each control strategy. Using this data we are able to suggest critical thresholds that must be achieved to interrupt local transmission of yaws and achieve the goal of yaws eradication. This work contributes significantly to our understanding of the predicted impact of community mass treatment with azithromycin and provides important data to inform the design and roll-out of yaws control programmes worldwide.

83

THE "EMD SERONO GLOBAL HEALTH" APPROACH

Thomas Spangenberg[1], Béatrice Greco[1], Jutta Reinhard-Rupp[1], Jim Mulry[2], John Ambroziak[2], Philip Hewitt[3], Nada Abla Geiser[1], Sandra Fulbier[3], Elli Kourany-Lefoll[1]

[1]EMD Serono, Coinsins, Switzerland, [2]EMD Millipore, Temecula, CA, United States, [3]EMD Serono, Darmstadt, Germany

Launched in 2014 to address key unmet medical needs for children from developing countries suffering from tropical diseases, EMD's Global Health unit is a R&D platform focusing primarily on malaria and schistosomiasis. Under its "One Merck for Children" concept, the goals are to develop innovative, affordable, implementable and integrated health solutions including new pediatric medicines, tailored diagnostics & associated

delivery & eHealth technologies through leveraging from EMD's cross competencies and in partnership with leading Global Health institutions and organizations in both developed and developing countries. To address the need of new antimalarial to continue fighting against emergence of resistance, EMD Serono Global Health aims at building a small sustainable portfolio of molecules on selected key existing gaps in the current fight against malaria: long lasting, liver & gametocyte acting compounds. Also, in collaboration with EMD Millipore, a new malaria diagnostic assay is being developed to measure levels of parasitemia as well as identification of the infectious type in very small amount of blood to address pediatric sample limitations. This assay will be compatible with an existing point of care compact flow cytometry platform (MUSE) that has already demonstrated its capacity to measure with very high sensitivity and specificity counts and % of CD4T cells during its clinical trials in African countries. For schistosomiasis, there is a pressing need to treat preschool children and the current Pediatric Praziquantel Consortium is actively developing a suitable formulation of the L-enantiomer of PZQ. Beyond closing treatment gaps by developing a new pediatric PZQ formulation, the PZQ usage to tackle other helminthic diseases is also considered by building a small drug discovery portfolio to complement PZQ as a single drug. It also aims at identifying options to co-develop diagnostic tools, addressing the impact on co-infections, on female/male genital schistosomiasis and contributing to strengthen the Merck Praziquantel Donation Program by enhancing the R&D competence at EMD in the area of human schistosomiasis.

84

USE OF M-HEALTH AT COMMUNITY LEVEL TO PROMOTE GOVERNANCE AND EQUITY WITHIN THE HEALTH SYSTEM: DESIGN, IMPLEMENTATION AND CHALLENGES THE RURAL HEALTH DISTRICT, BURKINA FASO

Maurice Y, Cheik Bagagnan, Ourohire Millogo, Idriss Tinto, Ali Sie

Nouna Health Research Center, Nouna, Burkina Faso

The use of mobile phone has been described as offering a remarkable potential to deliver primary health care, provide antenatal are services and remind patients about follow-up appointments. In Burkina Faso, high maternal mortality rates and persistent numbers of people living with HIV are priorities to address by government. A strong primary health care approach is required to ensure that people are able to access adequate, affordable and equitable health services and guidance within their community. Here we described the potential of an innovative mobile phone platform that helps to overcome barriers of access to health service information by community members in remote areas. A community-based mobile phone project was implemented to enhance better access to health information, better health care delivery for mother, newborn and people living with HIV. An interactive voice system was developed and incorporated major local languages to overcome literacy barrier. Overall 423 pregnant women, 319 newborn mothers and 116 HIV/AIDS patients were followed-up by the mobile phone system in 2014 by 62 community health workers. An average 177 patient's reminder for appointment was completed. There was an 8% increase of antenatal care uptake and 3.5% for newborn BCG vaccine coverage. Better compliance of HIV patients to antiretroviral services was also noted. However, running mobile devices in remote areas is challenging. About 29% of cell phone and 24% of solar recharging system were changed. Users also faced a regularly network breakdown for the major phone company. Community data integration within national health system and system interoperability were a big challenge to address. Use of mobile phone at community level is undoubtedly a powerful tool to increase their equitable access to health care information and participation local health care governance. However the issue of cell phone robustness, ease of use and availability of sustainable source of energy need to be more explored.

85

SCALING UP MALARIA RAPID DIAGNOSTIC TESTS IN PRIVATE SECTOR SUPPLY CHAINS IN UGANDA: ADAPTING MULTI-CRITERIA DECISION ANALYSIS AS A METHODOLOGY TO UNDERSTAND DECISIONMAKING AND PREFERENCES

Corinne Carland[1], Jarrod Goentzel[1], Elizabeth Streat[2], Gilberto Montibeller[3]

[1]Massachusetts Institute of Technology, Cambridge, MA, United States, [2]Malaria Consortium, Kampala, Uganda, [3]London School of Economics, London, United Kingdom

Diagnosis of malaria is important in order to ensure early and effective treatment, to facilitate public health surveillance, and to prevent drug resistance. Rapid diagnostic tests (RDTs) are an important tool in resource-constrained settings, as they do not rely on costly lab equipment and specially trained personnel. In Uganda's private sector clinics and drug shops, which is where the majority of patients first seek care, diagnosis of malaria is often presumptive and patients receive neither RDT nor microscopy. Several studies have focused on the patient perspective (e.g. willingness to pay) but much less understood about the supplier perspective (e.g. willingness to stock). This study aimed to understand stocking strategies for agents across the malaria RDT supply chain in Uganda using multi-criteria decision analysis. This methodology was adapted to be relevant and understandable for agents in Uganda so that we could analyze business decisions incorporating aspects such as selling price, purchase cost, sales volume, complexity of regulations, waste management, and training available. Data surveys and semi-structured interviews were collected from 28 private sector retailers (i.e., shopkeepers, pharmacists, clinic managers), two first line buyers, three distributors, and two manufacturers. Analysis resulted in value functions for all agents and quantified the tradeoffs among decision criteria. Our results offer critical insights for understanding how to engage the private sector in scaling up usage of malaria RDTs. The study also demonstrates how to adapt the multi-criteria decision analysis methodology for studying supply chains in resource-constrained contexts.

86

FIELD EVALUATION OF HOME-BASED AND CLINIC-BASED MULTIPLEX DEVICES FOR TRANSMISSION OF RESULTS VIA A SECURE BIO-SURVEILLANCE NETWORK IN IQUITOS, PERU

Robert D. Hontz[1], Amy C. Morrison[2], Valerie Paz-Soldan[3], Erin McDonough[4], Shawn P. Mulvaney[5], David Stenger[5], Eric S. Halsey[6], Christopher A. Myers[4]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]U.S. Naval Medical Research Unit - 6, Iquitos, Peru, [3]Tulane University, New Orleans, LA, United States, [4]Naval Health Research Center, San Diego, CA, United States, [5]Naval Research Laboratory, Washington, DC, United States, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States

The Defense Threat Reduction Agency (DTRA) is partnered with the U.S. Naval Medical Research Unit No. 6 to evaluate the speed and efficiency of result reporting from novel multiplex diagnostic devices to a novel bio-surveillance ecosystem (BSVE). Handheld devices ("buddy care") will be observed for ease-of-use in homes of local residents in Iquitos, Peru. Participants' comprehension of basic instructions followed by self-administration of one lateral flow test will be observed and documented. Clinic-based devices ("role 1") will be used by healthcare professionals on febrile patients in one of six clinics throughout the city. Both of the buddy care devices (ChemBio DPP Febrile Illness Test and the InBios Active-Dengue-Melioidosis Detect Rapid Test) will be distributed throughout an existing cohort in the city of Iquitos. First, movement teams will recruit up to five households of non-febrile participants in each block to use buddy care tests under supervision. Second, a maximum of thirty households per block will receive one of the buddy care devices and will then be asked to either perform the test alone or while receiving assistance by

trained medical personnel in cases of febrile symptoms. The role 1 devices will be distributed in six Iquitos medical clinics where NAMRU-6 trained phlebotomists will enroll febrile participants for the study. All results from both buddy care and role 1 devices will be uploaded into the BSVE and compared with results from gold-standard, laboratory-based testing. All protocols and informed consent documents have been approved, and city blocks within the cohort area where the buddy care devices will be distributed have been selected. The role 0 portion of this study is set to begin by mid-April, which includes observations for ease-of-use by non-febrile participants, as well as distribution of buddy care devices in the homes. To achieve success, we need greater than 90% accuracy in transmission of results to the BSVE, as well as 75% and 85% sensitivity for the buddy care and role 1 devices compared with the gold standard tests, respectively. Preliminary tests uploading results into the BSVE have been promising.

87

DISPARITIES THE QUALITY OF ANTENATAL CLINIC CARE THE KENYA: ANALYSIS OF KENYA DEMOGRAPHIC HEALTH SURVEY 2008 - 2009

Collins O. Asweto

Capital Medical University, Beijing, China

ANC provides the opportunity for early detection and treatment of pregnancy anomalies, and to deliver preventive health services. However, detailed information about the quality and content of ANC in practice in Kenya is scanty. We reviewed data from the 2008/9 KDHS, a nationally representative survey and analysed data from women aged 15-49 years. Descriptive data summaries were presented as proportions while association was measured as prevalence odds ratios. In this study 50.9% of women sought ANC services either in health centres or dispensaries. Maternal age, regional residence, urban residence, wealth index, education and the media influenced ANC initiation and ANC 4+ visits. There were coverage gaps existing on iron-folate supplementation (66.1%), tetanus toxoid (66.5%), presumptive/preventive treatment for malaria with SP (38.7%) and education on pregnancy complication (44.3%). Nearly 24 % of women missed the screening for complication during pregnancy. Quality of ANC service provided is associated with type of health facility. Facilities common in rural communities and informal urban settlements had lower quality service. Even though ANC visit is high, quality of service varies greatly. Women attending clinics at dispensaries and government health centres are likely getting the lowest quality service, presenting disparities in a rural-urban context. It is important that more resources, including equipment and skilled health workers be availed in these facilities to reverse this trend.

88

FACTS AND RUMORS: SOCIAL MEDIA REACTION TO INFORMATION AND MISINFORMATION ON EBOLA

Isaac Chun-Hai Fung[1], King-Wa Fu[2], Chung-Hong Chan[2], Benedict Shing Bun Chan[3], Chi-Ngai Cheung[4], Thomas Abraham[2], Zion Tsz Ho Tse[5]

[1]Georgia Southern University, Statesboro, GA, United States, [2]The University of Hong Kong, Hong Kong, Hong Kong, [3]Hang Seng Management College, Shatin, Hong Kong, [4]Emory University, Atlanta, GA, United States, [5]The University of Georgia, Athens, GA, United States

We analyzed the misinformation circulating on Twitter and Sina Weibo (the leading Chinese microblog platform) at the outset of the 2014 Ebola epidemic. We retrieved Twitter and Weibo data created within 24 hours of the WHO announcement of Public Health Emergency of International Concern (Batch 1) and seven days later (Batch 2). We obtained a 1% random sample of the Twitter universe, of which tweets containing the keyword Ebola were analyzed. We retrieved all Weibo posts with Chinese keywords for Ebola for analysis. Trending and fading analysis was performed for keywords, hashtags and web links. We identified misinformation by manual coding and categorization of randomly selected sub-datasets. Ebola-related misinformation constituted a minority of Twitter and Weibo contents. The predominant content was information released by public health agencies and the major news agencies. Two misinformed speculated "treatment" predominated in Twitter posts. Saltwater was speculated to be protective against Ebola in the first batch of tweets, but faded a week later. "Nano-silver" was on the top 10 trending Twitter list. Chinese microblogs focused on the Chinese government sending medical assistance to Africa. In conclusion, in the 2014 Ebola epidemic, Twitter and Weibo are platforms that circulate outbreak news and scientific health information.

89

A QUALITATIVE EVALUATION OF STAKEHOLDER PERSPECTIVES ON THE MILLENNIUM VILLAGE PROJECT SUCCESSES AND CHALLENGES IN SAURI, KENYA

Yesim Tozan[1], Eui Young Kim[1], Alexander N. Morse[1], Yumary Ruiz[2]

[1]New York University, Global Institute of Public Health, New York, NY, United States, [2]Purdue University, Department of Health and Kinesiology, West Lafayette, IN, United States

The Millennium Villages Project (MVP) is a 10-year, multi-sectorial, rural development program that strives to achieve the Millennium Development Goals at an annual cost of US$110 per capita through implementation of evidence-based interventions across sectors, including agriculture, health, and education. Focusing on early implementation of the first MVP site in Sauri, Kenya, perspectives held by major stakeholders (N=27) in the planning and implementation of project activities were examined using semi-structured interviews. Key stakeholders represented implementing agency and partners from village sector committees (VSCs), local and regional government agencies, international health agencies, non-governmental organizations, and academic and policy institutions. Interviews were recorded, transcribed, and analyzed using NVivo10, a qualitative software. Interviews were coded inductively and independently by three researchers to ensure high inter-rater reliability. Data suggest differing views among stakeholders around program successes. Additionally, although MVP sought to impact changes in three areas -namely, agriculture, health, and education- during its early phase, most emphasized positive effects in health and agriculture, with fewer mentioning achievements on education. Distinctions in expressed challenges were found with most indicating planning difficulties regarding development and mobilization of VSCs and others identifying implementation barriers associated with program adoption and adaption. Conflict was apparent in stakeholder comments around resolving village-level power struggles and reconciling conflicts between MVP activities and government policies. Findings also suggest enhancement in community cohesion and capacity. This qualitative evaluation of stakeholder perspectives on MVP successes and challenges contributes to the current debate at national and international levels in setting and implementing rural development policies.

90

DISTRIBUTION OF *PHLEBOTOMUS ORIENTALIS* IN MERTI KENYA

Elizabeth N. Kioko

Kenya Medical Research Institute/US Army Medical Research Unit, Kisumu, Kenya

Visceral leishmaniasis (VL) is a neglected tropical disease in East Africa whose principle vector of the disease casing agent is the sand fly ***Phlebotomus martini*** and ***P. orientalis***, however not much is known on the distribution and biogeography. The sandfly, ***P. orientalis*** is a principal vector of leishmaniasis in Sudan and Ethiopia, where it has been associated with black cotton soil and Acacia seyal and Balanites aegyptica trees. The range of ***P. orientalis*** has not historically involved Kenya, but

recent surveillance data has revealed that these sandflies are present in high numbers sufficient for it to sustain transmission. The objective of the current study was to explore the distribution of ***P. orientalis*** in Merti and Isiolo, Kenya by sampling in multiple habitats. Sampling was conducted for five nights using CDC light traps baited with dry ice placed along a river bed, in a village next to houses, a cattle camp, and next to a goat shed in open fields. The village, cow and goat sheds, were more than two kilometers from the river in this rural area of Kenya. All sampled sand flies were separated into Phlebotomus and Sergentomyia genera. Identification was completed on all Phlebotomus and 10% of the Sergentomyia sandflies collected. A total of 344, ***P. orientalis*** were sampled over the five nights of trapping. Human dwellings had 27% (94), representing four ***P. orientalis*** per trap per night, the river bed had 29% (101) representing three ***P. orientalis*** per trap night. Cow and goat sheds had 25% (86) and 19% (63) representing 14 and 32 ***P. orientalis*** sandflies per trap night, respectively. The majority of the sand flies caught were females. A few of the males sampled had unrotated genitalia; implying that all habitats sampled were breeding habitats. This is the first recorded sampling of ***P. orientalis*** in animal and human dwellings in Kenya. This study illustrates that ***P. orientalis*** is more widely distributed than previously thought. Further studies that investigate the possible blood meal sources and natural infection rates are needed because of the evidence of this leishmanisis vector breeding near human dwellings.

91

THE IMPACT OF FOUR YEARS OF SEMI-ANNUAL IVERMECTIN TREATMENT ON TRANSMISSION OF *ONCHOCERCA VOLVULUS* AND THE FEASIBILITY OF ONCHOCERCIASIS ELIMINATION THE SOME GHANAIAN COMMUNITIES

Francis B. Veriegh

Council for Scientific and Industrial Research-Water Research Institute, Accra, Ghana

Since 2009 onchocerciasis endemic villages in Ghana have shifted from annual to semi-annual ivermectin treatment due to a change in the control strategy by the African Programme for Onchocerciasis Control (APOC) from morbidity control to elimination of infection. A standard annual dose of ivermectin kills close to 99 % of skin microfilariae and temporarily halts microfilariae production by female adult worms. We used entomological techniques to assess the impact of semi-annual ivermectin treatments on ***Onchocerca volvulus*** transmission and to explore the feasibility of onchocerciasis elimination in Ghana. Adult female ***Simulium damnosum*** s.l. were collected from 17 onchocerciasis endemic communities, which have been receiving annual rounds of ivermectin treatment, using human land catches and analysed for parity rates and ***O. volvulus*** infection. ***O. volvulus*** transmission indices were estimated from manual fly dissection data. A total of 53,675 female blackflies were analysed after four years of vector collection, 19,156 (35.7 %) of which were parous and 776 flies were infected with ***O. volvulus*** larvae. 265 (0.5 %) flies haboured 439 L3s in the head representing an overall infectious rate of 0.82 %. Monthly biting rates (MBR) varied from a minimum of 0 bites in the dry season to a maximum of 10579 bites in the wet season while the monthly transmission potential (MTP) ranged from 0 to 320.3 infective bites. The vector infectivity rates also varied from 0 to 219.5 L3s per 1000 parous flies. After four years of semi-annual treatment seasonal biting rates, ranging from 15.3 to 15,694 bites, remained high and transmission of ***O. volvulus*** had reduced drastically in all communities except New Longoro, Tainso, Agborlekame I and Wiae. Infection appears to have been interrupted in 4 of the 17 communities with seasonal transmission potentials (STP) below postulated thresholds of under 20 L3s per 1000 parous flies after three years of semi-annual ivermectin treatment. The implications for onchocerciasis elimination in Ghana will be discussed.

92

HIGH-THROUGHPUT MULTIPLEX FRAGMENT ANALYSIS FOR IDENTIFICATION OF *ANOPHELES GAMBIAE* SL IN MALARIA ELIMINATION ERA

Majidah B. Hami-Adiamoh, Muna Affara, Davis Nwakanma

Medical Research Council Unit, Banjul, Gambia

Identification of mosquito vector species is important in control of vector-borne disease as it provides better understanding of local vector species involved in disease transmission. Large scale frequent sampling is common in entomological surveillance in malaria elimination programs and requires robust genotyping method. Although various molecular assays have been developed for vector identification in regional control programs, they are not suitable for large sample size vector surveillance. Therefore, a robust, rapid, high-throughput and portable genotyping method is needed where species of as large as a thousand mosquito specimens can be identified from a single PCR plate within a short period to inform timely control measures. Here, we describe the optimization and validation of a novel method, multiplex fragment analysis (MFA) to enable routine and rapid identification of large scale surveillance specimens. PCR amplification of mosquito specimens was performed using modified forward oligonucleotide primers of two widely-used protocols followed by fragment separation with capillary electrophoresis and detection by laser using DNA analyzer. Up to a thousand mosquito specimens were pooled together in a single PCR plate and identified by differences in their sizes and colors. Validation was done with previously genotyped genomic DNA of 1,056 specimens. Agreement in species identification between the novel MFA and current methods was compared using Kappa statistics and turn around times for specimen processing were calculated. The novel MFA showed ~100% agreement with current methods in identifying An. arabiensis, An. gambiae ss, An. colluzzii and An. melas. The estimated turn around time for processing 1,056 specimens using the novel method was 20 working hours (~3 working days) but 54 working hours (~7 working days) with classical methods. The novel MFA is rapid, reproducible and highly applicable for large scale entomological surveys compared to the existing methods. It is also less-laborious and has better genotyping resolution than the current gel agarose electrophoresis-based methods.

93

SYSTEMATICS OF THE *AMBLYOMMA MACULATUM* GROUP OF SPECIES *(ACARI: IXODIDAE)*

Paula Lado[1], Danielle Hibbs[1], Santiago Nava[2], Lorenza Beati[1]

[1]Georgia Southern University, Statesboro, GA, United States, [2]Instituto Nacional de Tecnologia Agropecuaria, Rafaela, Santa Fe, Argentina

The "***Amblyomma maculatum*** group" currently includes 5 species: ***A. maculatum*** Koch, 1844; ***A. neumanni*** Ribaga, 1902; ***A. parvitarsum*** Neumann, 1901; ***A. tigrinum*** Koch, 1844 and A. triste Koch, 1844. ***Amblyomma maculatum***, ***A. triste***, and ***A. tigrinum*** exhibit a striking morphological similarity, more obvious between the first two species. This fact has led to misleading identifications more than once in the past. As the distribution areas of the three species sometimes overlap, identifications can become even harder. The three species are vectors of pathogens of public health importance, such as ***Rickettsia parkeri***. Therefore, a correct identification is the first step towards establishing control and prevention strategies. The main objective of our work was to reassess the taxonomic status of ***A. maculatum, A. triste*** and ***A. tigrinum*** by using 6 different molecular markers. Tick specimens were obtained from different North, Central and South American countries. The molecular markers employed were the fast evolving 12SrDNA, 16SrDNA, D-loop, COI, COII (mitochondrial) and ITS2 (nuclear) genes. The phylogenetic analyses were consistent in identifying three different genetic clades. One of them, corresponding to ***A. tigrinum***, exhibits values of genetic divergence from the other species high enough to consider it a separate species, whereas preliminary phylogenetic results could be consistent with ***A. maculatum*** and ***A. triste*** being conspecific.

94

HOUSE INFESTATION DYNAMICS OF *TRIATOMA DIMIDIATA* IN SAN LORENZO, ECUADOR

Natalie A. Cain[1], Jorge Monroy Nicola[2], Hugo Jurado Salazar[2]

[1]University of Miami Miller School of Medicine, Miami, FL, United States, [2]Ministry of Public Health, Guayaquil, Ecuador

Triatoma dimidiata is the main vector of Chagas disease in Ecuador. It is an invasive species widely distributed in house parameters along the tropical pacific coast. Despite the Ecuadorian Ministry of Health's goal to eliminate the vector by 2017, its vectorial capacity and infestation patterns remain to be elucidated. This study fills the gap by providing new knowledge in the extent of distributional patterns and infestation rates of ***T. dimidiata*** in a remote, high-risk community. Triatomines were collected during November 2013 and April 2014 in the rural community of 205 houses in San Lorenzo, Ecuador. Houses were noted as fully searched, partially searched, or closed and mapped using Picasa GPS to show insect distribution. Intra- and peri-domiciliary searches were performed in a two-man team for ***T. dimidiata.*** The data were used to calculate entomological indices including infestation index, density, crowding, and colonization index. Positive houses and those in the perimeter were sprayed with deltamethrin at 25 mg a.i./m^2. A total of 435 ***T. dimidiata*** (324 of which were nymphs) were collected in November in 28 houses, 27 of which had peri-domiciliary infestation. 388 (301 nymphs) specimens were found in April in 24 peri-domiciliary houses. Vectors were most frequently discovered in bird nests and construction materials stored outside of homes. Colonization indices of 89.9% and 100% respectively show vector reproduction was occurring in almost all homes. An infestation index of 15.6% and 21.4% respectively shows nearly a quarter of the community housed ***T. dimidiata***. Re-infestation was observed in 8 houses, possibly due to insufficient insecticide capacity. New infestation occurred in 5 houses, notably in those located next to closed homes. Our data suggest that ***T. dimidiata*** house infestation in San Lorenzo is not randomly distributed, primarily peri-domiciliary, well established and reproducing. The quantity of specimens collected emphasizes its importance as a Chagas vector and suggests that increased community surveillance and effective insecticides are needed to attain ***T. dimidiata*** elimination in Ecuador.

95

SURVEILLANCE REPORTS AND RECOLONIZATION OF *TRIATOMA INFESTANS* FOLLOWING AN URBAN VECTOR CONTROL CAMPAIGN IN AREQUIPA, PERU

Fernando S. Malaga Chavez[1], Ricardo Castillo-Neyra[2], Corentin M. Barbu[3], Juan G. Cornejo del Carpio[1], Andy Cataccora Rospigliossi[4], Michael Z. Levy[5]

[1]Dirección Regional del Ministerio de Salud, Arequipa, Arequipa, Peru, [2]Universidad Peruana Cayetano Heredia, Arequipa, Peru, [3]INRA, Paris, France, [4]Red de Salud Arequipa, Arequipa, Peru, [5]University of Pennsylvania, Philadelphia, PA, United States

In the city of Arequipa, Peru, a Chagas disease vector control campaign has been ongoing since 2003. After the attack phase of insecticide residual spraying, treated areas enter a surveillance phase, which mainly consists of resident reports of vector return to health posts. We previously analyzed homeowner reports received between 2009 and 2012 and developed multivariate models to identify risk factors, collected during the attack phase, Multivariate models provided the the surveillance phase of the campaign confirm that nonparticipation in the initial treatment phase is a major risk factor (odds ratio [OR] 21.5, 95% CI 3.35-138). Infestation during surveillance also increased over time (OR 1.55, 95% CI 1.15-2.09 per year). In addition, we observed a negative interaction between non- participation and time (OR 0.73, 95% CI 0.53-0.99), suggesting that recolonization by vectors progressively dilutes risk associated with nonparticipation. Here we use these models to identify high-risk households for survey, and test the sensitivity and specificity of the models to detect infestation in a new dataset, consisting of vector reports between 2012 and 2015. We then field-test the model by conducting additional active search for vectors in the city.

96

A SURVEY OF TICK SPECIES *(ACARI: IXODIDAE)* AND SCREENING OF TICK-BORNE RICKETTSIAL PATHOGENS IN BELIZE, CENTRAL AMERICA

Suppaluck Polsomboon[1], David F. Hoel[1], Jittawadee R. Murphy[1], Chien Chung Chao[2], Wei Mei Ching[2], Richard G. Robbins[3], Nicole L. Achee[4], John P. Grieco[4]

[1]Department of Preventive Medicine and Biostatistics, Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Viral and Rickettsial Diseases Department, Infectious Disease Directorate, Naval Medical Research Center, Silver Spring, MD, United States, [3]Armed Forces Pest Management Board, Silver Spring, MD, United States, [4]Department of Biological Sciences, Eck Institute for Global Health, University of Notre Dame, Notre Dame, IN, United States

Tick-borne rickettsial infections are emerging as an important public health concern in travel medicine. These pathogens are transmitted to humans and animals by the bite of ixodid ticks. There is a lack of data on rickettsial pathogens associated with ixodid tick species in Belize, Central America. This study was conducted to investigate the presence of ***Rickettsia*** species in ticks from three of the six districts of the country. Ticks were collected from domestic animals and by tick-drag sampling in 23 different villages in northern and western Belize in November 2014 and February 2015. A total of 1,966 ticks were collected and morphologically identified to species. They were then pooled, according to species and life stage, for DNA extraction and screening for ***Rickettsia*** by real-time PCR (qPCR) using genus-specific primers targeting the ***17kDa*** gene. Positive samples were tested by PCR using primers specific for spotted fever group (SFG) and typhus group (TG) ***Rickettsia*** followed by sequencing for confirmation. The majority of ticks collected were ***Amblyomma mixtum*** (previously known as ***Amblyomma cajennense***), ***A. maculatum***, ***A. ovale***, ***Dermacentor nitens*** and ***Rhipicephalus sanguineus***. Additionally, a small number of ***R. microplus***, ***Ixodes affinis*** and ***I. boliviensis*** were captured. Thus far, a pool of ***A. mixtum*** has been confirmed with spotted fever group ***Rickettsia*** infection. Data from this study will be used for mapping tick distribution as well as modeling the risk of rickettsial infections associated with ixodid tick species in Belize.

97

THE ECOLOGY OF *WOLBACHIA* IN NATURAL MOSQUITO HOSTS

Jill N. Ulrich

University of Miami, Coral Gables, FL, United States

Wolbachia are a group of endosymbiotic bacteria infecting 25-76% of arthropods. The newly developed strategy of combating mosquito-borne diseases by releasing Wolbachia-transinfected mosquitoes into disease-afflicted regions is based on the ability of Wolbachia to suppress many human pathogens in insects, including dengue fever virus and human malaria parasites, and to spread through insect populations by the mechanism of cytoplasmic incompatibility. While aspects of Wolbachia ecology have been studied in recently trans-infected mosquitoes and in several other arthropod hosts, little is known about the ecology of Wolbachia in natural mosquito hosts. In mosquito species such as container-breeder ***Aedes notoscriptus*** and salt marsh inhabitant ***Culex sitiens***, Wolbachia infection frequencies in the field range from 25-85% and 50-100%, respectively. Ecological factors such as the role of ovarian microbiota in maternal transmission and the effect of environmental conditions on larval Wolbachia titre may be responsible for the patchy distribution of Wolbachia infections in these species. The results of

experiments exploring these ecological phenomena in ***Ae. notoscriptus*** and ***Cx. sitiens*** will be presented. Findings may be relevant to the success of releasing Wolbachia transinfected mosquitoes for disease control.

98

PROTEOMIC AND GENOMIC ANALYSIS OF *SARCOPTES SCABIEI*

Marjorie S. Morgan, S. Dean Rider, Jr., Larry G. Arlian, William C. Grunwald, Jr., David R. Cool

Wright State University, Dayton, OH, United States

Scabies is a pruritic skin disease caused by the burrowing of the mite ***Sarcoptes scabiei.*** Symptoms mimic other skin diseases and thus it is difficult to diagnose. No reliable blood or molecular diagnostic test is available. The aim of this project was to identify scabies mite proteins, including those that may be useful in the development of a diagnostic test, using a combined proteomic and genomic approach. Scabies mite extract was separated by 2-dimensional electrophoresis and 844 Coomassie Blue stained protein spots were excised, subjected to trypsin digestion and analyzed by MALDI-TOF/TOF mass spectrometry (MS). In parallel, a draft genome of ***Sarcoptes scabiei*** var. ***canis*** was generated from paired end sequences using DeBruijn graph-based assembly methods. Assembled contigs covered 56.2 megabases with a contig N50 of 11.1 kb. The assembly was used to predict the ***S. scabiei*** proteome. Maker was used for structural annotations of 10-12,000 protein-coding genes. Roughly 70% of the predicted proteins could be assigned to an orthologous group, and were given natural language identifiers based on their homology to other proteins. The assembled genome and predicted proteome were then used to help deduce the origins of peptides identified by mass spectrometry. Deduced sequences that aligned to tryptic fragment sequences determined by MS were then searched by BLASTp vs. the NBCInr database (with taxonomy restricted to Acari) leading to the identification of > 150 proteins. Only 14 proteins hit to previously-identified scabies proteins with 12 yielding significant hits to dust mite homologs. Most other sequences (~100) aligned to proteins in other mites and ticks while the remainder possessed conserved protein domains. These data will now allow us to determine the identity of the proteins to which scabies patients produce antibodies, including those that may be good candidates for inclusion in a diagnostic test.

99

HEAT TREATMENT TO CONTROL TRIATOMINE VECTORS OF CHAGAS DISEASE

Ricardo Castillo-Neyra[1], Renzo Salazar[2], Carlos Condori[2], Cesar Naquira[2], Michael Z. Levy[1]

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]Universidad Peruana Cayetano Heredia, Lima, Peru

Currently, treatment to control triatomine vectors of ***Trypanosoma cruzi***, the causative parasite of Chagas disease, is mostly based on the use of insecticides through indoor residual spraying campaigns. These spraying campaigns are costly and expose a large number of people to chemicals. In the US and other countries, pests from the Hemiptera order, such as bedbugs, are controlled with heat treatment. Heat treatment has the advantages of preventing the development of insecticide resistance and being environmentally friendly. We first tested, under laboratory conditions, the effect of different temperatures on the survival and reproduction indexes of ***Triatoma infestans***, the most important vector of ***T. cruzi*** in the southern cone of South America. We found that ***T. infestans*** shows susceptibility to moderately high heat temperatures beginning at 48°C. We designed and implemented a transportable greenhouse chamber with low-cost and common materials. The chamber was big enough to contain household items such as mattresses, clothing, brick piles, etc. We placed ***T. infestans*** of different stages and eggs on top and within the household items. We field tested the chamber and found that on days with sufficient sun, it reaches temperatures that kill 100% of ***T. infestans*** and completely reduce the viability of triatomine eggs. The use of this chamber could complement the work of insecticide spraying campaigns in instances in which the use of insecticide would be cumbersome and much insecticide would be wasted (e.g. large piles of rocks, bricks, or other construction materials), reluctance of dwellers to accept insecticide spraying because of the presence of animals, or in the case of infestation of kissing bugs within mattresses or other items that would otherwise have to be destroyed or damaged to remove the insects.

100

IDENTIFICATION, DIVERSITY AND DISTRIBUTION OF POTENTIAL SAND FLY VECTORS IN ENDEMIC AREAS OF LEISHMANIASIS AT THE PERU, BRAZIL, AND BOLIVIA TRI-BORDER REGION

Roberto Fernandez[1], Liz Espada[1], Victor Zorrilla[1], Albino Urquía[1], Reginaldo Brazil[2], Craig Stoops[1], Frederick M. Stell[3], Andrés G. Lescano[1], **Gissella M. Vásquez**[1], Hugo O. Valdivia[1]

[1]U.S. Naval Medical Research Unit - 6, Callao, Peru, [2]Oswaldo Cruz Institute, FIOCRUZ, Rio de Janeiro, Brazil, [3]Armed Forces Pest Management Board, Silver Spring, MD, United States

The Peru-Brazil-Bolivia tri-border region is a highly endemic area for leishmaniasis in the Amazon, yet information about the diversity and distribution of sand fly vectors is limited. Recent expansion of the New World visceral leishmaniasis vector, ***Lutzomyia longipalpis***, into non-endemic regions in Brazil and Bolivia could pose a serious risk to populations in Peru where neither the disease nor the vector are found. The goal of this study was to characterize the sand fly fauna and identify potential leishmaniasis vectors in two communities near the Peru-Brazil-Bolivia tri-border. Sand flies were collected in Flor de Acre and Villa Primavera (Tahuamanu, Madre de Dios, Peru) from February-September 2014, using CDC light traps, CDC UV traps, and Shannon traps. A total of 6,185 sand flies were identified to the genera ***Lutzomyia*** (49 species) and ***Brumptomyia*** (2 species). The most abundant species were ***Lu. yucumensis*** (32%), ***Lu. whitmani*** (19%), ***Lu. davisi*** (8%), and ***Lu. carrerai*** (4%); all reported as cutaneous leishmaniasis vectors in the Amazon. The subgenus ***Trichophoromyia*** was also abundant (17%), among which ***Lu. auraensis***, potential cutaneous leishmaniasis vector, was identified. ***Lutzomyia longipalpis*** was not recorded. Sand fly species number (36) was comparable between sites but species composition differed. Sand fly abundance was higher in Flor de Acre (5,561) than in Villa Primavera (624); the Shannon-Weaver diversity index (H) was lower in Flor de Acre (H=0.73) than in Villa Primavera (H=0.93). Potential sand fly vector abundance was higher in Flor de Acre (97%) than in Villa Primavera (75%), which could be linked to leishmaniasis transmission. We provide information about the diversity and abundance of putative cutaneous leishmaniasis vectors in the Peruvian side of the Peru-Brazil-Bolivia tri-border where ***Lu. longipalpis*** is still absent. Recent results in the Brazilian side confirmed the abundance of the subgenus ***Trichophoromyia*** among which ***Lu. aurensis*** was recorded; however, ***Lu. longipalpis*** was also absent. Future studies will determine ***Leishmania*** infection rates of these sand flies to predict disease transmission potential.

101

INVESTIGATING THE ROLE OF TSETSE PGRP-LA IN THE FLY'S RESISTANCE TO TRYPANOSOMES

Aurelien Vigneron[1], Emre Aksoy[1], Xin Zhao[1], Xiaoli Bing[1], Jingwen Wang[2], Serap Aksoy[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Fudan University, Shanghai, China

Tsetse flies (***Glossina*** spp.) are the sole vectors of protozoan African trypanosomes, which cause Human and Animal African Trypanosomiases (HAT and AAT, respectively) in sub-Saharan Africa. While most tsetse flies are highly refractory to parasite infection, a small proportion of individuals are susceptible and thus responsible for disease transmission. Tsetse's

ability to immunologically detect trypanosomes following ingestion of an infectious blood meal is of paramount relevance to infection outcomes. The insect immune system relies on several Pattern Recognition Receptors (PRRs), among which the PeptidoGlycan Recognition Proteins (PGRPs) play a central role. PGRPs form a conserved family of proteins that function to sense Microbe Associated Molecular Patterns (MAMPs), trigger innate immune pathways, modulate immune responses, or present direct anti-microbial activity. The tsetse fly genome encodes six different PGRPs. Using real-time quantitative PCR we show that ***pgrp-la*** is significantly up-regulated in the gut associated proventriculus organ (cardia) of trypanosome-infected flies. RNAi-mediated knockdown of ***pgrp-la*** expression facilitates the establishment of parasite infections in tsetse. Thus, we suggest that the PGRP-LA may play a key role in parasite detection and the subsequent regulation of host immune responses. Unraveling the immune mechanisms that underlie tsetse detection of pathogenic trypanosomes may lead to the development novel disease control strategies based on enhancing the fly's ability to perceive and immunologically respond to the presence of parasites.

EVIDENCE FOR POPULATION REPLACEMENT AND ECOLOGICAL ADAPTATION IN *ANOPHELES DARLINGI* FROM THE PERI-IQUITOS REGION OF PERU

Jan E. Conn[1], William Lainhart[2], Sara A. Bickersmith[1], Kyle Nadler[2], Marta Moreno[3], Marlon Saavedra[4], Virginia M. Chu[2], Paulo E. Ribolla[5], Joseph M. Vinetz[3]

[1]Wadsworth Center, New York State Department of Health, Slingerlands, NY, United States, [2]Department Biomedical Sciences, State University of New York at Albany, Albany, NY, United States, [3]Division of Infectious Diseases, Department of Medicine, University of California San Diego, San Diego, CA, United States, [4]Asociacion Benefica PRISMA, Iquitos, Peru, [5]Universidade Estadual Paulista, Botucato, Brazil

The Neotropical malaria vector, ***Anopheles darlingi***, was reintroduced into the Iquitos, Loreto, Peru area during the early 1990s, where it caused a major epidemic (158,115 reported cases in 1997) of ***Plasmodium vivax*** and ***P. falciparum***. We investigated the population genetic structure of ***An. darlingi*** sampled before and after the introduction of insecticide treated nets (ITNs) for evidence of population change, and tested current samples of ***An. darlingi*** for a signature of ecological adaptation to highway versus riverine habitat, linked to forest cover. Several analyses of microsatellite loci from seven settlements (2006) and nine settlements (2012-2014) in the Iquitos area detected distinctive populations with little overlap, although it is unclear whether this population replacement is associated with ITN distribution or climatic events. Interestingly, this current population of ***An. darlingi*** is most closely related to mosquitoes collected in northwestern Bolivia in 1991. Two highly admixed subpopulations, A and B, identified within the current population, were differentiated by habitat with B significantly overrepresented in highway, and both in near-equal proportions in riverine. There is strong evidence of population expansion in both subpopulations, and moderate genetic differentiation between them. Habitat and forest cover had a significant effect on human biting rate (HBR), such that risk of ***Plasmodium*** transmission, as measured by entomological inoculation rate (EIR), in peridomestic (within village) riverine settlements was three-fold higher than in peridomestic highway settlements. Subpopulations A and B may be in an early stage of differentiation triggered by anthropogenic alterations to local habitat.

103

COMPARATIVE MICROBIOME OF *TRIATAMA INFESTANS*, VECTOR OF CHAGAS DISEASE

Natalie M. Bowman[1], Jonathan J. Juliano[1], Katty Borrini Mayori[2], Renzo S. Salazar Sanchez[2], Carlos Condori Pino[2], Eric Barnett[1], Steven R. Meshnick[1], Robert H. Gilman[3], Michael Z. Levy[4]

[1]University of North Carolina Chapel Hill, Chapel Hill, NC, United States, [2]Universidad Peruana Cayetano Heredia, Arequipa, Peru, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]University of Pennsylvania, Philadelphia, PA, United States

The microbiota of the insect gut has been shown to be important for several vector-pathogen relationships; for example, the bacterium Wolbachia has profound effects on mosquito life span and fitness as a vector of dengue and other infections. Triatomine bugs are the vector of Chagas disease, a chronic parasitic infection caused by ***Trypanosoma cruzi*** that affects 8-12 million Latin Americans. We used deep sequencing to describe the hindgut microbiome of the most important vector of ***T. cruzi***, ***Triatoma infestans***. We compared the diversity and composition of the gut microbiome of 3 groups of triatomines: 1) lab-raised ***T. cruzi***-infected, 2) lab-raised ***T. cruzi***-uninfected, and 3) uninfected bugs caught in households in Arequipa, Peru. We conducted amplicon sequencing of the V4 region of bacterial 16S RNA using Ion Torrent. We analyzed 3-4 bugs per group, using 2-3 replicate PCRs per sampled bug. Diversity between individuals and groups was compared using MG-RAST, EstimateS, and QIITA. Rarefaction curves were approaching their asymptote suggesting most genera were likely detected in the majority of samples. The microbiomes of wild-caught bugs were more diverse than the microbiomes of either lab-raised group, though this was largely driven by samples from one fifth-stage nymph whose gut contained more than 300 species (twice that of the next most-diverse sample). ***Enterococcus*** and ***Arsenophonus*** were the predominant genera found in lab raised bugs, with the exception of one ***T. cruzi***-uninfected bug where ***Morganella*** predominated. In contrast, there was no one predominant genus identified in wild-caught bugs, and ***Enterococcus*** and Enterbacteriaciae were not substantial components. There were not large differences in α diversity between lab-raised ***T. cruzi***-infected and -uninfected bugs. Future studies should examine geographic differences in triatomine microbiome composition and diversity, microbiome changes with bug stage and infection status both in the lab and in the wild, and the effect of antibiotic-mediated disruption of the triatomine gut on susceptibility to infection by ***T. cruzi***.

104

PHYLOGEOGRAPHY OF *TRIATOMA DIMIDIATA*, A MAJOR VECTOR OF CHAGAS DISEASE, IN BELIZE

Angela Caranci[1], John Grieco[2], Nicole Achee[2]

[1]Uniformed Services University, Kensington, MD, United States, [2]University of Notre Dame, Notre Dame, IN, United States

Triatoma dimidiata is the main triatomine vector of Chagas disease throughout Central America and southern Mexico. Throughout this broad distribution range, differences in vector behavior have been observed that could likely impact the vectorial capacity of local insect populations. Coupled with recent publications regarding the intraspecific genetic variability within ***T. dimidiata*** which have successfully distinguished five groupings within what is now designated ***T. dimidiata*** sensu lato, these observations support the need for additional research. Extensive investigation regarding the phylogeography of ***T. dimidiata*** s.l. has revealed broad patterns describing the divergence and genetic isolation of groupings with the species complex. Here, we characterize the genetic profiles of vectors collected from northern and central Belize, a region which has been strongly underrepresented in the relevant literature. The data presented here appear to lend support to previously reported trends in the divergent evolution and geographic radiation of the subgroupings

within ***T. dimidiata*** s.l. As the genetic profiles of these seemingly isolated populations are further defined, it is possible that concomitant behavioral attributes with implications for efficient vector control may be revealed.

105

EVIDENCE OF GENE FLOW IN FEMALE OF *ANOPHELES GAMBIAE* S.S RESULTING OF MASS CROSSING OF *AN. COLUZZII* AND *AN. GAMBIAE* S.S GILES

Chabi Joseph

Noguchi Memorial Institute for Medical Research, Accra, Ghana

Hybridization between ***Anopheles coluzzii*** and ***An. gambiae*** Giles has been increasingly reported in sub Saharan African countries over the past decade. ***An. coluzzii*** (previously referred to as ***An. gambiae*** M molecular form) and ***An. gambiae*** s.s Giles (previously referred to as ***An. gambiae*** S molecular form) were considered to be reproductively isolated, yet hybrid specimens have been found in the field. This phenomenon was studied in laboratory by crossing ten virgin females and males of each form in separated small cages and allowed them to mate. The resulting progeny were analyzed using PCR methods to detect molecular forms. An average of 50 mosquitoes including males and females were analyzed per generation, giving approximately 1000 mosquitoes for the two crossing ways of the experiments and the five generations analyzed. The results showed 100% hybrid females at the first progeny (F1 generation) and 100% males carrying the parent female's phenotype. A decrease in the hybrid proportion was observed from the second generation which was due to the fact that the male were not hybrid (analysis of progenies is still going on). On the other hand, it has been noted a shift of the male forms, which were inversely changed following the female parent form in the two experiments at the first progeny stage. This study confirmed the ability of M and S molecular forms to hybridize. Further monitoring is required to understand the extent of hybridization in the field. A better understanding of the interaction between these two species is required, particularly in the context of differing resistance genotypes.

106

LESSONS LEARNED, CHALLENGES AND PROSPECTS AFTER SIX YEARS OF EXPERIENCE IN THE IMPLEMENTATION OF INDOOR RESIDUAL SPRAYING IN BENIN, WEST AFRICA

Martin Akogbeto, Rock Aïkpon, Gil Padonou, Razaki Osse, Fiacre R. Agossa, Anges Yadouléton

CREC, Cotonou, Benin

From 2008 to 2013, a prevention intervention against malaria based on Indoor Residual Spraying (IRS) supported by the President's Malaria Initiative (PMI) of the US Government was implemented in Benin. This intervention protected more than 350,000 people in the south and over 650,000 people in the north. From 2008 to 2012, Ficam M, a Bendiocarb-containing product was used for house spraying and in association with Pirimiphos methyl EC (Actellic EC) in 2013. Entomological Monitoring-Evaluation (M&E) is based on IRS impact on Human Biting Rate (HBR), Entomological Inoculation Rate (EIR) and blood meal inhibition in ***Anopheles gambiae***, the main malaria vector in the study area.The purpose of this project was to draw attention to the lessons learned during the M&E, new challenges and future prospects for the success of IRS in Benin and generally in Africa. The main strength of the intervention was a large-scale operation in which more than 80% of the structures were treated, thanks to the massive support of the population. In addition, a drastic reduction of the Entomological Inoculation Rate of ***An. gambiae*** in areas under IRS were observed in the first 4 months following the treatment of structures. However there were many challenges including the high cost of IRS implementation and the identification of suitable areas to implement IRS. This was because of the low short residual effect of the insecticides recommended for IRS and the difficulties to manage vector resistance to insecticides. These indicated challenges are accompanied by suggested solutions. For example, the presence of international NGOs supporting the implementation of IRS in Africa, particularly in Benin, should be limited in time to allow local organizations with the relevant skills in terms of IRS planning and implementation to take over. Such organizations must ensure a better partnership with the NMCPs. Concerning insecticide resistance management, we proposed various ways among which an alternation of IRS campaigns with LLINs distribution campaigns. IRS will then be implemented every 3 years. Between the three years, two years of extensive use of LLINs will be inserted.

107

ARTIFICIAL COURTSHIP SONGS FOR CONTROL OF ADULT MOSQUITO POPULATIONS

Deodatus F. Maliti

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Traditional methods of controlling adult mosquito populations involve the use of insecticides in form of residual sprays or embedment of the drugs in bed nets. These methods apart from causing contamination of environments and posing possible direct effects on human health; they are now faced with the threat of being rendered ineffective as a result of the development of insecticide resistance. Dispensing of insecticides in the form of residual sprays or insecticide-treated bed nets implies individual efforts at each specific household which may be impossible especially for poor or unwilling individuals. Moreover, these traditional methods are applicable only inside houses while not effectively preventing malaria transmission taking place outdoors. There is therefore a need to device new ways which are safer, insecticide-resistance-proof, while at the same time offering communal protection to individuals staying both indoors and outdoors. Since courtship songs are a crucial event leading to mating and consequently reproduction in mosquitoes, targeting of mosquito populations during this event by interrupting the mating process may lead to collapse of mosquito populations within as a large area as a village. Based on the knowledge of particular mating-songs frequencies and their patterns, we have developed artificial courtship songs which imitate mosquito natural mating songs with the hope that when these songs are played from a stationed sound transmitter will disrupt the swarming events in mosquitoes at a given radius thus leading to unsuccessful mating and thus collapse of local mosquito populations with time. Initial semi-field experiments have been able to show collapse of a caged population of mosquitoes when treated with certain sound frequencies similar to those produced during mating events, while the control cage population without treatment continued to propagate. Further research is needed to develop high capacity sound delivery systems that may be applied across a wider range to cover the size of typical village to enable field intervention programs targeting to control adult mosquito populations.

108

INSECTICIDE RESISTANCE MUTATIONS MODULATE *ANOPHELES GAMBIAE* HOST SEEKING BEHAVIOR

Angélique Porciani

Institut de Recherche pour le Developpement, Montpellier, France

Major means of malaria vector control are based on use of insecticides. Their efficiency is threatened by widespread resistance mechanisms. In addition to the physiological resistance mechanisms already well studied, the issue of the behavioral modulation as cause or consequence of the resistance is largely overlooked. Nevertheless there are evidences that insecticide-based control tools alter mosquito behavior before any contact, suggesting that the mosquitoes can detect the presence of the insecticide. In the present study, we tested this hypothesis by investigating the behavioral responses of different resistant genotypes (differing by presence of L1014F (***Kdr***) mutation and ***Ace-1***) of ***Anopheles gambiae*** to host odors and insecticide treated equipment. Behavior experiments involving ***kdr***-carrier mosquitoes, showed that heterozygous were more actives than two other genotypes. Moreover, homozygous resistant preferred host behind the permethrin treated net than host behind untreated net.

For ***Ace-1***-carrier mosquitoes, results showed that mutation and the duplication of the resistance gene impact negatively the spontaneous activity of mosquitoes and their perception of host odors. Nevertheless, duplication seems to decrease this negative effect. We did not evidencing any significant effect of insecticide on host choice for these mosquitoes. Our results confirm the interaction between insecticide resistance mutations and behavior. Moreover, ***Kdr*** resistant mosquitoes can perceive insecticide on net and adapt their behavior in response of it. Our original study highlighted the urgent need for further investigations of chemical ecology of malaria vector in a vector control pressure context.

109

A LOW COST DEVICE FOR CONTROLLING OUTDOOR HOST SEEKING MOSQUITOES

Stella Kessy[1], Bruno Nyundo[2], Jane Mccaw[3], Andreas Rose[3], Bart Knols[4], Ladislaus Mnyone[1], Issa Lyimo[1]

[1]Environmental Health and Ecological Science Thematic Group, Ifakara Health Institute, Ifakara-Morogoro, United Republic of Tanzania, [2]University of Dar-Es-Salaam, Dar-Es-Salaam, United Republic of Tanzania, [3]Biogents, Regensburg, Germany, [4]In2care, Wageningen, Netherlands

Residual transmission of malaria is maintained by mosquito vectors biting at dusk and dawn outside houses. Outdoor baited traps have been promising,yet,difficult to implement in poor resource areas because of the expensive source of Carbon dioxide (CO_2), delivery of synthetic attractants like CO_2 and power source. This study aims to design a passive outdoor host seeking device (OHD) and assessing the efficacy of OHD when incorporated with attractive synthetic blends, non-repellent bioactives (e.g. bendiocarb) and natural CO_2 to attract and kill malaria vectors outside houses. Experiments were conducted to assess efficacy of OHD using rectangular chamber (2.06x1.50x 1.47m) inside semi field system at Ifakara Health Institute in Tanzania. The device was either treated or untreated during experiments. The OHD device was hanged inside and outside rectangular chamber. The installation of the device outside the chamber, involved the use of a fan to suck out natural CO_2 from human volunteer sleeping inside the chamber. Group of 100 female ***Anopheles arabiensis*** were released outside the chamber and left to forage overnight. Next morning mosquitoes were recaptured and identified as either dead or alive. The live mosquitoes were held in the insectary to record 24 hours mortality rates. The proportion of dead mosquitoes was compared between treated and untreated. Each experiment, treated or untreated was replicated three times.When OHD was hanged in the center of the chamber with synthetic attractants, the treated OHD improved its killing effect than untreated device. The percentage of attracted and killed mosquitoes were 18% for the worn socks, 36% for mbita strips and 33% for Ifakara strips. When the source of natural CO_2 was added into OHD, the mortality rates were 65% for worn socks, 65% for Mbita strips and 51% for Ifakara strips treated device. Therefore,the source of natural CO_2 sucked by the fan improved the attractiveness of OHD 2-3 times than with no CO_2. Further studies are ongoing to test the OHD installed outside the chamber with no fan, hanged near bed net inside houses, hanged outside houses at the eave level and near cow sheds.

110

PROFILING INSECTICIDE RESISTANCE AND OUTDOOR MALARIA TRANSMISSION IN ETHIOPIA: IMPLICATIONS FOR SUSTAINING CONTROL

Delenasaw Yewhalaw

Jimma University, Jimma, Ethiopia

Abstract Indoor Residual Spraying (IRS) and long-lasting insecticidal nets (LLINs) are key components in malaria prevention and control strategy in Ethiopia. However, the development of resistance by vectors to insecticides recommended for IRS and/or LLINs could affect insecticide-based malaria vector control. We assessed the susceptibility levels of Anopheles arabiensis to insecticides used in malaria control, characterize basic mechanisms underlying resistance and their biting activity from southwestern Ethiopia. Susceptibility status of An. arabiensis was assessed using WHO bioassay tests against insecticides used in public health. Mosquito were screened for knockdown resistance (kdr) and insensitive acetylcholinesterase (ace-1R) mutations using AS-PCR and PCR-RFLP, respectively. Populations of An. arabiensis from the study site were highly resistant to DDT, permethrin, deltamethrin and malathion. However, the mosquito populations were susceptible to bendiocarb, propoxur and Pirimiphos methyl.The West African kdr allele was found with a frequency ranged from 95% to 100%. Ace-1R mutation was not detected. Baseline levels of metabolic resistance were assessed in population of An. arabiensis for esterases, mixed function oxidases (MFO), glutathione s-transferase (GST) and insensitive acetylcholinesterase (ACHE). The results of the biochemical assays showed that there were highly elevated activities of esterases and MFO in the mosquito population. However, elevated activities of glutathione s-transferase and insensitive acetylcholinesterase were not observed. Populations of An. arabiensis showed both endophagic and exophagic behavior with peak biting activity from 19:00h to 22:00h. The observed multiple-resistance coupled with outdoor and early biting behaviour in populations of An. arabiensis could profoundly affect malaria vector control programme in Ethiopia. This needs an urgent call for implementing integrated vector control intervention, rational resistance management strategy and looking for new alternative vector control tools.

PLASMODIUM FALCIPARUM MULTIPLICITY OF INFECTION PRE- AND POST-VECTOR CONTROL CAMPAIGNS IN NCHELENGE DISTRICT, ZAMBIA

Julia Pringle, Smita Das, Tamaki Kobayashi, Kelly Searle, Mwiche Siame, Ben Katowa, Mike Chaponda, Mbanga Muleba, Modest Mulenga, Douglas Norris, William J. Moss

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Plasmodium falciparum malaria is holoendemic in Nchelenge District, Zambia where the primary vectors are ***Anopheles gambiae*** s.s. and Anopheles funestus s.s.. In Nchelenge District, indoor residual spray (IRS) and long-lasting insecticide net (LLIN) campaigns were conducted to reduce malaria transmission. In other settings, decreased malaria transmission as a result of LLIN/ITN use can lead to changes in the genetic diversity of ***P. falciparum***. It is therefore critical to monitor the effect of the recent vector control interventions in Nchelenge District, focusing on multiplicity of infection (MOI)_defined as the number of genetically distinct ***P. falciparum*** clones present in a given infection. A pre-IRS analysis of three parasite gene loci from Anopheles mosquitoes indicated that 93.9% of mosquitoes harbored polyclonal infections with an average complexity of infection of 6.4 unique clones. Preliminary data from human dried blood spot (DBS) samples suggests the MOI in humans is lower. This comparative analysis is limited, however, by the low number of genetic loci analyzed, as well as the fact that whole mosquito samples must be considered both diploid and haploid while human samples are only haploid. Following these preliminary results, we will use a SNP-based barcoding assay which characterizes 24 parasite loci to analyze DBS samples from study participants as well as salivary gland samples containing haploid parasite from mosquitoes. By comparing the MOI between vector and host as well as pre- and post-IRS, we can monitor the effect of vector control strategies on parasite genetic diversity. We hypothesize that decreased malaria transmission due to vector control strategies will lower the MOI in both vector and human samples with possible implications for acquired immunity, likelihood of disease severity, and rate of drug resistance development.

112

EFFICACY AND PERSISTENCE OF PIRIMIPHOS-METHYL (ACTELLIC 300CS) FOR INDOOR RESIDUAL SPRAYING IN ZANZIBAR

Khamis A. Haji[1], Narjis G. Thawer[2], Bakari O. Khatib[1], Juma H. Mcha[1], Abdallah R. Salum[1], Abdullah S. Ali[1], Chris Jones[3], Stephen M. Magesa[2], Mahdi M. Ramsan[2], Issa Garimo[4], Jeremiah. M. Ngondi[2]

[1]Ministry of Health Zanzibar, Zanzibar, United Republic of Tanzania, [2]RTI International, Dar-Es-Salaam, United Republic of Tanzania, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]RTI International, Zanzibar, United Republic of Tanzania

Indoor Residual Spraying (IRS) is a principal vector control intervention for malaria control in Zanzibar. In 2006, Zanzibar Malaria Control Programme introduced IRS with lambda-cyhalothrine (ICON 10WP/CS). Following detection of pyrethroid resistance in 2010, insecticide resistance mitigation plan was proposed and IRS with Bendiocarb started in 2011. As a resistance management strategy, Actellic 300CS replaced the Bendiocarb from 2014. The study investigated residual efficacy of Actellic 300CS sprayed on common surfaces of human dwellings in Zanzibar. Bioefficacy tests aimed to determine mortality of female Anopheles mosquitoes exposed to sprayed surfaces and identify onset of specific decline in toxic effect of Actellic 300CS deposits applied to different surfaces. Six houses with different wall surfaces (mud wall, oil and water painted walls, lime washed wall, un-plastered cement block wall and un-plastered stone blocks) were sampled from each district of Zanzibar. Actellic 300CS was sprayed on surfaces at a dose of one gram of active ingredient/m2. Ten susceptible females ***Anopheles gambiae*** s.s (age range 2-5 days old) were introduced through a sucking tube into a cone exposed on sprayed surfaces. Subsequent tests were undertaken on monthly basis using the World Health Organization (WHO) guideline. Insecticide resistance testing was also undertaken to investigate susceptibility of local malaria vectors against Actellic 300CS using WHO protocols. Twenty five unfed females ***Anopheles gambiae*** s.l (age range 2-5 days) were introduced into a tube containing Actellic impregnated paper (0.25%) for one hour and kept in holding tube with 10% sugar solution. Mortality was counted at the end of 24hrs holding period. Baseline tests conducted one day post-spraying revealed 100% mortality on all sprayed surfaces. Bioassay tests conducted over 214 days showed 100% 24 hours mortality on all sprayed surfaces. Results of resistance tests showed that malaria vectors in Zanzibar are 100% susceptible to Actellic 300CS. Based on the findings collected through bioassay testing, Actellic 300CS is highly effective and appropriate for IRS in Zanzibar.

113

DOES HETEROGENEITY IN INSECTICIDE RESISTANCE CONTRIBUTE TO MALARIA HOTSPOTS IN THE GAMBIA?

Kevin O. Opondo[1], David Weetman[2], Musa Jawara[1], Mathurin Diatta[1], Amfaal Fofana[1], Florence Crombe[2], Julia Mwesigwa[1], Umberto D'Alessandro[1], Martin Donnelly[2]

[1]Medical Research Council (UK) Unit, The Gambia, Banjul, Gambia, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Malaria transmission hotspots consistently have higher than average transmission intensity and are predicted to become increasingly common as malaria continues to decline. Little is known about the role of insecticide resistance in maintaining hotspots. The status of insecticide resistance was investigated in vector populations from six local pairs of villages from across The Gambia, comprising of a high and low malaria sero-prevalence village within each pair. Larvae and blood fed ***Anopheles gambiae*** s.l. were collected from each village to generate adults for use in World Health Organization insecticide bioassay tests. Of 1047 mosquitoes asssayed, 23.5% were An. arabiensis, 31.2% ***An. gambiae***, 43.3% ***An. coluzzii***, 2.04% were hybrids of ***An. coluzzii*** × ***An. gambiae***. In 3 village pairs, species population and composition varied significantly between high and low transmission villages. Resistance to DDT and deltamethrin was heterogeneous within and among species, but most prevalent in ***An. gambiae*** s.s. from eastern Gambia. Resistance was strongly associated with the target site (kdr) mutation L1014F (DDT, OR=256.7, (95% CI 48.6 - 6374.3, p<0.001) and deltamethrin, OR= 9.14, (95% CI 4.2 - 21.4, p<0.001). A metabolic resistance mutation, Gste2-114T in ***An. gambiae*** s.s. also conferred significant resistance to both DDT (OR=3.4, 95% CI 1.4 - 9.2, p = 0.006) and deltamethrin, (OR= 3.4, 95% CI 1.2 - 10.3, p=0.024. Resistance to DDT was more likely to be found in villages with high malaria sero-prevalence, (Wilcoxon test, p=0.025) but this was not the case for deltamethrin, p= 0.238). Whilst causality of relationships requires further investigation, variation in vector species and insecticide resistance is associated with malaria sero-prevalence setting in The Gambia. Our results suggest that in areas with heterogeneous malaria transmission, the role of the vector should be investigated to guide malaria control interventions.

114

BREEDING CONDITIONS INFLUENCE SUSCEPTIBILITY TO INSECTICIDES IN MOSQUITOES

Henry F. Owusu, Pie Müller

University of Basel/Swiss Tropical and Public Health Institute, Basel, Switzerland

As insecticide resistance increasingly threatens malaria control programs, it is very important to understand the processes and factors that interact to produce observed phenotypes. The contribution of the environment and breeding conditions to the susceptibility of the mosquito has been largely ignored. In this study, we evaluate how temperature, population density (crowding) and nutrition during the larval stage interact to influence the susceptibility of the adult mosquito to public health insecticides. Larvae of ***Anopheles gambiae*** (KISUMU) and ***Anopheles stephensi*** were bred under different combinations of temperature, population density and nutrition using a factorial experimental design. Emerging adults were tested against the lethal concentration of permethrin that would kill 50% of the mosquito population under standard rearing conditions in the World Health Organization insecticide susceptibility tests. . As a secondary endpoint to mortality, mosquito body weight was measured and included in the data analysis. Additional experiments explored the relationship between immediate knock down and 24 hours mortality, as these endpoints are often used interchangeably. Mosquitoes bred under different conditions showed significant differences in body sizes and mortality. Dry weight was strongly related to mortality (OR = 0.0000992, p < 0.001) in both experiments but was not significantly associated with time-to-knockdown (coeff -6.70; P = 0.176). In conclusion, the breeding conditions of mosquito larvae have a significant impact on the dry weight as well as susceptibility status of the adult mosquito. It is therefore important to incorporate the size of the mosquito when studying insecticide susceptibility in mosquitoes

115

AGRICULTURAL PRACTICES SUSCEPTIBLE TO TRIGGER THE DEVELOPMENT OF INSECTICIDE RESISTANCE IN MALARIA VECTORS

Fodjo Kouadio Behi, Chouaïbou S. Mouhamadou, Benjamin G. Koudou

Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire

Vector control is a main component of all malaria control strategies. Unfortunately the effectiveness of vector control is more and more affected by the increasing phenomenon of vectors resistance to insecticides. The different approaches proposed by the Global Plan for Insecticide Resistance Management (GPIRM) to overcome this situation of resistance assumes that the vector control itself is the main source of resistance; whereas the agricultural surfaces constituted sometimes by gigantic mosquito breeding sites polluted with pesticides could exert a

resistance selection pressure on mosquito larvae. The present study has been carried out in the rice perimeters of the locality of Tiassale located in the south of the Cote d'Ivoire to highlight farming practices that could trigger the development of resistance to insecticides. We have investigated the management of different pesticides used against crop'pests, for soil fertilization, or weed. The questionnaire covered among others, the procurement of products, the doses of application, the frequencies of treatment, and all the hygiene rules relating to the use or storage of products. We have also determined the residues of various pesticides in the mosquito breeding sites located within the farms. The results of this study are in the process of analysis and will be presented during the scientific exchanges.

116

SAVE MOSQUITOES, SAVE MONEY: A RESAMPLING ANALYSIS TO DETERMINE HOW MANY MOSQUITOES ARE NEEDED TO TEST A LONG-LASTING INSECTICIDAL NET

Thomas Kesteman, Sanjiarizaha Randriamaherijaona, Christophe Rogier, Sébastien Boyer

Institut Pasteur de Madagascar, Antananarivo, Madagascar

The reference method for testing the insecticide activity of Long-Lasting Insecticidal Nets (LLIN) distributed in the field needs a hundred live female mosquitoes per LLIN. To test 100 nets, one needs an entomological facility capable to produce 10,000 two days-old females plus the mosquitoes needed for maintenance of female breeding. If one could reduce the number of mosquitoes needed to test the effectiveness of LLIN, the human and animal resources, costs, and the duration of nets evaluation would be equally reduced, enhancing the ability of entomology labs to evaluate the effectiveness of LLIN. The WHOPES protocol proposes to tests the insecticide bio-efficacy of LLIN by cutting equal and predetermined positions' areas in each of the 5 sides of the net with 4 cones in which 5 mosquitoes are introduced. A LLIN is considered as valid if mortality after 24 hours is ≥80% or if Knock-Down rate (KD) after 60 minutes is ≥95%. We resampled a database of 200 LLIN collected from the population in Madagascar and tested appropriately, of which 41.1% were considered as valid. Each random resampling was performed 10,000 times. Receiver Operating Characteristic (ROC) curves for 1, 2, and 3 cones showed excellent performances of the mortality criterion while KD demonstrated a low reproducibility. Using 2 cones instead of 4, and considering mortality only, had 99.0% sensitivity and 98.2% specificity. The average error in the measured proportion of valid LLIN was 0.8%. The 95% confidence intervals (CI) of sensitivity and specificity narrowed while the sample size increased, and the 95% CI of the difference between 2-cones-testing and 4-cones-testing proportions of valid LLIN didn't exceed 5% when the sample was ≥40 LLIN. As a conclusion, testing the bio-efficacy of LLIN with twice less mosquitoes provides a fair evaluation of the proportion of LLIN valid when considering mosquitoes' mortality only, and a sufficient sample size (e.g. ≥40 LLIN). We propose to focus on mortality in the evaluation of the bio-efficacy of LLIN. This protocol will help entomology labs to double their capacity in testing the effectiveness of LLIN or divide its cost by two.

117

FINE-SCALE PATTERNS OF PYRETHROID RESISTANCE IN *AEDES AEGYPI* FROM YUCATAN, MEXICO

Marissa Grossman[1], Audrey Lenhart[2], Regan Deming[3], Anuar Medina-Barreiro[4], Edgar Koyoc-Cardeña[4], Jose Valentin Uc[4], Sergio Dzib-Flórez[4], Azael Cohuo-Rodriguez[4], Marco Torres-Castro[4], Eduardo Geded-Moreno[4], Pablo Manrique-Saide[4], Gonzalo Vazquez-Prokopec[1]

[1]Emory University, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Global Ministries of the United Methodist Church, New York, NY, United States, [4]Universidad Autónoma de Yucatán, Merida, Mexico

As observed with other medically important arthropods, the strong reliance on pyrethroid insecticides to control ***Aedes aegypti***, the principle vector of dengue and chikungunya viruses, has led to the evolution of insecticide resistance. The "knock-down resistance" (***kdr***) mechanism arises from point mutations on the voltage-gated sodium channel gene, and it confers resistance to pyrethroids in ***Ae. aegypti***. Understanding the dynamics of resistance at a fine scale within urban environments is key to both managing resistance and maintaining vector control efficacy. In this study, we analyzed the within-city distribution of ***kdr*** alleles in ***Ae. aegypti*** populations in time and space given heterogeneous selection pressures. During two consecutive years, 2013-2014, we collected 2,227 adult mosquitoes from inside 580 homes in four towns of Yucatan, Mexico. In each town, we sampled 5 blocks, with the exception of one town in which we sampled 24 blocks to better understand fine-scale dynamics. For each mosquito, we used PCR to detect the V1016I and F1534C ***kdr*** mutations. Additionally, we conducted CDC bottle bioassays to characterize phenotypic resistance to pyrethroids. Frequencies of the resistant alleles in 2013 ranged from 0.47 to 0.74 for 1016I and from 0.59 to 0.96 for 1534C. Intensive sampling of one small town, about 16 square kilometers, showed that ***kdr*** frequencies are highly heterogeneous between blocks, ranging from 0.18 to 0.64 for 1016I and from 0.36 to 0.73 for 1534C mutation. Spatial analyses showed a statistically significant difference from homogeneity in the allele frequencies, indicating an absence of spatial clustering (Weighted K function, $p<0.05$). High variability in the frequency of pyrethroid application suggests that heterogeneous, sporadic insecticide applications could be contributing to the observed differences in resistance patterns observed at a fine scale. Understanding the scale at which resistance arises and can be maintained in ***Ae. aegypti*** can aid in developing novel intervention strategies that exploit the fitness cost of the resistance alleles in sub-populations that are not heavily controlled with insecticide.

118

STEROL CARRIER PROTEIN, SCP2, IS CRITICAL FOR *PLASMODIUM* TO ESTABLISH INFECTION IN *ANOPHELES STEPHENSI*

Jingwen Wang, Yuebiao Feng, Guolei Xu

Fudan University, Shanghai, China

Mosquitoes are the vectors of multiple diseases which account for over 700 million deaths annually global wide. Little is known about lipid metabolic interactions between mosquitoes and parasites. Lipids are essential components of cell membranes and have key roles in different signaling pathways. We found that malaria parasites (***Plasmodium berghei***) infection resulted in significant alterations in metabolic profiling in ***Anopheles stephensi***. Sterol carrier protein (AsteSCP2), a soluble protein that facilitates the uptake of lipids in mosquitoes, is responsible for promoting parasites invasion. Silencing SCP2 impaired the ability of ***Plasmodium*** to establish infection in mosquitoes. In addition, AseSCP2 helps to maintain homeostasis of microbiota. Knocking down SCP2 led to significantly reduction of total bacteria number in comparison to dsGFP controls. Thus, SCP2 plays a vital role in controlling both ***Plasmodium***

infection and microbiota proliferation. Further experiments need to be done to investigate mechanisms of influence of SCP2 on parasites infection and microbiota homeostasis.

119

LAND USE, AN ENVIRONMENTAL RISK FACTOR FOR A VERY HIGH MALARIA TRANSMISSION

Arthur D. Sovi, Martin Akogbeto

Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

The goal of the study is to investigate if local agricultural practices have an impact on malaria transmission in four villages located in the same geographical area within a radius of 15 kilometers in southern Benin. Among the villages, one (Itassoumba) is characterized by the presence of a large fish farming area on which several fish ponds are dug. The three others (Itakpako, Djohounkollé and Ko-Koumolou) are characterized by traditional food-producing agriculture. Human biting rate (HBR) was evaluated using human-landing catches, two nights per month from july 2011 to june 2012. Collected mosquitoes were identified morphologically. Species molecular identification was also performed using PCR. Female ***Anopheles*** mosquitoes were tested for the presence of ***Plasmodium falciparum*** antigen using ELISA technique in order to determine the sporozoitic index [S]. The entomological inoculation rate (EIR) was also calculated (EIR = HBR x [S]). ***An. coluzii*** (93.7%) was identified as the main malaria vector. The EIR ranged from 9.7 to 21.7 infected bites of ***An. gambiae*** per human per year in Djohounkollé, Itakpako and Ko-Koumolou against 1159.7 in Itassoumba ($p<0.0001$). The heterogeneous character of malaria epidemiology was confirmed. Land use through fish ponds creation contributed to the development of suitable and permanent breeding sites for ***Anopheles*** mosquitoes. That led to a drastically high malaria transmission in Itassoumba. We recommend that the human dwellings be located far from these fish farming activities so that the populations can avoid to be exposed to the high rate of infected bites. It is also important to target the exact areas where high transmission is persisting such as Itassoumba so that the control operations can be more prioritized and focused in these areas.

120

EFFECTS OF NEUTRALIZING ANTIBODIES AND HUMAN COMPLEMENT PROTEINS ON DENV INFECTION LEVELS IN *AEDES AEGYPTI*

Berlin L. Londono-Renteria[1], Crystal Gripping[1], Andrea Troupin Troupin[1], Jenny C. Cardenas[2], Thomas Weitzel[3], Tonya M. Colpitts[1]

[1]Tulane University, New Orleans, LA, United States, [2]Hospital Los Patios, Los Patios Norte de Santander, Colombia, [3]Laboratorio Clínico Programa Medicina del Viajero Clínica Alemana, Santiago, Chile

Dengue virus (DENV) causes the most common vector-borne viral disease in humans living in the tropics. While secondary infection with DENV is frequently associated with severe disease, the majority of DENV infections are mild or asymptomatic. Protection against DENV infection may depend on neutralization capacity of antibodies (ab) in serum. Transmission of DENV occurs when a mosquito takes a blood meal from a DENV infected host. The blood meal of a mosquito consists of host cells, fluids and immune factors. Previous studies have shown that immune factors may remain active in the arthropod midgut and retain the ability to interact with pathogens and affect their viability several hours after ingestion. Antibodies transferred from the host may then also block pathogen infectivity in the vector. So far, no studies have evaluated the effect of neutralizing antibody titers and complement activity in human blood on DENV infectivity of ***Aedes aegypti***. Thus, we decided to evaluate these effects by experimentally infecting mosquitoes with both field-collected and laboratory strains of DENV2 in mixture with human serum samples. Serum contained varying titers of neutralizing antibodies against serotype-specific DENV (Exp), and we also included control sera (Ctl) with no previous history of DENV exposure. Serum was either inactivated (IA) or non-inactivated (NIA) serum at the time of the feeding. Using quantitative Real-Time-PCR, we found no significant difference in relative viral RNA quantity between mosquitos fed with Exp or Ctl serum 1h after blood meal, although mosquitoes receiving inactivated serum form both groups had higher relative viral RNA quantity than those that ingested blood with non-inactivated sera. However, at 3h post feeding, mosquitoes receiving Exp sera had significantly higher virus concentration than those fed with Ctl sera. Our findings indicate that heat inactivation of human serum increases DENV infectivity in mosquitoes and that the presence of anti-DENV antibodies in blood potentially play an important role in viral disease transmission to mosquitoes.

121

DIFFERENTIAL EXPRESSION IN DENGUE-INFECTED *AEDES ALBOPICTUS* REVEALS GENES IMPORTANT FOR ANTIVIRAL RESPONSE

Hitoshi Tsujimoto, Kathryn A. Hanley, Immo A. Hansen

New Mexico State University, Las Cruces, NM, United States

The Asian tiger mosquito, ***Aedes albopictus*** is an important vector of dengue virus, which is responsible for recent epidemics in urban temperate and subtropical regions. Its ability to inhabit colder zones than the major epidemic vector, ***Ae. aegypti*** poses risks to expand the epidemic or endemic areas. We investigated transcriptomes of dengue-infected and -uninfected ***Ae. albopictus*** using Illumina sequencing technology. This study reveals how mosquito gene expression is modulated in early time points following dengue infection.

122

CHANGES IN MALARIA VECTOR DYNAMICS POST-IRS IN NCHELENGE DISTRICT, ZAMBIA

Christine Jones[1], Mbanga Muleba[2], Maureen Kessler[1], Smita Das[1], William Moss[1], Douglas Norris[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Tropical Disease Research Center, Ndola, Zambia

Nchelenge District of northern Zambia, lying along Lake Mweru and sharing a border with the Democratic Republic of the Congo, experiences high transmission of malaria despite almost a decade of malaria control interventions, including implementation of long-lasting insecticide-treated nets (LLINs) and indoor residual spraying (IRS). From October to November in 2014, an IRS campaign using the organophosphate pirimiphos-methyl as the residual insecticide was implemented in Nchelenge, targeted mainly to households lying along Lake Mweru. In association with the Southern Africa International Centers for Excellence in Malaria Research (ICEMR) project, Centers for Disease Control light-trap (CDC LT) collections have been ongoing in Nchelenge for several years at households throughout the study site, both in IRS-targeted and IRS-negative homes. These collections were compared to evaluate possible differences in mosquito abundance and foraging behaviors that may have resulted from vector control. In addition, pyrethroid spray catch (PSC) and barrier screen collections were conducted to assess resting behaviors of vector mosquitoes in Nchelenge in IRS and non-IRS zones. The data resulting from these studies will increase our understanding of malaria vector dynamics and transmission in highly endemic regions, with implications for future vector control.

123

EVALUATION OF INTERVENTIONS AIMING AT INTERRUPTING MALARIA TRANSMISSION IN BAGAMOYO, TANZANIA

Mgeni M. Tambwe, Said A. Jongo, Seif A. Shekalaghe, Salim Abdulla, Marta Maia

Ifakara Health Institute, Bagamoyo, United Republic of Tanzania

The persistence malaria transmission despite of well-planned vector control programs, early diagnosis and treatment with artemisinin combination therapy (ACT) in many settings, threat the available control measure. In 2012, World Health Organization, estimated that there are about 207 million cases of malaria and 627, 000 deaths are related to malaria. 90% of these deaths occur in sub-Saharan Africa. In responding to these challenges, the Malaria Eradication Research Agenda (malERA) initiative was conceive as a rigorous scientific consultative process to identify knowledge gaps and new tools that will be needed to eliminate and eradicate malaria globally. The malERA pointed out the need to include transmission-blocking interventions to interrupt malaria transmission by targeting the infectious gametocytes carriers that are responsible to maintain malaria transmission. In response to the recommendation, Ifakara Health Institute (IHI) has established a level 3 insectary laboratory and Phase I Clinical Trial Facility to be used to evaluate different interventions such as vaccines and drugs aiming at interrupting malaria transmission both at individual and community levels. Some interventions have already been evaluated using these platforms. Recently, we have evaluated whether, ARCO and EURARTESIM have the potential to clear post treatment gametocytes reservoir. This study involved adult aged 18 and above with uncomplicated malaria. Participants were assigned to either of the interventions and admitted at the facility for three (3) days to monitor treatment then discharged home. On day seven post treatment, direct skin feeding using blood naïve lab-reared sterile mosquitoes was done. Analysis of midgut by PCR is going on at Nijmegen, Netherland and results will be available soon hoping to present them during the coming ASTMH meeting.

124

SPATIO-TEMPORAL DISTRIBUTION AND ABUNDANCE OF IMMATURE STAGES OF *AEDES AEGYPTI* ON THE SOUTHERN COAST OF KENYA

Francis M. Mutuku[1], Uriel Kitron[2], Bryson Ndenga[3], Njenga Ngugi[4], Peter Siema[5], Dunstan Mukoko[6], John Vulule[3], Charles King[7], Desiree A. LaBeaud[8]

[1]Technical University of Mombasa, Mombasa, Kenya, [2]Department of Environmental Sciences, Emory University, Atlanta, GA, United States, [3]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [4]Department of Biological Sciences, Chuka University, Chuka, Kenya, [5]Vector Borne Disease Unit, Msambweni, Kenya, [6]Vector Borne Disease Unit, Nairobi, Nairobi, Kenya, [7]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States, [8]Department of Pediatrics, Division of Infectious Diseases, Stanford University School of Medicine, Stanford, CA, United States

In endemic areas, ***Aedes aegypti***, the principal vector of dengue and chikungunya viruses breeds in a variety of container habitats both indoors and outdoors. Understanding of the vector ecology is essential for effective vector control. In Kenya, where dengue and chikungunya are prevalent, little is known about larval ecology of the vector. As part of a larger study, all indoor and outdoor water- holding containers that might harbor ***A. aegypti*** larvae and pupae were examined monthly from March to October 2014 in 20 selected houses from a Msambweni (rural site) and Ukunda (Urban site). Of 1928 containers inspected in Msambweni (1194) and Ukunda (734), 3.7% and 10.6% were positive for ***A. aegypti***, respectively. Seven out of the 16 container habitat types were commonly found harboring ***A. aegypti*** immature stages - animal watering containers, water drums, water tanks, buckets, Jerry-cans, tires and food tins. In the rural site, , the most persistent container habitat types were buckets and water tanks, while in the urban site, the animal watering containers, Jerry cans and tires were most persistent. Of 9,269 larvae and 919 pupae of mosquitoes collected, 83% and 78% of the collected larvae and pupae, respectively, were ***A. aegypti***. House, Container and Breeding indices were always higher in the urban site (46%, 10% and 2.1, respectively) in comparison to the rural site (33%, 4% and 0.7, respectively, $p<0.0001$), and outdoors compared to indoors ($p<0.0001$). In both sites, all indices were high in May, June and July, after rainy periods, and lowest in March and October, after dry periods, suggesting a lagged correlation with prior rainfall. In conclusion, key container habitats were identified in the two study sites and ongoing entomological surveys will help determine the most productive habitats. Targeting productive container habitats for dengue and chikungunya vectors will make vector control efforts affordable and feasible in the study area.

125

BEHAVIOR OF *ANOPHELES DARLINGI* IN THREE COMMUNITIES IN THE PERI-IQUITOS REGION OF AMAZONIAN PERU

Marlon P. Saavedra[1], Marta Moreno[2], Sara A. Bickersmith[3], William Lainhart[4], Carlos Tong[5], Freddy Alava[6], Joseph M. Vinetz[2], Jan E. Conn[3]

[1]Asociación Benéfica Prisma, Lima, Peru, [2]Division of Infectious Diseases, Department of Medicine, University of California San Diego, La Jolla, CA, United States, [3]Wadsworth Center, New York State Department of Health, Albany, NY, United States, [4]School of Public Health, Department of Biomedical Sciences, Albany, NY, United States, [5]Laboratorio ICEMR-Amazonia, Laboratorios de Investigacion y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [6]Direccion Regional de Salud de Loreto, Iquitos, Peru

Malaria transmission in the peri-Iquitos region of Amazonian Peru has been designated as seasonal and hypoendemic with recently described hyperendemic hotspots. Despite relatively recent distribution of LLINs, before the start of the study, malaria in Amazonian Peru persists and increased substantially in 2014 compared to previous years. ***Anopheles darlingi***, the main malaria vector, is known for its variable behavior depending on locality and environment. To evaluate vector biology metrics in relation to seasonality and malaria transmission, mosquito collections were carried out in three localities (Lupuna, Cahuide and Villa Buen Pastor) in the peri-Iquitos region, Loreto, Peru in 2011-2012. HLC, SHA and CDC trap types were compared for effectiveness in a Neotropical setting. Abundance, human biting rate, and EIRs were measured to provide an updated view of transmission patterns post-LLINs distribution. HLC collected significantly more anopheline mosquitoes than Shannon traps and CDC light traps. ***An. darlingi*** was the most prevalent species in all three villages (84% overall). Biting patterns varied depending on trap type, season and village. EIRs varied temporally and spatially and the highest (2.52) occurred during the 2012 malaria outbreak in Cahuide. Unexpectedly we found high Infection rate 1.47 (57 mosquitoes analyzed) and 1.75 (52 mosquitoes) outside the normal malaria transmission season, coincident with a second local outbreak in CAH. Our data underscore the importance of HLC as the most meaningful collection method for measuring vector biology indices in this amazon region. Our study clearly demonstrated microgeographic differences in Anopheles. darlingi peak biting times, biting patterns, infectivity and EIR. The trend of an increase in outdoor biting together with early evening infected mosquitoes may undermine the effectiveness of LLINs as a primary malaria intervention. Anopheles. darlingi was the most abundant species and the only one infected with ***Plasmodium***, confirming its importance as the major malaria vector in the area. HLC is still the most effective trap for ***An. darlingi*** in this region.

126

SEMINAL INFLUENCES: THE ROLE OF MALE TRANSFERRED 20E IN *ANOPHELES GAMBIAE* REPRODUCTIVE FITNESS

Adam South[1], Evdoxia Kakani[2], Andrea Smidler[1], Enzo Mameli[2], Flaminia Catteruccia[1]

[1]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [2]Università degli Studi di Perugia, Perugia, Italy

Reducing the burden of malaria induced mortality and morbidity via targeting of the mosquito vector requires an increased investment into understanding the reproductive ecology of Anopheles mosquitoes. With increasing levels of insecticide resistance threatening the efficacy of existing vector control strategies, the induction of sexual sterility in natural vector populations is an attractive alternative. However, a lack of knowledge regarding many of the basic elements of ***Anopheles*** mating hampers development of these strategies. Recently, our group has demonstrated that the suite of mating induced physiological and behavioral changes in ***An. gambiae*** females is largely mediated by the receipt of the steroid hormone 20-hydroxyecdysone (20E) as part of the male mating plug. We have also shown that females choose to mate with males that transfer higher levels of male 20E during mating. Here, we demonstrate through GC/MS analysis that males whose mating attempts are accepted and rejected exhibit different chemical contact cue profiles, a sensory modality that females can use for mate discrimination. Furthermore, behavioral assays reveal that a transgenic line of ***An. gambiae*** males deficient in 20E synthesis suffers a cost in terms of their mating competiveness relative to a control line, further underscoring the role of male synthesized 20E in mechanisms of pre-copulatory mate choice. Finally, we also analyze whether male 20E levels are heritable, and reveal that 20E transfer provides females with both direct and indirect benefits. Taken together, these results provide compelling evidence that 20E is a key factor determining reproductive fitness for both sexes across sequential episodes of sexual selection. This work provides critical insights into the mating ecology of a major disease vector while extending our understanding of mating system dynamics in both swarming and monandrous insect species.

127

ARTEMISININ-RESISTANT *PLASMODIUM FALCIPARUM* CLINICAL ISOLATES INFECT DIVERSE VECTORS OF SOUTHEAST ASIA AND AFRICA

Brandyce St. Laurent[1], Becky Miller[1], Timothy Burton[1], Chanaki Amaratunga[1], Men Sary[2], Siv Sovannaroth[2], Robert Gwadz[1], Jennifer M. Anderson[1], Rick M. Fairhurst[1]

[1]National Institutes of Health, Rockville, MD, United States, [2]National Center for Parasitology, Entomology, and Malaria Control, Phnom Penh, Cambodia

Artemisinin-resistant ***Plasmodium falciparum*** parasites are rapidly spreading in Southeast Asia, yet very little is known about their transmission. This knowledge gap, and the possibility of their future spread to sub-Saharan Africa, endangers global efforts to control malaria. Studies on the population genetic structure of ***Plasmodium falciparum*** isolates from Cambodia revealed drug-resistant parasites that fell into highly structured groups, as distinct from each other as from African parasite isolates. The discovery of Kelch13-propeller polymorphism, a new marker for artemisinin resistance, helped to further resolve these parasite populations. To investigate the transmission dynamics of these parasites, we performed membrane feeding assays with Cambodian clinical isolates from several distinct parasite populations recently shown to be artemisinin resistant in patients and ***in vitro***, to infect native and non-native mosquito vectors. We found that that multiple artemisinin-resistant and artemisinin-sensitive isolates successfully infected two Southeast Asian vectors, ***Anopheles dirus*** and ***An. minimus***, as well as the major African vector, ***An. gambiae***, and also produced human-infective sporozoites. The ability of artemisinin-resistant parasites to infect highly diverse Anopheles species, combined with their higher gametocyte prevalence in Cambodian patients, may explain their rapid and extensive spread in Southeast Asia and further challenge regional efforts to contain and eliminate them.

128

MOLECULAR CHARACTERIZATION OF METABOLIC FACTORS REQUIRED FOR SPERM FERTILITY AND STORAGE IN THE MAJOR MALARIA VECTOR *ANOPHELES* MOSQUITOES

Maurice A. Itoe

Harvard T.H. Chan School of Public Health, Boston, MA, United States

The application of vector control methods based on the use of insecticides has yielded resounding success in reducing the incidence of malaria and its impact on global health. The insurgence and spread of insecticide resistance in mosquito populations however is threatening these control methods, and new strategies are urgently needed. Among these, the use of sterile insect techniques (SIT) to control malaria vector populations and thus reduce disease transmission has gained renewed attention. To strengthen our knowledge of the use of SIT, an understanding of the molecular mechanisms essential for survival and functionality of sperm and reproductive success of ***Anopheles*** mosquitoes is absolutely required. To this end, we set out to characterize metabolic pathways essential for sperm production and function. Our data indicate that sperm function depends on key rate-limiting enzymes involved in lipid metabolism. Further molecular dissection of these pathways is underway to assess whether their impairment will affect fertilization of eggs after mating. This study may identify new targets to reduce natural mosquito populations and hence impact malaria transmission.

129

MORPHOLOGICAL AND MOLECULAR CHARACTERIZATION OF ANOPHELINE MOSQUITOES AND THEIR BEHAVIORAL PATTERNS IN UYO, SOUTH-SOUTH NIGERIA

Inyang Asuquo Atting[1], Mfonobong E. Akpan[2]

[1]University of Uyo/University of Uyo Teaching Hospital, Uyo, Nigeria, [2]University of Uyo, Uyo, Nigeria

Adult mosquito vectors were collected from two areas in Uyo, Nigeria where no information exists on the major malaria vectors associated with human malaria. Samples collection was carried out between May and October 2013 using Knockdown and Human Landing Catches (HLC) techniques. A Molecular Method using Polymerase Chain Reaction (PCR) was used to further characterize and identify ***Anopheles gambiae*** sibling species. A total catch of 1,300 mosquitoes was recorded out of which 700 was used for morphological identification. A total of 90 (12.8%) of these were identified as female anopheles mosquitoes consisting of 21(23.3%) Anopheles nili and 69 (76.7%) ***An. gambiae*** complex. A PCR based test on the ***An. gambiae*** complex identified 66(96.0%) as ***An. gambiae*** sensu stricto. The study also revealed that the resting behaviour of ***An. gambiae*** complex species in this area is endophilic whereas the resting behaviour of An. nili is exophagic/exophilic. The peak biting activity of ***An. gambiae*** complex species occurred at 2300 hours (indoor) and 1900 hours (outdoor) in July whereas that of An. nili occurred at 2200 hours (indoor) and 1800 hours (outdoor) in June. The total number of ***An. gambiae*** collected was more than ***An. nili*** and Human Biting Rates (HBR) recorded for ***An. gambiae*** was higher than ***An. nili***. It is concluded from the study that there is a need for a comprehensive knowledge on the behaviour and heterogeneities that exist within and among malaria vector species in Uyo if the goal of malaria elimination is to be achieved. It is recommended from the study that more insecticide treated nets should be used in this area for effective control of malaria vectors in Uyo, South-South geopolitical zone and generally, in Nigeria.

130

RESPONSE OF MOSQUITOES TO OVITRAPS SET IN DIFFERENT COLOURED CONTAINERS AT THEIR NATURAL BREEDING SITES AND THE BIO-INSECTICIDAL ACTIVITY OF *BACILLUS* SPP ON MOSQUITO LARVAE

Millicent Captain-Esoah[1], James Owusu-Kwarteng[1], Martin Bonu-Ire[1], Fortune Akabanda[1], Martin N. Donkor[2], Elijah A. Dakorah1[1], Kwadwo K. Frempong[3], Francis B. D. Vereigh[3], Samuel Dadzie[3], Maxwel Appawu[3], Daniel Adjei Boakye[3]

[1]Department of Applied Biology, University for Development Studies, Navrongo, Ghana, [2]Department of Applied Chemistry and Biochemistry, University for Development Studies, Navrongo, Ghana, [3]Department of Parasitology, Noguchi Memorial Institute for Medical Research, Accra, Ghana

The behavioural choices of female adult mosquitoes to different colour substrate and the bio insecticidal activities of ***Bacillus*** species were studied in order to develop surveillance and monitoring systems for vector control. Five different colour containers; viz, black, blue, green, yellow and white were selected for the ovitraps and observed daily for mosquito eggs. A total of 1149 mosquitoes belonging to three genera, ***Aedes, Anopheles*** and ***Culex*** were collected from the five ovitraps in the study site. The highest occurring species was ***Culex*** species 963 (83.8%), followed by ***Aedes*** 170 (14.8%), and Anopheles 16 (1.4%). The colour preference for the mosquitoes was in this order: black 53.8 % (618), blue 23.2 % (266), green 10.4 % (119), yellow 8.5% (98) and white 4.2% (48). High numbers of ***Culex*** and ***Aedes*** species were found ovipositing in black 563 (58.5%), blue 238 (24.7%) and yellow 98 (10.2%) containers with relatively few numbers in green and white containers. The bio-insecticidal activity of three different ***Bacillus*** spp (***B. thuringiensis, B. subtilis***, and ***B. cereus***) at different treatment levels (0%, 10%, 20%, 30%, 40%, and 50% of breeding water) were introduced on three different mosquito genus; ***Aedes***, ***Anopheles***, and ***Culex*** and observed for mortality over 72 hours. ***B. cereus*** at concentrations of 30% and 40% was very effective on all the three mosquito species. ***B. subtilis*** showed total mortality (100%) on ***Aedes*** species at all concentrations after 72 hours. ***B. thuringiensis*** was more effective on the ***Culex*** and ***Aedes*** larvae as compared to the ***Anopheles***. ***B. cereus*** and ***B. subtilis*** must be considered as bio-insecticide for controlling ***Aedes***, ***Culex***, and ***Anopheles***. These findings are significant for mosquito vector control programmes and could be employed for future mosquito control campaigns in the Navrongo community, following further investigations.

131

MOSQUITOES SPECIES DIVERSITY AND ABUNDANCE IN NEIGHBORHOODS WITH PREVIOUS ARBOVIRUS ACTIVITY IN IQUITOS, PERU, 2010-2013

Helvio Astete[1], Kanya C. Long[2], Eric S. Halsey[3], Rommel Vasquez[4], Julia S. Ampuero[3], Amy C. Morrison[5]

[1]U.S. Naval Medical Research Unit - 6, Iquitos, Peru, [2]Andrews University, Berrien Springs, MI, United States, [3]U.S. Naval Medical Research Unit - 6, Lima, Peru, [4]University of California Davis, Davis, CA, United States, [5]U.S. Naval Medical Research Unit - 6; University of California, Davis, Iquitos, Peru

Arbovirus infections with alphavirus (Venezuelan Equine Enchephalitis (VEE), Mayaro), and orthobunyavirus (Guaroa, Oropuche, Group C) have been observed through clinic-based surveillance in the Amazonian City of Iquitos, Peru since the 1990s. Small outbreaks have occurred within urban neighborhoods in this isolated city of approximately 400,000 people. To identify the vectors transmitting these alphaviruses, we carried out mosquito collections in 4 neighborhoods with a history of VEE transmission. Two collection activities were done in the northern part of the city that are completely flooded by the Nanay River a few months of each year. The other two neighborhoods, located in the center and south of the city, are situated near rivers but do not flood. A total of 116 separate collections using two CDC light traps with dry ice (1800-0600) per neighborhood were carried out between 2010 and 2013. After species identification, mosquitoes were pooled and stored for virus testing. We estimated species diversity using the Shannon Index (H'). We collected 29,938 mosquitoes belonging to 49 species during that period. Species diversity (H') ranged from 0.86 to 2.05. The neighborhoods with the highest levels of seasonal flooding during a few months out of the year (houses located on stilts), had lower species diversity than the more urbanized neighborhoods. The most abundant species collected were ***Culex declarator/mollis*** (56.3%), ***Culex quinquefasciatus*** (18.5%), ***Aedeomyia squamipennis***(5.0%), ***Culex*** (***Melanoconion***) spp. (3.2%), ***Culex*** (***Melanoconion) ocossa*** (3.1%), ***Culex*** (***Aedinus) amazonensis*** (2.8%), ***Mansonia indubitans/titillans*** (1.9%). Although mosquito densities were lower than those observed in nearby rural communities, urban areas of Iquitos support a broad range of species that are known vectors of arboviruses. Of these the most notable were from the ***Culex*** (Melanoconion) group, previously incriminated as vectors of Venezuelan Equine Encephalitis virus.

TRANSMISSION PATTERNS AND RISK CLUSTERING OF DENGUE VIRUS INFECTION IN PUERTO MALDONADO, PERU

Gabriela Salmon[1], M. Claudia Guezala[1], David L. Blazes[2], Andres G. Lescano[1], Joel M. Montgomery[3], Daniel G. Bausch[4], William K. Pan[5]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]Navy Medicine Professional Development Center, Bethesda, MD, United States, [3]Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [5]Duke Global Health Institute and Nicholas School of Environment, Duke University, Durham, NC, United States

Understanding spatial patterns of dengue virus (DENV) transmission and underlying human behavioral and environmental factors are important to effective control. We assessed clustering and transmission factors for DENV among residents of Puerto Maldonado, Peru, a city in the southern Amazon Basin. We conducted a cross-sectional demographic and serosurvey and knowledge, attitudes, and practices (KAP) assessment in randomly selected households in 2012. Serum samples were screened by ELISA for DENV antibodies with confirmation by plaque reduction neutralization test to distinguish between primary and secondary infections. We used an ordinal model in SaTScan to assess spatial patterns adjusting for other covariates (available services and infrastructure, residence time, income) and created an ordinal multivariate model introducing variables measuring the distance of households to potential vector and infection sources (***i.e***. markets, cemeteries, hospitals, flooding areas, river shore). Data were collected from 270 households, over 60% of which were migrants to the city. Primary DENV infections were noted in approximately 40% of households and secondary infections in over 25. We identified five clusters of high DENV seroprevalence. The most likely cluster had a radius of 0.75 Km in which primary and secondary cases were noted in 15% and 30% of households, respectively. In the multivariate analysis, higher income (OR 1.6, 95% CI 1.1-2.3) and higher KAP scores (OR_{Q1} REF; OR_{Q2}: 1.5, 95% CI 0.7-3.0; OR_{Q3}: 2.2, 95% CI 1.1-4.4; OR_{Q4} 2.6, 95% CI 1.3-5.4) were positively associated with DENV infection, while odds of infection decreased with increasing distance (meters) from flooding areas (OR 0.999, 95% CI 0.998-0.999). No association was noted with migration time, distance to other features in the city or the presence of services and infrastructure. We found clustering of DENV infection in Puerto Maldonado, with increased risk surprisingly associated with higher income and KAP score. We speculate that higher income serves as proxy for increased exposure time to DENV in the city.

133

CHARACTERIZATION OF CHIKUNGUNYA VIRUS INFECTIONS IN CHILDREN IN MANAGUA, NICARAGUA

Lionel Gresh[1], Sergio Ojeda[1], Nery Sanchez[1], Federico Narvaez[2], Brenda Lopez[1], Douglas Elizondo[1], Andrea Nuñez[3], Aubree Gordon[4], Angel Balmaseda[3], Eva Harris[5]

[1]Sustainable Sciences Institute, Managua, Nicaragua, [2]Hospital Infantil Manuel de Jesús Rivera, Ministry of Health, Managua, Nicaragua, [3]Laboratorio Nacional de Virología, Centro Nacional de Diagóstico y Referencia, Ministry of Health, Managua, Nicaragua, [4]School of Public Health, University of Michigan, Ann Arbor, MI, United States, [5]School of Public Health, University of California, Berkeley, Berkeley, CA, United States

Chikungunya is a viral disease transmitted by ***Aedes aegypti*** and ***Ae. albopictus*** mosquitoes. In late 2013, chikungunya virus (CHIKV) was introduced in the Caribbean island of St. Martin. Since then, over 1,250,000 chikungunya cases have been reported by PAHO and most countries in the Americas report autochthonous transmission of CHIKV. In Nicaragua, the first imported case was described in July 2014 and the first autochthonous case in September. We analyzed the epidemiology and clinical presentation of chikungunya in two prospective pediatric cohort studies in Managua, Nicaragua: a community-based cohort study and a hospital-based study. Suspected chikungunya cases in both studies and cases with undifferentiated fever in the community cohort were screened by RT-PCR for CHIKV infection. From September 2014 to February 2015, a total of 96 and 83 chikungunya cases were identified in the community cohort and the hospital study, respectively. In the community cohort, cases were equally distributed by sex; however, more males presented to the hospital (67%, p=0.001). Most chikungunya cases were identified from November to January (community cohort: 83%, hospital: 92%). In the first six months of the epidemic, the incidence of symptomatic CHIKV infection in children aged 2-14 years in the community cohort was 4.6 cases per 1,000 person-months (95%CI: 3.8-5.7). Clinical presentation in the community cohort ranged from undifferentiated fever (13%) to children requiring hospitalization (16%). CHIKV-positive children were older than the rest of the children in the cohort study (9.9 vs. 8.1 years, p<0.001), and CHIKV-positive children presenting with typical chikungunya symptoms were older than those with undifferentiated fever (10.1 vs 8.1 years, p=0.03). A detailed analysis of acute symptoms in our chikungunya cases is underway. Additionally, patients with confirmed CHIKV infection will be followed longitudinally to characterize chronic symptoms associated with CHIKV infection. Finally, healthy annual serum samples collected from cohort participants in March 2014 and 2015 will be used to estimate the rate of subclinical CHIKV infections.

134

CONTINUOUS OUTBREAK OF CHIKUNGUNYA VIRUS IN THE PHILIPPINES CAUSED BY 2 GENOTYPES, 2011-2014

Ava Kristy Sy, Amado Tandoc, Saito Mariko

Research Institute for Tropical Medicine, Muntinlupa City, Philippines

Chikungunya (CHIKV) is a mosquito-borne infection that caused large outbreaks in several tropical countries. Prior to 2011, the last reported outbreak of Chikungunya in the Philippines was in 1996 involving a small agricultural village. Limited information about the virus from the country is available. Here, we report the circulation of 2 Chikungunya genotypes causing its re-emergence in the Philippines. Serum samples collected from patients presenting with fever, rash, and joint pains from several provinces were tested for Chikungunya IgM. Samples collected <5 days after onset of symptoms and with negative IgM were tested for CHIKV RNA. The partial E1 gene was amplified using one-step RT-PCR and followed by direct Sanger sequencing. Phylogenetic analysis was performed using neighbor joining method using Kimura-2 parameter model (K2+G) on the partial E1 gene (733nt) by MEGA 6.05. Of the 6,549 serum samples collected from 2011 to 2014, 53% have detectable anti-Chikungunya IgM. CHIKV RNA was detected from 105 samples while 31 samples were sequenced for partial E1 gene. Most of the Philippines strains were grouped into Asian genotype and clustered into the same branch, which showed high similarity with the strains reported from Indonesia and Malaysia. Three samples from Davao have the East/Central/South African (ECSA) genotype. And have the alanine to valine substitution in the codon 226 (A226V) which increased the transmissibility of the virus. Chikungunya has caused outbreaks throughout the country. Initially detected in 2 provinces in southern Philippines in 2011, it increased to 30 provinces with reported cases in 2012 and to almost 90% of the provinces in 2013 and continued to invade new areas in 2014. In southern Philippines, strains of 2 genotypes, Asian and ECSA, circulated in the same time. During this outbreak, an ECSA genotype with the A226V mutation was reported in the country. The determination of the epidemic transmission route of CHIKV may be helpful to fully understand the epidemiology and molecular evolution of the virus into the country as well as its role in the ongoing Caribbean outbreak.

135

EPIDEMIOLOGIC CHARACTERISTICS AND CLINICAL MANIFESTATIONS OF CHIKUNGUNYA IN A NAIVE POPULATION, PUERTO RICO 2015

Danulka Vargas[1], Milagros Silva[1], Aidsa Rivera[2], Luzeida Vargas-Lasalle[1], R. Iván Iriarte[1], Luisa I. Alvarado[1]

[1]Ponce School of Medicine of the Ponce Health Sciences University/Saint Luke's Episcopal Hospital, Ponce, Puerto Rico, [2]Dengue Branch, Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, San Juan, Puerto Rico

Chikungunya (CHIK) is a mosquito-borne disease caused by the chikungunya virus that was first detected in the Americas in October 2013, with the first laboratory confirmed Puerto Rico case detected in May 2014. Common clinical features are: fever, rashes and arthralgia/arthritis; rarely atypical or severe manifestations occur. Risk groups for severe disease include neonates, older persons and those with co-morbidities. We describe the epidemiology and clinical manifestations of laboratory confirmed CHIK in a naïve population and compare outcomes by age, sex and previous health status. Data was collected from patients with acute febrile illness (AFI) enrolled in the Sentinel Enhanced Dengue Surveillance System (SEDSS) project who presented to St. Luke's Episcopal Hospitals in Ponce and Guayama, Puerto Rico from May to September 2014. Blood, urine, nasal and oropharyngeal specimens were collected and RT-PCR and immunodiagnostic testing was performed for 21 pathogens, which included dengue and chikungunya viruses, influenza and other respiratory viral pathogens. Demographic and clinical information was collected on enrollment. Of 2,262 AFI patients enrolled, 663 (29%) had laboratory confirmed CHIK. Fifty-two percent were female, the mean age was 34 (SD±23). Nine percent of cases were admitted. The highest proportion of admission was among infants (75%) and adults over 60 (14%), 1 death was reported. Clinical manifestations included: arthralgia (86%), headache (77%), back pain (68%), rash (67%), conjunctivitis (64%), and arthritis (47%). Eight percent had mucosal, intestinal or urinary tract bleeding manifestations. Diabetic cases were more likely to be admitted than non-diabetics (OR= 3.0 CI 95%: 1.5, 5.99) and hypertensive cases more than non-hypertensive (OR= 2.9 CI 95%: 1.45, 5.9). Chikungunya presented in all age groups with the highest proportion of hospital admissions among infants and older adults. Adults with co-morbidities had a higher risk of admission. The study will continue to the end of the first epidemic in Puerto Rico and should provide useful information for health professionals in the clinical management of CHIK.

136

SEQUENCING OF CHIKUNGUNYA VIRUS STRAINS CIRCULATING IN NICARAGUA, 2014-2015

Chunling Wang[1], Saira Saborio[2], Lionel Gresh[3], Poornima Parameswaran[1], Meghana Eswarappa[1], Federico Narvaez[4], Guillermina Kuan[5], Andrea Nuñez[2], Angel Balmaseda[2], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [3]Sustainable Sciences Institute, Managua, Nicaragua, [4]Hospital Infantil Manuel de Jesús Rivera, Ministerio de Salud, Managua, Nicaragua, [5]Centro de Salud Sócrates Flores Vivas, Ministerio de Salud, Managua, Nicaragua

Chikungunya is a re-emerging infectious disease caused by a mosquito-borne arthrogenic alphavirus, chikungunya virus (CHIKV). The 12-kb positive-sense RNA genome contains a 5'UTR, non-structural protein genes (NS1-4), structural protein genes (C-E3-E2-6K-E1), and a 3'UTR. The disease involves sudden onset fever, intense pain and inflammation in joints, and muscles and an impaired ability to ambulate that lasts for months or years. Endemic areas include Africa and Asia. Since 2004, CHIKV has expanded into Europe and the Pacific region, and since the end of 2013, into the Caribbean and Central America. Viral sequences from St. Martin, the point of introduction in the Americas, belonged to the CHIKV Asian genotype. In Nicaragua, the first imported case was described in July 2014 and the first autochthonous case in September. Here, we sequenced CHIKV strains circulating in Nicaragua using samples from national surveillance and 2 ongoing pediatric studies in Managua: a community-based cohort and a hospital-based study. The initial sample set included 5 imported cases from August 2014 and 16 autochthonous cases from October 2014 to February 2015; sequencing of additional strains is underway. Whole genome amplification of nucleic acids isolated from serum samples, combined with Nextera technology, was used to generate libraries for deep sequencing on the HiSeq2000 platform (Illumina). Complete full-length sequence was obtained from one individual and partial genome sequence was obtained from 2 other samples. We also designed primers to amplify and sequence the E1 gene via Sanger methodology, yielding sequence from 5 imported and 14 autochthonous cases. Results to date indicate that the Nicaraguan strains belong to the Asian genotype and are similar to those in the Caribbean and Panama. Some of the autochthonous strains have silent mutations and some have non-synonymous mutations (e.g., E1-I173V or E1-V302I). All imported and autochthonous cases thus far contain E1-A226. Additional genome regions and samples are being analyzed to better understand the evolutionary dynamics of CHIKV during its introduction and dissemination in Nicaragua.

A ROLE FOR SYNDECAN PROTEOGLYCANS IN ALPHAVIRUS ENTRY

Whitney C. Lane, Kate D. Ryman, William B. Klimstra

University of Pittsburgh, Pittsburgh, PA, United States

Eastern equine encephalitis virus (EEEV) is unique among encephalitic alphaviruses in both its high rate of neurovirulence and its natural ability to bind cell surface heparan sulfate (HS). Among non-neurovirulent alphaviruses, efficient HS binding usually accompanies positive-charge mutation in the E2 attachment glycoprotein resulting from passage in cell culture. This type of cell culture adaptation typically renders the virus less virulent but for EEEV, HS binding is essential to its neurovirulence in adult mice and may facilitate mosquito infection. Thus, HS-binding residues in E2 are maintained in naturally circulating EEEV. Similarly, HS binding is critical for the neurovirulence of Sindbis viruses (SINV) containing a mutation at E2 position 55 selected for adult mouse virulence. We hypothesize that the connection between neurovirulence and HS binding for EEEV and neurovirulent SINV lies in their specific receptor usage. Using a Raji cell system that exhibits a receptor-entry defect and minimal infectivity for alphaviruses yet expresses forms of HS capable of non-productively binding HS-dependent alphaviruses, we have determined that syndecan proteoglycans can facilitate entry and productive infection of these cells by HS-dependent alphaviruses. Syndecans are a four-membered family of transmembrane glycosaminoglycans, each modified with multiple, distinct HS moieties. Notably, the capacity for infection facilitation by individual syndecans was different between different viruses suggesting qualitative differences in virus-HS receptor interactions. Effects of syndecan receptor utilization on replication and cellular responses to infection are currently being investigated.

138

INDUCTION OF HOST TRANSLATION SHUTOFF CONTRIBUTES TO THE ANTIVIRAL STATE RESISTANCE OF VENEZUELAN EQUINE ENCEPHALITIS VIRUS

Nishank Bhalla, Chengqun Sun, Long K. Lam, Kate D. Ryman, William B. Klimstra

University of Pittsburgh, Pittsburgh, PA, United States

Alphavirus antagonism of induction or effector phases of the IFN response is poorly understood. We recently demonstrated that eastern equine encephalitis virus (EEEV) avoids IFN-α/β and antiviral effector induction via microRNA-mediated suppression of virus replication in myeloid cells. Arthritogenic alphaviruses such as Sindbis virus (SINV) or chikungunya virus (CHIKV) cause a limited, non-fatal infection in adult mice suggesting limited antagonism of the IFN response. In contrast, Venezuelan equine encephalitis virus (VEEV) mouse infection is rapidly fatal, associated with systemic replication, widespread myeloid cell infection and rapid induction of high levels of serum IFN-α/β. In cell culture, VEEV replication is more resistant to the established antiviral state than SINV, CHIKV or EEEV. VEEV resistance is temporally associated with host macromolecular synthesis shutoff (transcription, translation or both) and STAT1 signaling blockade. In the current studies we found that increased resistance of VEEV was first evident after initial translation of viral genomes, and production of nonstructural proteins (nsPs). Using a plasmid expression system, we observed that expression of VEEV, SINV, CHIKV or EEEV nonstructural protein 2 (nsP2) alone each blocked STAT1 signaling. VEEV, SINV or CHIKV nsP2 or VEEV capsid, but not EEEV nsP2 inhibited cellular translation, while SINV and CHIKV nsP2 and VEEV or EEEV capsid, also inhibited cellular transcription. Importantly, VEEV nsP2 significantly reduced host translation in IFN-α/β primed cells while SINV nsP2 was less effective. Finally, VEEV nsP2 reduced the efficacy of the antiviral state versus other viruses in IFN-primed cells. Our results suggest that nsP2-mediated translation shutoff is an important factor in the antiviral state resistance of VEEV, and that closely related viruses such as VEEV and EEEV have evolved very different strategies to overcome innate antiviral responses.

139

EVIDENCE OF MICROSCALE HUMAN MOVEMENT DRIVING CHIKUNGUNYA SPREAD IN BANGLADESH

Henrik Salje[1], Kishor Paul[2], Andrew Azman[1], M. Waliur Rahman[2], Mahmudur Rahman[3], Derek Cummings[1], Justin Lessler[1], Simon Cauchemez[4], Emily Gurley[2]

[1]Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]IEDCR, Dhaka, Bangladesh, [4]Institut Pasteur, Paris, France

Human movement has been implicated in pathogen spread. However, evidence to support this role is limited as it requires good data on human movement and also a sound characterization of the spatial spread of pathogens, which is challenging where chains of transmission are unobserved. To address this knowledge gap, we collected nationally representative movement data from Bangladesh. We also collected detailed epidemiological data from an outbreak of chikungunya and developed models to characterize pathogen spread. We visited 70

randomly selected communities and gave ten individuals a GPS device that recorded their location every minute for up to four days and calculated the distance to their home. The chikungunya outbreak occurred in Tangail district in 2012. An investigation team visited every home in the outbreak village and collected information on disease symptoms from all individuals (N=1970). From this data, we fit transmission models using the time and location of symptom onset. In the movement study, we found that children (those under 16 years) were 0.9 as likely to be at home than adults (95% confidence interval: 0.7-1.1) at any time point. In addition females were 1.5 times more likely to be at home than males (1.2-1.8). When outside the home, individuals often still remained nearby, with a median distance between their location and home of 88m (77m-101m). These findings were virtually identical to our estimates of transmission risk in the chikungunya outbreak: we estimated the relative risk of children being infected was 0.9 compared to adults (0.7-1.2) and the relative risk of being infected for females was 1.5 times that for males (1.2-1.8). The median distance for transmission events outside the home was 95m (74-124). Basic mechanistic models demonstrated that these findings were consistent with infections happening within homes and that despite the presence of an intermediary vector, chikungunya spread is highly correlated with human movement (and lack of movement). Interventions to prevent chikungunya transmission, such as insecticides and removal of ovipositioning sites, should be targeted at small spatial scales.

140

DEVELOPMENT OF A CHIKUNGUNYA VACCINE CANDIDATE USING EILAT VIRUS AS A PLATFORM

Jesse Erasmus[1], Shannan Rossi[1], Grace Leal[1], Jason Kaelber[2], Wah Chiu[2], Vsevolod Popov[1], Farooq Nasar[3], Scott Weaver[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Baylor College of Medicine, Houston, TX, United States, [3]United States Army Medical Research Institute of Infectious Diseases, Frederick, MD, United States

In December of 2013, chikungunya virus (CHIKV), an alphavirus in the family ***Togaviridae***, was introduced into the island of Saint Martin in the Caribbean, resulting in the first autochthonous cases reported in the Americas. As of April 2015, CHIKV has been reported in 50 American countries with over 1.3 million suspected cases. CHIKV causes a severe arthralgic disease for which there are no approved vaccines or therapeutics. We developed a "pseudoinactivated" vaccine for the disease using Eilat virus (EILV) as a platform. EILV is an alphavirus isolated from a pool of mosquitoes collected in Israel. It replicates efficiently in insect cells but is unable to replicate in vertebrate cells. EILV is host-restricted in at least two points in its replication cycle: 1) attachment/entry, and 2) viral RNA replication. Our central hypothesis was that a chimeric alphavirus containing the non-structural protein genes of EILV and the structural protein genes of CHIKV will retain the vertebrate host restriction of EILV and provide safe, effective protection against CHIKV challenge. To test this hypothesis, we generated chimeric EILV/CHIK infectious cDNA using standard cloning techniques, and rescued the virus in insect cells. We then performed immunogenicity and safety experiments in mice. After a single vaccination, EILV/CHIK protected mice from disease following challenge with CHIKV, induced higher neutralizing antibody titers, and resulted in higher CD4+ and CD8+ T cell responses when compared to live-attenuated and inactivated vaccine strains of CHIKV. Additionally, EILV/CHIKV showed no neurovirulence in immunocompromised infant mice after intracranial inoculation. These results suggest that chimeric EILV/CHIKV can elicit a protective immune response against CHIKV challenge following a single dose in mice while maintaining an ideal safety profile, warranting its further development as a potential CHIK vaccine candidate.

141

CHARACTERIZATION OF VENEZUELAN EQUINE ENCEPHALITIS VIRUS NON-STRUCTURAL PROTEIN 3 WITH HOST FACTORS IN INFECTED CELLS

Moushimi Amaya, Aarthi Narayanan

George Mason University, Manassas, VA, United States

The mosquito-borne virus Venezuelan Equine Encephalitis Virus (VEEV) belongs to the ***Togaviridae*** family and is considered an important biodefense pathogen and select agent. There are currently no approved vaccines or therapies to treat the disease, therefore it is imperative to identify novel targets for therapeutic development. The VEEV genome encodes for 4 nonstructural proteins (nsP1-4) and 5 structural proteins (capsid, envelope 3 (E3), E2, 6K and E1). Apart from its role in viral RNA synthesis, nsP3 has not yet been fully characterized. Viral replication is facilitated by interaction of the nsPs with host factors involved in replication, translation and signaling, notably host kinases that are modulated by VEEV during infection. We have previously reported that VEEV-nsP3 interacts with the host protein Inhibitor of nuclear factor kappa-B kinase subunit beta. In our current study, we aim to investigate the effects of additional host-nsP3 interactions on the phosphorylation status of nsP3 and the consequences of these interactions on viral replication. An HA tagged nsP3 infectious clone (rTC-83-nsP3-HA) and expression plasmid was constructed. Replication kinetics and protein expression of rTC-83-nsP3-HA was compared to rTC-83 to ensure that the presence of the tag did not interfere with viral kinetics or viral protein production. It has been reported that there are several possible phosphorylation residues on nsP3 rendering it a highly phosphorylated protein and our mass spectrometry analysis corroborated those reports. Ongoing studies involve identifying host proteins that interact with nsP3 and investigating the effects of the identified interactions on the phosphorylation status of nsP3. This study will aid future investigations in identifying host proteins as potential broad spectrum therapeutic targets for treating VEEV infections.

142

A STOCHASTIC FRAMEWORK TO MODEL THE IMPORTATION OF CHIKUNGUNYA-INFECTED TRAVELLERS INTO THE US

Luis Mier-y-Teran-Romero, Michael Johansson

Dengue Branch, Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States

Chikungunya virus (CHIKV) is transmitted by the bite of infected mosquitoes of certain species, including ***Aedes aegypti*** and ***Aedes*** albopictus which are quite common in the American continent. Though rarely fatal, Chickungunya disease often produces severe symptoms in those infected and can persist for several months or even years after the virus is cleared from the human host. From the month of December 2013 to February of 2015, the Pan-American Health Organization (PAHO) reported more than 1.25 million cases in the continent, most of them concentrated in South and Central America and the Caribbean. In the absence of vaccines and treatments specific to Chikungunya, a good understanding of the mechanisms of CHIKV transmission is critical to guide policies aimed at limiting further propagation of the disease. In this work, we developed a stochastic modeling framework in order to estimate the number of monthly arrivals of CHIKV-infected individuals at each state of the US. Our framework is built by incorporating PAHO prevalence data from the affected countries in the American continent together with detailed data for airline travel from these same source countries into the US. A comparison of our importation estimates with US surveillance data at the state level shows reasonable agreement and suggests significant under-reporting at many of the source countries. Our framework, coupled with country-level forecasts, should prove useful to local public health officials for obtaining estimates of the expected number of imported Chikungunya cases during outbreaks abroad.

143

MOLECULAR CHARACTERIZATION OF CIRCULATING CHIKUNGUNYA VIRUS IN SUCRE - COLOMBIA

Erwin Camacho Burgos, **Margaret Paternina Gomez**, Viviana Ruiz, Sindy Martinez, Sindy Cabarca, Pedro Blanco

Investigaciones Biomédicas - Universidad de Sucre, Sincelejo, Colombia

Chikungunya virus (CHIKV) is an Alphavirus from the Togaviridae family transmitted by mosquitoes. With an approximately 12 Kb single-stranded genome, two open reading frames code two polyproteins: structural (C, E3, E2, 6K y E1) y nonstructural (nsP1, nsP2, nsP3 y nsP4) proteins. It have been identified three genotypes related to their geographic origin: West African, East/Central/South African (ECSA) and Asian. The virus cause a disease with signs and symptoms very similar to other prevalent diseases in tropical areas, but the main clinical symptom is a painful and invalidating poly-arthralgia. The first case in America was reported in December 2013 in Saint Martin´s Island and in September 2014 an endemic outbreak started in Colombia. Until February 2015 in Colombia 189.959 cases have been reported and 19.365 in the department of Sucre. In this study we describe the molecular detection of CHIKV in febrile patients and corresponding genotype present in Sucre - Colombia, during the 2014 - 2015 outbreak in the country. There were collected serum samples and clinical information from Chikungunya fever compatible participants, during acute phase. Molecular detection of CHIKV was performed by RT-PCR with specific primers (nsP1). Positive samples were passed in C6/36 cells to obtain viral isolates and supernatants were used to amplify and sequence E1 gene for further phylogenetic analysis (Bayesian inferences). A total of 128 participants were included in the study from November 2014 to February 2015, been the arthralgia and rash the more frequent clinical findings. Forty-two (32.8%) participants were positive for molecular detection with an average age of 20 years old. There were identified 19 isolates causing cytopathic effect to cell monolayers. Phylogenetic analysis with 1044 nt complete E1 gene sequences revealed that all isolates belonged to the Asian genotype, with genetic distances below 1% within them. The Asian genotype with recent introduction in the Americas was circulating in the department of Sucre during 2014-2015 outbreak and with no significant genetic changes to those previously reported isolates in other geographic areas.

144

EILAT VIRUS HOST RANGE RESTRICTION IS PRESENT AT MULTIPLE LEVELS OF THE VIRUS LIFE CYCLE

Farooq Nasar[1], Rodion V. Gorchakov[2], Robert B. Tesh[1], Scott C. Weaver[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Baylor College of Medicine, Houston, TX, United States

Most alphaviruses are mosquito-borne and exhibit a broad host range, infecting many different vertebrates, including birds, rodents, equids, humans, and nonhuman primates. This ability of most alphaviruses to infect arthropods and vertebrates is essential for their maintenance in nature. Recently, a new alphavirus, Eilat virus (EILV), was described, and in contrast to all other mosquito-borne viruses, it is unable to replicate in vertebrate cell lines. Investigations into the nature of its host range restriction showed the inability of genomic EILV RNA to replicate in vertebrate cells. Here, we investigated whether the EILV host range restriction is present at the entry level and further explored the viral factors responsible for the lack of genomic RNA replication. Utilizing Sindbis virus (SINV) and EILV chimeras, we show that the EILV vertebrate host range restriction is also manifested at the entry level. Furthermore, the EILV RNA replication restriction is independent of the 3′ untranslated genome region (UTR). Complementation experiments with SINV suggested that RNA replication is restricted by the inability of the EILV nonstructural proteins to form functional replicative complexes. These data demonstrate that the EILV host range restriction is multigenic, involving at least one gene from both nonstructural protein (nsP) and structural protein (sP) open reading frames (ORFs). As EILV groups phylogenetically within the mosquito-borne virus clade of pathogenic alphaviruses, our findings have important evolutionary implications for arboviruses.

145

A NOVEL METHOD TO IDENTIFY THE MOST POTENT HUMAN MONOCLONAL ANTIBODIES AGAINST DENGUE VIRUSES

Trung T. Vu[1], Long T. Vo[1], Dui T. Le[1], Nhu T. Vu[1], Cameron P. Simmons[2]

[1]Oxford University Cinical Research Unit, Ho Chi Minh, Vietnam, [2]Department of Microbiology & Immunology, University of Melbourne, Victoria, Australia

We have developed an ***ex vivo*** viremic blood neutralization assay (ViBNA) that uses viremic blood from hospitalized dengue patients, human mAbs and ***Aedes aegypti*** mosquitoes. The ViBNA allowed us to rank a panel of human mAbs for their potency in neutralizing the infectiousness of dengue virions for ***Ae. aegypti*** mosquitoes. Our data identifies human mAbs that bind quaternary epitopes within or between DENV homodimers as the most potent class of antibodies elicited by natural DENV infection. Other classes of mAbs, such as those that bind the fusion loop or domain III, were less potent or not potent at all in blocking transmission of DENV. Our results set a new benchmark for evaluating the potency and relevance of human mAbs and have implications for identifying correlates of immunity and for mAb-based therapeutic strategies.

146

SCREENING OF DENGUE VIRUSES IN HUMAN SERA AND ANALYSIS OF SPECIFIC SEROTYPES FROM LAHORE PAKISTAN

Nusrat Jahan, Noreen Mumtaz

GC University Lahore, Lahore, Pakistan

Dengue is a vector borne viral infection which poses a serious threat to public health in most of the tropical and subtropical countries around the world, including Pakistan. Dengue has been occurring as an annual epidemic since 2006 in Pakistan. More than fifteen thousand cases were listed in 2011 from Punjab with about > 250 deaths. Dengue situation is alarming with high risk of epidemics in future. About four antigenically varying dengue viruses are reported for dengue infection. Current study was designed to detect Dengue viruses with molecular detection of dengue serotype using RT-PCR in infected human sera. Dengue infected human sera (n=100) were collected during July 2013 to January 2014 for screening of DENV serotypes using dengue NS1 AG specific ELISA kit. DENV positive samples (n=40) were used for molecular detection of dengue viruses serotypes by reverse transcriptase PCR (RT-PCR) using universal and type specific primers for dengue viruses nucleotide sequencing targeting the C-prM gene junction. Among forty dengue NSI AG ELISA positive samples, 12 sera (30%) were found positive with type specific nested PCR. Out of 12 PCR +ve samples, five samples (41.6%) were positive for each DEN-2 and DEN-3. Whereas, two samples (16.6%) revealed the simultaneous presence of DEN-2 and DEN-3 serotypes. In conclusion, current study documented for the first time the detection of dengue viruses serotypes in human sera with DEN-2 and DEN-3 prevailing serotypes during the study period in Lahore, Pakistan. Detection of particular prevailing serotype will be useful to control the spread of dengue disease in Pakistan.

147

EVALUATION OF A DENGUE DECISION SUPPORT TOOL

Rachel Lowe[1], Christovam Barcellos[2], Caio A. Coelho[3], Rafael De Castro Catão[4], Trevor C. Bailey[5], Giovanini Evelim Coelho[6], Walter Massa Ramalho[7], Marilia Sá Carvalho[2], David B. Stephenson[5], Xavier Rodó[1]

[1]Institut Català de Ciències del Clima (IC3), Barcelona, Spain, [2]Fundação Oswaldo Cruz (FIOCRUZ), Rio de Janeiro, Brazil, [3]Centro de Previsão de Tempo e Estudos Climáticos (CPTEC), Cachoeira Paulista, Brazil, [4]Universidade Estadual Paulista (UNESP), Presidente Prudente, Brazil, [5]University of Exeter, Exeter, United Kingdom, [6]Ministério da Saúde, Brasilia, Brazil, [7]Universidade de Brasília, Brasília, Brazil

In order to prepare for disease epidemics, decision support systems, which take into account multiple risk factors, are required to implement timely control measures. Seasonal climate forecasts and strong disease surveillance systems provide an opportunity to anticipate epidemics several months in advance. A prototype decision support tool was developed for dengue fever and tested ahead of the FIFA football World Cup, June 12-July 13, 2014, in Brazil. Probabilistic dengue forecasts for June 2014 were generated using a spatio-temporal modelling framework. The model was driven by seasonal climate forecasts and the observed epidemiological situation in Brazil at the forecast issue date. The forecasts were made available three months ahead of the games. Here, we evaluate the ability of the model framework to correctly determine the occurrence of low-, medium- and high-risk of dengue for the 12 host cities and all 553 microregions in Brazil, by comparing the probabilistic predictions to the observed dengue incidence rates for June 2014. For the 12 microregions of interest, the forecast achieved a hit score of 75%. For all 553 microregions across Brazil the forecast achieved a score of 70%. This decision support model framework may be useful, not only ahead of mass gatherings, but also before the peak dengue season each year, to control or contain potentially explosive dengue epidemics. It is hoped that this prototype will serve as an example for scientists, international health surveillance teams and decision makers of the data and tools required to produce and communicate timely predictions of climate-sensitive disease risk.

148

COMPARISON OF HEAMAGGLUTINATION INHIBITION ASSAY (HAI) AND ANTI-IGG MONOCLONAL ANTIBODY ELISA (IGG-MAB ELISA) BY USING 4G2 (FLAVIVIRUS MAB), 2H2 (DENGUE COMPLEX MAB), AND J93 (JE MAB) FOR DETECTION OF ANTI-DENV/JEV IMMUNOGLOBULIN G

Kanittha Sirikajornpan, Stefan Fernandez, Ananda Nisalak, Butsaya Thaisomboonsuk, In-Kyu Yoon

Department of Virology, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Hemagglutination Inhibition assay (HAI) is commonly used for serology diagnosis of DENV and JEV infections. However, HAI is time- and resource-intensive, because of the multiple steps required for serum processing. The purpose of this study was to evaluate if a monoclonal antibody-based capture enzyme-linked immunosorbent assay (mAb ELISA), is equally effective for IgG screening of DENV/JEV infections as the more traditional HAI. The IgG-mAb ELISA originally developed by Johnson, et al. uses the 4G2 monoclonal antibody (Flavivirus mAb), which targets the envelope protein on the surface of dengue virus (DENV). We selected 170 pairs of acute and convalescent serum specimens collected during routine DENV surveillance in Kamphaeng Phet, Thailand, in 2004-2005. These specimen pairs underwent testing by HAI to measure changes in neutralizing titers, followed by plaque reduction neutralization test (PRNT50) as confirmatory testing. Comparison of HAI and IgG-mAb ELISA showed that the specificity of the IgG-mAb ELISA was 100.0% when using the 4G2 mAb or when using the alternative 2H2/J93 mAbs. The sensitivity was 92.9% and 97.6% for 4G2 and 2H2/J93 mAbs, respectively. Our study supported that the results of both IgG-4G2 and IgG-2H2/J93 mAbs ELISAs correlated highly with the DENV/JEV HAI assay. Therefore, the anti-DENV/JEV IgG-mAbs ELISA is a potential assay for serological screening of DENV/JEV infections.

149

THE PREVALENCE OF DENGUE IN GRENADA: A FIVE-YEAR RETROSPECTIVE STUDY

Shanice McKain[1], Kevin King[1], Daniel High[1], Grant Lambert[1], Ravindra Naraine[1], Paul Fields[2], Amy Baldwin[1]

[1]St. George's University, St. George's, Grenada, [2]The Windward Islands Research and Education Foundation, St. George's, Grenada

Dengue has been endemic in Grenada for decades and ranks high among re-emerging pathogens that have increased globally. The goal of this study was to determine the recent prevalence of dengue and its serotypes (DENV 1-4) in Grenada. Our target population included symptomatic persons who sought care at the St. George's University (SGU), University Health Services (UHS) during 2009 - 2013. Individuals from our target population completed an Investigation Form for Suspected Dengue Infection, which included general patient data, questions about travel history and possible signs and symptoms associated with dengue. Dengue seropositivity was determined for all 298 samples taken over the five-year period; 90 were confirmed to be positive (30.2%). The annual prevalence of dengue from 2009 to 2013, based on serology, was found to be 34.38%, 36.96%, 26.79%, 16.21% and 29.27%, respectively. The CDC DENV-1-4 Real-Time RT-PCR Assay (Multiplex) was used for the detection and serotype identification of the dengue virus in seropositive samples taken during the acute phase. Sixty-five (65) of the 90 serologically confirmed dengue samples and 11 of the serologically negative samples were processed by qPCR. Serology data was compared to dengue qPCR data from the target population. The qPCR results showed that DENV-1 and DENV-2 were present in 2010, DENV-1 was present in both 2011 and 2012 and DENV-1 and DENV-4 were present in 2013. From the data gathered, it appears that dengue cases peak between August to November, which coincides with our rainy season. The highest prevalence was seen in 2010, and the lowest prevalence was seen in 2012. This study provides novel data on the prevalence of currently circulating dengue serotypes in Grenada. Our data will provide critical information for the formation of public health policies that will be developed for the control of mosquito-borne diseases such as dengue in Grenada. Future studies will include the sequencing of the detected DENV serotypes to determine the predominantly circulating strains.

150

INFLUENCE OF MATERNAL IGG PROFILE ON PLACENTAL TRANSFER OF DENGUE VIRUS-SPECIFIC ANTIBODIES TO NEONATES

Priscila M. Da Silva Castanha[1], Eduardo J. Nascimento[2], Marli T. Cordeiro[1], Ariani I. Souza[3], Claudeir D. Silva, Jr.[3], Willem G. Panhuis[4], Celina T. Martelli[5], Ernesto T. Marques, Jr.[2], Cynthia Braga[1]

[1]Centro de Pesquisas Aggeu Magalhaes, Recife, Brazil, [2]Center for Vaccine Research, University of Pittsburgh, Pittsburgh, PA, United States, [3]Instituto de Medicina Integral Prof. Fernando Figueira, Recife, Brazil, [4]Department of Epidemiology, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States, [5]Instituto de Patologia Tropical e Saude Publica, Goiania, Brazil

Maternally transferred dengue IgG antibodies are likely to play an essential role in immunity and pathogenesis of dengue infection in infants. In order to investigate the kinetics of dengue-specific maternal antibodies transferred to children in the first years of life, a birth cohort of children living in an area of intense circulation of dengue virus in the northeast of Brazil has been established. Here, we carried out the analysis of 376 mother-newborn pairs to investigate the transference of antigen-

specific antibodies via placenta. Maternal and umbilical cord samples were obtained during the time of delivery. Serotype-specific antibody profile was determined by PRNT, while in-house ELISA was used to both measure DENV-specific IgG titers (total and subclasses) and quantify IgG in the sera. Antibody titers were log-transformed and placental transfer calculated as ratio (value infant/value mother). In maternal sera, 202 out of 376 (53.7%) showed a monotypic profile against DENV3, 30.6% to the combination of DENV3/DENV4 and 5.3% had detectable neutralizing antibodies against others serotypes combinations. Dengue-specific IgG titers were significantly higher in cord blood than in maternal samples ($p<0.05$), which is consistent with an active transport mechanism across the placenta. Same pattern was also observed when comparing serotype-specific antibodies titers to DENV3 and DENV4 in infants and mothers. DENV-specific IgG1 were more efficiently transferred to the neonate than IgG4 antibodies. More importantly, higher levels of maternal total IgG antibodies were associated with reduced transference of total IgG (R-squared=0.3015, $p<0.05$) and DENV3 antibodies to the neonate (R-squared=0.0129, $p=0.021$). Additionally, placental transference of DENV-specific IgG was reduced in mothers who experienced multitypic previous infections. These results suggest that maternal IgG levels directly influence placental transfer of DENV-specific antibodies and, thus, may contribute for dengue immunophatology on neonates.

ACUTE FEBRILE ILLNESS DUE TO DENGUE VIRUS INFECTIONS AMONG CHILDREN IN WESTERN KENYA

Bryson A. Ndenga[1], Noah Mutai[1], Claire Heath[2], David Vu[2], Francis Mutuku[3], Dunstan Mukoko[3], John Vulule[1], Charles King[4], Angelle D. LaBeaud[2]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Stanford University, Stanford, CA, United States, [3]Ministry of Health, Division of Vector Borne and Neglected Diseases, Nairobi, Kenya, [4]Case Western Reserve University, Cleveland, OH, United States

Although dengue virus (DENV) is the most common arthropod-borne viral disease, little is known about DENV burden and disease between epidemics. Recent outbreaks of DENV have occurred in coastal Kenya; therefore, there is a need to confirm the presence of dengue virus infections and disease elsewhere in Kenya. Febrile children, aged 2-17 years, presenting at Chulaimbo (rural site) and Obama Children's (urban site) hospitals in western Kenya had RNA extracted from whole blood and standard PCR was performed in a two-step protocol (pan-DENV followed by DENV serotyping). Malaria testing by microscopy was performed on all samples. Of 113 children tested, 31 (27%) were positive, and 82 (73%) were negative. Those from the rural site were more likely to be positive ($p<0.05$): 12% (4/33) were positive from the urban site vs. 34% (27/80) from the rural site. There was no statistical difference between genders. Older children were more likely to be acutely infected (mean age 5.3 vs. 3.6 years; $p<0.01$). All positive samples were DENV 1. For acute DENV infections, mean days of illness were 2.3, mean temperature was 38.9°C and was statistically higher in the DENV positive group ($p<0.05$). No children with acute DENV were hospitalized. DENV positives were more likely to be from households with more residents ($p<0.05$). DENV cases from the rural area occurred from July 11 to November 14, 2014, after the long rains. Sixty-one percent of samples were blood smear positive for malaria and 78% of DENV positives were blood smear positive. Testing is ongoing and positive PCR results will be confirmed by sequencing. In conclusion, preliminary findings of this study confirm the existence of acute dengue virus infections with resultant febrile disease in childhood from serotype DENV1 in both rural and urban villages in western Kenya. The rural village site was more likely to have acute dengue cases than the urban site, and they occurred toward the end of the rainy season. Those with acute DENV were malaria blood smear positive in most cases, therefore on site diagnosis needs to be available for accurate classification of febrile disease etiology.

152

AN IMMUNOGENICITY OF E-DOMAIN III IS BOOSTED BY TRIMETHYL CHITOSAN (TMC) NANOPARTICLES DELIVERY SYSTEM

Nattika Nantachit[1], Panya Sunintaboon[2], Sukathida Ubol[1]

[1]Department of Microbiology, Faculty of Science, Mahidol University, Bangkok, Thailand, [2]Department of Chemistry, Faculty of Science, Mahidol University, Bangkok, Thailand

Dengue virus infection is a major public health problem due to its high prevalence, rapid transmission, and serious complication. Many attempts were made to establish the preventable vaccine. One of great interest is a subunit vaccine due to its safety, ease of dose adjustment, the large scale in manufacturing. Unfortunately, subunit vaccine is poor in immunogenicity. To overcome this limitation, nanoparticle delivering system is applied to achieve an accurate immunization. A key feature of nanoparticle-delivered vaccine is its ability to simultaneous deliver antigen with adjuvanticity to specialized immune cells. In this study, the potential use of trimethyl chitosan (TMC) nanoparticles (NPs) as an adjuvant and delivery system for E-domain III of dengue virus type 3 (EDIII) was investigated. Recombinant soluble EDIII was produced using ***Pichia pastoris*** expression system. Western blotting with EDIII-specific antibody demonstrated that antigenicity of EDIII was preserved. Purified EDIII was reacted with TMC under ionotropic gelation method to form EDIII-TMC NPs. The EDIII-TMC NPs possess mean particles size of 255 nm with narrow size distribution and positive charge. Immunoblot analysis revealed that the integrity of entrapped EDIII was preserved. A release study showed that within 24 h more than 70% of EDIII disassociated from TMC NPs at 37°C, pH 5. The immunogenicity of EDIII-TMC NPs was then evaluated using an ***ex vivo*** model, primary human dendritic cells (DCs). The EDIII-TMC NPs-treated DCs exhibited a viability exceeding 90% at 48 h of treatment. Flow cytometric analysis showed the strong up-regulation of maturation markers on treated DCs. The EDIII-TMC NPs-treated DCs cultures increased production of various cytokines including proinflammatory cytokines (IL-1β, IL-6, TNF-α), Th1-inducing cytokines (IFN-γ, IL-2, IL-12p70), Th2-inducing cytokine (IL-10), chemokines (MIP-1β, MCP-1), growth factors (G-CSF, GM-CSF). In conclusion, the EDIII-TMC NPs was successfully developed and was shown to exert strong immunogenicity. These findings highlight the potential of using TMC NPs as an adjuvant delivery system for dengue vaccine.

153

ANALYSIS OF VIRAL QUASISPECIES AND DENGUE DISEASE SEVERITY BASED ON NEXT GENERATION SEQUENCING DATA

Ma. Jowina H. Galarion, Brian E. Schwem, Coleen M. Pangilinan, Raul V. Destura

National Institutes of Health, Manila, Philippines

The error-prone nature of RNA polymerase and the intra-serotypic recombination due to rapid geographical spread of dengue cause high mutation rates in the viral genome, resulting in a genetically diverse population of viruses known as quasispecies. Although quasispecies have been well studied in the pathogenesis of chronic infections, its role in acute infections such as dengue remains to be elucidated. The analysis of dengue quasispecies is imperative especially in geographically-isolated countries, such as the Philippines, where there is a notable persistence of a single genotype yet dengue hemorrhagic fever epidemic cycles and severe forms of the disease are exhibited. In this study, next generation sequencing was used to analyze the sequences and estimate the frequencies of quasispecies isolated from 20 acute dengue serum samples, and correlate the genomic variations to disease progression and severity. Viral RNA was extracted from confirmed dengue sera with well-defined clinical profiles and prepared for whole genome sequencing with the Illumina MiSeq. Software packages ShoRAH and ViQuas were used in parallel for the quasispecies inference and reconstruction pipeline. The diversity and estimated frequencies of reconstructed haplotypes were

subsequently compared to the samples' clinical profiles. The sequences are currently undergoing quasispecies analysis. Once completed, the diversity and frequency of the quasispecies will be compared to the severity of disease corresponding to the sample. The target date of completion for this study is on June 30, 2015.

154

CELLULAR ANTIVIRAL RESPONSE AGAINST DENGUE VIRUS REPLICATION

Cybele C. Garcia

Laboratory of Virology, Biochemistry Department, School of Sciences, University of Buenos Aires, Buenos Aires, Argentina

The intrinsic antiviral defense is based on cellular restriction factors that are constitutively expressed and, thus, active even before a pathogen enters the cell. The promyelocytic leukemia (PML) nuclear bodies (NBs) are discrete nuclear ***foci*** that contain several cellular proteins involved in intrinsic antiviral responses against a number of viruses, but little information is available regarding the antiviral role of PML against RNA viruses. Dengue virus (DENV) is an RNA emerging mosquito-borne human pathogen affecting millions of individuals each year by causing severe and potentially fatal syndromes. Since no licensed antiviral drug against DENV infection is currently available, it is of great importance to understand the factors mediating intrinsic immunity which may lead to the development of new pharmacological agents. In the present study, we investigated the ***in vitro*** antiviral role of PML in DENV-2 A549 infected cells. First, we evaluated the impact of PML silencing and overexpression on DENV-2 replication. The silencing of all PML isoforms caused about 0.76 log increment in DENV-2 titre. On the other hand, the PMLIV isoform overexpression reduced significantly the extracellular DENV-2 production. These results were in accordance with the viral antigen expression observed by immunofluorescence. Moreover, we analyzed the intracellular localization of PML-NBs during DENV-2 replication. Confocal microscopy images showed that the typical punctuate nuclear staining pattern of PML-NBs was lost during DENV-2 infection. Furthermore, it was observed a weak viral protein signal in neighboring cells, which also displayed increased number and size of PML-NBs. The pattern of PML did not change during the early stages of infection, and only after the new progeny of DENV-2 was released, a reduction in PML-NBs staining was observed. Altogether these results strongly suggest that a viral protein might be responsible of the PML-NBs disruption. These host- virus interactions may serve as targets for antiviral intervention.

155

POST CHIKUNGUNYA EPIDEMIC CLUSTER OF DENGUE-1 VIRUS INFECTION AMONG SCHOOL CHILDREN IN GRESSIER REGION, OUEST DEPARTMENT OF HAITI

Maha A. Elbadry[1], Madsen Beau De Rochars[1], Mohamed Rashid[1], Glenn Morris[1], Jacques Boncy[2], Yves Jean Frantz Louis[3], John Lednicky[1], Bernard Okech[1]

[1]University of Florida, Gainesville, FL, United States, [2]National Public Health Laboratory, Delmas, Haiti, [3]d'Épidémiologie de Laboratoire et de Recherche, Delmas, Haiti

Dengue is the most common tropical and subtropical mosquito-borne viral infection caused by four distinct serotypes (1-4). In May 2014 an outbreak of chikungunya virus (CHIKV) started in the Ouest department in Haiti and the epidemic spread throughout the country. As the epidemic waned in the fall of 2014; febrile illnesses among a cohort of school children in the Gressier region remained relatively high. 177 febrile cases suspected for CHIKV infection reported from September 2014 to February 2015were tested for CHIKV and all four DENG serotypes using RT-PCR. Fourteen percent (25/177) were positive for Dengue-1 virus by RT-PCR while none were positive for CHIKV. The results indicate a common misdiagnosis of CHIKV, and active back to back transmission of DENG-1 virus in this region of Haiti.

156

EVIDENCE OF TRANSMISSION OF DENGUE AND CHIKUNGUNYA VIRUSES IN WESTERN KENYA

David M. Vu[1], Sandra Musaki[2], Bryson A. Ndenga[2], Francis M. Mutuku[3], Eva Harris[4], Mark T. Heise[5], Dunstan Mukoko[6], John Vulule[2], Uriel Kitron[7], Charles H. King[8], A. Desiree LaBeaud[1]

[1]Division of Infectious Diseases, Department of Pediatrics, Stanford University School of Medicine, Stanford, CA, United States, [2]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [3]Technical University of Mombasa, Mombasa, Kenya, [4]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [5]University of North Carolina School of Medicine, Chapel Hill, NC, United States, [6]Division of Vector Borne and Neglected Diseases, Ministry of Health, Nairobi, Kenya, [7]Department of Environmental Sciences, Emory University, Atlanta, GA, United States, [8]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States

Dengue virus (DENV) and chikungunya virus (CHIKV) are important re-emerging mosquito-borne pathogens that have been spreading rapidly, causing endemic and epidemic disease in tropical and sub-tropical regions. For many African countries, limited resources and lack of national surveillance systems make evaluating the true burden of DENV and CHIKV disease difficult. In 2014, we initiated a prospective study to measure DENV and CHIKV incidence in children who develop febrile illnesses, and seroprevalence among healthy children in western and coastal Kenya. Testing of serum samples for IgG and IgM to DENV and CHIKV by ELISA is ongoing, and neutralizing antibodies will be measured in a subset of samples. Preliminary results from IgG assays of samples from children residing in western Kenya confirm active transmission of both DENV and CHIKV. Specifically, among children who presented at the local health center with undetermined febrile illness from whom paired acute and 1-month convalescent serum samples were obtained, 1 of 221 (0.5%) paired sera from children who resided in the rural village of Chulaimbo demonstrated seroconversion for DENV IgG vs. 3 of 117 (2.6%) paired sera from children residing in Kisumu, a large urban center (p=0.12). For CHIKV IgG, 6 of 209 (2.9%) sera from Chulaimbo children seroconverted vs. none of 115 in Kisumu children (p=0.09). Further, we found that among healthy children, 11.5% of Chulaimbo children were positive for serum DENV IgG vs. 2.8% of Kisumu children (p=0.0003). CHIKV IgG seroprevalence was similar between rural and urban centers (6.8% in Chulaimbo vs. 6.3% in Kisumu, p=1.0). No difference in seroprevalence was noted based on gender, overall or by location, with 39% of DENV- and 41% of CHIKV-seropositive children female. Children who were seropositive for either virus were older than seronegative children (mean age 8.6 vs. 7.1 years, p≤0.0001). These data provide evidence that DENV and CHIKV transmission is presently occurring in western Kenya and underscore the need for surveillance of these rapidly re-emerging infections to monitor developing outbreaks and allocate limited public health resources.

157

GENETICALLY MODIFIED *AEDES AEGYPTI*: THE SOLUTION TO OUR PROBLEM?

Chidinma B. Okafor

Armstrong State University, Savannah, GA, United States

This presentation intends to analyze the workings of the ongoing genetically modified ***Aedes aegypti*** initiative and its possible elimination of the spread of dengue fever, yellow fever and chikungunya. The diseases associated with ***A. aegypti*** are public health burdens with high incident and prevalent rates in Africa, Asia, Europe and Americas leading to morbidity and mortality. This exposition addresses the following question: What are the breeding mechanisms of genetically modified ***A. aegypti***? How can these modified arthropods play a role in the elimination of dengue fever, yellow fever and chikungunya? What are the possible

adverse effects in humans? To answer these questions, this study critically examines ongoing research and experimental results pertaining to this innovation. Moreover, it will offer recommendations for continuous eradication of dengue fever, yellow fever and chikungunya.

158

DENGUE AND MALARIA: ETIOLOGIES OF ACUTE FEBRILE ILLNESS IN ABIDJAN, IVORY COAST, 2011-2012

Maïna L'Azou[1], Tiphanie Succo[1], Mamadou Kamagaté[2], Abdoulaye Ouattara[3], Elia Gilbernair[4], Edgar Adjogoua[5], Christine Luxemburger[1]

[1]Sanofi Pasteur, Lyon, France, [2]University Hospital of Cocody, Abidjan, Côte D'Ivoire, [3]Institut Pasteur de Côte d'Ivoire, Abidjan, Côte D'Ivoire, [4]Sanofi Pasteur, Abidjan, Côte D'Ivoire, [5]Institut Pasteur, Abidjan, Côte D'Ivoire

Dengue disease is endemic in most tropical areas; however, dengue burden is uncertain in Africa. A prospective study was conducted in two hospital settings in Abidjan, Ivory Coast, from December 2011 to December 2012 to estimate the proportion of dengue and malaria cases among febrile patients and to describe the clinical and virological features of confirmed dengue cases. One week per month, blood samples were taken from patients of all ages who presented to outpatients clinics with fever (≥38°C). Patients with fever for more than 7 days, or a fever of known origin, and patients with jaundice were excluded. Thick blood films were examined and anti-DENV IgM and reverse transcription-polymerase chain reaction (RT-PCR) were performed. Eight hundred and twelve (812) subjects were studied (48.3 % women and 51.7% men) with 46.4 % of patients aged less than 9 years old. Seven hundred ninety six subjects (796; 98%) were tested for anti-dengue virus IgM and RT-PCR and thick blood film tests were performed on 807 samples. Four hundred and nine subjects (409; 50.4%) were clinically diagnosed as malaria, and no dengue case was reported based on clinical diagnosis. Three febrile patients (0.4%) had laboratory-confirmed dengue with one sample positive for DENV-3 and 234 patients (29%) had laboratory-confirmed malaria. This study confirmed the presence of dengue virus in Abidjan outside of an epidemic. These results continue to question dengue transmission in Africa and stress the importance of laboratory capacity to ascertain dengue burden in Africa.

159

STATISTICAL FITS OF MINIMAL WITHIN-HOST MODELS PROVIDE INSIGHTS INTO VIROLOGICAL DIFFERENCES BETWEEN DENGUE SEROTYPES

Rotem Ben-Shachar, Katia Koelle

Duke University, Durham, NC, United States

Dengue infections range in severity from asymptomatic infection to life-threatening dengue hemorrhagic fever and dengue shock syndrome. Though dengue pathogenesis is still poorly understood, epidemiological studies have shown that a heterologous secondary infection and the infecting serotype are important risk factors. Here, we present mathematical within-host models of primary and secondary dengue infections that are the first to quantitatively describe how the interaction of the immune system with dengue virus leads to high cytokine production that impacts the probability of manifesting severe disease. Statistical fits of these models to viral load data from a clinical cohort of patients infected with dengue serotypes 1, 2, or 3 yield two hypotheses for important virological differences between dengue serotypes: (1) serotypes differ in their infectivity of host cells; and (2) serotypes differ in their ability to subvert viral clearance mechanisms. We show that dengue disease risk critically depends on which of these two hypotheses are at play. This work highlights the complex relationship between serotype-specific dengue viral load patterns and the risk of developing disease, and the critical need for viral load data early on in infection to discriminate between these hypotheses.

160

DESIGNING MULTIFACETED DENGUE SURVEILLANCE SYSTEMS

Samuel V. Scarpino[1], Lauren Ancel Meyers[2], Michael A. Johansson[3]

[1]Santa Fe Institute, Santa Fe, NM, United States, [2]The University of Texas at Austin, Austin, TX, United States, [3]Harvard T.H. Chan School of Public Health, Boston, MA, United States

Dengue is a mosquito-borne viral disease that affects millions of people every year. Timely and accurate surveillance of dengue at multiple geopolitical scales is critical to prevention and control. Despite their clear importance, surveillance systems are often shaped by historical, logistical and economic constraints rather than optimized to address specific objectives. Here, we designed and evaluated a sentinel surveillance system to monitor regional, island-wide, and serotype-specific dengue incidence in Puerto Rico. Using 15 years of historical clinic-level dengue data, we identified the subset of clinics that best achieves these diverse surveillance objectives. The optimal group of 22 clinics identified by our methodology is expected to be almost as informative as the entire system of 105 clinics, and more informative than subsets of clinics chosen using alternative criteria such as patient volume and geographic diversity of clinics or patients. In out-of-sample validation, the optimized system captured more than 78% of the spatiotemporal variation for each objective: 86% for serotype-specific incidence, 78% for regional incidence, and 97% for island-wide incidence. In general, our data-driven selection method can identify sentinel surveillance sites that robustly achieve diverse public health objectives.

161

TEMPERATURE ALTERS DENGUE VIRUS BLOCKING BY *WOLBACHIA* IN MOSQUITOES

Henry Yixin Ye, Alison Carrasco, Yi Dong, Scott O'Neill, Elizabeth McGraw

Monash University, Melbourne, Australia

Up to half of the world's population is at risk of contracting dengue, a disease caused by the dengue virus (DENV) and transmitted by mosquitoes. ***Wolbachia pipientis***, an obligate intracellular bacterium, is being developed as a biocontrol strategy against dengue because it limits replication of the virus in the mosquito. The ***Wolbachia*** strain ***w***Mel, which has been stably introduced into the mosquito vector, ***Aedes aegypti,*** has been shown to invade natural mosquito populations and spread to near fixation in field releases. However, conditions in the field can differ substantially from those in the laboratory and environmental factors such as temperature affect the infection and transmission of DENV in mosquitoes. Recently, the diurnal temperature range (DTR), which reflects the variation and fluctuation in temperature that occurs from the highs and lows during the day was found to significantly change the outcome of infection of the mosquitoes as compared to a constant temperature that is normally used in laboratories. Here, we studied the dissemination and transmission rate of DENV in ***A. aegypti*** under three temperature regimes (25±0°C constant, 25±4°C diurnal and 28±4°C diurnal). Firstly, we found that the constant temperature of 25±0°C overestimates the dissemination rates and transmission potential of the virus as compared to a diurnal temperature of 25±4°C. Raising the baseline of the diurnal temperature from 25±4°C to 28±4°C enhances the dissemination rates and transmission potential of the virus in the mosquitoes. Secondly, ***Wolbachia*** mediated virus blocking in terms of DENV infection rate in mosquito head and head DENV titer were affected by temperature (ie. temperature x ***Wolbachia*** effect). More specifically, a higher temperature resulted in a greater reduction of ***Wolbachia***-infected mosquitoes achieving dissemination. Lastly, higher temperature also significantly reduced ***Wolbachia*** density in the head of the mosquitoes. Our study raises the importance of not confining the study of vector-pathogen interactions to a constant rearing temperature of 25°C.

SUBSET DISTRIBUTION AND PARTIAL MATURATION OF DENDRITIC CELLS DURING ACUTE DENGUE INFECTION

Nattawat Onlamoon, Ampaiwan Chuansumrit, Kulkanya Chokephaibulkit, Kanchana Tangnararatchakit, Chonnamet Techasaensiri, Nopporn Apiwattanakul, Sakaorat Lertjuthaporn, Kasama Sukapirom, Premrutai Thitilertdecha, Kovit Pattanapanyasat

Mahidol University, Bangkok, Thailand

Dendritic cell (DC) is considered as a cellular target for dengue virus. Dengue viral infection may block full phenotypic and functional maturation of DC resulting in change in the ratio of DC subsets which correlates with disease severity and might be the cause of the failure to induce protective adaptive immunity. The study to investigate distribution of DC subsets, maturation of DC during acute dengue infection and its potential function during the course of infection are warranted. In this study, flow cytometric analysis of the frequency and maturation stage of myeloid dendritic cells (mDCs) and plasmacytoid dendritic cells (pDCs) were conducted. To study the change in DC subsets in the peripheral blood of dengue infected patients, the patient blood samples were determined for phenotypic characterization of mDCs and pDCs. mDCs were identified as cells that are lin-/DR+/CD11c+/CD123- whereas pDCs were identified as a gated population of cells that are lin-/DR+/CD11c-/CD123+. Results showed that while a transient increase in the frequency of pDCs were observed in some patients, mDCs were a major population presented during acute infection. To determine the maturation of mDCs and pDCs, a panel of monoclonal antibodies against CD86/CD83/CD40/CD80 was used. While no significant expression of maturation marker was observed for pDCs, the result showed high expression frequency of maturation markers including CD40 and CD86 for mDCs. In contrast, the expression of CD80 and CD83 could not be observed. To identify subpopulations of mDCs, a panel of monoclonal antibodies against CD1b/CD141/CD16 was used. While CD1b, CD141 and CD16 were used to identify different mDCs subsets, only CD16+ mDCs and CD141+ mDCs were observed at high frequency. Taken together, the results showed the presence of specific subpopulations of mDCs and a partial maturation of mDCs were induced during acute dengue infection. More importantly, the data obtained in this study suggested for a rationale design of a novel dengue vaccine with an aim to enhance DC maturation in order to induce a protective immune response against dengue viral infection.

PHASE 1 STUDY OF A TETRAVALENT DENGUE PURIFIED INACTIVATED VACCINE (DPIV) IN HEALTHY U.S. ADULTS: SAFETY AND IMMUNOGENICITY RESULTS THROUGH MONTH 13 AND AFTER A BOOSTER DOSE IN A SUBSET OF SUBJECTS

Leyi Lin[1], Luis J. Martinez[1], Richard G. Jarman[1], Rafael De La Barrera[1], Kristopher Paolino[1], Kenneth H. Eckels[1], Edith Lepine[2], Bruce L. Innis[3], Alix Collard[2], Richard C. Ruck[1], Alexander C. Schmidt[2], Stephen J. Thomas[1]

[1]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]GlaxoSmithKline Vaccines, Rixensart, Belgium, [3]GlaxoSmithKline Vaccines, King of Prussia, PA, United States

We report safety and immunogenicity of an investigational tetravalent DPIV up to Month 13 (M13) and after a booster dose in Year 2 (Y2). In this Phase 1, observer-blind study (NCT01666652), 100 healthy adults in the continental United States were randomized 1:1:1:1:1 to receive saline placebo or 1 of 4 DPIV formulations (1µg of each dengue virus [DENV] type adjuvanted with either aluminum hydroxide [Alum], $AS01_E$ or $AS03_B$, or 4µg of each DENV type adjuvanted with Alum) at Day (D) 0 and D28. A subset of 4µg+Alum (n=3) and 1µg+$AS01_E$ (n=6) recipients received a booster dose (same formulation) 15–21M post-dose 2. Subjects were followed up for serious adverse events (SAEs), potential immune-mediated diseases (pIMDs) and medically-attended AEs (MAEs). Solicited and unsolicited AEs were monitored respectively for 7D and 28D post-booster. Neutralizing antibody titers were determined by microneutralization assay (MN50). Four SAEs were observed through M13 (3 in 1µg+$AS03_B$; 1 in 1µg+$AS01_E$); none were related to vaccination. No pIMDs and 11 MAEs were reported. In the 9 booster recipients, 1 grade 3 solicited AE was reported (muscle aches, 1µg+$AS01_E$); no unsolicited AEs, pIMDs or SAEs were reported. The M13 per-protocol cohort for immunogenicity included 84 dengue-naïve subjects; the dose 3 cohort included all 9 subjects. Geometric mean antibody titers (GMTs) waned from D56 to M7 then stabilized through M13 in all DPIV groups. M13 GMTs against DENV-1, -2, -3, -4 ranged from 5.3–7.9 (1µg+Alum), 7.3–13.2 (4µg+Alum), 9.3–36.7 (1µg+$AS01_E$), 8.2–24.9 (1µg+$AS03_B$), and 5.0 (placebo). Booster recipients had rapid rises in MN50 titers: 1M post-booster, median MN50 titers against DENV-1, -2, -3, -4 were, respectively, 4421, 3909, 5662, 20370 (1µg+$AS01_E$), and 7570, 3989, 3747, 20390 (4µg+Alum); 6M post-booster, these were 1115, 806, 1290, 792 (1µg+$AS01_E$), and 436, 625, 936, 700 (4µg+Alum). All DPIV formulations at D0 and D28 were well tolerated with favorable safety profiles up to M13, and induced balanced immune responses. GMTs stabilized from M7 through M13, and a booster in Y2 led to strong anamnestic responses. Whether a booster is required remains to be determined.

164

REGULATORY EFFECTS ON THE SYNTHESIS OF DENGUE VIRAL E PROTEIN DURING THE UNFOLDED PROTEIN RESPONSES (UPR) IN MOSQUITO CELLS

Yi-Hsuan Chiang, Tien-Huang Chen, **Wei-June Chen**

Chang Gung University, Tao-Yuan, Taiwan

Dengue fever and dengue hemorrhagic fever/dengue shock syndromes are increasing in their importance as a life-threating infectious disease in the world, particularly in tropical and subtropical areas. Dengue virus is its etiological agent and is naturally transmitted by ***Aedes*** mosquitoes between humans. As a result, the virus is able to replicate in both mammalian and mosquito cells. However, unlike in mammalian cells which usually end up with apoptosis in response to dengue virus infection, mosquito cells usually survive the infection with trivial damage to the infected cells. It facilitates that the invaded virus forms a huge number of progeny virions in mosquito cells; in the meantime, virus-induced endoplasmic reticulum (ER) stress is usually induced due to the unfolded protein responses (UPR) in infected cells. We have demonstrated that BiP/Grp78 is upregulated and eventually involved in viral E protein folding during dengue virus infection in mosquito cells. In addition, spicing of X-box-binding protein-1 (XBP1) is found to be activated, leading to promotion of protein disulfide isomerase (PDI) expression and thus appropriate synthesis of viral E protein. This study provides evidence to elucidate how disulfide bond-containing viral proteins may be formed via a collaborative modulation of chaperones and transcription factors.

165

HYPOXIA FAVORS ANTIBODY DEPENDENT DENGUE

Esther S. Gan, Hwee Cheng Tan, Kuan Rong Chan, Eng Eong Ooi

Duke-NUS Graduate Medical School, Singapore, Singapore

Dengue virus (DENV) enters humans through the infective saliva of a blood-feeding ***Aedes*** mosquito. This virus is thought to rapidly infect dendritic and Langerhans cells, which then migrate to draining lymph nodes. There, DENV is amplified before spread to other target organs, such as the spleen and liver. Lymph nodes, spleen and liver are hypoxic under homeostatic conditions. Previous studies have shown that hypoxia can modify the transcriptome of human monocytes affecting its immunoregulatory responses and could therefore have profound but yet unexplored effects on DENV infection. We report here that, compared to cells cultured at 20% O2 (normoxia), infection of THP1 and primary

monocytes at 3% O2 (hypoxia), which is the reported O2 levels in lymph nodes, produced 2-fold more infectious DENV. Interestingly, the protein levels of FcγRIIA but not FcγRIIB is up-regulated under hypoxic conditions. The differential expression of these FcγR explains our observed increased uptake of DENV immune complexes and requirement for higher antibody concentration to fully neutralize DENV in monocytic cells cultured under hypoxic compared to normoxic conditions. These findings suggest that FcγRIIA expression is under the control of hypoxia, for which hypoxia-inducible-factor 1a (HIF1α) plays a major role in regulating the cellular response to hypoxia. Indeed, treatment of THP1 cells with desferrioxamine (DFX) to inhibit the degradation of transcription factor HIF1α under normoxic conditions resulted in increased FcγRIIA expression and DENV immune complex uptake. Finally, using high resolution microscopy, we show that FcγRIIA directly mediates internalization of DENV immune complexes. Collectively our data indicates that the host response to antibody dependent DENV infection in lymphoid organs that are physiologically under hypoxic conditions is fundamentally different from those observed ***in vitro*** under normoxia.

166

SERUM ANTIBODY AVIDITY AND SUBCLASS IN SUBCLINICAL AND SYMPTOMATIC DENGUE VIRAL INFECTIONS

Dina E. Popuche[1], Roger Castillo[1], Robert Hontz[1], Maya Willians[2], Amy Morrison[1], Brett Forshey[3]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]Naval Medical Research Center, Silver Spring, MD, United States, [3]Armed Forces Health Surveillance Center, Silver Spring, MD, United States

Existing assays for dengue virus infection, including virus neutralization, are poorly predictive of clinical protection from infection and disease. The objective of this study was to evaluate the utility of serotype-specific serum antibody avidity and IgG subclass in predicting protection from clinical illness following DENV infection. Serum samples were collected from participants in longitudinal cohort and community-based febrile surveillance studies in Iquitos, Peru. We compared serotype-specific neutralization titers, IgG avidity (as measured by immunoassay), and IgG subclass titers (as measured by immunoassay) in pre- and post-infection samples from individuals with symptomatic or subclinical DENV infection. Based on preliminary analysis of DENV-3 and DENV-4 infections, there was a modest but statistically significant correlation between post-infection neutralization titers and IgG avidity. In pre-infection samples, IgG avidity was increased among subclinical infections compared with symptomatic infections. For IgG subclasses, IgG1 was the dominant subclass of antibodies, followed by IgG4; however, we did not observe clear relationship between titers of specific IgG antibody subclass and outcome from infection (i.e., subclinical or symptomatic). Based on our preliminary analysis, IgG avidity warrants further evaluation as a marker of protection. Potential implications for dengue epidemiological studies and vaccine candidate evaluation will be discussed.

A COMPARATIVE STUDY ON ACTIVE AND PASSIVE EPIDEMIOLOGICAL SURVEILLANCE IN FIVE LATIN AMERICA COUNTRIES

Elsa Sarti[1], Maina L´Azou[2], Marcela Mercado[3], Pablo Kuri[4], Erick Solis[1], Fernando Noriega[5], Leon Ochai[2]

[1]Sanofi Pasteur, México City, Mexico, [2]Sanofi Pasteur, Lyon, France, [3]Instituto Nacional de Salud, Bogota, Colombia, [4]Universidad Nacional Autónoma de México, México City, Mexico, [5]Sanofi Pasteur, Washington, DC, United States

Dengue is a public health problem that concerns more than 100 countries in the world. Usually the disease burden estimates come from the National Epidemiological Surveillance Systems (NESS), but the depth and breadth of the system, as well as the quality of the data are often criticized. We aim to describe main characteristics of NESS in five countries in Latin America (Brazil, Colombia, Honduras, México and Puerto Rico) where a clinical trial was conducted, and contrast the NESS data with the placebo arm of the trial data to better understand differences in dengue burden. NESS data on incidence of suspected and/or confirmed dengue cases by age group and by different geographical levels, if available, were extracted for the period between 2011 and 2014. Incidence rate of confirmed dengue fever (DF) cases ranged from 0.01% per year in Honduras to 0.31% in Brazil. The incidence rate of DHF had a great variability and ranged from 35 per 100,000 population in Honduras to less than 1 per 100,000 population in Puerto Rico and Brazil. The Phase III randomized, placebo-controlled dengue vaccine trial (CYD15) prospectively collected data from children aged 9-16 years and followed up between June 2011 and April 2014. 6,939 children from the placebo arm were included in the analysis. There were 389 virologically confirmed DF cases from 3,617 febrile episodes (2.84 per 100 person-year), ranging between 1.5 in Puerto Rico and 4.1 in Honduras. Ten DHF cases were found, for an incidence of 0.07 per 100 person-year. Rate difference in the similar age groups between CYD15 placebo group and NESS at the national level ranged between 16x in Brazil and 61x in México. At lower geographical level (state) were 6.9x in Brazil and 17.6x in Mexico, and in city (site) level were 3.9x in Brazil and 12.6x in Mexico . The rate differences highlight that dengue burden data depends heavily on case definitions and clinical assessment. Our results help to better understand the clinical burden of dengue disease in these 5 countries and contribute to the WHO objective to estimate the true burden of dengue disease by 2015.

T CELL IMMUNITY TO VACCINATION WITH A LIVE ATTENUATED TETRAVALENT DENGUE VACCINE CANDIDATE IN NON HUMAN PRIMATES

Charalambos Partidos[1], Yuping Ambuel[1], Haiyan Chu[1], Eva Rakasz[2], Dan T Stinchcomb[1], Jorge E Osorio[1]

[1]Takeda Vaccines, Inc., Deerfield, Chicago, IL, United States, [2]Primate Research Center, University of Wisconsin, Madison, WI, United States

Dengue virus (DENV) causes a rapidly spreading mosquito-borne human viral disease that has major impact on global health and economics. Currently, there is no licensed vaccine against DENV. We have developed a live attenuated tetravalent dengue vaccine candidate (TDV) based on an attenuated dengue 2 virus (TDV-2) and three chimeric viruses containing the pre-membrane and envelope genes of DENV-1, -3 and -4 expressed in the context of the attenuated DENV-2 genome (TDV-1, 3, and -4, respectively). In this study we sought to characterize the cellular responses elicited by the TDV backbone in non-human primates (NHPs), identify the target proteins of this response, and determine their multifunctional and cross-reactive nature. Using peptide arrays and intracellular cytokine staining, we demonstrated that the vaccine elicits $CD4^+$ and $CD8^+$ T cell responses targeting the non-structural NS1, NS3 and NS5 proteins of DENV-2. Both T cell subsets produced IL-2, IFN-γ, and TNF-α, and were multifunctional in nature. In addition, $CD8^+$ T cells expressed the CD107a marker, and exhibited cross-reactivity with the NS proteins of the other three DENV serotypes. Overall, these findings highlight the immunogenic profile of TDV vaccine candidate and support the further evaluation of clinical samples from ongoing phase II clinical trials.

DENGUE IGG/IGM IN FEBRILE PATIENTS SUSPECTED TO HAVE MALARIA IN LAGOS, NIGERIA

Wellington A. Oyibo, Queen U. Esi

ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Idi-Araba, Lagos, Nigeria

Malaria is the most suspected cause of febrile illness in Nigeria not dengue as there are dearth of information on dengue in Nigeria though dengue exists in West Africa especially in Côte d'Ivoire. Malaria and dengue are the most common arthropod-borne diseases in humans exhibiting

similar geographic distribution and clinical presentation. The objective of this study was to screen suspected patients who presented with fever at Badagry general hospital, Regina Mundi hospital, Mushin, Randle general hospital, Suru-lere, and Igando general hospital facilities in Lagos, southwest, Nigeria, for malaria using microscopy and dengue by using the ELISA IgG and IgM. A total of 247 children and adult patients were screened at presentation: The patients presented with the following symptoms: temperature ≥37°C [(13.9%)], history of fever in the last 48hour 34 (52.5%), chills (43.1%), loss of appetite (42%), headache (48%), and weight loss (28.2%). 14 (5.7%) were positive for malaria and 9 (3.70%) for dengue IgG while 3 (1.2%) were positive for dengue IgM. Of the dengue IgG positives, only 1 patient showed positivity with further IgM capture ELISA test (MAC-ELISA). There were no cases of malaria and dengue co-infections. Both malaria and dengue showed statistical association with fever but not with sex or age. In order to further compare the relationship between malaria and dengue IgG and IgM using chi-square test, no statistical significant relationship existed between the two infections. Similarly, there was also no statistically significant relationship between malaria and dengue IgM infections. Dengue fever which is regarded as one of the most important mosquito-borne viral disease is clinically difficult to diagnose at the early stage especially in developing countries and could be mistaken for malaria. Attention is currently not focused on dengue at the moment in Nigeria. An expanded study is suggested to document possible dengue as well as confirmatory tests on capture IgM ELISAs so that cases could be detected early when they present as well as encouraging proper surveillance.

170

LONG TERM DENGUE DISEASE PATTERNS IN BANGKOK, THAILAND: 1973 TO 2012

Butsaya K. Thaisomboonsuk[1], Ananda Nisalak[1], Hannah E. Clapham[2], Siripen Kalayanarooj[3], Chonticha Klungthong[1], Stefan Fernandez[1], Louis R. Macareo[1], Justin T. Lessler[2], Derek A. Cummings[2], In-Kyu Yoon[1]

[1]Department of Virology, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Department of Epidemiology, Johns Hopkins School of Public Health, Baltimore, MD, United States, [3]Queen Sirikit National Institute of Child Health, Bangkok, Thailand

Since 1962, Queen Sirikit National Institute of Child Health (QSNICH) and the Armed Forces Research Institute of Medical Sciences (Armed Forces Research Institute of Medical Sciences) have engaged in collaborative studies of dengue. Here, we analyze 40 continuous years of dengue surveillance from 1973 to 2012. We describe long-term trends in dengue disease including serotype predominance, age distributions, relative proportions of primary and secondary infections, and disease severity. Data were analyzed from 25,715 patients with laboratory-confirmed DENV infection admitted to QSNICH. DENV-1 and DENV-2 predominated for long periods, while DENV-4 has never reached the same peaks. In recent years, all four serotypes have more consistently circulated at the same time. The mean age of dengue cases increased from 7.12 to 8.14 years old in our study consistent with a decrease in force of infection. There was also an increase after 1990 in the proportion of cases that were secondary for DENV-1 and DENV-3. An overall decrease in disease severity occurred during the 40 year study period. Concurrently, a decrease in the proportion of dengue cases that were DHF and DSS in secondary infections with increasing age was observed after nine years old. We shed light on how this dengue epidemiology has interacted with other changes in the population such as demography and healthcare changes. Our findings may inform similar changes that may only now be occurring in other countries.

171

MOLECULAR EPIDEMIOLOGY OF DENGUE VIRUS CIRCULATING IN BANGKOK, THAILAND, 2003-2013

Chonticha Klungthong[1], Thipwipha Phonpakobsin[1], Butsaya Thaisomboonsuk[1], Wudtichai Manasatienkij[1], Ananda Nisalak[1], Siripen Kalayanarooj[2], Warunee Punpanich Vandepitte[2], Louis R. Macareo[1], Robert V. Gibbons[3], Richard G. Jarman[4], Stefan Fernandez[1], In-Kyu Yoon[1]

[1]U.S. Army Medical Component-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Queen Sirikit Institute of Child Health, Bangkok, Thailand, [3]USAISR, Fort Sam Houston, TX, United States, [4]Walter Reed Army Institute of Research, Silver Spring, MD, United States

Dengue virus (DENV) is the most prevalent arbovirus globally and is hyperendemic in Southeast Asia (SEA). Thailand is considered a potential epicenter for transmission of all four DENV serotypes (DENV-1 to 4) throughout SEA. Previous studies of the molecular epidemiology and evolution of DENV in Thailand were conducted by phylogenetic analyses using samples collected from 1973-2002. In this study we use recent and current DENV strains circulating in Thailand to update our DENV genetic diversity phylogenetic analyses. Envelope gene sequences from 287 DENV isolates obtained from Bangkok in 2003-2013 were evaluated. Phylogenetic analysis revealed genotype I (DENV-1), Asian I (DENV-2), genotype II (DENV-3), and genotype I (DENV-4) to be the major circulating genotypes during the study period. Clade extinction and replacement events were found for all serotypes. The highest viral diversity was found in DENV-3 with three genotypes detected: I, II, and III. The re-emergence of DENV-3 genotype III was identified in 2009 and this genotype has been co-circulating with genotype I in recent years. Only one DENV-3 genotype II strain was detected in 2012 and was likely imported from a neighboring country. Our DENV genotypic analysis provides the necessary baseline to help monitor the arrival of emerging new strains.

172

HUMAN PLASMABLAST RESPONSES TO SECONDARY DENGUE INFECTION

Lalita Priyamvada[1], Alice Cho[1], Nattawat Onlamoon[2], Kulkanya Chokephaibulkit[2], Kovit Pattanapanyasat[2], Rafi Ahmed[1], Patrick C. Wilson[3], Jens Wrammert[1]

[1]Emory University, Atlanta, GA, United States, [2]Mahidol University, Bangkok, Thailand, [3]University of Chicago, Chicago, IL, United States

Despite the massive disease burden and pressing need for antivirals and vaccines against dengue, the immunology of dengue virus (DENV) infections remains poorly understood. In this study, we describe B cell responses generated during the acute phase of DENV infection. Our lab has previously shown that a large population of DENV-specific plasmablasts appears in the blood of dengue patients around the time of fever subsidence. To understand the functional properties of these acute-phase cells and what role the antibodies they make play in an immune response, we isolated plasmablasts from 4 Thai patients experiencing secondary DENV infection and generated 53 monoclonal antibodies (mAbs) by single-cell RT-PCR and cloning of the plasmablast VDJ genes. We determined that a large majority of the DENV envelope-specific mAbs in our panel was either fully (4 serotypes) or partially (2-3 serotypes) cross-reactive, with a large majority also exhibiting cross-neutralizing activity ***in vitro***. Serotype-specific neutralizing mAbs represented <20% of the entire mAb panel. Interestingly, more than half of the mAbs generated from two patients displayed stronger neutralization of DENV1 than DENV2 even though they were diagnosed with DENV2 at the time of sample collection. This is reminiscent of original antigenic sin, given all patients had prior DENV exposures. Further, a majority of serotype-specific neutralizing mAbs either moderately or potently enhanced DENV infection of U937 cells indicating that the potential for ADE is not limited to cross-reactive mAbs.

These initial characterizations of plasmablast-derived mAbs give insight into the specificity and function of early antibody responses in dengue infection at a single-cell level.

173

EFFECT OF REPEAT HUMAN BLOOD FEEDING ON *WOLBACHIA* DENSITY AND DENGUE VIRUS INFECTION IN *AEDES AEGYPTI*

Hilaria E. Amuzu[1], Cameron P. Simmons[2], Elizabeth A. McGraw[1]

[1]Monash University, School of Biological Sciences, Clayton, Australia, [2]University of Melbourne, Department of Microbiology and Immunology, Parkville, Australia

Wolbachia is an endosymbiotic bacterium that has been introduced into ***Aedes aegypti*** to limit the replication of dengue virus (DENV) in the vector. In both mosquito cell lines and in whole mosquitoes higher ***Wolbachia*** infections show increased DENV blocking. ***Wolbachia*** density is known to be affected by several factors including host nutrition. Since ***Ae. aegypti*** are "sip" feeders returning often to obtain blood meals there was a need to assess whether a relationship exists between ***Wolbachia*** densities and human blood feeding as this could lead to greater DENV inhibition over the life of the mosquito. The ***w***Mel ***Wolbachia*** infected ***Ae. aegypti*** line and the Wildtype ***Ae. aegypti*** mosquito which is not infected with ***Wolbachia*** were concurrently reared for this study. There were three treatment groups for each mosquito line; a control group which was not fed human bloodmeal, a second group which was given one human bloodmeal and a third group which was given two successive human bloodmeals two weeks apart. Apart from the controls which were not blood fed, all mosquitoes were first given human bloodmeal 5 days post eclosion. The mosquitoes in the third treatment group were given a second human blood meal 12 days post eclosion. All the three treatment groups were orally infected with DENV simultaneously 19 days post eclosion. The midguts and salivary glands which are the tissues necessary for infection and transmission of DENV in the mosquito, were dissected from each individual mosquito 10-11 days post infection. RNA/DNA was then simultaneously extracted from each dissected tissue and carcass/remainder of the mosquito body for DENV RNA copies and ***Wolbachia*** density quantification respectively. We found no clear evidence that ***Wolbachia*** density increased with feeding and therefore saw no corresponding improvements in DENV blocking. Hence ***Wolbachia***-based DENV blocking should be stable with respect to mosquito feeding cycle.

174

KNOWLEDGE, ATTITUDES AND PRACTICES REGARDING DENGUE AND ITS SOCIODEMOGRAPHIC DETERMINANTS IN COLOMBIA: A MULTIPLE CORRESPONDENCE ANALYSIS

Diana Rocio Higuera-Mendieta, Sebastian Cortés, Catalina González-Uribe, Juliana Quintero

Fundación Santa Fe de Bogotá, Bogotá, Colombia

During the last decades, a number of studies have been analyzed the knowledge, attitudes and practices (KAP) of the population regarding dengue. However, none of them have applied multivariate geometric data analytic techniques to generate indexes from KAP domains. Likewise, results of such analysis have not been used in order to determine the potential effects of sociodemographic variables on the levels of KAP. The objective was to determine the sociodemographic factors related to different levels of KAP regarding dengue in two hyper-endemic cities of Colombia using a multiple correspondence analysis (MCA). In the context of a Cluster Randomized Trial, 3998 households were surveyed in two Colombian cities between 2012 and 2013. To generate indexes of KAP we performed a MCA followed by a hierarchical cluster analysis to classify each score in different groups (from less to more score). A quantile regression analysis for each score group was conducted considering fixed effects. Indexes explained 56%, 79% and 83% of the variance of knowledge, attitudes and practices domains with means 4.2, 1.4 and 3.2, respectively. The highest values of the index denoted higher levels of knowledge and practices while the attitudes index did not show the same relationship and was excluded from the analysis. In the quantile regression, age 0.06 (IC95% 0.038, 0.076), years of education 0.15 (IC95% 0.09, 0.2), and history of dengue in the family 0.21 (IC95% 0.15, 0.27) were positive related to lower levels of knowledge. However, the effect of such factors gradually decreases or disappears when knowledge was higher. Only decision-making about family health care increased knowledge score in the higher quantile. Practices indexes did not evidence correlation with sociodemographic variables. Multiple Correspondence Analysis is a new useful tool for the analysis of knowledge and practices regarding dengue from KAP questionnaires because allows for the transformation of several categorical variables into a single coherent index. Moreover, the magnitude of the effect of sociodemographic variables in the knowledge scores varies according to the levels of knowledge

175

HEALTH SEEKING BEHAVIOR AND TREATMENT INTENTIONS OF DENGUE AND FEVER: A HOUSEHOLD SURVEY OF CHILDREN AND ADULTS IN VENEZUELA

Jelte Elsinga[1], Erley Lizarazo[1], Maria F. Vincenti[1], Masja Schmidt[1], Luzlexis Arias[2], Zoraida I. Velasco-Salas[1], Adriana Tami[1]

[1]Department of Medical Microbiology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]Instituto de Investigaciones Biomédicas, Universidad de Carabobo, Maracay, Bolivarian Republic of Venezuela

Dengue in Venezuela is a major public health problem with an increasing incidence of severe cases. Early diagnosis and treatment influences the outcome of dengue illness, as delay in care-seeking is associated with severe dengue. We aimed to understand patterns of health seeking behaviour (HSB) in individuals exposed to high dengue transmission in order to improve early attendance to health centres. Between September 2013 and February 2014 a cross-sectional household survey was performed in Maracay, Venezuela. Intended HSB of adults and parents/guardians was assessed. Data was collected through structured questionnaires from 105 individuals. In the case of suspected dengue, most people (60%) would choose to first seek medical help versus first treating at home, in contrast to 11% in the case of fever . Amongst those who decided to visit a doctor, a suspected dengue infection would prompt them to search medical help earlier than if having fever ($p<0.001$). Multivariate analysis of the determinants associated with the intention to firstly visit a doctor versus treating at home in the case of dengue showed that feeling at risk prompted people to first seek medical help (OR=3.29; p=0.042). Determinants of first treating a dengue infection at home were: deciding in the conduct of a child (as opposed to an adult) (OR=0.30, p=0.021), reporting a previous dengue infection (OR=0.29; p=0.031) and living in the neighbourhood Caña de Azúcar (OR=0.28, p=0.038). Understanding the patterns of HSB helps target dengue control interventions. Improving awareness and dengue disease recognition may enhance early attendance to medical care of affected populations and thereby reduce mortality and the development of severe illness. Especially for those with a previous dengue infection, efforts have to be made to promote prompt health centre attendance.

176

ANALYSIS OF CLONAL LINEAGES OF DENGUE VIRUS ENVELOPE PROTEIN SPECIFIC ANTIBODIES FROM A SINGLE PATIENT

John S. Schieffelin[1], Lindsey Bazone[1], Kristen M. Kahle[2], Sharon Isern[3], Benjamin J. Doranz[2], James E. Robinson[1], Scott F. Michael[3]

[1]Tulane University, New Orleans, LA, United States, [2]Integral Molecular, Inc, Philadelphia, PA, United States, [3]Florida Gulf Coast University, Fort Meyers, FL, United States

The humoral immune response to dengue infection plays a key role in homotypic immunity and, theoretically, in the antibody dependent enhancement of infection during heterotypic, secondary infections. Our understanding of the human anti-dengue antibody repertoire is limited. The goal of this study was to determine the genetic diversity of anti-dengue envelope proteins produced by a single patient. Human monoclonal antibodies (HMAb) targeting the DENV envelope protein were generated by molecular cloning and characterized. All antibodies where tested for neutralizing and enhancing activity. Epitope mapping was done using shotgun mutagenesis. The heavy and light chain variable regions of each HMAb were then sequenced and analyzed using IMGT/V-QUEST and Cloanalyst software programs. All hMAbs bound to the E protein of one or more DENV serotype. Epitope mapping studies revealed that all of the hMAbs targeted epitopes located on Domain II (DII) of the E protein. Functional characterization of these hMAbs revealed extensive cross-reactivity among the four DENV serotypes as well as marked heterogeneity with regards to relative binding affinity and neutralization and enhancement potential. Categorizing individual hMAbs into three distinct epitope classes revealed that hMAbs within a particular epitope class shared similar functional characteristics. Analysis of VDJ genes encoding the heavy and light chain variable regions revealed three separate lineages that closely matched the groupings based on functional characteristics. Clonal analysis of hMAbs from a single patient revealed distinct lineages of broadly neutralizing, weakly neutralizing and non-reactive hMAbs that bind to adjacent regions of the E protein. These results could impact vaccine design, ie development of sub-unit vaccine that will stimulate distinct population of memory B cells.

177

EBOLA PREPAREDNESS IN MALAWI: NATIONWIDE HEALTH EDUCATION USING A SHORT MESSAGE SERVICE (SMS) ON MOBILE PHONES

Samuel Kampondeni

Queen Elizabeth Central Hospital, Blantyre, Malawi

Novel approaches are needed to rapidly educate whole populations on Ebola prevention in the face of the epidemic. Since September 2014, an SMS (Short Message Service) health information delivery platform called Moyo Wanga was introduced across Malawi to disseminate information on Ebola and other diseases in English and the local language, Chichewa. Malawi has a population of 14million with 5 million cellphone users. A database of over 300 SMS texts covering Ebola, HIV/Aids, Tuberculosis and other Tropical diseases were placed on a server. The server was connected to the three major cellphone networks in Malawi using an internet VPN (virtual private network). Using any type of cellphone, a user dials one shared code for any of the three networks to access the Moyo Wanga database and selects an SMS using drop down menus. The platform also has a dialogue facility that allows a user to send back questions and a physician to offer solutions. Beginning with the initial 7,700 SMS's downloaded in the first 2 weeks, the service continues to show ever increasing downloads. With people sharing SMS's within and across networks health information is disseminated rapidly across the country. Mobile technology using SMS's is being used effectively to rapidly disseminate crucial preventive information about Ebola and other diseases in Malawi. Knowledge of the transmission and preventive steps are critical in stopping Ebola spread to Malawi and other countries where the disease has not reached.

INFLUENZA SEROCONVERSION RATES IN A COHORT OF YOUNG CHILDREN, BANGKOK, THAILAND

Kamonthip Rungrojcharoenkit[1], Kamonthip Rungorjcharoenkit[2], Wanitchaya Kittikraisak[3], Darunee Ditsungnoen[3], Sonja J. Olsen[4], Piyarat Suntarattiwong[5], Tawee Chotpitayasunondh[5], Chonticha Klungthong[1], In-Kyu Yoon[1], Fatimah S. Dawood[4], Stefan Fernandez[1], Kimberly Lindblade[3], Kimberly Lindblade[4]

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Department of Microbiology, Faculty of Science, Mahidol University, Bangkok, Thailand, [3]Thailand MOPH- U.S. Centers for Disease Control and Prevention Collaboration, Nonthaburi, Thailand, [4]Influenza Division, Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Queen Sirikit National Institute of Child Health, Bangkok, Thailand

Influenza causes a substantial burden of disease in young children. In 2011, we began enrolling a cohort of children aged <36 months to estimate the burden of influenza in Bangkok, Thailand. Children with and without underlying conditions (e.g., low birth weight, respiratory, cardiopulmonary and neurological disease) who sought care at Queen Sirikit National Institute of Child Health were followed for 2 years. Serum samples were collected every 6 months from children enrolled within the first 6 months of birth and tested by hemagglutination inhibition (HI) assay using representative of influenza viruses circulating at the time of the study (A/California/07/2009 (H1N1), A/Victoria/361/2011 (H3N2), B/Brisbane/60/2008, and B/Wisconsin/1/2010). Seroconversion was defined as >4-fold rise in HI titers in 2 consecutively collected serum samples. We excluded vaccinated children and reported preliminary finding of seroconversion rates by high-risk and healthy children. Between August 2011 and September 2013, 63 (34 healthy and 29 high-risk) of the 299 enrolled children have been tested to date. The median age at baseline blood collection was 3.9 months (range, 0.5-6.3) and it did not differ between 2 groups (p=0.76). No children had influenza seroconversion during the first 6 month of age. Over 2 years, 16 healthy and 11 high-risk children seroconverted (2.6 vs. 2.0/100 person-months [PM]; p=0.50). Seroconversion rates were nonsignificantly higher in healthy than in high-risk children during >6-12 months (2.1 vs. 0.6/100 PM; p=0.26), >18-24 months (3.1 vs. 2.7/100 PM; p=0.86) and >24-30 months (7.3 vs. 2.4/100 PM; p=0.36) periods. The rates were nonsignificantly lower in healthy than in high-risk children during >12-18 months period (3.0 vs. 4.0/100 PM; p=0.65). Six (37%) healthy and one (9%) high-risk children who seroconverted reported no respiratory symptoms within 1 month before seroconversion. Influenza seroconversion within the first 2 years of life was detected. There was no difference in the rates of seroconversion between high-risk and healthy children; however, the sample size was small. Asymptomatic infection was observed.

179

RAPID DETECTION OF ALL KNOWN EBOLA VIRUS SPECIES BY REVERSE TRANSCRIPTION LOOP MEDIATED ISOTHERMAL AMPLIFICATION (RT-LAMP) ASSAYS

Olamide K. Oloniniyi, Yohei Kurosaki, Jiro Yasuda

Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan

Ebola virus disease (EVD) is a highly virulent infectious disease caused by ***Ebola virus*** and with a case fatality rate ranging from 25-90%. Since the first outbreak in 1976, EVD has been characterized by sporadic outbreaks in different parts of Africa with the current outbreak in West Africa being the latest. Limitation of spread of outbreaks therefore relies on accurate diagnosis and quarantine of cases. Reverse transcription-loop mediated isothermal amplification (RT-LAMP) is a nucleic acid amplification method which amplifies nucleic material using DNA polymerase with

strand displacement activity under isothermal conditions. Five sets of six oligonucleotide primers were designed for specific identification of each of the five species of ***Ebolavirus*** using PrimerExplorerV4, a LAMP primer design software. The limits of detection of the ***Ebolavirus*** species-specific primer sets were evaluated using ***in vitro*** transcribed RNAs. Comparison between each ***Ebolavirus*** species-specific RT-LAMP assays and RT-PCR and qRT-PCR was done using viral RNA of each species. The lowest detection limit of species-specific RT-LAMP assays for Zaire (EBOV), Sudan (SUDV), Tai Forest (TAFV), and Reston (RESTV) ebolavirus was 410, 320, 140, or 62 copies/reaction, respectively, and the detection time (measured in minutes and given as a mean ± standard deviation of 3 different experiments) for each of the species-specific RT-LAMP assays was 16.8 ± 1.2, 13.9 ± 0.9, 16.5 ± 1.4, or 19.0 ± 1.1, respectively. EBOV species specific RT-LAMP assay had a better sensitivity than qRT-PCR using ENZ-FP, ENZ-RP, and ENZ-P, while it had a similar sensitivity with qRT-PCR using enp-F, enp-R, and enp-P. EBOV RT-LAMP assay was also more sensitive than the nested RT-PCR assay by a factor of 10. SUDV RT-LAMP assay had a similar sensitivity with qRT-PCR. TAFV and RESTV RT-LAMP assays were more sensitive than the conventional RT-PCR assay by a factor of 100 and 10, respectively. ***Ebolavirus*** species-specific RT-LAMP assays show promise and could become an important diagnostic tool for the detection of EVD.

180

BOOSTING THE NOVEL EBOLA VACCINE CANDIDATE CHAD-EBOV Z WITH MODIFIED VACCINIA VIRUS ANKARA (MVA) SIGNIFICANTLY ENHANCES EBOLA-SPECIFIC ANTIBODY RESPONSES

Georgina Bowyer[1], Katie Ewer[1], Thomas Rampling[1], Danny Wright[1], Egeruan B. Imoukuhede[1], Ruth Payne[1], Navin Venkatraman[1], Verena Krähling[2], Daphne A. Stanley[3], Nancy J. Sullivan[3], Julie E. Ledgerwood[3], Thomas Strecker[2], Sarah Katharina Fehling[2], Nadine Biedenkopf[4], Stephan Becker[4], Barney Graham[3], W. Ripley Ballou[5], Sarah C. Gilbert[1], Adrian V. Hill[1]

[1]The Jenner Institute and Centre for Clinical Vaccinology and Tropical Medicine, University of Oxford, Oxford, United Kingdom, [2]Institute of Virology, Philipps University Marburg, Marburg, Germany, [3]Vaccine Research Center, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [4]Institute of Virology, Philipps University Marburg and German Centre for Infection Research (DZIF), Marburg, Germany, [5]GlaxoSmithKline Biologicals, Rixensart, Belgium

The ongoing Ebola virus outbreak in West Africa is the largest and most complicated to date with over 23,000 cases and almost 10,000 deaths. There are currently no licensed vaccines for Ebola, although several candidates are in clinical trials. Despite falling incidences, an effective vaccine may still be necessary to contain the current Ebola outbreak and would be a significant component of the response effort to future outbreaks. The viral vector vaccine Chimpanzee Adenovirus 3 (ChAd3) encoding Zaire Ebolavirus surface glycoprotein (EBOV GP) has shown efficacy in non-human primate studies and was selected for rapid assessment in clinical trials. We previously conducted a Phase 1 clinical study of this vaccine in 60 healthy UK adults to assess safety and immunogenicity. The single-dose vaccine induced only moderate anti-EBOV GP antibody titres that were significantly lower than those previously seen in protected macaques. We conducted a Phase 1 clinical trial to assess the impact of a heterologous viral vector boost on the immune response primed with ChAd3-EBOV Z. In this study 30 individuals were boosted with an MVA encoding Zaire GP and 3 additional filovirus antigens. Anti-EBOV GP titres peaked 2 weeks post-boost with geomean titres 7-fold higher than the peak post-prime. This is around the level that was previously shown to be protective in macaques after vaccination with rAd5 expressing Ebola Glycoprotein. At 2 weeks post-boost 100% of individuals had neutralising titres against the Mayinga strain of Ebola, compared to just 43% at the peak post-prime. Ebola-specific antibody titres and neutralising activity induced by ChAd3-EBOV Z can be significantly enhanced by boosting with a heterologous viral vector vaccine. Assessments of these vaccines are ongoing and a large-scale efficacy trial of this prime-boost regimen is planned to begin in West Africa shortly.

EVALUATION AND INTRODUCTION OF REAL TIME PCR NEW ASSAYS FOR THE DIAGNOSTIC AND SURVEILLANCE OF HUMAN RESPIRATORY VIRUS

María K. Martínez[1], Alexander Piñón[2], Belsy Acosta[2], Odalys Valdés[2], Mayra Muné[2], Clara Savón[2], Amely Arencibia[2], Grehete González[2], Suset Oropesa[2]

[1]Faculty of Biology, Havana, Cuba, [2]Tropical Medicine Institute "Pedro Kourí", Havana, Cuba

This study proposed the evaluation of four multiplex real time PCR for the diagnosis of 15 human respiratory viruses causing acute respiratory infection, as well as the introduction of the optimized system for the diagnosis and laboratory surveillance. For the optimization of multiplex real time PCR 352 nasopharyngeal swabs from July-August 2013 were used, multiplex RT-PCR was used as ¨gold standard¨ technique. Sensitivity, specificity, positive and negative predictive values and kappa index of multiplex real time PCR was determined. Efficiency of simple and multiplex real time PCR was calculated by calibration curve and slope determination. In addition, laboratory diagnosis in the period September 2013 to May 2014 with the optimized multiplex real time PCR was performed. Of the total of samples processed for optimization, 162 were positive by multiplex real time PCR and 112 by gold standard technique. Sensitivity, specificity, positive predictive value, negative predictive value and average kappa of the evaluation assays was 100%, 98.4%, 67%, 100% and 0.8, respectively. Furthermore, efficiency values for multiplex real time PCR systems were in the range 90.30 % to 103.09 % similar to those obtained by the simple system. Introduction of optimized assays allowed the detection of 1290 clinical samples positive for respiratory viruses, with the highest positivity percentage for human respiratory syncytial virus, 47.83%. In summary, multiplex real time PCR was more sensitive than multiplex RT-PCR and the efficiency values were similar to the simple real time PCR. These optimized systems allowed to update the algorithm for the diagnosis and surveillance of respiratory viruses in Cuba.

182

IMPACT ON IMMUNOGENICITY OF VARYING THE INTERVAL BETWEEN THE PRIME AND BOOST OF A CANDIDATE EBOLA VACCINE CHAD3-EBO Z AND MVA-BN FILO IN HEALTHY UK ADULTS

Danny Wright[1], Katie Ewer[1], Thomas Rampling[1], Georgina Bowyer[1], Egeruan Imoukuhede[1], Ruth Payne[1], Navin Venkatraman[1], Nancy Sullivan[2], Julie Ledgerwood[2], Barney Graham[2], W. Ripley Ballou[3], Sarah Gilbert[1], Adrian Hill[1]

[1]Jenner Institute, Oxford, United Kingdom, [2]Vaccine Research Center, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [3]GlaxoSmithKline Biologicals, Rixensart, Belgium

The current Ebola epidemic is the largest in history, resulting in more deaths than all previous outbreaks combined. Development of an effective vaccine would maximise safety of those at greatest risk of disease during outbreaks. A leading candidate vaccine strategy currently under development involves heterologous prime-boost immunisation with a chimpanzee Adenovirus (ChAd3) followed by a Modified Vaccinia Ankara virus (MVA), both containing a Zaire strain of the Ebola glycoprotein. Previous trials with viral vectored malaria vaccines have been administered in a prime-boost sequence with an interval of between 4 and 8 weeks, and resulted in very high T cell responses in addition to moderate antibody levels. There is no previous data showing the effect on T cell or antibody immunogenicity of reducing this interval between prime and boost

vaccinations to less than 4 weeks. We undertook a phase I study to assess the safety and immunogenicity of such a vaccination strategy involving healthy adults in the UK. 62 volunteers received ChAd3 followed by MVA, both containing a Zaire strain of the Ebola glycoprotein, at intervals between 1-10 weeks. IFN-γ production by T-cells was measured by ELISpot at various points throughout the trial. Intracellular cytokine staining was used to determine the relative proportions of CD4+ and CD8+ T-cells secreting IL-2, IFN-γ and/or TNFα in response to peptide stimulation. IgG responses were also measured by ELISA. While this trial is ongoing, preliminary data showed that a shorter interval was associated with an enhanced T-cell response, while there was no significant difference in antibody levels.

183

EFFECTIVENESS OF A BRIEF, INTENSIVE, PHYLOGENETICS-FOCUSED, BIOINFORMATICS WORKSHOP IN A MIDDLE INCOME COUNTRY

Simon Pollett[1], Mariana Leguia[1], Martha I. Nelson[2], Irina Maljkovic Berry[3], George Rutherford[4], Daniel G. Bausch[1], Matthew Kasper[5], Rick Jarman[3], Melanie Melendrez[3]

[1]U.S. Naval Medical Research Unit-6, Lima, Peru, [2]Fogarty International Center, Bethesda, MD, United States, [3]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]University of California San Francisco, San Francisco, CA, United States, [5]Global Emerging Infections Surveillance and Response System, Silver Spring, MD, United States

There is an increasing role for bioinformatic and phylogenetic applications in tropical medicine research. However, scientists often lack training to utilize these methods, with a paucity of accessible courses available in this field. To help address this training gap, we offered a brief, intensive bioinformatics workshop in Lima, Peru, in January 2015. To improve future workshops, we objectively measured participants' baseline knowledge in pathogen-applied bioinformatics and assessed workshop efficacy in improving such knowledge. We also sought to identify baseline and residual bioinformatic training needs. A 20-point written questionnaire was administered to all participants at the beginning and end of the five-day hands-on workshop covering knowledge domains of sequence quality control, alignment/formatting database retrieval, models of nucleotide evolution, sequence statistics, tree building, and results interpretation. Changes in median questionnaire scores and associations of score changes with previous bioinformatic experience were analysed using non-parametric tests. All 21 workshop participants were Peruvian and 52% had prior phylogenetic analysis experience. The mean years of scientific work/training were 4.9 (SD 3.4). Models of evolution/tree-building methods was the lowest scoring domain at baseline (median score 1/5, 20%) and after the workshop (median score 3/5, 60%). The greatest score gains were in results interpretation and models of evolution/tree-building methods ($p < 0.001$). There was considerable median gain in total knowledge scores (increase of 30%, 6 point gain, $p < 0.001$) with gains as high as 55% (11 point gain). Higher baseline median scores were seen in those with previous phylogenetic experience as compared to those without ($p = 0.04$). Despite the small sample size, the knowledge gained from the workshop was sufficiently large to be detected in this study. An intensive five-day workshop model appears to be effective in improving pathogen-applied bioinformatics knowledge of scientists working in a middle income country setting.

184

STUDY THE EFFECTS OF INFLUENZA VACCINATION ON CHILDREN IN THAILAND BY USING NEXT GENERATION SEQUENCING

Wudtichai Manasatienkij[1], Wiriya Rutvisuttinunt[1], Piyawan Chinnawirotpaisan[1], Piraya Bhoomiboonchoo[1], Sriluck Simasathien[2], In-Kyu Yoon[1], Chonticha Klungthong[1], Stefan Fernandez[1]

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Phramongkutklao Hospital, Bangkok, Thailand

Influenza vaccination has been practiced to prevent seasonal influenza infections in high risk groups including children and elderly. The effects of the influenza vaccines in the influenza virus (IFV) subpopulations have not yet well understood. Nasopharyngeal swaps collected from 18 children diagnosed with influenza infections by serology and molecular assays (with and without vaccination) were collected: 6 cases of influenza A H3N2, 6 cases of influenza A pdm H1N1/09 and 6 cases of influenza B. High-throughput sequencing was utilized to study the IFV subpopulations. A total of 22.3 millions of passed-filter sequence reads were identified IFV. Approximately 80.3%-95.9% had ≥Q30 quality score. Diverse depth of coverage (DOC) was observed with sequence alignment analysis against their corresponding influenza reference strains: A/California/07/2009, B/Wisconsin/01/2010 and B/Brisbane/11/2010. The DOC is found to be parallel to the amount of the IFV in the specimens. The nucleotide heterogeneity (measured numbers of variances or numbers of mixed bases in the genome), is utilized to determine population diversity. Nearly all genomic fragments of the 18 clinical specimens contain variances compared to the vaccine reference strains. Slightly less nucleotide heterogeneity were observed in the vaccinated group compared to the unvaccinated group for influenza A H3N2 infection (DOC = 13.4-1191.7). On the contrary, the breakthrough influenza A pdm H1N1/09 and influenza B infections contains less DOC that nucleotide heterogeneity cannot be determined.

185

DESCRIPTIVE EPIDEMIOLOGY OF THE EBOLA VIRUS DISEASE OUTBREAK IN NIGERIA, JULY TO SEPTEMBER 2014

Elizabeth B. Adedire[1], Akinola Fatiregun[2], Adebola Olayinka[1], Kabir Sabitu[3], Patrick Nguku[1]

[1]Nigerian Field Epidemiology and Laboratory Training Program, Abuja, Nigeria, [2]Department of Epidemiology and Medical Statistics, University College Hospital, Ibadan, Nigeria, [3]Department of Community Medicine, Ahmadu Bello University, Zaria, Nigeria

The current epidemic of Ebola virus disease (EVD) was first reported in March 2014 in West Africa which is the largest ever reported globally. Nigeria had its first imported case on the 23rd of July 2014; we investigated and described the epidemiological profile of this outbreak that affected two megacities in the Nigeria in terms of person, place and time characteristics of the cases identified. Using field investigation techniques, cases were identified through contact tracing, line-listed and described. We adopted the WHO case definitions for EVD. A suspected case was defined as any person with axillary temperature ≥38oC, who has visited an affected area within past 21days or has had contact with a confirmed or probable case and has two or more cardinal symptoms of EVD. A confirmed case was a suspected case with positive reverse transcription (RT)-PCR laboratory result and a probable case was a suspected case evaluated by a clinician or any deceased suspected case with an epidemiological link with a confirmed EVD case. A total of 20 cases were identified (19 laboratory-confirmed Ebola cases and one probable case); 16 (80%) in Lagos State and 4 (20%) in Rivers State. The mean age of cases was 39.5±12.4 years with over 75% within the age group 20-39 years. There were more females 11 (55%) than males 9 (45%). The most frequent exposure type was direct physical contact 14 (73.7%) and median incubation period was 11days. The overall case-fatality ratio (CFR)

was 40%; CFR was higher among healthcare workers (46%) compared with non-healthcare workers (22%). The epidemic curve initially shows a typical common source, followed by a propagated pattern and duration of epidemics was 43 days. Investigation revealed the size and spread of the outbreak and provided information on the characteristics of persons, time and place. Enhanced surveillance measures, including contact tracing and follow-up proved very useful in early case detection and containment of the outbreak.

186

CONTRIBUTION OF LOCAL COMMUNITY MEMBERS IN THE DETECTION OF NEW PATHOGENS OF ZOONOTIC POTENTIAL IN THE DEMOCRATIC REPUBLIC OF CONGO

Prime M. Mulembakani[1], Placide Kingebeni Mbala[1], Ipos Lukusa Ngay[1], Joseph Losoma Atibu[2], Brad Schneider[1], Corina Monagin[1], Maria Makuwa[1], Emile Wemakoy Okitolonda[2], Jean-Jacques Tamfum Muyembe[3]

[1]Metabiota Inc., San Francisco, CA, United States, [2]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [3]Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo

In the past decade, 60 % of emerging infectious disease (EID) events were zoonosis and of those 72% of the pathogens involved were of wildlife origin. Activities like subsistence hunting, butchering and trading of wild animals are key factors for the risk of zoonotic infections in humans. The United States of America Aid for International Development (United States Agency for International Development) Emerging Pandemic Threat (EPT) PREDICT project, in collaboration with the "Institut National de Recherche Biomedicale" and the Kinshasa School of Public Health, implemented a surveillance system for zoonotic pathogens at the Human-Wildlife interface in geographic hot spots. Local community members, especially hunters were recruited, sensitized and trained in prevention technics of zoonosis. They participated to the surveillance effort by collecting dry blood spots (DBS) from wild hunted animals, under the supervision of trained field staffs. From December 2010 to September 2012, a total of 14,779 samples were collected from wild animals under the PREDICT project. Of these samples, hunters and other community members collected 5,395 (36,5%) on DBS. From those DBS, 285 tested positive for known or new viral pathogens of zoonotic potential using PREDICT protocols. Community members who participated to the PREDICT project collected good quality samples that were used to identify known and new zoonotic pathogens. Their inclusion on a national base can improve disease surveillance for EID.

187

RAPID DIAGNOSIS AND FIRST CHARACTERIZATION OF THE VIRUSES RESPONSIBLE FOR THE 2014 EBOLA VIRUSES OUTBREAK IN THE DEMOCRATIC REPUBLIC OF CONGO

Placide Kingebeni Mbala[1], **Ipos Lukusa Ngay**[1], Maria Makuwa[1], Corina Monagin[2], Damien Joly[2], Charles Chiu[3], Jean-Jacques Muyembe[4], Prime Mulembakani[1], Bradley S. Schneider[2]

[1]INRB/METABIOTA, Kinshasa, Democratic Republic of the Congo, [2]Metabiota, San Francisco, CA, United States, [3]University of California San Francisco, San Francisco, CA, United States, [4]Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo

Following a request from the Ministry of Health (MoH), we made a rapid diagnosis of the etiologic agent responsible for an outbreak of hemorrhagic fever in Boendé, within the Equateur Province of DRC. On 11 August 2014, a woman died in Ikanamongo village following symptoms of hemorrhagic fever. On the following day, additional suspected cases were reported in nearby villages. Epidemics caused by Ebola virus often occur following contact with a sick or dead animal. Congruently, the putative index case had butchered a wild animal of unknown species. Blood samples from the first 8 subjects, individuals who had close contact with the index case, were collected and transported to the INRB laboratory by a MoH team on August 22nd. The presence of the Zaire Ebola virus was confirmed in these specimens by conventional PCR that amplifies a 550 bp section of the filovirus L-gene. Analysis of the sequences obtained confirmed that the outbreak in DRC was caused by a different strain of the Ebola virus than is associated with the large outbreak in West Africa, and thus these concurrent outbreaks are derived from independent origins. Subsequent next generation sequencing of the patient specimens enable full-genome sequencing of two isolates and nearly full-genome sequence of a third. All sequences were immediately publically released via Genbank and ProMED. The swift laboratory diagnosis allowed the DRC government to implement effective control measures, including quarantines, installation of mobile diagnostic laboratory, intensive monitoring of cases, and contact tracing, which prevented a broader geographic spread of the outbreak and led to its relatively rapid conclusion.

188

NOVEL VIRUSES DETECTED IN *ANOPHELES GAMBIAE* IN WEST AFRICA

Joseph R. Fauver

Colorado State University, Fort Collins, CO, United States

Adult bloodfed ***Anopheles gambiae*** mosquitoes were collected during a field study conducted in West Africa in order to monitor pathogens infecting humans in the area. Mosquitoes were pooled and RNA-Seq was performed. Within the data set two putative insect specific viruses new to ***Anopheles gambiae*** were discovered: Phasi Cheron Like Virus (PCLV), a Phlebovirus originally described from ***Aedes aegypti*** in Thailand, and a novel insect specific flavivirus, provisionally designated ***Anopheles*** flavivirus (AnFV). In this study we report genetic characterization of these viruses. In particular we (1) compared the reads to PCLV in our dataset to the published genome, (2) assembled the AnFV genome, and (3) reconstructed phylogenies of both viruses. In addition, we determined the field prevalence of both viruses. We also discovered what appears to be a new virus in the order Mononegavirales. Our data demonstrated that PCLV from ***Anopheles*** is genetically similar to the previously published genome, and has a relatively low field prevalence in our study area. Also, AnFV forms a new clade within insect specific flaviviruses and has a similar field prevalence to other insect specific flaviviruses. The results of this study add knowledge to the understudied field of insect specific viruses, including the first ***Anopheles*** specific flavivirus.

189

POTENTIAL DISTRIBUTION OF EBOLA, MARBURG, AND LASSA VIRUSES IN AFRICA

Abdallah M. Samy[1], Arwa Elaagip[2], Ahmed Abd El Wahed[3]

[1]Faculty of Science, Ain Shams University, Abbassia, Cairo, Egypt and Biodiversity Institute and Department of Ecology and Evolutionary Biology, University of Kansas, Lawrence, Kansas, United States, [2]Department of Parasitology and Medical Entomology, Faculty of Medical Laboratory Sciences, University of Khartoum, Sudan, [3]Unit of Infection Models, German Primate Centre, Goettingen, Germany

Numerous recent studies have illuminated the current distribution of Ebola, Marburg, and Lassa viruses. Hitherto, the potential distributions of key reservoir species have not been incorporated integrally into the efforts of the risk mapping of these deadly viruses. With the most complex and worse outbreaks in West Africa, it became highly desirable to understand the current and future surprises of the distribution of these viruses in Africa. This will shed the lights to the future strategy for both diagnostic and control programs. Here, we identified the potential distribution of the three viruses, and tested their niche equivalence based on time-specific data from the NASA's Terra Satellite. We also provided the rich maps for the regions where two or more of these viruses occur. These rich maps were based on the maximum entropy approach that estimate the probability of virus or animal reservoir occurrences from independent

disease events as well as environmental and demographic factors. All maps was hosted as digital rich pictures into mobile system to be accessed by researchers and health professionals in the field. This study took the advantage of including time-specific data for both the recent outbreaks in West Africa and the environmental factors. Our results assess the most recent situation of the distribution of hemorrhagic fever viruses, and offer the possibility to be translated into action in the national and international control programs of hemorrhagic fevers in Africa.

ROBUST EXPRESSION OF EARLY INNATE IMMUNITY IMMUNITY GENES IN DROMEDARY CAMEL PLASMACYTOID DENDRITIC CELLS

Ashley Malmlov[1], Vincent Munster[2], Sandra Quackenbush[1], Tony Schountz[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Rocky Mountain Laboratories, National Institute of Allergy and Infectious Diseases, Hamilton, MT, United States

Middle Eastern respiratory syndrome coronavirus (MERS-CoV) has caused more than 1000 confirmed cases of disease with a 36% fatality rate. ***In vitro*** studies demonstrated that MERS-CoV is sensitive to type I and type III interferons (IFN) and the virus down regulates the interferon response in human respiratory cells, suggesting that innate immunity plays a critical role in the outcome of infection. Plasmacytoid dendritic cells (pDC) produce high amounts of IFN in response to viral infection and are particularly important in controlling viral infections. Human DCs secrete large amounts of type I and type III IFN when cultured with MERS-CoV. Furthermore, while studies are conflicting, MERS-CoV does not appear to replicate in human DCs. Dromedary camels (Camelus dromedarius) are thought to be reservoir hosts of MERS-CoV. A large number of domesticated camels in the Middle East have antibody to the virus, suggesting a potential for spillover to humans. Experimental infection of camels with MERS-CoV showed that camels were susceptible to MERS-CoV infection with subclinical to mild disease that is confined to the upper respiratory tract, including regional lymph nodes. We sought to characterize the innate immune response to MERS-CoV in camel pDCs to delineate differences between humans and camels. Flt3L-derived pDCs were established from camel bone marrow and cultured with MERS-CoV. No virus replication occurred and the cells remained healthy upon microscopic examination. Many genes involved in viral sensing were elevated after 8 hours of exposure to MERS-CoV, including TLR7, STAT1, MDA5, RIG-I, IKKE and TBK1. Expression of genes late in the IFN signaling pathway appeared less sensitive to MERS-CoV, or viral accessory proteins inhibit their expression. TNF expression was substantially elevated at 2 and 8 hours; however, it had subsided by 24 hours. These data indicate that camel pDCs are responsive to MERS-CoV, are not productively infected, and may control virus early after cellular entry.

PREVALENCE OF THE RUBELLA IN CHILDREN FROM SIX MONTHS TO FIVE YEARS IN DEMOCRATIC REPUBLIC OF THE CONGO

Patrick K. Mukadi

National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo

Background Rubella can be a very contagious and severe disease for the fetus, but preventable by a safe and effective vaccine. Epidemiological data based on measles laboratory surveillance introduced by the DRC Ministry of Health confirm circulation of rubella virus in Democratic Republic of Congo. Furthermore, studies among pregnant woman in Kinshasa found circulation of the virus in 90 % of screened women, however no study has estimated virus circulation among children at the national level. To date, the Expanded Programme of Immunization (EPI) has not yet introduced the rubella vaccine in the routine immunization schedule. During the second Demographic and Health Survey (DHS) held by the government in 2013, a serological evaluation of exposure to Rubella virus was conducted among children 6 months to 5 years old. Material and methods A total of 8,116 of dried blood spots were collected during the second DHS from 540 locations in DRC and forwarded to University of California Los Angeles-DRC Research program Laboratory located at the National Institute of Biomedical research (INRB) in Kinshasa. Serologic testing was made by ELISA technique using Dynex M2 Multiplex rubella IgG detection. Results Overall prevalence was 34.4 %. However, we observed a progression of prevalence within age groups; 14% among children 6 to 8 months and 47.6% among children 48 months to 59 months. Conclusions: Current data support circulation of Rubella virus in the whole country with an increase of exposure with the age. In DRC, there is has need to re-evaluate immunization strategies for introduction of Rubella Vaccine in Routine Immunization.

192

RIFT VALLEY FEVER EMERGENCE OF UNPRECEDENT MAGNITUDE IN SENEGAL IN 2013-2014

Abdourahmane Sow[1], Ousmane Faye[1], Yamar Ba[2], Diawo Diallo[2], Gamou Fall[1], Cheikh Loucoubar[1], Vincent Richard[3], Denis Malvy[4], Anta Tal Dia[5], Mawlouth Diallo[2], Amadou Alpha Sall[1]

[1]Arbovirus and Viral Hemorrhagic Fevers Unit, Institut Pasteur de Dakar, Dakar, Senegal, [2]Medical Entomology Unit, Institut Pasteur de Dakar, Dakar, Senegal, [3]Epidemiology of Infectious diseases Unit, Institut Pasteur de Dakar, Dakar, Senegal, [4]Institut de Santé Publique d'Epidémiologie et de Développement, Centre de recherche INSERM U897 Epidémiologie-Biostatistique, Bordeaux, France, [5]Institut Santé et développement, Université Cheikh Anta Diop, Dakar, Senegal

Rift Valley fever (RVF) is an acute viral anthropozoonosis causing epizootics/epidemics associated with high toll of morbidity and mortality among human and livestock populations in Africa. In Senegal, RVFV has been repeatedly detected among humans, livestock, and mosquitoes especially in the Northern and the Southern regions. In 2013, multiple RVFV epizootics ***foci*** and 5 RVF human confirmed cases were identified countrywide including in the capital city. This paper reports multidisciplinary field investigations and laboratory findings of this outbreak. Human suspected cases and their contacts, ruminants and arthropods in contact with confirmed and/or suspected cases were sampled in affected areas including Linguere (Northern), Mbour (Central) and Kedougou (SouthEastern) regions. Human and animal sera were tested by ELISA (IgM, IgG) and RT-PCR for RVFV. Mosquitoes were sorted in monospecific pools and tested for RVFV RT-PCR detection and isolation. During the human investigation, 535 patients were sampled from which 2.05% (11/535) were tested positive for RVFV (10 IgM, 1 RT-PCR) including 8 in Mbour, 2 in Kedougou and 1 in Linguere and 4.48%(24/535) had evidence of RVFV past infection (IgG). In term of clinic signs, it was the first time that RVF severe case with encephalitis and retinitis notified in Senegal. Fifty two animals (12.06%) were tested positive by RT-PCR for RVFV only in Northern regions. Although no animal's evidence of RVFV recent infection was found in Central and SouthEastern regions, IgG antibodies were significantly higher in Mbour (75%) than in Kedougou (25.8%)($p<0.0001$). Concerning entomologic investigation, 645 arthropods were collected and RVF was detected in one pool of mosquitoes in Linguere. Phylogenetic analyses showed that the strains from human and mosquito clustered together. In conclueion, it was the largest spreading of RVFV touching urbanized areas including the capital city. Regarding the potential risk of reemergence through familial breeding, RVF surveillance should be implemented in order to provide promptly suitable and effective preventing and control measures.

193

RAPID AND SENSITIVE DETECTION OF BAT INFLUENZA VIRUSES BY REAL TIME RT-PCR ASSAYS

Krista Queen, Yan Li, Kui Yang, Clinton Paden, Ruben O. Donis, Suxiang Tong

Centers for Disease Control and Prevention, Atlanta, GA, United States

Influenza viruses are important human and livestock pathogens and new reassortants of zoonotic origin have potential to cause pandemics. Aquatic birds harbor diverse influenza A viruses and are recognized as major influenza virus reservoirs in nature. However the recent discovery of influenza viruses of a new H17N10 subtype in Guatemalan fruit bats and a new H18N11 subtype in Peruvian fruit bats, along with preliminary seroprevalence studies suggest that New World bats may carry divergent influenza viruses and could be an unrecognized reservoir in nature. To understand how influenza viruses are maintained in bat populations, systematic and global prevalence studies using more sensitive and efficient screening methods are needed. In this study, we developed two real time RT-PCRs targeting conserved regions within the NS and M gene segments of known bat influenza viruses to enable sensitive and efficient detection from bat clinical samples. These assays are simple, rapid and at least 4X more sensitive for detection of bat influenza viruses compared to the generic pan-flu PCR used previously. These assays were used to screen collections of bat swabs previously screened. A total of 803 rectal and 95 oral swabs from Guatemala (2009-2011) and Peru (2010) were tested by generic pan-flu PCR and rescreened with the bat influenza M and NS real time RT-PCRs. In addition to the previously tested flu-positive bat samples, one additional rectal swab sample (***Carollia perspicillata)*** from Guatemala (2010) was positive for bat influenza virus by real time PCRs, but missed by generic flu PCR. Full genome sequencing was performed by Sanger and NGS methods. Phylogenetic analysis showed that this latest bat flu virus is more closely related to H18N11 (82.5%-96.3% nt identity to 8 orf segments of A/bat/Peru/10) rather than to H17N10 (53.5%-81.0% nt identity to 8 orf segments of A/bat/Guat/09). These new assays provide a rapid and sensitive tool to screen bat populations to better understand the ecology and evolution of bat influenza viruses.

ERYTHROCYTE INVASION MECHANISMS OF *PLASMODIUM FALCIPARUM* CLINICAL ISOLATES FROM THREE ENDEMIC AREAS IN GHANA

Henrietta E. Mensah-Brown[1], Nicholas Amoako[2], James Abugri[1], Lindsay B. Stewart[3], Godfred Agongo[4], Emmanuel K. Dickson[5], Michael F. Ofori[5], Jose A. Stoute[6], David J. Conway[3], Gordon A. Awandare[1]

[1]West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana, [2]Kintampo Health Research Centre, Kintampo, Ghana, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom, [4]Navrongo Health Research Centre, Navrongo, Ghana, [5]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [6]Department of Medicine, Pennsylvania State University College of Medicine, Hershey, PA, United States

Plasmodium falciparum invades human erythrocytes using an array of ligands which interact with several receptors including sialic acid (SA), complement receptor 1 (CR1) and basigin. Naturally acquired immunity against several blood stage ligands have been shown to effectively block invasion and parasite growth ***in vitro***, making these antigens potential vaccine candidates. Based on this, we hypothesized that in malaria-endemic areas, parasites vary invasion pathways under immune pressure. Furthermore, parasites from areas with varying endemicity would differ in the receptor-ligand interactions used for erythrocyte invasion. Therefore, invasion mechanisms of clinical isolates collected from three zones of Ghana with different levels of endemicity (Accra<Navrongo<Kintampo) were compared using standardized methods. Blood samples were collected from children aged 2-14 years diagnosed with malaria. Erythrocyte invasion phenotypes were determined using enzymes, which selectively cleave receptors from the erythrocyte surface. In addition, antibodies against CR1 and basigin were used to determine the contributions of these receptors to invasion. Gene expression levels of ***P. falciparum*** invasion ligands were compared against parasitemia levels and age. The parasites generally expressed SA-independent invasion phenotypes across the endemic areas, with parasites from Kintampo showing the highest invasion rates in neuraminidase-treated erythrocytes. CR1 was a major mediator of SA-independent invasion while basigin was essential for both SA-dependent and SA-independent invasion mechanisms. Relational analyses between ligand gene expression levels with age and parasitemia of donors at enrolment showed that PfRh5 had the strongest correlation with parasitemia. In conclusion, erythrocyte invasion phenotypes expressed by ***P. falciparum*** are influenced by endemicity levels. The PfRh5-basigin pathway is a potential vaccine target.

THE ENDOTHELIAL PROTEIN C RECEPTOR (EPCR) RS867186-GG GENOTYPE IS ASSOCIATED WITH INCREASED LEVELS OF SOLUBLE EPCR AND PROTECTION FROM CEREBRAL MALARIA IN UGANDAN CHILDREN

Estela Shabani[1], Robert O. Opoka[2], Paul Bangirana[2], Gregory S. Park[3], Gregory M. Vercellotti[3], Chandy C. John[4]

[1]University of Minnesota and Indiana University, Indianapolis, IN, United States, [2]Makerere University, Kampala, Uganda, [3]University of Minnesota, Minneapolis, MN, United States, [4]Indiana University, Indianapolis, IN, United States

Endothelial protein C receptor (EPCR) expression on brain microvasculature endothelium may be an important determinant of disease severity in malaria. Plasma soluble EPCR (sEPCR) levels are higher in individuals with the rs867186-G allele, and in Thai adults the rs867186-GG genotype was associated with protection from severe malaria. In the present study, we performed rs867186 genotyping in Ugandan children with cerebral malaria (CM, n=326), severe malarial anemia (SMA, n=227), uncomplicated malaria (UM, n=71) and healthy community children who lived in the same extended household or neighborhood as children with CM or SMA but had no history of CM or SMA and did not develop either during 12-month follow-up (CC, n=262). Plasma and CSF sEPCR levels were assessed in children with adequate sample volume (Asserachrom® sEPCR immunoassay). The rs867186-GG genotype was more common in CC (3.0%) than CM (0.3%, p=0.007). The presence of rs867186-G was associated with increased plasma sEPCR levels in each disease group ($p<0.0001$ for all). Plasma sEPCR levels were significantly higher in CC or UM than in CM or SMA ($p<0.0001$ for trend). In children with CM, plasma sEPCR correlated positively with TNF-α (p=0.02) and parasite biomass (***Plasmodium falciparum*** histidine-rich protein-2 level, p=0.006) but not IL-1β or IFN-γ. Plasma sEPCR levels were not associated with differences in mortality or neurocognitive morbidity. CSF sEPCR levels were elevated in children with CM as compared to North American controls ($p<0.0001$), but were not associated with mortality or morbidity. In Ugandan children, the presence of rs867186-G correlates with increased plasma sEPCR levels, increased plasma sEPCR levels correlate with decreased malaria disease severity, and the rs867186-GG genotype is associated with protection from cerebral malaria. The results suggest that the rs867186-GG genotype may decrease risk of cerebral malaria in part through effects on bound and soluble EPCR.

196

A MODIFIED CONCEPT OF MALARIAL RELAPSE

Miles B. Markus

University of the Witwatersrand, Johannesburg, South Africa

The idea that the hypnozoite (a term coined by me decades ago) is the origin of relapse in ***Plasmodium vivax*** (and ***P. ovale***) malaria, something for which there is as yet no formal proof, has become dogma.

For particular reasons which will be explained, it would be surprising to discover that hypnozoites are not the source of malarial relapse. Nevertheless, it is now apparent from various recent research findings that hypnozoites are not necessarily the origin of all relapse-like recurrences of malaria caused by ***P. vivax***. We could be missing the elephant in the room; and indirect evidence from several publications will be provided to support this novel, genetically based concept that nonhypnozoite parasite stages might give rise to relapse-like, recurrent human malaria. Re-evaluation of the hypnozoite theory of relapse is timely because of the renewed focus on ***P. vivax*** and liver stages of ***Plasmodium***. Hypnozoites have also assumed a new significance because they are seen as a threat to the current (post-2007) goal of eradicating malaria worldwide.

197

DEVELOPMENT OF SPLENOMEGALY DURING RODENT MALARIA BY MYELOID-RELATED PROTEIN (MRP)

Haruka Mizobuchi, Shoko Isokawa, Sachiko Yamakoshi, Chizu Sanjoba, Yoshitsugu Matsumoto, Yasuyuki Goto

The University of Tokyo, Tokyo, Japan

Splenomegaly is one of the typical symptoms of malaria. However, the pathogenesis of splenic enlargement still remains unclear. Myeloid-related protein (MRP) 8 and MRP14 are expressed by inflammatory macrophages and secreted upon activation. Previous studies have demonstrated that the accumulation of MRP-expressing macrophages is associated with the pathological changes in various inflammatory diseases. In order to elucidate whether MRP-expressing macrophages are also involved in splenomegaly during malaria, we investigated expression of MRP in the spleens of mice infected with ***Plasmodium berghei***. Enlargement of the spleen was prominent on day 7 post-infection, and histological analyses of the spleens demonstrated deposition of malaria pigments and accumulation of macrophages. Immunohistochemical staining of the tissue revealed the accumulation of macrophages expressing MRP. In these infected mice, MRP levels in the plasma were higher than those of uninfected controls. In order to verify whether plasma MRP is involved in the splenomegaly during malaria, we intravenously administrated recombinant MRP8 and MRP14 to ***P. berghei***-infected mice. The administration of MRP did not affect parasite number in the peripheral blood or hematocrit. On the other hand, the splenomegaly was exacerbated in MRP-treated mice, and their spleen weight increased significantly more than PBS-treated controls. Immunohistochemical staining of the spleen showed that more MRP-expressing macrophages accumulated in MRP-treated mice than PBS-treated controls after infection. Also, even in the absence of ***Plasmodium*** infection, administration of MRP could induce enlargement of spleen along with the accumulation of MRP-expressing macrophages in naïve mice. These data indicates that elevated MRP during malaria is one of the key molecules for development of splenomegaly.

LIVER FUNCTION TESTS IN PRESCHOOL NIGERIAN CHILDREN WITH SYMPTOMATIC UNCOMPLICATED *PLASMODIUM FALCIPARUM* INFECTION

Joshua Toochukwu Meremikwu, Friday A. Odey

University of Calabar, Calabar, Nigeria

Malaria remains the leading cause of childhood morbidity and mortality in Nigeria. The liver is involved in the pathophysiology of malaria, and severe falciparum malaria may affect liver function. In order to evaluate the status of liver function in uncomplicated malaria, the authors analysed baseline liver function test results of preschool children with parasitologically confirmed symptomatic uncomplicated ***Plasmodium falciparum*** infection. Study was conducted in Calabar in Southeast Nigeria, an area with perennial stable malaria transmission. Children aged 6-59 months with fever were included if they had asexual ***P. falciparum*** parasite density ≥ 2000/mm3, no feature of severe malaria; and written parental confirmed consent. Thick blood smear was stained with 3% Giemsa for microscopic detection and quantification of malaria parasites. Assay of plasma levels of liver enzymes (alanine aminotransferase - ALT and aspartate aminotransferase - AST), bilirubin and creatinine were performed using standard biochemical laboratory methods. Results showed mild elevation of plasma levels of ALT (i.e. ALT > 45 U/L) and AST (i.e. AST >55 U/L) respectively in 8.5% and 21.1% subjects. Moderate elevation of ALT (i.e. ALT >90U/L) and AST (i.e. > 110 U/L) was observed in 1.5% and 3.2% subjects respectively. Creatinine was normal in all subjects except 0.6% with mild elevation (>62mmol/L). Those with bilirubin level higher than double the group mean were 7.18%. Malaria parasite density was marginally positively correlated with elevation of AST (correlation coefficient= 0.02; p<0.001) and ALT (correlation coefficient= 0.01; p=0.67). Researchers conclude that in children with uncomplicated ***Plasmodium falciparum*** infection, liver function is essentially normal; with only mild elevation of liver enzyme in a few.

199

ONE OF THE *PLASMODIUM* RHOPTRY PROTEINS IS ESSENTIAL FOR MALARIA SPOROZOITE GLIDING MOTILITY, WHICH IS REQUIRED FOR MOSQUITO SALIVARY GLAND INVASION MACHINERY

Sirasate Bantuchai[1], Mamoru Nozaki[2], Takafumi Tsuboi[3], Motomi Torii[2], Tomoko Ishino[2]

[1]Department of Molecular Parasitology, Graduate School of Medicine, Ehime University, Toon, Ehime, Japan, [2]Division of Molecular Parasitology, Protea-Science Center, Ehime University, Toon, Ehime, Japan, [3]Division of Malaria Research, Proteo-Science Center, Ehime University, Mastuyama, Ehime, Japan

Mosquito salivary gland invasion of ***Plasmodium*** sporozoite is an essential step for malaria transmission. Sporozoites, the malaria infective stages are formed inside oocyst on mosquito midgut then released into hemocoel. Sporozoites then migrated via hemolymph circulation and finally invade salivary glands. To initiate the salivary gland invasion, a parasite locomotion called gliding motility is required for this invasion step. To date, micronemal protein, thrombospondin-related anonymous protein (TRAP) has been shown to be involved in gliding motility. However, the molecular mechanisms for mosquito salivary gland invasion are still remaining unclear. To determine the mechanisms of sporozoite invasion machinery, we focus on rhoptry proteins because it has been suggested that they are involved in host cell invasion by merozoite. Since it is well known that most of rhoptry proteins could not be disrupted, sporozoite stage specific gene silencing system had been estrablished. Recently, we found that rhoptry neck protein 2 (RON2) is also involved in salivary gland invasion by sporozoite. We intend to elucidate the roles of all possible rhoptry proteins during sporozoite invasion using gene silencing method. We generate sporozoite stage specific gene silencing transgenic parasites, replaced the endogenous promoter to the merozoite specific promoter using rodent malaria parasite, ***P. berghei***. It was shown that our target rhoptry protein expression in mutant sporozoites was reduced approximately 10 times less than those in control parasite by western blotting. The mutant sporozoites were formed in oocyst and released into hemocoel normally. Whereas, the number of invaded mutant sporozoites collected from salivary gland were about 100 times less than those of control parasites. Furthermore, these mutant sporozoites display a severe defect in gliding motility. These results demonstrated that this target rhoptry protein plays an important role in sporozoite gliding and involved in salivary gland invasion.

200

THE FUNCTIONAL ANALYSES OF A *PLASMODIUM* ALVEOLIN PROTEIN DURING MOSQUITO STAGE PARASITE DEVELOPMENT

Natcha Lorsuwannarat[1], Naoaki Shinzawa[2], Mayumi Tachibana[2], Riko Katsube[1], Takafumi Tsuboi[3], Motomi Torii[2], Tomoko Ishino[2]

[1]Department of Molecular Parasitology, Graduate School of Medicine, Ehime University, Toon, Ehime, Japan, [2]Division of Molecular Parasitology, Proteo-Science Center, Ehime University, Toon, Ehime, Japan, [3]Division of Malaria Research, Proteo-Science Center, Ehime University, Matsuyama, Ehime, Japan

Plasmodium spp. has unique structure named inner membrane complex (IMC) beneath the plasma membrane in all invasive stages. IMC is composed of the membranous sacs which connect motor complex and microtubule cytoskeleton, and might has important roles during invasion. It has been reported that some proteins, containing the conserved peptides, are localized to IMC named as Alveolin family. Until now, 12 ALVs are listed in ***Plasmodium*** by genomic sequencing. Some of them are mosquito stage specific, while the others are expressed in all invasive forms. The diversity of alveolins might be required for differentiation, membrane stability, motility or invasive ability of different stage parasites to proceed the complicated life cycle efficiently. To elucidate the functions of conserved ALVs, we have developed the mosquito stage-specific gene silencing system by promotor exchange. Using this system, we previously reported that ALV5 is essential for ookinete initial elongation and motility. To understand the comprehensive functions of ALV family proteins during malaria life cycle, we selected another ALV family protein which is also commonly expressed in all three invasive stages. We produced transgenic parasites (ALV-cKD) that repress the new ALV gene expression during ookinete and sporozoite stage. Target ALV protein amount in ALV-cKD cultured ookinetes was decreased by 90% of that in wild type using western blotting analysis. Approximately only 6% of ALV-cKD ookinete had morphologically normal mature shape inside mosquito midguts whereas 49% showed mature ookinete shape in wildtype. In accordance with this result, oocyst number of ALV-cKD on midgut was reduced 9 times less than that of wild type. These results demonstrated that our target ALV is required for ookinete normal structure, which might be related to their cell transversal ability. In addition, only few ALV-cKD sporozoites were collected from salivary glands. It suggested that our target ALV is also involved in sporozoite formation and/or salivary gland invasive ability, which is different from the ALV5 function.

201

HUMANIZED MOUSE MODEL OF *PLASMODIUM FALCIPARUM* INFECTION IN BLOOD STAGE

Shulin Xu, Alison E. Roth, Kenneth O. Udenze, Richard T. Luque, Laurelis Santiago, Samantha Barnes, John H. Adams

University of South Florida, Tampa, FL, United States

Malaria is a devastating mosquito-borne infectious parasitic disease resulting in substantial disease burden and morbidity. ***Plasmodium falciparum*** is the most deadly of the species causing human malaria. Plans to eliminate malaria as an important disease is hampered by the lack of an effective vaccine and widespread resistance to antimalarial drugs. An important limitation in developing new therapies for this human pathogen is the lack of accessible ***in vivo*** model systems for research studies. In this study we have analyzed a humanized mouse model for studying blood-stage infections of ***P. falciparum.*** The commercially available NOD scid gamma (NSG) mouse (Taconic) were engrafted with human red blood cells (huRBC) in conjunction with clodronate treatments (O^+ huRBC every 3 days IV with 100µl clodronate liposome IP). After 3 cycles of engraftment, NSG mice supported high level of huRBC (approximately 25%) in circulation. This huRBC-engrafted NSG model supported robust growth ***P. falciparum*** parasite line-PfKF7G4, which constitutively expresses luciferase and mCherry, achieving parasitemias of >10% in circulating human RBCs. By Giemsa-stained blood smear all stages of ***P. falciparum*** asexual development were observed in circulation. Mature gametocytes produced ***in vivo*** were infective for mosquitoes leading to oocyst formation in the mosquito midgut and salivary gland sporozoites. The huRBC-engrafted NSG model was modified for support of ***P. vivax*** blood stage studies by engrafting with adult blood enriched for reticulocytes are going on. This humanized model will help to accelerate the development of novel drug and vaccine study in malaria research.

IDENTIFICATION OF RED CELL AND METABOLIC ENZYME VARIATION ASSOCIATED WITH PRIMAQUINE SAFETY AND EFFECTIVENESS AGAINST *PLASMODIUM VIVAX* MALARIA

Rajeev K. Mehlotra[1], Ricky Chan[1], Rosalind E. Howes[2], Julie Rosenjack[1], Seth Schulte[1], Johnathan Sheele[1], David Serre[1], Andrea Gaedigk[3], Babu L. Tekwani[4], Larry A. Walker[4], Arsene C. Ratsimbasoa[5], Peter A. Zimmerman[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]University of Oxford, Oxford, United Kingdom, [3]University of Missouri, Kansas City, Kansas City, MO, United States, [4]University of Mississippi, Oxford, MS, United States, [5]University of Antananarivo, Antananarivo, Madagascar

Plasmodium vivax (Pv) presents challenges to malaria elimination because it produces hypnozoites, dormant liver-stages that cause relapse infections from weeks to years without mosquito transmission. If untreated, hypnozoites are a disease reservoir whose extent is unknown. Primaquine (PQ) is the only WHO-recommended drug that kills Pv hypnozoites to achieve radical cure but causes life-threatening hemolytic anemia in G6PD deficient (G6PDdef) people. Thus, PQ usage has been limited in many malaria-endemic countries and undermines Pv elimination efforts globally. Also, polymorphic expression of the drug-metabolizing enzyme Cytochrome P450 2D6 (CYP2D6) have been associated with PQ failure through observing Pv relapses in people who have received standard PQ treatment (30 mg/14 days). These findings suggest that optimizing PQ usage requires an understanding of G6PD and CYP2D6 genetic variation. Here, G6PD and CYP2D6 gene sequences were amplified using long-range PCR strategies. Combined post-PCR SNP, deletion and duplication genotyping and Illumina sequencing was used to assess variation. Study participants included n=7 subjects from the USA (multiple ethnicities) and n=22 Madagascar. G6PD and CYP2D6 Illumina sequencing results were compared to reported reference sequences (X55448, G6PD normal; AY545216, CYP2D6*1). G6PD sequence analysis identified known allelic variants and showed concordance with predicted G6PD normal and G6PDdef enzyme activity phenotypes. CYP2D6 alleles predictive of low, intermediate and extensive metabolism were observed. Illumina sequence and CYP2D6 genotyping results were concordant. For the Malagasy study participants, sequences of both African and Southeast Asian origins were observed suggesting that the Malagasy population is rather unique. Our results indicate that genetic variation in G6PD and CYP2D6 genes may both confound safe and effective PQ use. This intersection of human genetic variation must be better understood to develop safe and effective PQ usage strategies to achieve elimination of Pv in endemic regions of the world.

203

BIOENERGETICS STUDIES OF *PLASMODIUM FALCIPARUM* MITOCHONDRION USING SEAHORSE FLUX ANALYZER

Tomoyo Kato, Dyann F. Wirth

Harvard School of Public Health, Boston, MA, United States

In recent years, the malaria parasite's mitochondrion has drawn attention as a validated drug development target largely based on its molecular and functional divergence to human mitochondrion and successful development and clinical use of a mitochondrial electron transport chain (ETC) inhibitor, atovaquone. However, in contrast to the deep molecular and biochemical understanding of the mitochondrion in mammalian cells,

many aspects of ***Plasmodium*** mitochondrial function, bioenergetics, and associated metabolomics still remain unclear. In order to conduct bioenergetic studies of ***P. falciparum*** parasites, we developed a novel assay protocol utilizing the Seahorse flux analyzer, which allows us to assess the parasite's respiration and glycolytic activities in real-time and simultaneously with a readout of an oxygen consumption rate (OCR) and extracellular acidification rate (ECAR). Using schizont stage parasites that were isolated from red blood cells by saponin lysis, we successfully monitored the kinetics of various metabolic substrates and products of the tricarboxylic acid cycle and ETC. As results, we found that glutamate, but not pyruvate, was able to increase OCR, and that glycerol-3-phosphate dehydrogenase had the largest potential as an electron donor among tested mitochondrial dehydrogenases. We also observed oligomycin-sensitive OCR elevation by ADP with the presence of glucose, providing supportive evidence for the existence of oxidative phosphorylation in ***Plasmodium***. Furthermore, we tested various mitochondrial inhibitors to see how these small molecules affect OCR. Cytochrome bc1 inhibitors, such as antimycin A, decreased OCR when any dehydrogenases of ETC were activated, while a dihydroorotate dehydrogenases (DHOD) inhibitor, genz669178, only decreased the OCR induced by dihydroorotate. This result demonstrated that our assay system provides a novel method for not only target identification but also mode of action study of mitochondria targeting antimalarials. Further studies including bioenergetic profiling of developmental stages and drug resistant lines will be discussed.

204

THE EFFECT OF IRON SUPPLEMENTS ON HEME IN PREGNANT WOMEN WITH MALARIA AND WITHOUT MALARIA

Hassana Salifu[1], N. O. Wilson[1], M. Liu[1], F. Botchway[1], Nelly Yatich[2], John Keenan[2], Cornelius Turpin[2], Pauline Jolly[2], J. K. Stiles[3]

[1]Morehouse School of Medicine, Atlanta, GA, United States, [2]University of Alabama, Birmingham, AL, United States, [3]Morehouse School of Medicine, Atlanta, GA, United States

Plasmodium falciparum malaria threatens about 200 million people worldwide resulting in 655,000-1000000 deaths annually with pregnant women and children at high risk. Although current anti-malarial treatment are effective in targeting parasites, recent studies have shown that the pathogenesis of severe malaria is not only due to parasitemia but also by parasite derived factors and host factors such as heme and heme oxgenase-1 (HO-1) as a result of hemolysis. Pregnant women in general are routinely recommended to take iron during pregnancy with the aim of meeting the increased iron demands during pregnancy. The objective of this study was to assess the effect of iron supplements on Heme in pregnant women with malaria and without malaria. We hypothesized that pregnant women with malaria who take iron supplements will have higher levels of Heme than pregnant women without malaria who do not take iron supplements. A cross-sectional study of women presenting for delivery at two hospitals in Kumasi, the Komfo Anokye Teaching Hospital and the Manhyia Polyclinic, and one hospital in Accra the Korle-Bu teaching hospital. The preliminary results showed that pregnant women with malaria who took iron supplements had significant higher median levels of heme 59.301 (43.08060.4) than pregnant women without malaria who did not take iron supplements 35.714 (33.03662.202), p = 0.026. In conclusion, malaria in pregnancy is associated with increased Heme reflecting the degree of hemolysis induced by parasites (sequestered or systemic) and pregnancy outcomes. Findings from this study may provide insight on the effect of iron supplements on malaria derived heme in pregnancy which may result in development of preventive chemotherapy that target both parasites and hemolysis.

205

PFEMP-1 EXPRESSION AND ANTIBODY IMMUNITY IN MALAWIAN PEDIATRIC CEREBRAL MALARIA PATIENTS

Anne Kessler[1], Sarah Hochman[1], Karl Seydel[2], Terrie E. Taylor[2], Kami Kim[1]

[1]Albert Einstein College of Medicine, Bronx, NY, United States, [2]Blantyre Malaria Project, Blantyre, Malawi

PfEMP-1, a family of variant antigens expressed on the surface of ***Plasmodium falciparum*** infected erythrocytes, has been implicated in parasite evasion of the host immune system. PfEMP-1 is encoded by a family of 60 var genes that encode protein domains that enable infected erythrocytes to adhere to vascular endothelium and other erythrocytes. The var genes are classified on the basis of promoter sequence, chromosome position and protein domains. Recent studies suggest that parasites expressing a subset of PfEMP-1 variants are associated with more severe malarial disease, including cerebral malaria (CM). As CM remains a major cause of death amongst pediatric patients in Malawi, we employed qRT-PCR to determine the PfEMP-1 types expressed by parasites in the blood of pediatric patients admitted with stringently defined CM. Despite the wide range of variability in the ***P. falciparum*** isolates and the associated var genes, we were able to amplify and characterize the var repertoire of Malawian parasites using a panel of PCR primers initially used on parasites isolated from pediatric malaria patients in Tanzania. From this cross-sectional study, we report the diversity and types of PfEMP-1 antigens isolated from Malawian pediatric CM patients. Our results will be discussed in the context of other clinical (retinopathy status, MRI features, outcome) and immune parameters.

PLASMODIUM FALCIPARUM K13 PROPELLER GENE MUTATION FROM NORTHWEST ETHIOPIA ASSOCIATED WITH DAY-3 POSITIVITY

Abebe Genetu Bayih[1], Gebeyaw Getnet[2], Abebe Alemu[2], Sisay Getie[2], Abu Nasir Mohon[1], Dea Shahinas[3], Dylan R. Pillai[1]

[1]University of Calgary, Calgary, AB, Canada, [2]University of Gondar, Gondar, Ethiopia, [3]University of Toronto, Toronto, ON, Canada

Artemisinin combination therapy (ACT) is considered first-line to treat uncomplicated falciparum malaria worldwide. Recently, artemisinin resistance has emerged in Southeast Asia. Resistance to artemisinin has been shown to be highly associated with mutations on the propeller domain of ***Plasmodium falciparum*** K13 gene. The mutations identified in Southeast Asia have not been observed in Africa to-date. In this study, we show a unique mutation in the K13 propeller domain of ***P. falciparum*** strains in Northwest Ethiopia that has not been previously reported in Asia and Africa. Confirmed falciparum malaria patients (n=148) in five districts in Northwest Ethiopia were enrolled in a 28-day ACT trial. Nested PCR for K13 propeller gene was performed on DNA samples extracted from filter paper blood spots. The PCR product was sequenced bi-directionally and the sequences were compared with the reference sequence of K13 gene (PF3D7_1343700).***P. falciparum*** K13 propeller gene was amplified from genomic DNA isolated from 125 out of 148 blood samples collected from the five sites. We have found a unique mutation in K13 propeller domain (R622I) in 3/125 (2.4%) samples. The three isolates with R622I mutation came from Negade-Bahir and Aykel districts close to the Ethiopia-Sudan border. One of the three patients infected with the mutant strain had a day-3 positive result by microscopy. Homology modeling of the mutant protein indicates that the mutation is highly likely to disrupt the function of the protein. The study has shown the emergence of a novel mutation on the propeller domain of the ***P. falciparum*** K13 gene in Northwest Ethiopia with possible association to day-3 positivity.

MUTATIONS IN K13, PFCRT AND PFMDR1 GENES AND EFFICACY OF ARTEMETHER-LUMEFANTRINE IN RELATION TO TREATMENT OUTCOMES IN KENYAN CHILDREN WITH UNCOMPLICATED FALCIPARUM MALARIA

Luicer I. Olubayo, Dennis W. Juma, Angela A. Omondi, Ben M. Andagalu, Hoseah M. Akala, Bernard Ogutu, Edwin Kamau

United States Army Medical Research Unit - Kenya, Kisumu, Kenya

Artemisinin-based combination therapies (ACTs) remain highly efficacious in sub-Saharan Africa (SSA) but resistance is found in Southeast Asia (SEA). Mutations in the ***Plasmodium falciparum*** K13-propeller domain are important determinants of ACTs resistance in SEA but there is no evidence of such in SSA. However, ACTs have been shown to select for K76 in pfcrt gene and N86, 184F and D1246 (NFD) in pfmdr1 gene (K+NFD haplotype) in SSA. An open-label randomized study was conducted to investigate selection of K76, N86, 184F and D1246 genotypes, and K-13 mutation in recurrent parasites in western Kenya. 454 children with uncomplicated falciparum malaria were enrolled in the study and followed up for 42 days. Parasite clearance rates were calculated following WHO recommendation. Parasites collected on day 0 and subsequent days were genotyped by direct sequencing or by PCR-based single-base extension on Sequenom MassARRAY platform. Pfmdr1 copy numbers were determined by real-time PCR. The median slope half-life was 2.18 (range: 0.94, 6.94) with a 90% parasite clearance achieved in 40 hours. Day 0 (129) and subsequent days parasites (135 re-infections and 17 recrudescence) were successfully genotyped. On day 0, the prevalence of K76, N86, 184F and D1246 was 50% and 71.2%, 34.9% and 67.2% respectively. There was no significance difference in prevalence of genotypes for day 0 vs. re-infection parasites. However, there was statistically significant difference for day 0 vs. recrudescence parasites in K76, N86 and D1246 loci; K76 and N86 were significantly associated with recrudescence. Recurring parasites harbored statistically higher K+NFD haplotype compared to day 0. There was no variation in pfmdr1 copy number. Analysis of K13 mutations is underway. ACTs remain highly efficacious in western Kenya. However, a few parasites had high half-lives. These parasites are of interest and more detailed genetic analysis is underway. In line with previous studies, we showed selection of K76 and N86 in recurring parasites. There is need for considerations of new policies for management of sustained ACTs efficacy in SSA.

208

GENETICALLY DETERMINED RESPONSE TO ARTEMISININ BASED COMBINATION THERAPY IN WESTERN KENYA *PLASMODIUM FALCIPARUM* PARASITES

Lorna J. Chebon[1], Ngalah Bidii[2], Luicer A. Ingasia[2], Hoseah M. Akala[2], Wallace Bulimo[2], Ben Andagalu[2], Edwin Kamau[2]

[1]Institute of Tropical Medicine and Infectious Diseases, College of Health Sciences, Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya; Department of Emerging and Infectious Diseases, United States Army Medical Research Unit-Kenya, Nairobi, Kenya, [2]Department of Emerging and Infectious Diseases, United States Army Medical Research Unit-Kenya, Kenya Medical Research Institute/Walter Reed Project, Kisumu, Kenya

In 2006, artemether-lumefantrine (AL) became the first-line treatment of uncomplicated malaria in Kenya due to widespread SP resistance. AL remains highly efficacious but there are heightened concerns because ACTs resistance is now well documented in Southeast Asia (SEA). SNPs in K13-propeller gene have been identified as the determinants of ACTs resistance in SEA though they are not present in Kenyan parasites. Genetically determined artemisinin resistance in ***Plasmodium falciparum*** has been described in SEA in association with slow parasite clearance rates (CRs). This study attempted to elucidate whether parasite genetics can provide basis for discovering genetic markers associated with ACTs resistance in Kenya. A randomized open labeled trial was conducted to evaluate whether genetic factors play a role in CRs in patients treated with ACTs from western Kenya. In addition, the genetic profiles of these parasites were compared to those collected before the introduction of AL (pre-ACTs). 118 subjects were enrolled in the study and randomized to receive either AL or Artesunate Mefloquine. A panel of 12 microsatellites (MS) and 91 SNPs distributed across the ***P. falciparum*** genome were genotyped. Parasite CRs were calculated using the WWARN online parasite clearance estimator tool. All subjects achieved parasite clearance within 42 hours of treatment with a median clearance half-life of 2.55 hours (1.19-5.05). The 12 MS showed high polymorphism with post-ACTs parasites being significantly more diverse compared to pre-ACTs ($p < 0.0001$). Based on SNP analysis, 15 of 90 post-ACTs parasites successfully analyzed were single-clone infections. Analysis revealed 3 SNPs in chromosome 12 and 14 were significantly associated with delayed parasite CRs and might be useful in tracking artemisinin resistance in Kenya. Further, genetic analysis using Bayesian tree revealed parasites with similar parasite clearance as more closely related. Therefore, we have described parasites with genetically determined response to artemisinin treatment which can provide basis for discovering genetic markers associated with ACTs resistance in Kenya.

209

GENETIC CHARACTERISTICS OF *PLASMODIUM FALCIPARUM* FOUND IN SUBJECTS RANDOMIZED TO DISCONTINUATION VERSUS CONTINUATION OF COTRIMOXAZOLE PROPHYLAXIS

Dennis W. Juma

U.S. Army Medical Research Unit-Kenya, Kisumu, Kenya

The WHO recommends cotrimoxazole (CTX) prophylaxis for HIV-1 infected individuals in regions with high prevalence of infectious diseases. However, with scale-up of antiretroviral therapy (ART), the usefulness of CTX is not well defined especially since it is thought its usage might increase risk of developing cross-resistance to closely related drugs such as sulfadoxine-pyrimethamine (SP). We conducted a non-blinded non-inferiority randomized controlled trial in Homabay, western Kenya to assess CTX prophylaxis discontinuation (DIS) vs. continuation (CON) among HIV-1 infected adults. The subjects had to be on ART for >18 months with CD4 >350 cells/mm3. 500 subjects were enrolled; 250 in DIS arm and 250 in CON arm. Blood samples were collected every 3 months, at time-points in months 0, 3, 6, 9 and 12. Malaria prevalence and mutations associated with SP resistance in pfdhfr and pfdhps genes were assessed by direct sequencing. The prevalence (overall) of ***Plasmodium*** was 3.8%, with 3.2% in DIS and 0.6% in CON. The prevalence of mutant haplotype for each arm at each time-point was calculated and compared. Pfdhfr 51I/59R/108N haplotype was present only in DIS arm in all the 5 time-points (prevalence 16.7% - 66.7%) except for month 9 in CON arm. Pfdhfr 51I/108N/164L was present in months 0, 9 and 12 in both DIS and CON arms. In pfdhps gene, 437G/540E haplotype appeared in both arms at all time-points whereas 437G/540E/581G was present only in month 6 in DIS arm only. Combined 51I/59R/108N/437G/540E appeared only in DIS arm in all time-points (prevalence 16.7%-50%) whereas N51I/C59R/108N/437G/540E appeared only in CON arm in month 9 (prevalence 33.3%). Homabay has malaria prevalence of over 40%. In this study, both arms had overall malaria prevalence of less than 4%, with CON arm having less than 1%. Our data does not show evidence of selection of mutations associated with SP resistance. Given high mortality and morbidity caused by malaria, CTX demonstrates usefulness and eliminates the need for use of SP as intermittent preventive treatment in pregnant women and infants.

210

SELECTIVE SWEEPS AND GENETIC LINEAGES OF *PLASMODIUM FALCIPARUM* MULTI-DRUG RESISTANCE (PFMDR1) GENE IN KENYA

Peninah Muiruri, Dennis W. Juma, Edwin Kamau

US Army Medical Research Unit-Kenya, Kisumu, Kenya

Artemether-lumefantrine (AL) has been the first-line treatment for uncomplicated falciparum malaria in Kenya since 2006. AL selects for K76 in pfcrt and N86, 184F and D1246 in pfmdr1 genes in recurring parasites compared to the baseline infections. Microsatellite (MS) analysis of loci flanking genes associated with antimalarial drug resistance has been used in defining the geographic origins and dissemination of resistant parasite. Kenya has diverse malaria transmission intensities with varying malaria endemicities. This study investigated evidence of selective sweep and genetic lineages in pfmdr1 genotypes selected for by AL in treatment of malaria infections in Kenya. Parasites (247) from different regions in Kenya (Kisumu, Kisii, Kericho and Malindi) were analyzed for polymorphisms at codons 86, 184 and 1246 in pfmdr1. Samples were typed for 8 NMS and 13 MS loci flanking pfmdr1. Full data set was obtained in 79% (186) of the samples. Overall, prevalence of N86 and D1246 was highest at 85.1% and 90.5% respectively. The most prevalent haplotype was NFD at 53.2% whereas the least prevalent was YFY at 1.1%. Per site, N86 was highest in Kisumu at 92.6% and lowest in Malindi at 65.1%. Kericho had the lowest prevalence of mutant alleles in all the loci whereas Malindi had the highest. Kisumu had the highest prevalence of NFD (63.4%) whereas Malindi had the lowest (29.7%). The mean HE for NMS was 0.96 vs. 0.627 for the 13 MS indicating selection. Parasites carrying mutant alleles had reduced HE compared to the wild type NYD except for NFD. Analysis of parasite genetic lineages is underway. Data show high prevalence of NFD and NYD, difference in genetic diversity between sites and evidence of selection in pfmdr1 gene that is statistically different between sites. Data indicate parasites are evolving differently in response to AL drug pressure from one region to another suggesting rate at which AL tolerance will develop in different regions of Kenya might vary.

211

ARTEMISININ-BASED COMBINATION THERAPY EFFICACY IN KISUMU, WESTERN KENYA: *IN VIVO* AND *IN VITRO* EFFICACY FINDINGS

Ben Andagalu, Dennis Juma, Luicer Ingasia, Lorna Chebon, Irene Onyango, Angela Omondi, Agnes Cheruiyot, Hosea Akala, Edwin Kamau

Department of Emerging and Infectious Diseases, United States Army Medical Research Unit-Kenya, Kenya Medical Research Institute/Walter Reed Project, Kisumu, Kenya

Plasmodium falciparum (Pf) resistance to artemisinin is prevalent in Southeast Asia (SEA) and is a threat to malaria control efforts. Africa is currently spared, but this observation is evocative of the emergence of chloroquine and sulphadoxine-pyrimethamine resistance that was first observed in SEA and later in Africa. More comprehensive monitoring is required in malaria endemic areas. In 2013-2014, we conducted an efficacy study of artemether lumefantrine (AL) and artesunate mefloquine (ASMQ) for the treatment of uncomplicated Pf malaria in Kisumu, Western Kenya - an area with high malaria transmission. A total of 118 subjects were randomized in a 1:1 ratio to receive either AL or ASMQ. Treatment was directly observed. Blood draws for malaria tests were performed at hours 0, 4, 8, 12, 18, 24 and 6 hourly thereafter until 2 consecutive negative malaria blood films (MBFs) were obtained. Blood samples for MBFs were also collected during weekly follow-up visits from day 7 to 42. Hour 0 samples were tested for ***ex vivo*** sensitivity to antimalarial drugs. Findings from the AL arm are presented here. The geometric mean parasitemia at presentation was 37892.5 parasites/µL (95% CI 25294.2, 56765.6). There were no cases of early treatment failure. Before PCR correction, 54.2% (32/59) had 28 day adequate clinical and parasitological response (ACPR) and 35.6% (21/59) had 42 day ACPR. After PCR correction, 100% had 28 and 42 day ACPR. The median time to clear 99% of parasitemia (PC99) was 21.19 hours (range 10.40 - 32.25), while the median time to clear 50% of parasitemia (PC50) was 7.42 hours (range 0.83 - 15.54). The median parasite clearance slope half-life was 2.45 hours (range 1.56 - 4.02). The influence of age on the parasite clearance parameters was not statistically significant. Hour 0 drug sensitivity IC50 median values for artemether, dihydroartemisinin and lumefantrine were 4.13 nmol (IQR 1.68, 10.75), 8.34 nmol (IQR 1.84, 35.21) and 31.69 nmol (IQR 3.40, 111.49) respectively. AL efficacy for the treatment of uncomplicated malaria in Kisumu is still high. This study provides baseline malaria parasite clearance profiles that must continuously be monitored.

212

HIGH LEVEL *PLASMODIUM FALCIPARUM* SULFADOXINE-PYRIMETHAMINE RESISTANCE WITH THE CONCOMITANT OCCURRENCE OF THE SEPTUPLE HAPLOTYPE IN TANZANIA

Vito Baraka

National Institute for Medical Research,Tanzania, Tanga, United Republic of Tanzania

Sulphadoxine-pyrimethamine (SP) was abandoned as the first-line treatment; however, it is still being used for intermittent preventive treatment during pregnancy (IPTp-SP). Here, we assessed the pattern of ***Plasmodium falciparum*** dhps and dhfr haplotypes in areas with different transmission intensities in Tanzania. A total of 264 samples were collected during cross-sectional survey in three districts of Muheza, Muleba and. The haplotypes were amplified by PCR and then detected by SSOP-ELISA. Results: The triple Pfdhfr mutant haplotypes (CIRNI) were predominant in all sites with significantly higher frequencies at Muheza district (93.9%) when compared to Muleba (73%) and Nachingwea (65.15%), ($p<0.001$). In contrast, the prevalence of triple Pfdhps SGEGA haplotype was significantly higher at Muheza (38.8%) as compared to Muleba (1.5%) and none at Nachingwea ($p<0.001$). The combinations of Pfdhfr-Pfdhps as quintuple CIRNI-SGEAA (n=25), sextuple CIRNI-SGEGA (n=24) and CIRNI-AGEGA (n=53) haplotypes were detected including the emergence of a septuple mutant haplotype CIRNI-AGEGA (n=9) predominantly at Muheza. In conclusion, the high prevalence of Pfdhfr-Pfdhps mutant haplotypes could undermine the efficacy of IPTp-SP leading to poor pregnancy outcomes.

213

PREVALENCE OF ANTIMALARIAL DRUG RESISTANT ALLELES ACROSS VARIABLE TRANSMISSION ZONES IN THE GAMBIA

Sukai Ceesay, Joseph Okebe, Abdoulie Touray, Haddy Nyang, Julia Mwesigwa, Muna Affara, Davis Nwankanma, Umberto D'Alessandro, Alfred Amambua-Ngwa

The Medical Research Council, Banjul, Gambia

Exacerbation of interventions and the introduction of artemisinin combination therapies (ACTs) are thought to have accounted for the decline in Malaria transmission across sub-Saharan African (sSA). However emergence of artemisinin resistance in South-East Asia and fears of spread to Africa calls for vigorous monitoring of ACT efficacy and anti-malarial drug resistance markers. In parts of sSA approaching malaria elimination, low transmission and loss of immunity can lead to epidemics and establishment of imported or emerging drug resistant strains. This study therefore sought to map the prevalence of drug resistance markers across hot and low transmission areas across the Gambia which in the last decade has shown declining malaria prevalence approaching pre-elimination levels. Polymorphic markers for kelch gene (K13 SNP 580, 543, 539), ***Plasmodium falciparum*** multi-drug resistant protein-1 (***Pf***mdr1 SNP N86Y, D1246Y,) ***Pf***ATPase402 and the ***Pf***crtK76T SNPs were typed in 335 parasite isolates using Taqman allelic discrimination assays or Sanger

sequencing. Samples were collected from cross-sectional surveys and passively detected infections. Preliminary results of genotype proportions in the coastal regions of the Gambia indicate that there were 10.5% mutant alleles for *Pf*ATPase402, increasing to 20% in the central river flood plains and 14% in rural settlements in the East. *Pf*mdr1 N86Y mutant allele proportion was highest in the coastal regions (14%), 3% in the central regions and 10% in the upper river regions. *Pf*mdr1 SNP D1246Y attained 1.6% in the coastal region. Only reference alleles of the K13 propeller polymorphisms were identified. This study shows the persistence of MDR mutations in the Gambia despite the discontinuation of Chloroquine. These markers are indirectly associated with delayed clearance in ACT treatment and will require continuous monitoring.

214

MAINTAINED EFFICACY A DECADE AFTER THE INTRODUCTION OF ARTESUNATE PLUS SULPHADOXINE-PYRIMETHAMINE FOR *PLASMODIUM FALCIPARUM* MALARIA IN AFGHANISTAN

Ghulam R. Awab[1], Mallika Imwong[2], Sasithon Pukrittayakamee[2], Arjen Dondorp[3], Nicholas P. Day[3], Nicholas J. White[3], Faizullah Kaker[4], Charles J. Woodrow[3]

[1]Nangarhar University, Jalalabad, Afghanistan, [2]Mahidol University, Bangkok, Thailand, [3]Oxford University, Oxford, United Kingdom, [4]Ministry of Public Health, Kabul, Afghanistan

Combination therapy with artesunate plus sulphadoxine-pyrimethamine was adopted as recommended treatment for ***Plasmodium falciparum*** infection in Afghanistan in 2003. We have performed a series of efficacy studies to examine the efficacy of AS+SP against ***P. falciparum*** in sentinel sites in Afghanistan from 2007 to 2014, accompanied by relevant molecular studies. Initial work (n=120) involved randomising patients to artesunate plus sulphadoxine-pyrimethamine or dihydroartemisinin-piperaquine, while subsequent studies were therapeutic efficacy studies of artesunate plus sulphadoxine-pyrimethamine. The studies enrolled 303 patients across four provinces in the north and east of the country. Efficacy was high in all the trials, with an adequate clinical and parasitological response (ACPR) of more than 95% in all groups and trial stages. Genotyping for drug-resistance alleles at dhfr indicated fixation of the S108N mutation and a prevalence of the C59R mutation of approximately 95%. Other mutations in dhfr and dhps were generally rare or absent entirely. The prevalence of the dhps K540E mutation fell over the course of the study (5/60 samples to 0/135; p = 0.0024) suggesting that despite the ongoing use of sulphadoxine-pyrimethamine, there is no evidence of worsening resistance to it components. For the study undertaken in 2012-2014, only two samples of 60 successfully sequenced carried a K13-propeller mutation.These data confirm maintained efficacy of the artesunate plus sulphadoxine-pyrimethamine combination against ***P. falciparum*** and suggest that the extent of sulphadoxine-pyrimethamine resistance has not worsened and may be improving.

215

PHARMACOKINETICS OF TRANSFER OF PIPERAQUINE INTO THE BREAST MILK OF PAPUA NEW GUINEAN MOTHERS

Brioni R. Moore[1], Sam Salman[1], John Benjamin[2], Madhu Page-Sharp[3], Gumal Yadi[2], Kevin T. Batty[3], Peter M. Siba[2], Ivo Mueller[4], Timothy M. Davis[1]

[1]University of Western Australia, Perth, Australia, [2]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [3]Curtin University of Technology, Perth, Australia, [4]The Walter and Eliza Hall Institute, Parkville, Australia

Women living in malaria-endemic areas, such as coast Papua New Guinea (PNG), are at high risk of malaria infection during pregnancy. Currently recommended treatment strategies include prompt treatment of symptomatic malaria and intermittent presumptive treatment in pregnancy (IPTp). A promising candidate for IPTp is dihydroartemisinin-piperaquine (DHA-PQ) which has been assessed in a number of safety, efficacy and pharmacokinetic studies. Whilst available data suggests this combination is safe and effective for use in pregnancy, there are no published pharmacokinetic studies of the transfer of PQ into breast milk and its subsequent ingestion by the infant. The transfer of PQ into breast milk was investigated in 27 pregnant PNG women who received a 3-day course of DHA-PQ or sulfadoxine-pyrimethamine-PQ during the second/third trimester. Breast milk samples were collected 1, 2, 3-5, 7-11 and 14-17 days post-delivery with a maternal blood sample also collected at time of delivery. Milk and plasma PQ was assayed using high performance liquid chromatography. A population-based approach was used to model log e (plasma) and milk concentration-time data. PQ breast milk transfer was found to be best described by a sigmoid Emax model. A milk:plasma ratio was found to be 0.58 (population average) with a peak of 2.5 found at delivery. The median estimated absolute and relative cumulative infant PQ doses were 22 µg and 0.07%, respectively, corresponding to absolute and relative daily doses of 0.41µg/kg and 0.004%. Model-based simulations for PQ treatment given at birth, 1 week post-delivery and 6 weeks post-delivery showed that the highest median estimated relative total infant dose (0.36%, or median absolute total dose 101 µg/kg) was seen after maternal PQ treatment 6 weeks postpartum. The maximum simulated relative total and daily dose from any scenario were 4.3% and 2.5%, respectively, lower than the recommended 10% upper limit. Therefore, it was demonstrated that PQ is transferred into breast milk after maternal treatment but the level of infantile exposure appears safe.

216

A SURVEY OF THE RESERVOIR OF MOLECULAR MARKERS OF *PLASMODIUM FALCIPARUM* ANTIMALARIAL DRUG RESISTANCE FROM A HIGH TRANSMISSION SETTING IN BONGO DISTRICT, GHANA

Charles A. Narh[1], Kathryn E. Tiedje[2], Christiana O. Onwona[1], Thomas Anyorigiya[3], Godfred Agongo[3], Daniel Azongo[3], Timothy Awine[3], Raymond Aboriga[3], Abraham Oduro[3], Mercedes Pascual[4], Kwadwo A. Koram[1], Karen P. Day[2], Anita Ghansah[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]School of BioSciences, The University of Melbourne, Melbourne, Australia, [3]Navrongo Health Research Center, Navrongo, Ghana, [4]Department of Ecology and Evolutionary Biology, University of Michigan, Ann Arbor, MI, United States

Despite significant strides made to decrease the burden of malaria globally, billions of infections still persist for months in the human population. These chronic infections constitute the reservoir of infection and if left untreated, serve to fuel continued transmission. ***Plasmodium falciparum*** resistance to anti-malarial drug treatments threatens malaria control and elimination activities worldwide. To eliminate malaria, it is essential that parasite populations be monitored so that genetic diversity, including drug resistance, is examined before, during and after interventions. A study based on a panel of 4 drug resistant genes; Pfcrt, Pfmdr1, Pfdhfr, and Pfdhps, was completed on 242 slide positive ***P. falciparum*** isolates collected from a cross-sectional survey of asymptomatic participants (>1 year) in two villages at the end of the 2012 dry season in Bongo District (BD), Ghana. The loci investigated include codons 72, 73, 74, 75 and 76 of the Pfcrt gene; 86, 184, 1034, 1042, and 1246 of the Pfmdr1 gene; 51, 59, 108, and 164 of the Pfdhfr gene; 436, 437, 540, 581, and 613 of the Pfdhps gene. Mutations in key codons associated with resistance were detected (MEGA V6) following sequencing of the positive PCR amplicons. Over 15% (n=139), 81% (n=207), 90% (n=186), and 80% (n=228) of samples had at least one of the mutations in Pfcrt, Pfmdr1, Pfdhfr, and Pfdhps, respectively. The prevalence of Pfcrt mutation K76T was 7% and 12% for Pfmdr1 mutation N186Y. The prevalence of Pfdhfr S108N mutant was 87%, and the Pfdhps mutation A437G was 80%. C72V73I74E75T76 haplotype had a prevalence of 3.6%. In addition, 15 atypical/novel non-synonymous mutations that have not been previously reported in Ghana, were observed among 21% of samples in Pfdhps and Pfdhfr. This data also predicted ≈35 ***P. falciparum*** clades within BD using a neighbor-joining

phylogeny. Our data portray a highly diverse ***P. falciparum*** population circulating in BD with possible resistance to CQ and SP. This data will be useful for improving malaria surveillance and for determining the specific parameters that need to be utilized when monitoring the effects of interventions on ***P. falciparum*** diversity.

217

PLASMODIUM FALCIPARUM PFCRT-RESISTANT HAPLOTYPES IN CHILDREN WITH UNCOMPLICATED MALARIA FOUR YEARS AFTER CHANGE IN POLICY FROM CHLOROQUINE AS FIRST-LINE ANTIMALARIAL MEDICINE IN LAGOS, NIGERIA

Oladipo O. Oladosu

ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Lagos, Nigeria

Chloroquine (CQ) was widely used for the treatment of ***Plasmodium falciparum*** for several decades. Despite the change in National malaria drug policy to artemisinin combination therapy (ACT) in Nigeria in 2005 due to CQ resistance to ***P. falciparum***, CQ is still widely used in the treatment of malaria because it is cheap, affordable and accessible. Genetic markers to predict ***Plasmodium*** parasites' resistance especially for single nucleotide polymorphisms (SNPs) have the potential to provide information on P falciparum resistance to antimalarial. This study determined the prevalence of Pfcrt haplotypes and point mutations in Pfmdr1 genes four years after the change in antimalarial treatment policy to the ACTs in Lagos, a commercial city in Nigeria.It was a cross sectional study of uncomplicated malaria in children less than 12 years that presented with fever and other symptoms suggestive of malaria. Parasites DNA were extracted from 119 patients out of 251 children that were positive for ***P. falciparum*** by microscopy and amplified. The occurrence of haplotypes was investigated in Pfcrt gene using probe-based qPCR and nested PCR for SNPs in Pfmdr1 gene.The majority of the children (91.6%) harboured parasites with the mutant Pfcrt haplotype (CVIET). Five of the isolates (4.2%) had a mixture of genotypes encoding CVMNK and CVIET,while 4.2% had the wild type (CVMNK). SVMNT was not seen in this population. Furthermore, the frequency of point mutations in Pfmdr1 was 62.2% and 69.0% for codons Y86 and F184 respectively. There were no mutations at codons 1034, 1042 and 1246 of the Pfmdr1 genes. The high frequency of the CQ-resistant haplotypes (CVIET) and mutations in the Pfmdr1 known to be associated with CQ failure seen in this study suggest that CQ resistance ***P. falciparum*** parasites are still in circulation. Continuous use of CQ may increase the level of resistant Pfcrt haplotypes and point mutations in Pfmdr1 genes and could threaten the efficacy of current ACTs. There is need to strengthen current case management efforts at promoting ACT and restricting access to CQ and other antimalarial monotherapy by the drug regulatory Agency.

218

MOLECULAR SURVEILLANCE OF POLYMORPHISMS IN THE K13 PROPELLER DOMAIN OF *PLASMODIUM FALCIPARUM* MALARIA FROM THIES, SENEGAL, 2011-2014

Yaye D. Ndiaye[1], Awa Bineta Deme[1], Baba Dieye[1], Mouhamadou Ndiaye[1], Sarah Volkman[2], Donald Krogstad[3], Julie Thwing[4], Eric S. Halsey[4], Eldin Talundzic[4], Venkatachalam Udhayakumar[4], Daouda Ndiaye[1]

[1]Universite Cheikh Anta Diop, Dakar, Senegal, [2]Harvard School of Public Health, Boston, MA, United States, [3]Tulane University, New Orleans, LA, United States, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States

In Senegal, artemisinin combination therapy (ACT) has been adopted in 2006 as the first-line treatment for uncomplicated ***Plasmodium falciparum*** malaria. Recent reports have provided evidence for the evolution of artemisinin resistance in the Greater Mekong Subregion, threatening current malaria control and elimination efforts. Monitoring of the recently identified artemisinin resistant K13 propeller mutations in the context of therapeutic efficacy studies has now been adopted as a way to monitor changes in the sensitivity patterns of parasites to artemisinin drugs. Some of the mutations in the K13 propeller domain have been found to be associated with delayed parasite clearance and ring stage parasite survival. The goal of this study was to determine the presence or absence of K13 propeller mutations from ACT therapeutic efficacy study samples collected in Thies, Senegal, during 2011-2014. We performed Sanger sequencing of the K13 propeller gene using protocols established in our laboratory. A total of 251 samples were analyzed for mutations in the K13 propeller domain using the Geneious Pro R8 software. An automated single nucleotide polymorphism (SNP) calling workflow developed in our laboratory using Geneious Pro R8 was used for this analysis. Briefly, by selecting a user defined sequence list and reference sequence as an input, the workflow automatically mapped the input sequences to the reference sequence, identified all SNPs, and exported the final SNP calls. Each step created a sub-folder allowing the user to check the results. SNPs were only called if both the forward and reverse strands had the mutation. No mutations were detected in the K13 propeller domain; all 251 samples from Thies, Senegal, were wild type. Overall, the K13 molecular data is consistent with the therapeutic efficacy study results which showed ACT remains efficacious in Thies, Senegal.

DYNAMICS OF MALARIA DRUG RESISTANCE IN THE GAMBIA

Fatou Joof

Medical Research Council, The Gambia Unit, Banjul, Gambia

Chemotherapy has been one of the most effective malaria control measures, but has always been limited by repeated appearance and spread of resistance to almost all antimalarial drugs in use. Recent reports of uprising resistance to Artemisinin in South East Asia calls for the surveillance of its development and spread. This current study is based in a rural setting in eastern part of The Gambia, where participants (n=120) diagnosed with uncomplicated malaria were recruited from a health facility. Samples were collected before and after treatment, with participants followed for 42 days. Parasites were tested ***ex vivo*** against 11 popular anti malarial drugs including artemisinin and its derivatives. Median IC_{50} values were generated and for n=50 (Piperaquine = 30.3nM; Artemisinin = 7.4nM; Dihydroartemisinin = 3.15nM; Lumefantrine = 82.43nM; Amodiaquine = 11.4nm; Quinine = 69.4nm; Chloroquine = 61.3nM; Pyremethamine = 8410nM; Artesunate = 4.6nM; Mefloquine = 27.2nM and Artemisinin = 10.3nM). Analysis is being conducted to compare ***ex vivo*** data with ***in vivo*** clinical response, which reported 30% (n=120) recurrence of parasites, primarily in the last 2 weeks of follow up visit. Genotyping by both SNP barcode and MSP are being used to investigate the parasite populations at initial infection and subsequent recrudescence or re-infection. In addition, molecular analysis of drug resistant mutations (pfcrt, pfmdr1, dhps, dhfr) will be correlated with the ***ex vivo*** response and the observed ***in vivo*** clinical outcome. This analysis will help provide a picture of the efficacy of the current line of treatment (Artemisinin based combination Therapy) in a sub-Saharan setting as well the distribution of drug resistance markers in a parasite population.

220

RECRUDESCENT *PLASMODIUM FALCIPARUM* ISOLATES FROM DHA-PIPERAQUINE FAILURES IN CAMBODIA: *IN VITRO* SUSCEPTIBILITY TO NEWER ANTIMALARIAL DRUGS

Vorleak Try[1], Dalin Dek[1], Sokunthea Sreng[1], Seila Suon[1], Sivanna Mao[2], Chantha Sopha[3], Didier Leroy[4], Chanaki Amaratunga[5], Jennifer M. Anderson[5], Pharath Lim[5], Rick M. Fairhurst[5]

[1]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [2]Sampov Meas Referral Hospital, Pursat, Cambodia, [3]Makara 16 Referral Hospital, Preah Vihear, Cambodia, [4]Medicines for Malaria Venture, Geneva, Switzerland, [5]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States

Dihydroartemisinin-piperaquine (DHA-PPQ) is the frontline artemisinin combination therapy (ACT) for falciparum malaria in Cambodia, but recent treatment failures - caused by resistance to both DHA and PPQ - are now prevalent in this country's western provinces. Alternative treatments, including ACT partner drug replacements, are urgently needed. To investigate potential treatments, we culture-adapted ***Plasmodium falciparum*** clinical isolates that recrudesced following treatment with DHA-PPQ in Cambodia in 2012-2013, and measured their in-vitro susceptibilities to two novel potent antimalarial compounds (NITD609, OZ439), various alternative ACT partner drugs [lumefantrine (LUM), pyronaridine (PYN), ferroquine (FQ), naphthoquine (NQ)], and PPQ. Using a SYBR Green I fluorescence assay, we calculated the in-vitro IC_{50} values of these drugs for 36 recrudescent parasites - both the initial isolate at the time of clinical presentation and the recrudescent isolate at the time of treatment failure. The geometric mean IC_{50} values (GMIC50s) for initial isolates were: 0.9 nM for NITD609, 2.4 nM for OZ439, 21.8 nM for LUM, 6.8 nM for PYN, 33.7 nM for FQ, 12.9 nM for NQ, and 51.5 nM for PPQ. The $GMIC_{50}$s for all seven drugs were not significantly different between initial and recrudescent isolates. Additionally, there were no positive correlations between GMIC50s between drugs, except for NQ versus PYN. These data indicate that contemporary Cambodian isolates causing DHA-PPQ failures are highly susceptible to newer antimalarials, and suggest that these drugs might be useful components of alternative combination therapies for multidrug-resistant malaria in Southeast Asia. These data also provide valuable baseline GMIC50s for these drugs should they become routinely used in Cambodia in the near future.

ASSESSMENT OF THE EFFICACY OF ARTESUNATE-AMODIAQUINE: RECOMMENDED THERAPY BY THE NATIONAL MALARIA CONTROL PROGRAM (NMCP) IN WESTERN MADAGASCAR

Tovonahary A. Rakotomanga[1], Thierry Franchard[1], Brune Ramiranirina[1], Tiana Ramanatiaray[1], Arsene Ratsimbasoa[1], David Serre[2], Rosalind E. Howes[3], Peter A. Zimmerman[4]

[1]National Malaria Control Programme of Madagascar, Antananarivo, Madagascar, [2]Genomic Medicine Institute, Cleveland Clinic, Cleveland, OH, United States, [3]Department of Zoology, University of Oxford, Oxford, United Kingdom, [4]Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States

Madagascar remains malaria endemic, but there are plans to shift from malaria control policies towards achieving pre-elimination status. Although there is evidence that four malaria species are transmitted across Madagascar, ***Plasmodium falciparum*** is the predominant species nationally, with clusters of ***P. vivax*** transmission particularly in the highland fringe regions of western Madagascar. In order to assess the efficacy of 3-day artesunate-amodiaquine (ASAQ) therapy in Madagascar, drug efficacy was evaluated in children presenting with uncomplicated malaria. Children between six months and 5 years with uncomplicated ***P. falciparum*** and ***P. vivax*** malaria were enrolled in May 2012 to September 2012, in Tsiroanomandidy, in a western, endemic area of Madagascar. The day-28 treatment failure rate assessed by conventional microscopy was compared to molecular diagnostic evaluation by a ligase detection reaction-fluorescent microsphere assay (LDR-FMA). Risks of clinical and parasitological treatment failure after adjustment by molecular diagnosis were estimated using Kaplan-Meier survival analysis. Secondary outcomes included fever clearance, parasite clearance, change in hemoglobin levels between Day 0 and the last day of follow-up, and the incidence of adverse events. Comparison of microscopy and LDR-FMA data was performed for eight individuals for whom data from day 0 to day 28, one person was missing the day 21 samples. Among these 8 individuals parasitemia cleared by day 2 post-treatment, however, parasitemia was observed to return on day 28 for one individual. The molecular diagnostic signal lingered beyond day 2 for all individuals for up to 21 days post-treatment. Return of molecular diagnostic signal was observed to return for 3 individuals. In the context of AS-AQ effectiveness studies, it will be important to monitor clearance of malaria by microscopy and molecular diagnostic strategies.

222

THE INFLUENCE OF THE 581G MALARIA PARASITE MUTATION ON INTERMITTENT PREVENTIVE TREATMENT IN PREGNANCY (IPTP): A SYSTEMATIC REVIEW AND META-ANALYSIS

R. Matthew Chico

London School of Hygiene & Tropical Medicine, London, United Kingdom

The World Health Organization (WHO) recommends the provision of intermittent preventive treatment with sulphadoxine-pyrimethamine (IPTp-SP) to pregnant women resident in areas of moderate (stable) or high malarial transmission to reduce the incidence of low birthweight (LBW) and other adverse birth outcomes attributable to malaria. However, the protective effect of IPTp-SP has been compromised due to parasite mutation. Of particular concern is the ***Plasmodium falciparum*** dihydropteroate synthetase (***Pfdhps***) resistance mutation at codon 581G which appears to render falciparum malaria parasites 'super resistant' to SP. We conducted a systematic review and meta-analysis of the protection against the incidence of LBW conferred by > 2 doses of IPTp-SP. Two or more doses of IPTp-SP versus placebo or no IPTp-SP cut the odds in half of delivering a LBW newborn among primi- and secundigravidae (odds ratio [OR] = 0.54; 95% Confidence Intervals [CI]: 0.35, 0.84; $P < 0.00$). Among multigravidae, the odds were reduced by 30% (OR = 0.70; 95% CI: 0.51, 0.95; $P = 0.04$). We then used a geographical database of biomarkers to obtain point prevalence estimates of the Pfdhps 581G mutation among parasites from the same locations where IPTp-SP studies had been conducted. Using these estimates, we carried out sensitivity analyses and found that IPTp-SP protected primi- and secundigravidae against the incidence of LBW where the prevalence of the parasite mutation 581G was < 10.1% (OR = 0.49; 95% CI: 0.29, 0.81; $P = <0.01$) and where the prevalence of 581G was > 10.1% (OR = 0.73; 95% CI: 0.29, 1.81; $P = 0.03$). In contrast, among multigravidae there was only borderline protection against LBW conferred by IPTp-SP in areas where the prevalence of 581G was < 10.1% (OR = 0.56; 95% CI: 0.37, 0.86; $P = 0.07$) and no evidence of protection in settings where the prevalence of 581G was > 10.1% (OR = 0.96; 95% CI: 0.70, 1.34; P = 0.47). This suggests that there may be a threshold that could be used to guide IPTp-SP policy change.

223

PLASMODIUM FALCIPARUM RECRUDESCENCE IN CULTURE FOLLOWING PULSE TREATMENTS WITH LUMEFANTRINE

Nahla B. Gadalla, Thomas E. Wellems

National Institutes of Health, Rockville, MD, United States

Multidrug-resistant ***Plasmodium falciparum*** is a major threat to global malaria control. Currently there is world-wide recommendation for the use of artemisinin-combination therapy (ACT). Artemether-lumefantrine is the recommended treatment for falciparum malaria in

51 countries. The lumefantrine component is a synthetic aryl-amino alcohol that mainly targets the mature asexual stages of the parasite. While there are no confirmed characterizations of parasite resistance to lumefantrine, there is substantial evidence for treatment failure in patients treated with artemether-lumefantrine. A risk for resistance is that the relatively long half-life of lumefantrine (3-5 days) exposes a proportion of parasites that have not yet been cleared to sub therapeutic levels of lumefantrine after artemether leaves the circulation. In this study, parasites from a Cambodian clone of ***P. falciparum*** (CP-803) were subjected to pulse treatment with lumefantrine at incremental concentrations. These treatment pulses reduced parasitemia to subpatent levels before recrudescent parasite populations were obtained. Interestingly the selected parasites were completely eliminated by continuous exposure for 28-days at <10% of the drug concentration used for the pulse treatments, and the lumefantrine IC_{50} levels of the selected line remained little changed from that of the unselected parasites.

224

POLYMORPHISMS IN K13, PFCRT, PFMDR1, PFDHFR AND PFDHPS IN PARASITES ISOLATED FROM SYMPTOMATIC MALARIA PATIENTS IN BOBO-DIOULASSO, BURKINA FASO

Anyirékun Fabrice Some[1], Thomas Bazie[1], Amadé Sawadogo[1], Frédéric Nikiema[1], Issaka Zongo[1], Laura Berne[2], Khim Nimol[2], Didier Menard[2], Jean-Bosco Ouedraogo[1]

[1]Institut de Recherche en Sciences de la Sante, Direction Regionale, Bobo-Dioulasso, Burkina Faso, [2]Pasteur Institute Cambodia, Phnom Penh, Cambodia

The emergence of resistance to artemisinin derivatives in western Cambodia could jeopardize the control and elimination of malaria. Known resistance-mediating polymorphisms in the K13, pfcrt, pfmdr1, pfdhfr and pfdhps are of greatest importance to monitor the spread of resistance. Samples for this study were collected in 228 malaria patients randomized to receive artemether-lumefantrine or artesunate-amodiaquine for the treatment of uncomplicated malaria in Colsama and Sakaby health centers, Bobo-Dioulasso, Burkina Faso. Blood sample were collected on filter paper on day 0,1,2,3,7 14,21,28 and on any day the patients felt ill. We evaluated the prevalence of polymorphisms in K13, pfcrt K76T, pfmdr1 (N86Y, Y184F) and pfdhps (A437G, K540E) in parasites collected prior treatment. We reported 1.8% (5/221) of K13 synonymous mutant alleles (two C469C, one Y493Y, one G496G, and one V589V), 24.5%, 19.5% and 70.0% respectively for mutant pfcrt 76T, pfmdr1-86Y and pfmdr1-184F. Sulfadoxine-pyrimethamine (SP) resistance associated pfdhfr 51I, 59R and 108N were found in 141/228 (61.8%), 124/228 (54.4%) and 146/228 (64.0%) samples and pfdhps 437G in 145/228 (63.5%) samples. These data provide baseline prevalence of key antimalarial drug-resistance polymorphisms in Bobo-Dioulasso, Burkina Faso. e results suggest that artemisinin combination therapies and SP may retain good efficacy respectively in the treatment and prevention of malaria in Bobo-Dioulasso, Burkina Faso.

225

THE ROLE OF THE MALARIA PARASITE SUGAR PHOSPHATASE, PFHAD1, IN FOSMIDOMYCIN RESISTANCE AND METHYLERYTHRITOL PHOSPHATE (MEP) PATHWAY REGULATION

Jooyoung Park, Ann M. Guggisberg, Audrey R. Odom, Niraj H. Tolia

Washington University School of Medicine, St. Louis, MO, United States

The methylerythritol phosphate (MEP) pathway for isoprenoid precursor biosynthesis is an attractive target for novel anti-malarial drug development, as compounds that target this pathway lack toxicity concerns for humans. The small molecule compound fosmidomycin inhibits the MEP pathway enzyme deoxyxylulose 5-phosphate (DXR) and is in clinical trials for combination therapy with other anti-malarial compounds. Fosmidomycin-resistant ***Plasmodium falciparum*** strains were generated ***in vitro***. Genetic analysis of these parasites revealed that they are highly enriched for mutations in PfHAD1. The crystal structure of PfHAD1 was solved in order to determine the effects of the mutations on PfHAD1 structure and function, which revealed that these mutations cause loss of PfHAD1 function via protein misfolding or interference with substrate binding. We found PfHAD1 to be a sugar phosphatase member of the haloacid dehalogenase (HAD) superfamily with catalytic activity towards a variety of sugar phosphate compounds, including intermediates of glycolysis - which feed into the MEP pathway. Metabolic profiling revealed that fosmidomycin-resistant parasite strains lacking PfHAD1 have substantial increases in MEP pathway metabolites. Together, these results demonstrate that PfHAD1 regulates substrate availability to the MEP pathway and that loss of PfHAD1 function confers fosmidomycin resistance in ***P. falciparum***. While the metabolic effects and a biological phenotype of PfHAD1 have been elucidated, the substrate specificity and mechanism of catalysis for PfHAD1, or HAD superfamily members generally, have not been well defined. Crystal structures of PfHAD1 in complex with three different upstream MEP pathway precursors reveal how domain movement in PfHAD1 enables diverse substrate recognition. These studies further inform the molecular role of HAD enzymes, in regulation of an ancient, evolutionarily conserved, and essential metabolic pathway.

MOLECULAR SURVEILLANCE FOR K13 GENE AND OTHER *PLASMODIUM FALCIPARUM* MOLECULAR MARKERS ASSOCIATED WITH ANTIMALARIAL RESISTANCE IN SURINAME

Stella M. Chenet[1], Sheila Akinyi Okoth[2], Curtis S. Huber[2], Alexandre Macedo de Oliveira[2], John Barnwell[2], Stephen Vreden[3], Venkatachalam Udhayakumar[2], Malti Adhin[4]

[1]ASM/Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Academic Hospital Paramaribo, Paramaribo, Suriname, [4]ADEK Universiteit van Suriname, Paramaribo, Suriname

The emergence and spread of antimalarial resistance in ***Plasmodium falciparum*** has the potential to severely limit the efficacy of antimalarial regimens. In Suriname, the current ***P.falciparum*** first-line treatment, artemisinin and lumefantrine (AL), is monitored every three years. One of the indicators for suspected resistance associated with artemisinin drugs is delayed parasite clearance (persistence of >10% of parasites on Day 3 after treatment initiation). An antimalarial trial using 3 days of artesunate monotherapy followed by mefloquine and primaquine was conducted during 2013-2014. Forty ***P. falciparum*** samples obtained at the time of enrollment were tested for the artemisinin resistance-associated K13 gene and for other known drug resistance markers, ***pfcrt, pfmdr1, pfdhfr,*** and ***pfdhps***. The K13 propeller domain and drug resistant genes were PCR amplified using established laboratory protocols and the amplicons were sequenced using Sanger method. Our results showed that all 40 samples contained only the wild type K13 sequence. In addition, all isolates carried the chloroquine-resistant ***pfcrt*** genotype SVMNT (codons 72-76), triple mutant pyrimethamine resistant ***dhfr*** genotype (50R/51I/108N), triple mutant sulphadoxine resistant ***dhps*** genotype (437G/540E/581G) and ***pfmdr1*** mutant genotype. Only a single isolate out of the 40 tested had two copies of ***pfmdr1*** gene, previously associated with mefloquine resistance. In addition, when analyzing neutral microsatellite data, the haplotypes found in Suriname were similar to those previously reported in Guyana, Venezuela, and Brazil, which indicates active migration in this area. In summary, this study found no evidence for the presence of artemisinin-resistant K13 alleles. Continued monitoring of antimalarial efficacy, using ***in vivo*** trials and molecular markers, are necessary to detect changes in treatment response and prevalence of ***P. falciparum*** resistant alleles.

227

IMPACT OF INTERMITTENT PREVENTIVE TREATMENT WITH DIHYDROARTEMISININ-PIPERAQUINE ON *PLASMODIUM FALCIPARUM* POLYMORPHISMS THAT MODULATE DRUG SENSITIVITY IN A TRIAL OF UGANDAN SCHOOLCHILDREN

Joaniter I. Nankabirwa[1], Jennifer Legac[2], Melissa D. Conrad[2], Bonnie Wandera[1], Simon J. Brooker[3], Sarah G. Staedke[3], Moses R. Kamya[1], Grant Dorsey[2], Philip J. Rosenthal[2]

[1]Makarere University Kampala, Kampala, Uganda, [2]Department of Medicine, University of California, San Francisco, CA, United States, [3]Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom

Dihydroartemisinin-piperaquine (DP) offers prolonged protection against malaria, due to the long half-life of piperaquine, but its impact on polymorphisms mediating ***Plasmodium falciparum*** resistance is uncertain. In a trial undertaken in Tororo, Uganda in 2011-12, monthly treatment with DP for one year in schoolchildren aged 6-14 years decreased the incidence of malaria by 96% and the incidence of asymptomatic parasitemia by 94% compared to children receiving placebo. To assess the impact of DP on parasite resistance-mediating polymorphisms in this trial, we assessed the prevalence of key polymorphisms between isolates that emerged at different intervals after treatment with DP. Blood was obtained during each episode of fever and monthly in asymptomatic children. Samples collected within 14 days of treatment for malaria (with artemether/lumefantrine) were excluded. 810 samples from symptomatic (160) and asymptomatic (650) episodes of parasitemia were assessed at 4 loci that modulate sensitivity to aminoquinoline antimalarials (N86Y, Y184F, D1246Y in pfmdr1 and K76T in pfcrt) utilizing a ligase detection reaction fluorescent microsphere assay. For pfmdr1 N86Y and pfcrt K76T, the prevalences of mutant genotypes, compared to wild type/mixed genotypes, were significantly greater in children who had received DP within 30 days of the episode of parasitemia (18% for N86Y; 96% for K76T) compared to those not treated within 60 days (8.3%, p=0.035 for N86Y; 86.1%, p=0.049 for K76T) or within 90 days (6.9%, p=0.012 for N86Y; 84.5%, p=0.031 for K76T). Associations were not seen between time since treatment and other SNPs. DP offered potent preventive efficacy against malaria, but parasites that emerged soon after treatment were more likely than parasites not under drug pressure to harbor pfmdr1 and pfcrt polymorphisms associated with decreased sensitivity to aminoquinoline antimalarials. DP offers promising preventive efficacy but additional studies of its potential selection of drug resistant parasites are warranted.

228

THE EFFICACY, SAFETY AND TOLERABILITY OF REPEAT DOSING WITH DIHYDROARTEMISININ-PIPERAQUINE FOR THE PREVENTION AND TREATMENT OF MALARIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Julie Gutman[1], Stephanie Kovacs[2], Andy Stergachis[3], Feiko O. ter Kuile[4]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Department of Epidemiology, University of Washington, Seattle, WA, United States, [3]Department of Epidemiology and Global Health, University of Washington, Seattle, WA, United States, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Intermittent preventive treatment (IPT) of malaria is a potential strategy for the control of malaria in infants, children, adults and pregnant women. Dihydroartemisinin-piperaquine (DP) is an effective and well tolerated antimalarial. The long half-life of piperaquine (~22 days) makes it an attractive choice for IPT. We conducted a systematic review and meta-analysis to determine the efficacy and safety of repeated exposures to 3-day courses of DP. We searched MEDLINE, EMBASE, Web of Science, Scopus, CINAHL Plus, the Cochrane Library databases, WHO Global Health Library and the Malaria in Pregnancy Consortium Library. Studies were eligible if they included prospective data on participants that received more than one dose of DP for IPT or case-management. Random effects models were used. Our search identified 745 citations; after title review 365 abstracts were reviewed. Nine unique patient populations were included: two repeat treatment studies (1 in children <5y [N=312] and 1 in pregnant women [N=5192]) and seven randomized, controlled IPT trials (5 in children <5y [N=5394], 1 in school children [N=740], 1 in adults [N=961]). In total, there were 12, 435 participants; 3099 were exposed to DP, including 2180 <5 years of age and 485 pregnant women. Comparator interventions included placebo, artemether lumefantrine, sulfadoxine-pyrimethamine (SP), SP-amodiaquine, SP-piperaquine, SP-chloroquine, and trimethoprim-sulfamethoxazole. The range of doses of DP was 3-18. Overall, monthly IPT-DP provided greater protective efficacy (PE) against any parasitemia than placebo (pooled PE: 88%, 95% confidence interval 84-93%). In total, 282 serious adverse events (SAEs) were reported, 62 among those exposed to DP; no study reported a disproportionate number of SAEs in DP recipients. Electrocardiogram results were reported from 19 participants from one study; all QTc intervals were reported within normal limits. The limited data on repeat DP exposures suggest that 3-day course of DP is safe and effective and a good option for IPT. Additional data are needed on the potential for QT prolongation and the safety of repeat exposures in pregnancy.

229

HEALTH WORKERS' KNOWLEDGE ON ADMINISTRATION OF INJECTABLE ARTESUNATE FOR TREATMENT OF SEVERE MALARIA IN OROMIA AND SNNPR REGION, ETHIOPIA

Zelalem Kebede[1], Takele Kefyalew[1], Tesema Awano[1], Madeleine R. Marasciulo[2], Prudence Hamade[2], James Tibenderana[2], Ebenezer S. Baba[2], Joaniter I. Nankabirwa[2]

[1]Malaria Consortium, Ethiopia, Addis Ababa, Ethiopia, [2]Malaria Consortium, Africa, Kampala, Uganda

The World Health Organization (WHO) recommends injectable artesunate as the first drug of choice for the treatment of severe malaria. Although Ethiopia adopted this recommendation and revised the malaria case management guidelines in 2012, no official training of health workers was performed on the new guidelines for management of severe malaria. We assessed the health workers knowledge on appropriate use of injectable artesunate for treatment of severe malaria cases. The study was conducted among 320 health workers randomly selected from 1,498 health facilities of malarious district of Oromia and Southern Nation Nationality and People Regional State (SNNPR). Self-administered questionnaires were used to assess the knowledge on proper administration of injectable Artesunate. Of the total participants, 66.3% were from Oromia state and 15.7% were doctors, 54.7% were nurses, 12.25% were health officers and the rest pharmacists. Majority (94.1 %) correctly responded that injectable artesunate is recommended for treatment of severe malaria but only 11 (3.4%) could demonstrate the steps for proper preparation and administration of the drug. Only 2% said that it is safe to administer injectable artesunate during all trimesters of pregnancy and 63% cited that proper administration sites for injectable artesunate. Although most health workers know that injectable artesunate is the first drug of choice for treatment of severe malaria, the study demonstrated that there is a lack of knowledge on preparation and administration of drug. Intensive training with practical sessions is required for health workers for proper managing severe malaria cases using injectable artesunate. Distribution of injectable artesunate, without building the capacity of health workers may result in risk of misuse of and development of resistance to artesunate.

230

AN ASSESSMENT OF INTERMITTENT PREVENTATIVE TREATMENT IN PREGNANCY COVERAGE ACROSS SUB-SAHARAN AFRICA FROM 2000-2015

Cristin A. Fergus[1], Michael Lynch[2], Richard Cibulskis[1], n. Global Malaria Programme, World Health Organization

[1]World Health Organization, Geneva, Switzerland, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States

Malaria in pregnancy has been shown to cause various poor health outcomes for mothers and their children. Intermittent Preventative Treatment of pregnant women (IPTp) with sulfadoxine-pyrimethamine (SP), the administration of one full treatment course of SP at routine second and third trimester prenatal visits, has been shown to reduce severe maternal anemia, low birthweight, and perinatal mortality with minimal adverse effects. Data from country reports and nationally-representative household surveys were used to assess the coverage levels of IPTp since the year 2000. Among the 37 countries with national IPTp policies, 30 reported on the number of women who attended ANC at least once and 31 reported on the number of doses of IPTp administered in 2013, more countries than in previous years. These reports were compared to the estimated number of pregnant women for each country, derived from UN population estimates. For 9 countries reporting on receipt of 3 or more doses of IPTp, a median of 17% of all pregnant women received 3 or more doses of IPTp; a median of 43% of pregnant women received 2 doses of IPTp in 31 countries, and 57% received at least one dose as reported by 30 countries. In 2013, a median 89% of pregnant women in reporting countries attended ANC, which, when compared to the proportion receiving at least one dose of IPTp, suggests a number of missed opportunities for delivery at ANC. The combination of yearly NMCP-reported IPTp distribution data with estimates of pregnant women and household survey data to assess trends over time shows an impressive increase in the uptake of all doses of IPTp through 2007, no substantial change during 2007-2010, followed by a modest upward trend projected through 2015. Given the importance of IPTp as a malaria intervention for a high risk population, continued efforts should be made to quantify the coverage levels.

231

IMPACT OF RAPID DIAGNOSTIC TESTS FOR THE DIAGNOSIS AND TREATMENT OF MALARIA AT A PERIPHERAL HEALTH FACILITY IN WESTERN UGANDA: AN INTERRUPTED TIME SERIES ANALYSIS

Ross Boyce[1], Anthony Muiru[1], Raquel Reyes[1], Edgar Mulogo[2], Moses Ntaro[2], Michael Matte[2], Mark Siedner[1]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]Mbarara University of Science and Technology, Mbarara, Uganda

The WHO recommends that all suspected malaria cases receive a parasitological diagnosis prior to treatment with artemisinin-based combination therapy. A recent meta-analysis of clinical trials evaluating RDTs for the management of patients with fever found substantial reductions in antimalarial prescriptions when health workers adhered to treatment protocols based on test results. However few studies have reported on the impact of RDTs on health systems outside research settings. We conducted a retrospective interrupted time series, comparing rates of malaria diagnosis, treatment, and resource utilization before and after introduction of RDTs at a peripheral health facility in rural Western Uganda. We graphically depicted the use of malaria diagnostic tests throughout the study period and fit regression models to identify correlates of three outcomes of interest: (1) length of stay (2) the proportion of patients referred to a higher-level health facility, and (3) administration of antibiotics. Over the course of the study period, 14,357 individuals underwent diagnostic testing for malaria with either a RDT (9,807) or microscopy (4,550). The proportion of patients with parasite-based diagnoses more than tripled to 34% after the introduction of RDTs. RDTs largely replaced microscopy as the diagnostic method of choice. Compared to patients admitted during the pre-RDT period, patients admitted to the health center with malaria in the post-RDT period had significantly reduced odds of being referred to another health center (AOR=0.49, P=0.038), receiving antibiotics (AOR=0.42, P<0.001), and a significantly shorter mean length of stay (β= -0.32, 95%CI -0.52 to -0.13). Our study is one of the few to demonstrate significant improvement in clinical outcomes and process measures following the introduction of RDTs for the diagnosis of malaria at a rural health facility in Uganda. We observed a reduction in referrals and shorter mean inpatient LOS even as antibiotics were prescribed less frequently. This change greatly increased laboratory throughput and the resultant proportion of patients receiving a parasite-based diagnosis.

232

DIAGNOSTIC PERFORMANCE OF A NOVEL MALARIA LOOP MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) ASSAY IN A FIELD SETTING

Eniyou C. Oriero[1], Joseph Okebe[1], Sarjo Njie[1], Jan Jacobs[2], Jean-Pierre Van geertruyden[3], Davis Nwakanma[1], Umberto D'Alessandro[1]

[1]Medical Research Council Unit, The Gambia, Fajara, Gambia, [2]Institute of Tropical Medicine, Antwerp, Belgium, [3]University of Antwerp, Antwerp, Belgium

In endemic settings, WHO recommends confirmation of malaria prior to treatment either by microscopic examination of blood films or the use of Rapid diagnostic tests (RDTs). The renewed interest in global eradication of malaria however, calls for more sensitive and high throughput diagnostic tools for the end game. Although RDTs have a faster turnaround time, there is a high rate of false positivity due to persistent circulation of antigen after infection; thus, molecular tools such as polymerase chain reaction (PCR) that amplify parasite DNA are being developed. Deployment of PCR in field settings or peripheral centers where they are most needed is not feasible therefore isothermal amplification methods such as Loop mediated isothermal amplification (LAMP) are being developed. In this study, we report the diagnostic performance of a novel highly sensitive LAMP assay targeting the apicoplast genome, in a field setting. The study was carried out in the screening stage of an ongoing trial comparing the effect of dihydroartemisinin-piperaquine (DHA-PPQ) alone or with single doses of Primaquine (PQ) on gametocyte carriage among individuals with asymptomatic malaria. Samples were collected from consenting individuals in the study villages around Basse and Walikunda in The Gambia from October to December 2014. From a single finger prick, samples were collected from 495 participants for microscopy, RDT and dried blood spots (DBS). DNA was extracted from the DBS by a simple methanol extraction method and the LAMP assay was performed in a field site the same day. A mean of 35 samples were collected daily and turnaround time for the LAMP assay was approximately two hundred and seventy minutes. Preliminary results show malaria prevalence of 38% by RDT and 34% by LAMP. Using RDT as the reference method, sensitivity of the LAMP assay was 77% (95%CI 63 - 88%) and specificity was 91% (95%CI 83 - 96%). Positive and negative predictive value of the LAMP assay was 84% and 87% respectively. As it becomes more feasible to deploy molecular tools for diagnosis of malaria at peripheral levels, global eradication of malaria can gradually become a reality.

SPREAD OF PFHRP2- AND PFHRP3-NEGATIVE *PLASMODIUM FALCIPARUM* PARASITES IN RURAL COMMUNITIES FROM THE PERUVIAN AMAZON REGION: IMPLICATIONS FOR RAPID DIAGNOSTIC TESTS

Mariella Quispe[1], Paulo Manrique[1], Oscar Nolasco[1], Henry Herrera[1], Anthony Gave[1], Joseph M. Vinetz[2], Joseph M. Vinetz[1], Joseph M. Vinetz[3], Dionicia Gamboa[1], Dionicia Gamboa[3]

[1]Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]University of California San Diego, San Diego, CA, United States, [3]Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

The ***Plasmodium falciparum*** Histidine-Rich-Proteins 2 and 3 (HRP2/3) is a parasite antigen that is a key target of rapid tests to diagnose malaria. Clinical field samples lacking pfhrp2, pfhrp3 and their flanking genes were recently reported in peri-urban communities of the Peruvian Amazon. Little is known about the geographical expansion of the deletion in rural far away communities from Iquitos city, and resulting implications for malaria diagnosis. The aim of this study was to estimate the frequency of the deletion in pfhrp2, pfhrp3 and their flanking genes from clinical samples in three communities far from Iquitos. 146 samples were collected in San José de Lupuna (13 in 2012, 102 in 2013, and 31 in 2014) a rural community crossing Nanay river, 10km from Iquitos city; 219 samples were collected in Cahuide (14 in 2012, 163 in 2013, and 42 in 2014), a rural community located 60 km from Iquitos and 178 samples came from Santa Emilia (March 2013 -June 2013), a remote community located 150 km from Iquitos. qPCR was used to confirm and quantify ***P. falciparum*** infections. Parasitemia levels were classified in 3 groups: high (>200 molecules/µl), medium (20-200 molecules/µl), and low (<20 molecules/µl). High and medium parasitemia levels were tested for the amplification of pfhrp2-3 and their flanking genes by PCR, with detection limit of 10 molecules/µl. Of 227 samples, 122 (54%) were negative for pfhrp2; 47 from Cahuide, 31 from Lupuna and 44 from Santa Emilia. Out of 122 of pfhrp2 negative samples, 71 also lack the PF3D7_0831900 gene and only 23 lack pfhrp2 and both flanking genes. For pfhrp3 gene, 110 (48%) were negative; 34 from Cahuide, 36 from Lupuna and 40 from Santa Emilia. Out of 110 of pfhrp3 negative samples, 52 also lack the PF3D7_1372100 gene and only 14 lack pfhrp3 and its flanking genes. This is the first report of the pfhrp2 and pfhrp3 gene deletion in remote and rural communities of the northeast Peruvian Amazon where the vast majority of malaria is located in Peru. These data suggest a high frequency of the pfhrp2-3 gene and flanking gene deletions. This parasite population is becoming fixed in the region, with implications for diagnosis and potentially pathogenesis.

EVALUATION OF MALARIA MICROSCOPY DIAGNOSIS FOLLOWING IMPLEMENTATION OF A QUALITY ASSURANCE PROGRAM IN LOW-TRANSMISSION AREAS, KENYA - 2014

Fredrick Odhiambo

Ministry of Health, Nairobi, Kenya

Malaria accounts for 9 million outpatient visits in Kenya annually. Prompt diagnosis of malaria is critical for early treatment, but microscopy services are often of poor quality or not available in health facilities. Kenya implemented a national malaria laboratory quality assurance (QA) program in 2013 to improve malaria diagnosis starting with low-transmission areas. We evaluated the performance of microscopy diagnosis after 8 months of QA implementation using blood slides archived in January and February 2014. From March to April 2014, we visited 21 health facilities in low-transmission areas implementing QA and 21 that had not started the QA program (control) matched on level of services provided and geographic location and randomly collected a total of 720 blood slides; 360 in each branch. The slides were re-examined by certified independent expert microscopists; results were used as the reference for validity and reliability. Eighty-four (23%) blood slides were malaria positive in each branch. Twenty-two (26%) slides were falsely positive in QA compared to 43 (51%) in control facilities. Sensitivity was 95% (95% CI: 87-99%) in QA facilities compared to 62% (95% CI: 49-74%) in control facilities. Specificity was 93% (95% CI: 89-95%) in QA compared to 85% (95% CI: 81-89%) in controls. The positive predictive and negative predictive values were 74% (95% CI: 63-83%) and 99% (95% CI: 97_100%), respectively, for QA facilities compared to 49% (95% CI: 38-60%) and 91% (95% CI: 87_94%), respectively, for controls. Primary county hospitals recorded the largest inter-observer agreement differences; kappa (κ) for QA facilities was 0.90 (95% CI: 0.81-0.99) and κ for controls was 0.38 (95% CI: 0.19-0.56). Overall, significant differences between inter-observer agreements were observed between QA facilities (κ=0.80; 95% CI: 0.72-0.88) and control facilities (κ=0.43; 95% CI: 0.32-0.54). Facilities implementing the malaria laboratory QA program in low-transmission areas performed unsatisfactorily in our evaluation of the validity and reliability of malaria microscopy diagnosis, although they outperformed matched control facilities.

235

NINA-LAMP COMPARED TO MICROSCOPY AND RDT FOR THE DETECTION OF MALARIA

Md Abu Naser Mohon[1], Lydia Lee[1], Abebe Genetu Bayih[1], Asongna Folefoc[1], Gisele Peirano[1], Robert Burton[2], Paul Labarre[2], Dylan R. Pillai[1]

[1]University of Calgary, Calgary, AB, Canada, [2]Program for Appropriate Technology in Health (PATH), Seattle, WA, United States

LAMP based method have shown potential to detect sub-microscopic infections. However, the requirement of electrical instrumentation has limited the use of LAMP in resource poor environments. PATH has introduced a new heating system that is called NINA for simple operation of LAMP. In the current study, we have evaluated the efficacy of NINA-LAMP for detection of traveler's malaria in comparison with Microscopy, nested PCR and the only FDA approved RDT (BINAX NOW Malaria). In total, 69 (38 falciparum and 31 non-falciparum) microscopy positive and 71 negative samples were selected retrospectively for this study. Samples were collected in different times at Calgary Laboratory Service from returning travelers with fever. LAMP was performed using a commercial kit from Eiken Chemical Company, Japan by both NINA and PCR machine. We did not find any consistent difference in assay between LAMP conducted in NINA versus PCR machine. LAMP was 100 %(95% CI, 93.43-100) sensitive and 95.77% (95% CI, 87.33-98.90) specific in comparison with microscopy whereas sensitivity and specificity were 100% (95% CI, 93.60-100) and 98.55% (95% CI, 91.11-99.92) when compared to nested PCR for detection of all malaria cases. We also demonstrate high accuracy for ***P. falciparum*** (sensitivity 100% and 97.61%; Specificity- 97.06% and 100%; Microscopy and nested PCR) and non-falciparum (sensitivity-100% and 100% Specificity- 100% and 99.08%; microscopy and nested PCR) detection. On the other hand, the RDT was overall 85.50 %(95% CI, 74.5-92.4) and 85.91% (95% CI, 75.16-92.68) sensitive and 97.18% (95% CI, 89.28-99.51) and 98.55% (95% CI, 91.11-99.92) specific compared to microscopy and nested PCR, respectively. Although the RDT was accurate in ***P. falciparum*** diagnosis (sensitivity-94.74% and 90.48%), poor performance was observed for non-falciparum malaria detection (sensitivity-74.19% and 70.97%) compared to microscopy and nested PCR. We conclude that LAMP assay is highly sensitive and specific for symptomatic malaria diagnosis. As NINA is a non-instrumented system, it has the potential to replace RDTs at both field site and point of care in all settings.

236

EVALUATION OF LAMP AS A MALARIA DIAGNOSTIC TOOL IN REACTIVE CASE DETECTION IN NAMIBIA WITH RDTS AS THE SOURCE OF DNA

Munyaradzi Tambo[1], Davis Mumbengegwi[1], Ronnie Bock[1], Hugh Sturrock[2], Rolly Gosling[2], Immo Kleinschmidt[2]

[1]University of Namibia, Windhoek, Namibia, [2]University of California, San Fransisco, San Fransisco, CA, United States

The number of sub patent infections increases up to 70% of the infected population as malaria decreases. Therefore, in low prevalence settings, malaria cases could be going undetected due to difficulty in detection of low parasite density infections with RDTs. Namibia is moving towards elimination and in order to eliminate malaria, all asymptomatic and symptomatic reservoirs of malaria that could perpetuate the spread of malaria need to be traced by reactive case detection in combination with LAMP. Consequently, the study evaluated the use of LAMP with nPCR as a reference in reactive case detection. All reported malaria cases from the Engela health district were followed up at their households, the reported case and all the individuals in the same household and 4 surrounding households were tested for malaria with RDTs and these RDTs were collected from all 2790 individuals that were tested. There were 1658 RDT samples from case neighbourhoods and 1132 samples from controls. DNA was extracted from the RDT samples for malaria diagnosis with LAMP. Nested PCR was performed on all LAMP positive samples and 10% of the negative samples as a reference standard. Species determination was done with RDTs, LAMP kits and cytochrome B digestion. RDTs detected 37 malaria infections with a sensitivity of 56.06%. LAMP detected 66 malaria infections with a sensitivity of 100%. A total of 64 of the LAMP positive samples were also nPCR positive and all LAMP negative samples were also nPCR negative. Both RDTs and LAMP determined that all the malaria infections were caused by P.falciparum and this was confirmed by n-PCR. The number of malaria infections detected doubled with the use of LAMP as compared to RDTs, in addition LAMP detected 4 times more secondary cases than RDTs. The majority of the malaria infections, 97%, were from case neighbourhoods. This indicates that individuals in proximity to malaria infections are more likely to be infected by malaria. Reactive case detection is an important surveillance tool in combination with LAMP and not RDTS to detect all cases around reported cases that are usually asymptomatic.

AN ADVANCED COMPUTER VISION PLATFORM FOR CLINICAL DIAGNOSIS OF MALARIA

Seth Salpeter, Arnon Houri-Yaifn, Joseph Joel Pollak

Sight Diagnostics, Jerusalem, Israel

Accurate malaria diagnosis is necessary to prevent unnecessary deaths, curb malaria drug resistance related to unnecessary treatment and uncover asymptomatic malaria patients. While numerous diagnostic assays exist, the need for a low-cost, rapid and highly accurate malaria test remains. We have merged inventions in sample preparation, machine design and software algorithms to create the first complete computer vision platform for blood analysis and malaria diagnosis. A blood sample is stained using a proprietary fluorescent dye and scanned in the automated microscopy system in a process that takes 4 minutes. The device then produces a malaria diagnosis, speciation and parasitemia per red blood cells. Clinical trials on the platform performed in Europe, Africa and India show a sensitivity of ~97% and a specificity of ~98% with speciation for ***Plasmodium vivax*** at 95.5% and ***Plasmodium falciparum*** at 99%, showing superior accuracy when compared with RDTs and microscopists. The device is currently commercially available and has achieved sales in Africa and India with projected device sales reaching 100 in 2015.

UNDERESTIMATION OF ADJUSTED ODDS-RATIO DUE TO IMPERFECT DIAGNOSTIC RESULTS AND A PRACTICAL CORRECTION APPROACH

Denis Valle, Joanna M. Tucker Lima, Justin Millar, Punam Amratia, Ubydul Haque

University of Florida, Gainesville, FL, United States

Logistic regression is a statistical model widely used in epidemiology to identify and quantify the effect of potential disease risk factors. Although it is acknowledged that imperfect diagnostic tests distort disease prevalence estimates, little is known about the impact of imperfect tests on adjusted odds-ratios. We derive a first order approximation that reveals that imperfect diagnostic test results can lead to substantially underestimated effect sizes and overly narrow 95% confidence intervals, with important implications regarding the identification of risk factors. To overcome this bias, we propose a Bayesian model that explicitly accounts for imperfect detection. Using simulations, we show that this method can substantially improve upon the results from the standard logistic regression. Using malaria data from Bangladesh, we demonstrate how the proposed method leads to point estimates that are 1.1 - 23.0 fold larger than the corresponding point estimates from the standard logistic regression. Our method has the potential for widespread adoption by researchers and offer substantial improvements to current modeling practice in epidemiology.

EMBRACING THE USE OF RAPID DIAGNOSTIC TESTING IN MALARIA DIAGNOSIS: EXPANDING ACCESS TO ACCURATE DIAGNOSIS

Mercy C. Rop[1], Edna Sang[2], Diana Menya[3], Jeremiah Laktabai[3], Elizabeth Turner[4], Adriane Lesser[4], Wendy O'Meara[4]

[1]Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya, [2]Duke Global, Inc., Nairobi, Kenya, [3]Moi University, Eldoret, Kenya, [4]Duke University, Durham, NC, United States

Malaria has remained a major public health problem in Kenya despite being treatable. Proper diagnosis before treatment is recommended as it allows for appropriate patient management. The main diagnostic methods available are microscopic examination of stained blood smears and Rapid diagnostic tests (RDTs). RDTs have been shown to be effective in expanding access to malaria diagnosis to populations with limited access to good quality microscopy due to their ease of use and interpretation, lower training requirements, and lack of requirements for electricity, among others. RDTs have also been shown to have higher sensitivity and specificity as compared to routine clinical microscopy. Despite the overwhelming support for the use of RDT, there is anecdotal evidence of people mistrusting their negative results after an RDT test and thus lack of compliance with their results. There are also widespread reports from community members and healthcare workers of RDT negative patients being found positive by microscopy. Mistrust of negative RDT results could be a result of limited prior experience with RDT as well as discrepancies between results of microscopy and RDTs and hence the uncertainty about the accuracy of results. In Kenya, there have been no reports of the perceptions of RDTs and adherence to RDTs since their roll-out in 2011. Here we will present baseline data from 1300 households in two malaria-endemic areas in western Kenya collected in preparation for the roll out of Community level subsidized RDT and ACTs. We will report the uptake of diagnostic testing for fevers, and people's self-reported confidence in the results of their test, stratified by type of test (microscopy vs. RDT). We will also compare reported confidence in the test to actual treatment decisions taken amongst malaria-positive and malaria-negative patients. The findings will enable us to evaluate the need to delve further into understanding the level of knowledge, experiences, acceptance and opinions about

the use of RDTs for malaria diagnosis in the population. These findings have important consequences for the success of community-based case management for malaria.

240

ASSESSING THE PERFORMANCE OF THREE HRP2 BASED RAPID DIAGNOSTIC TESTS FOR THE DIAGNOSIS OF MALARIA IN CENTRAL GHANA

Dennis Adu-Gyasi, Sabastina Amoako, David K. Dosoo, Nicholas Amoako, Love Ankrah, Samuel Kofi Tchum, George Adjei, Kwaku Poku Asante, Seth Owusu-Agyei

Kintampo Health Research Centre, Kintampo North, Ghana

Rapid Diagnostic Tests (RDTs) could give False-negative results which present a greater challenge which may lead to delay in the initiation of treatment. We evaluated the diagnostic accuracy of hrp2 based RDTs with pLDH using microscopy as gold standard and to possibly detect parasites with hrp2 deleted genes. The cross-sectional study randomly consented and enrolled 754 participants from the two major public hospitals in the middle-belt of Ghana. Blood samples obtained were screened for malaria using the three types of hrp2 based RDT from CareStart and SD Bioline. Ethical clearance was given by KHRC IEC. A prevalence of 39.1% of malaria using microscopy was recorded. There were 28.6% (215/752) males and 71.4% (537/752) females with the Mean(SD) age of 21.4(17.8) years. Compared to microscopy the Sensitivity, Specificity, Positive-Predictive-Value, Negative-Predictive-Value and the ROC were 98.2%, 66.5%, 82.6%, 95.6% and 0.82 for CareStart Hrp2, 98.2%, 66.5%, 82.6%, 95.6% and 0.82 for CareStart Hrp2/pLDH and 98.2%, 69.2%, 84.2%, 96.0% and 0.84 for SD Bioline RDTs. All three RDTs used recorded 1.8% (5/281) false negative results. In conclusion, the diagnostic performance of the three HRP2 based RDTs according to the WHO criteria was excellent. There have been extensive report of malaria parasite infections caused by strains with hrp2 deleted gene. The brands of RDTs which target pLDH of malaria parasites could hopefully enable practitioners identify patients infected with parasites strains with hrp2 gene deletion; kits which are only hrp2 based will miss. The kits with the added pLDH could identify infections which are current and also those infections which persist as a result of treatment failure. There is however a decrease in specificity which could result from the persistence of hrp2/hrp3 proteins even weeks after effective treatment of malaria.

241

USING THE EMERGENCY TRIAGE ASSESSMENT AND TREATMENT (ETAT) APPROACH TO REDUCE MORBIDITY FROM SEVERE MALARIA IN CHILDREN UNDER 5 IN HOSPITALS IN BENIN

Inoussa Akadiri[1], Fortune Dagnon[1], Gilbert Andrianandrasana[2], Pablo Aguilar[3], Ramine Bahrambegi[3], Joseph Carter[4]

[1]ARM3/MCDI, Cotonou, Benin, [2]ARM3/MCDI, Arlington, VA, United States, [3]MCDI, Silver Spring, MD, United States, [4]ARM3/MCDI, Silver Spring, MD, United States

The ARM3 consortium, led by Medical Care Development International (MCDI) and funded by United States Agency for International Development/PMI, supports the Government of Benin (GOB) in improving malaria health outcomes in accordance with the National Malaria Control Plan (NMCP), including the reduction of malaria-associated mortality by 70%. In Benin, most hospital deaths among children <5 occur within 24 hours of admission because the waiting period before consultation. In an effort to reduce severe malaria case fatality rate of under 5 children arriving at reference hospitals, ARM3 rolled-out the Emergency Triage Assessment and Treatment (ETAT) approach, developed by the World Health Organization, in 25 hospitals (beginning with 12 in July 2013, Phase 1, and 13 additional hospitals in April 2014, Phase 2). Through learning sessions based on the "Collaborative Approach to Health Care Improvement" methodology, the 25 hospitals trained health workers on ETAT implementation including: (1) conducting a review of ETAT indicators; (2) evaluating implementation of ETAT at each site; (3) identifying best practices and lessons learned for dissemination; (4) updating databases; and (5) developing a 3-month action plan for each site. ARM3, the DSME, and national/departmental NMCP conducted monthly data quality validation of the targeted indicators in order to assess each hospital's performance. After one year of ETAT implementation, for hospitals in Phase 1, the % of children under 5 evaluated upon arrival at hospitals, increased from 3.4% to 95%, and the adherence rate to ETAT standards rose from 10% to 78%. For hospitals in Phase 2, after 6 months of implementation, the ratio of adherence to severe malaria guidelines rose from 50.2% to 82.2 % and the case fatality rate of severe malaria declined from 5.9% to 4.8%. The ETAT approach has shown positive results in 25 hospitals and the ARM3 project will continue to work with the MOH and the NMCP to train additional health workers on ETAT in Benin. ARM3 will also work with the GOB to ensure that sufficient ETAT supplies are available at health facilities and that HR policies are designed to reduce turnover of health workers trained on ETAT.

242

MONITORING OF QUALITY OF RAPID DIAGNOSTIC TESTS IN SENEGAL, 2007-2014

Ibrahima Diallo[1], Moustapha Cisse[1], Medoune Ndiop[1], Alioune Badara Gueye[1], Mamadou Lamine Diouf[1], Babacar Faye[2], Mady Ba[1]

[1]Senegal National Malaria Control Program, Dakar Fann, Senegal, [2]Service de Parasitologie Faculté de Médecine UCAD, Dakar Fann, Senegal

In 2007, the Senegal National Malaria Control Program introduced rapid diagnostic tests (RDTs) to improve the quality of malaria case management. RDTs have been deployed in all health facilities in the country and at the community level. To ensure the quality and reliability of RDTs used in Senegal, a quality control system was implemented with the support of WHO / FIND / TDR. The Parasitology Laboratory at Universite Cheikh Anta Diop achieved accreditation as a reference laboratory for RDT quality control in 2009. Upon receipt of RDTs in country, lot samples are collected systematically and sent to the Parasitology Department of UCAD. Following the WHO protocol for the quality control of RDTs, a visual inspection is carried out and the sensitivity of the RDTs assessed according to results with samples of known parasite densities of 200 parasites /µl, 2000 parasites /µl, and negative control. From 2007 to 2014, 800 RDTs from 100 lots of two brands of HRP-2 based RDTs were tested, 100 RDTs annually upon reception in country. Sensitivity against both at 2000 parasites /µl and 200 parasites /µl was 100%, and specificity against negative controls was 100%. During these years, 500 RDTs from 60 lots were collected from health facilities around Senegal after variable time under field storage conditions, and also exhibited 100% sensitivity against 2000 parasites /µl and 200 parasites /µl knowns, and 100% specificity against negative controls. In 2014, problems were noted at the operational level with evaporation of solvent (buffer) in the individual bulbs in unit kits of RDTs after 18 months in storage conditions in the field, despite the confirmation of the quality of the RDTs at reception. This phenomenon has not been observed with the buffer bottles in kits of 25 tests. After this quality control, it is recommended that a systematic control of RDT lots at the reception at central level and every 6 months for the lots at the peripheral level as temperature and storage conditions vary from one zone to another. Finally inspections at the peripheral level should be strengthened to ensure good storage conditions for RDTs.

243

FIELD-BASED QUALITY MONITORING OF MALARIA RAPID DIAGNOSTIC TESTS IN RESOURCE-LIMITED SETTINGS: EXPERIENCE FROM UGANDA

Bosco B. Agaba[1], Alex Ojaku[2], Elizabeth Streat[3], Anthony Nuwa[4], Peter Okui[1], Seraphine Adibaku[2], Hope Ninsiima[5]

[1]Department of Disease Control, Malaria Program, Kampala, Uganda, [2]Uganda Malaria Research Center, Kampala, Uganda, [3]Malaria Consortium Africa Regional Office, Kampala, Uganda, [4]Malaria Consortium Uganda, Kampala, Uganda, [5]Mulago National Referral Hospital, Kampala, Uganda

Rapid Diagnostic Tests were introduced in Uganda as alternative diagnostic tool for malaria. Quality of Rapid Diagnostic Tests can deteriorate and requires monitoring under field setting. Positive control wells are in in advanced field trials but there are early concerns about their feasibility, application across varying endemicity and potential to increase the unit cost of Rapid Diagnostic Tests. In this high transmission remote setting, we piloted the use of locally prepared control blood samples and the use of sentinel sites expert microscopy for field monitoring of malaria Rapid Diagnostic Tests. Fresh blood samples were collected, prepared and characterized into high and low positive parasitemia and clear negative. The known blood controls were used to check the quality of sampled RDTs directly on site at the selected health facilities and communities across five districts. Additional testing was done with expert microscopy at sentinel sites. Monitoring of RDTs was done quarterly and integrated into the district-based routine supervision. Data on RDT performance, sensitivity and specificity was analyzed using SPSS version 12. Rapid Diagnostic Tests maintained an average accuracy of 98.8 % against standard known control blood samples. Sensitivity and specificity of RDTs against expert microscopy of blood smears at sentinel-sites was 94.5% and 84.3% respectively. The use of locally prepared known control blood samples and comparison with expert microscopy of blood smears at sentinel-sites is feasible and could potentially provide simple, effective, low-cost and sustainable alternative Quality monitoring system for Rapid Diagnostic Tests in resource limited and remote field settings.

FIELD ASSESSMENT OF *PLASMODIUM FALCIPARUM* DRIED TUBE SPECIMENS UNDER AMBIENT TEMPERATURE CONDITIONS IN BENIN

Michael Aidoo[1], Saliou Ramani[2], Suzanne Powell[1], Yves Eric Denon[3], Peter Thomas[4]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Ameliorating Malaria Morbidity and Mortality (ARM3)-Benin, Cotonou, Benin, [3]Malaria Control Program, Ministry of Health Benin, Cotonou, Benin, [4]Centers for Disease Control and Prevention-President's Malaria Initiative Benin, Cotonou, Benin

Quality control of malaria rapid diagnostic tests (RDTs) remains a challenge due to the lack of positive and negative control standards to monitor test quality and health worker performance. Dried ***Plasmodium falciparum*** parasite samples prepared as dried tube specimens (DTS) have been shown to be suitable as quality control samples for RDTs and are stable under refrigeration (4°C) and ambient temperature conditions in Ethiopia. A field assessment to test the stability of DTS under temperature conditions typical of tropical Africa, and to assess the utility of DTS for proficiency testing in Benin was conducted. Briefly, reactivity of replicate DTS samples containing 0, 500 and 1000 parasites/µl stored at 4°C at a reference laboratory (RL); Laboratoire du service des explorations diagnostique, Cotonou, were compared to reactivity of aliquots of the same samples stored at ambient temperatures at two health facilities (HFs); St. Michel health Center, Cotonou 5 and Ayelawadje Health Center Cotonou 2/3, where maximum and minimum temperatures were recorded once daily during July 2014 to January 2015. DTS testing was performed at 0, 4, 8, 12, 16, 20 and 24 weeks with each DTS tested on duplicate RDTs stored under manufacturer recommended temperatures at the RL and on RDTs stored under site-specific conditions at the two HFs. DTS were reactive at all time points irrespective of storage conditions. However, at 20 and 24 weeks, DTS stored under ambient conditions at the two HFs rehydrated poorly and relative band intensities observed by eye on RDTs were about 4-fold less compared to similar DTS stored at 4°C in the RL. Health worker testing of 4 vials of DTS with reactivity blinded to the health workers provided an opportunity to observe and address incorrect testing procedures. These data suggest that in sub-Saharan climates such as Benin's, DTS should be stored under refrigeration for optimal, prolonged stability and DTS is a useful tool for improving health worker performance of malaria RDTs in Benin.

245

DO ANTIBODIES TO *PLASMODIUM FALCIPARUM* HISTIDINE-RICH PROTEIN 2 (HRP2) INFLUENCE THE RESULTS OF HRP2-BASED DIAGNOSTIC ASSAYS?

Diane Wallace Taylor[1], Naveen Bobbili[1], Isabella A. Quakyi[2], Rose G. Leke[3]

[1]University of Hawaii, Honolulu, HI, United States, [2]University of Ghana, Accra, Ghana, [3]University of Yaoundé I, Yaoundé, Cameroon

Plasmodium falciparum Histidine-Rich Protein 2 (HRP2)-based assays have become valuable tools in the diagnosis and control of malaria. Although these assays have high sensitivity and specificity, false-negative and -positive results do occur. One speculation for misdiagnosis is that antibodies (Ab) to HRP2 might interfere with assay results. Surprisingly, no comprehensive study on Ab to HRP2 has been reported. This study sought to identify Ab to HRP2 and assess their prevalence, isotype and avidity. We reasoned that Ab to HRP2 would be 1) present in exposed, but not non-exposed, individuals, and ii) increase in titer with exposure (age). A bead-based multiplex assay was used to measure Ab to recombinant HRP2, and MSP1, MSP2 & MSP3 for comparison. Monoclonal Ab 2G12 that recognizes the central repeat sequence DAHHAADAHH of HRP2 (present in all isolates) and 1E1-A9 (to YAHHAHHA in 99.3% of isolates) were used to optimize the HRP2 assay. Titers of 1:100,000 and 1:1,000 were obtained, showing rHRP2 was appropriately coupled to the beads. As expected, high levels of IgG to the 3 merozoite antigens were detected in plasma from 100 Cameroonian adults living in a high transmission area, but not in 100 US unexposed controls. Unexpectedly, the frequency distribution curves were essentially identical for exposed and unexposed adults for IgG to HRP2. Further results showed no increase in IgG Ab to HRP2 with age using 120 plasma samples of Cameroonians living in a high transmission area aged 5 to 80 years. Avidity of IgG to HRP2 was equivalent in exposed and unexposed individuals. To detect IgM to HRP2, 81 samples from slide-positive children & adults were screened. A small difference in IgM reactivity to HRP2 in plasma from malaria-infected and healthy US controls was observed, but it was unclear if the increase was due to high background or IgM to HRP2. Overall, these results failed to conclusively detect Ab to HRP2. Theories as to why Ab to HRP2 might not be present in malaria-infected individuals will be discussed.

USE OF MALACHITE GREEN-LAMP FOR THE DETECTION OF MALARIA PARASITES IN FIELD STUDIES

Naomi W. Lucchi[1], Dragan Ljolje[2], Luciana Flannery[2], Venkatachalam Udhayakumar[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Atlanta Research and Education Foundation, Decatur, GA, United States

Molecular tools are increasingly being considered for detecting sub-microscopic infection of malaria parasites in active surveillance programs and research studies. The current molecular diagnostic tools include the nested PCR, real-time PCR and LAMP isothermal assay. The LAMP assays are more amenable for use in limited laboratory settings than other PCR methods as they do not require a thermal cycler to run the test. Different

groups have described the LAMP assay performed using specialized equipment platforms which, unfortunately, reduces the versatility of the LAMP technique for large scale field application. In order to overcome this limitation, we describe the use of the malachite green (MG) dye as a visual endpoint read out for the LAMP assay. Three primers sets to detect *Plasmodium* (pan species), ***P. falciparum*** and ***P. vivax*** were tested. The MG-LAMP assay was performed in a 40-well mini-heat block (<$300) and 0.04% MG dye was added to the amplification master mix prior to the amplification. Parasite DNA obtained by QIAGEN extraction method was used. The assay was run for 1 hour after which the tubes were removed and kept at room temperature for 10 minutes before being scored. Positive reaction was indicated by the retention of the light blue/green color and negative reaction was indicated by colorless reaction mixture. Samples were scored by three independent readers. The sensitivity and specificity of the MG-LAMP was determined using 397 clinical samples. The MG-LAMP assay results were compared to a real-time PCR assay (PET-PCR) as a reference test. The sensitivity/specificity of the genus MG-LAMP assay was shown to be 99.2%/88% and that of ***P. falciparum*** and ***P. vivax*** assays was shown to be 98.8%/99.2% and 94.7%/99.1% respectively. The inter-rater agreements for the three primers were 0.896 for genus, 0.969 for ***P. falciparum*** and 0.956 for ***P. vivax***. This report describes the MG-LAMP assay as an affordable, sensitive and scalable field colorimetric molecular assay for malaria parasite detection that can be further evaluated as a high-throughput tool for the assessment of infections in endemic countries.

QUANTITATIVE GLUCOSE-6-PHOSPHATE DEHYDROGENASE(G6PD) BIOSENSOR ANALYZER FOR THE POINT-OF-CARE TEST WITH CAPILLARY BLOOD

Chiun Ryu

ACCESSBIO KOREA Inc., Seoul, Republic of Korea

Accurate G6PD activity measurements are required to identify and treat vivax or ovale malaria patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency. This is because if such patients take 8-aminoquinoline antimalarials like primaquine or tafenoquine, they may experience acute hemolysis anemia by oxidative stress from the drugs. To this end, we have developed the CareStartTM G6PD biosensor analyzer for point-of-care test of the quantitative measurement of G6PD enzyme activity in the whole blood using an electrochemical method. In our recent clinical evaluation in Ethiopia, capillary blood samples (n=60) were collected from adults to compare the performance of the biosensor analyzer to that of a quantitative spectrophotometric method. The result showed no significant difference between these two methods (paired test-test, t=0.02, p=0.9855). The total enzyme activities ranged from 25.2 to 157.8 and 21.1 to 134.5 (U/dL blood) for spectrophotometric method and biosensor analyzer, respectively. In the meantime, the average of the total G6PD enzyme activity was 65.6 (U/dL blood) for both methods. The distribution of the G6PD activity was similar in two methods when two cut-offs (35 and 70 U/dL blood) of the G6PD activity were applied. For example, 5 persons (8.3%) were blow 35 in both methods; 35 (58.3%) and 37 persons (61.6%) were between 35 to 70; 20 (33.3%) and 18 persons (30.0%) were above 70 U/dL blood of G6PD activity in spectrophotometric and bioanalyzer method, respectively. The dimension of the system is 62x118x30(mm) with 98g of weight without two AAA alkaline batteries for the operation. The range of G6PD activity measured by the biosensor is 0 - 300 U/dL using 5µl blood. Up to 1,000 test results can be stored in the analyzer and the data is downloadable to a PC. The analyzer can be operated between 10 - 40 °C and 10 - 90 % relative humidity. The strip for the system can be stored at 2 - 40 °C for 2 years. The CareStartTM G6PD biosensor analyzer is an accurate and convenient point-of-care alternative to the spectrophotometric method for quantitative measurement of G6PD activity in whole blood.

248

WHAT IS AN OPTIMAL TREATMENT DEFINITION FOR QUANTITATIVE MOLECULAR DIAGNOSIS OF ERYTHROCYTE-STAGE *PLASMODIUM* INFECTION IN CONTROLLED HUMAN MALARIA INFECTION CLINICAL TRIALS?

Sean C. Murphy[1], Glenda Daza[1], Ming Chang[1], Lisa Shelton[2], Sebastian Mikolajczak[2], Ashley Vaughan[2], Stefan Kappe[2], James Kublin[3]

[1]University of Washington Medical Center, Seattle, WA, United States, [2]Seattle Biomedical Research Institute, Seattle, WA, United States, [3]Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Controlled human malaria infection (CHMI) studies allow for safe evaluation of the tolerability and efficacy of experimental drug and vaccine candidates. Subjects are monitored through clinical and laboratory follow-up, including traditional use of Giemsa-stained thick blood smears (TBS) and more recent use of nucleic acid tests (NATs) like PCR and reverse transcription PCR (RT-PCR). NATs allow the detection and quantitative measurement of peripheral parasitemia 2-6 days earlier than microscopy. With increased sensitivity, NATs afford CHMI studies the opportunity to forego the traditional approach of domiciling subjects during the malaria-associated symptom stage (typically 8-18 days post-CHMI) and follow subjects on an outpatient basis. We sought to develop a NAT-based definition of positive infections warranting curative treatment following CHMI that would (a) minimize both malaria-associated symptoms and any associated medical risk to subjects and (b) ensure that study efficacy data could be depended on to make go/no go decisions about the experimental products under investigation. We retrospectively analyzed TBS, RT-PCR and clinical records from several previous CHMI studies. The historical difference between time-to-positivity (TTP) for RT-PCR (analytical sensitivity 20 para/mL) vs. TBS was 3.9 days (95%CI 3.4-4.4 d). Based on this data, we evaluated how well various 'treatment thresholds' in asymptomatic patients would have performed. Using a threshold of two positive RT-PCR results (one per day) including 1 or more results of >250 parasites/mL, subjects would have been treated for breakthrough infection 2.8 days (95%CI 2.4-3.2 d) earlier than when using a traditional TBS-based threshold. With this threshold, most subjects would be expected to be treated before developing malaria-related symptoms. We have now conducted prospective CHMI studies guided by this treatment threshold that corroborate these predictions. We advocate that CHMI centers develop consensus guidelines for NAT-based treatment thresholds and for monitoring the adequacy of treatment.

249

ASYMPTOMATIC MALARIA DETECTION BY LOOP-MEDIATED ISOTHERMAL AMPLIFICATION DURING THE DRY SEASON IN KEUR SOCÉ, SENEGAL

Babacar Faye[1], **Xavier C. Ding**[2], Aminata Collé Lô[1], Aminata Lam[1], Jaco Batalaho[1], Magatte Ndiaye[1], Jean-Louis Ndiaye[1], Khadime Sylla[1], Iveth J. González[2], Oumar Gaye[1]

[1]Service de Parasitologie, Faculté de Médecine, Université Cheikh Anta Diop, Dakar, Senegal, [2]Foundation for Innovative New Diagnostics, Geneva, Switzerland

Submicroscopic malaria infections in asymptomatic carriers are considered to be an increasing source of malaria transmission in areas of decreasing endemicity and are, by nature, extremely difficult to identify and treat. Senegal has achieved a drastic reduction in malaria prevalence over the past 10 years, moving from more than 1.5 million cases in 2006 down to less than 300'000 in 2014 (80% reduction), and is likely to be facing significant residual transmission caused by such asymptomatic infections before elimination can be achieved. We evaluated the prevalence of asymptomatic malaria infections in the area of Keur Socé (Sudano-Sahelian region of Senegal, low transmission) during the dry season (March 2015). To that end, we screened a large population (n=1'250) of asymptomatic

adults for the presence of ***Plasmodium*** parasites using loop-mediated isothermal amplification (LAMP) reactions performed on-site. Around of 4% of the screened individuals were found to be asymptomatic ***Plasmodium*** carriers (n=49, prevalence=3.9%) using Loopamp™ MALARIA Pan Detection Kits. Positive samples were further tested using ***P. falciparum*** specific LAMP reactions (Loopamp™ MALARIA Pf Detection Kit) and 30 (65.3%) of these were found to be positive for ***P. falciparum***, suggesting that a large fraction (34.7%) of the asymptomatic infections detected are caused by non- ***P. falciparum*** species. Confirmation of LAMP results by nested PCR (nPCR) and parasitemia determination by quantitative PCR are pending. Based on previous studies, it is expected that the limit of detection, sensitivity and specificity of LAMP reactions will be close to that of nPCR. Importantly, the ability to perform LAMP reactions on-site allowed us to inform study participants of their infection status within 36 hours after sample collection and to ensure the adequate provision of antimalarial treatments to the identified asymptomatic carries. These results suggest that LAMP is a sensible approach to overcome the limited sensitivity of microscopy and rapid diagnostic tests for screen-and-treat interventions.

QUALITY ASSESSMENT OF MALARIA DIAGNOSTICS IN VIETNAM WITH POTENTIAL IMPACT ON MALARIA ELIMINATION OPERATIONS

Awalludin Sutamihardja[1], Phuc T. Nguyen[2], Dung K. Vu[2], Van T. Nguyen[2], Hang B. Hoang[2], Phu H. Nguyen[2], Xa X. Nguyen[2], Anh Q. Nguyen[2], Duong T. Tran[2], Nicholas Martin[3], Thang D. Ngo[2], Maciej Boni[4], Andrew A. Lover[1], **Colin Ohrt**[1]

[1]University of California, San Francisco, Hanoi, Vietnam, [2]National Institute of Malariology, Parasitology and Entomology, Hanoi, Vietnam, [3]Naval Medical Research Centre - Asia, Singapore, Singapore, [4]Nuffield Department of Medicine, University of Oxford, Oxford University Clinical Research Unit, Wellcome Trust Major Overseas Programme, Ho Chi Minh City, Vietnam

Accurate malaria diagnosis is essential for malaria elimination operations. In Vietnam, microscopy is the standard of care for malaria diagnosis, with front-line microscopists conducting initial testing at commune-based clinics and rechecks conducted two or three times at higher levels. Rapid diagnostic tests (RDTs) are now being rolled out to areas where microscopy is not available, where presumptive treatment was previously the standard of care. Quality assurance programs are in place in Vietnam for malaria microscopy to promote accuracy, quality and validity. We conducted assessments of malaria diagnostics in Phu Yen and Quang Tri Provinces, Vietnam. We randomly selected slides that had been cross checked to be reread again by WHO-qualified readers. Proficiency tests were conducted to assess the competency of microscopists working at each level. Laboratory performance was assessed using a WHO checklist. Results: The rereading of 654 negative slides revealed that in the routine malaria microscopy there were 14 (2.14%) false negative slides (3 ***Plasmodium falciparum***, 10 ***P. vivax***, 1 both species). Results from rereading of additional negative and all the positive slides, as well as RDT assessments, are on-going. The assessment of proficiency of 21 cross checker microscopists was 94.0% and 97.9% for sensitivity and specificity, respectively, while their species accuracy was 77.6%, ***P. falciparum*** sensitivity was 88.8%, and counting accuracy was 58.1%. The sensitivity and specificity for 13 front-line microscopists were 85.6% and 95.6% respectively, while their species accuracy was 68.5%. On-site visits revealed that laboratories assessed had no standard operating procedures or bench aids. Conclusions: Vietnam has a fully functioning malaria microscopy cross checking system with quality output. Still, false negative diagnostic results may hamper malaria elimination operations. In addition, mathematical modeling tools will be employed to investigate the benefit of malaria microscopy and RDTs, as well as estimate the potential danger of false negative diagnostic results in elimination settings.

251

INTENSIFIED CASE FINDING IN RESOURCE LIMITED SETTINGS USING VILLAGE-BASED STRATIFICATION: LESSONS FROM ANN TOWNSHIP, RAKHINE STATE, MYANMAR

Soy Ty Kheang

University Research Co., LLC, Bethesda, MD, United States

In 2013, Myanmar reported more than 333,800 confirmed malaria cases, however, the estimated burden of malaria is closer to 2.6 million suspected cases annually. Lack of a strong surveillance system and poor public health infrastructure contribute to the large discrepancy between the estimated number of cases and the number of reported cases. Malaria case burden has not been systematically used in Myanmar for planning or prioritizing malaria control activities in resource limited settings. Active case detection or temporary screening points by mobile outreach teams have been included in malaria case management activities in an effort to identify hidden malaria burden and provide malaria services in remote areas far from formal health facilities. These activities have incurred significant costs, in part due to the remote locations. The Control and Prevention of Malaria (CAP-Malaria) Project has implemented a village-based strategy (VBS) for intensified case detection (ICD) in an effort to identify and prioritize hidden malaria hotspots while trying to control costs. By introducing the VBS-ICD in Ann Township, CAP-Malaria was able to reallocate resources and better target malaria hotspots resulting in the identification of almost double the number of positive cases (October 2014 - March 2015) compared to the previous year. In Rakhine State, total contribution of malaria case burden from Ann Township increased from 55% to 75% among identified positive malaria cases (2,542 cases), compared to the previous year. The national program uses village micro-stratification which takes into account ecological information (e.g. topology and vegetation) and distance from health facilities, however, this information is not used as part of evidence-based programming and implementation. CAP-Malaria's experience has shown other factors, including malaria burden, can help to improve village malaria stratification allowing for improved results from intensive case detection efforts.

252

ANTIMALARIAL ACTIVITY AND INHIBITION OF THE HEMOZOIN FORMATION BY CHLOROQUINE-ANALOGUES

Anna C. Aguiar[1], Mario Meneghei[2], Antoniana Krettli[1]

[1]Centro de Pesquisas René Rachou, Belo Horizonte, Brazil, [2]Universidade Federal de Alagoas, Maceió, Brazil

Several studies have shown the high resistance of ***Plasmodium falciparum*** to chloroquine and other aminoquinolines used as traditional antimalarials, making the search for new drugs urgent. The aim of this study was to evaluate the ***in vitro*** activity of six chloroquine analogs (4-aminoquinoline derivatives) against ***P. falciparum***, using resistant (W2 clone) and sensitive parasites (3d7 strain) by Sybr green method. The citotoxicity was determined against monkey kidney cells (BGM) by neutral red assay, and the selectivity index (SI) calculated (a ration between MDL50 and IC50). The possible mechanism of action of chloroquine analogues was also studied ***in vitro*** using hemozoin formation assay. All of the evaluated compounds were obtained in good yields and were active ***in vitro*** against resistant (IC50 of 7 to 212 ng/mL) and sensitive parasites (IC50 of 16 to 373 ng/mL) not presenting cross resistance, besides that they were not toxic with SI up to 7652. Two of the 4-aminoquinoline derivatives, named CEQ and DAQ, received spatial atencion. CEQ is an aminoquinoline containing just a simple -(CH2)2- spacer and a NH2 final group. DAQ has a C≡C group in lateral chain and NEt2 as final group. Both compounds were tested ***in vivo*** against ***P. berghei*** and were active, reducing the parasitemia around 90% until the day 11 after the infection and increasing significantly the animal survival in comparison with untreated control. Four chloroquine analogs inhibited significantly the ***in vitro*** hemozoin formation, in a dose-response manner, at doses lower

than CQ. The results suggest that these aminoquinolines seem represent promising alternatives for the treatment of chloroquine-resistant malaria, and act on a crucial point of the parasite.

253

AKB9785 PRESERVES TIE2 PHOSPHORYLATION AND DECREASES ACUTE LUNG INJURY IN AN EXPERIMENTAL MALARIA MODEL

Kevin R. Barker[1], Sarah H. Higgins[1], Ziyue Lu[2], Kevin G. Peters[3], Kevin C. Kain[2]

[1]University Health Network/The University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Aerpio Therapeutics, Cincinnati, OH, United States

Malaria-induced acute lung injury (ALI) carries a high fatality rate despite the use of potent antimalarial therapies and optimal supportive care. Therapies targeting the underlying pathophysiology of ALI in malaria may be required to further improve clinical outcome. The angiopoietin-tyrosine kinase 2 (Ang-Tie2) signalling pathway is a key regulator of vascular integrity and emerging evidence indicates that disruption of Ang-Tie2 axis contributes to the development of ALI. AKB9785 is a phosphatase inhibitor that selectively inhibits vascular endothelial-phosphotyrosine phosphatase (VE-PTP)/HPTPβ, a receptor tyrosine phosphatase expressed in endothelial cells that negatively regulates Tie2 activation. We hypothesise that the use of AKB9785 as an adjunctive therapy will significantly improve survival, reduce vascular leak and decrease ALI in the ***Plasmodium berghei*** ANKA (PbA) model. C57BL/6 mice infected with $1x10^6$ PbA-infected erythrocytes received either 25 mg/kg AKB9785 or vehicle control q8h subcutaneously starting three days post-infection until sacrifice. IgM and total protein concentration were measured in bronchoalveolar lavage fluid (BALF) as a marker of vascular integrity, and Evans blue assay (EBA) in the lungs as a marker of vascular leak at baseline and day 6/7 post-infection. Biomarkers of endothelial activation/dysfunction were determined in the lung tissue and plasma. IgM was significantly reduced ($p=0.0194$, Mann-Whitney U test) and survival improved ($p=0.0027$, Log-rank test) in AKB9785 treated mice compared to controls. We will report additional measures of ALI in this model and in an additional murine model using angiopoietin-1 deficient mice, to test the hypothesis that Ang-1-Tie2 activation contributes to vascular integrity and ALI prevention. In conclusion, AKB9785 significantly improved survival and shows evidence of reduced pathological vascular leak associated with ALI in PbA-infected C57BL/6 mice. These findings suggest that targeting the Tie2 pathway with selective VE-PTP inhibitors could be used as adjunctive therapy for SM/ALI.

254

ASSESSMENT OF ACIDOSIS PROFILE IN PATIENTS WITH SEVERE MALARIA USING INNOVATIVE TECHNIQUE

Natthida Sriboonvorakul[1], Natchanun Leepipatpiboon[2], Sasithon Pukrittayakamee[1], Kanet Wongravee[2], Soparat Yutavorasit[2], Yaowalark Sukthana[3], Nicholas P.J. Day[4], Niklas Lindegardh[4], Nicholas J. White[4], Arjen M. Dondorp[4], Joel Tarning[4]

[1]Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University and Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]Department of Chemistry, Faculty of Science, Chulalongkorn University, Bangkok, Thailand, [3]Department of Protozoology, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [4]Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University and Centre for Tropical Medicine, Nuffield Department of Clinical Medicine, University of Oxford, Bangkok, Thailand

Acidosis is an important cause of mortality in severe falciparum malaria. A simultaneous bio-analytical method for qualitative and quantitative assessment in plasma of eight small organic acids potentially contributing to acidosis in severe malaria was developed and validated. High-throughput strong anion exchange solid-phase extraction in a 96-well plate format was used for sample preparation. Hydrophilic interaction liquid chromatography (HILIC) coupled to negative mass spectroscopy was utilized for separation, detection and quantification. Eight possible small organic acids; L-lactic acid (LA),α-hydroxybutyric acid (aHBA), β-hydroxybutyric acid (bHBA), p-hydroxyphenyllactic acid (pHPLA), malonic acid (MA), methylmalonic acid (MMA), ethylmalonic acid (EMA) and α-ketoglutaric acid (aKGA) were analyzed simultaneously using a ZIC-HILIC column. This method was validated according to U.S. Food and Drug Administration guidelines with additional validation procedures for endogenous substances. LC-MS acid concentration profiles in relation to clinical parameters of three groups; severe malaria (n=141), uncomplicated malaria (n=87) and healthy (n=68) were analyzed by pattern recognition analysis to compare, classify and predict unknown samples. The results of principal component analysis (PCA) showed that four acids (LA, aHBA, bHBA and pHPLA) have more significant discriminant power than other four, thus they all considered. In addition, PCA result showed that healthy could be classified from malaria completely with variance of three first PCs (73.11, 15.41 and 7.84%, respectively), however severe could not classify from uncomplicated completely. Linear discriminant analysis (LDA) model indicated excellent sensitivity and specificity for identification of malaria and healthy which are both (100%) in cross validated prediction. However, the result indicated fair sensitivity (65%) and good specificity (91%) for identification of severe and uncomplicated in cross validated prediction. This innovative technique could be useful tool for the assessment of acidosis in patients with severe malaria.

255

DRUG-DRUG INTERACTIONS BETWEEN PRIMAQUINE AND SSRI/SNRI ANTIDEPRESSANTS: IMPLICATIONS FOR PRIMAQUINE CO-ADMINISTRATION WITH CYP 2D6 INHIBITORS

Xiannu Jin, Brittney Potter, Chau Vuong, Thu-lan Luong, Lisa Xie, Jing Zhang, Ping Zhang, Jennifer Nelson, Patricia Lee, Jason Sousa, Qigui Li, Lisa Read, Brandon Pybus, Mara Kreishman-Deitrick, Philip Smith, Robert Paris, Gregory Reichard, Sean Marcsisin

Walter Reed Army Institute of Research, Silver Spring, MD, United States

The antimalarial activities of primaquine and other 8-aminoqinoline molecules are directly dependent upon bio-activation through CYP 2D6 metabolism. Factors that would reduce an individual's ability to metabolize primaquine through the CPY 2D6 pathway such as CYP 2D6 poor metabolizer status and/or co-administration of drugs that inhibit the CYP 2D6 enzyme activity could reduce anti-malarial activity and exacerbate drug-related toxicities. In the present study, the inhibitory potential of the selective serotonin reuptake inhibitor (SSRI) and serotonin norepinephrine reuptake inhibitor (SNRI) classes of antidepressants for CYP 2D6 mediated primaquine metabolism was assessed using ***in vitro*** and ***in vivo*** drug metabolism and pharmacokinetic assays. The SSRI/SNRI classes of drugs displayed a range of inhibitory activities on CYP 2D6 mediated metabolism of primaquine ***in vitro*** (IC_{50} 1-94 μM). Fluoxetine and paroxetine were the most potent inhibitors (IC_{50} ~ 1μM) of CYP 2D6 mediated primaquine metabolism, while desvenlafaxine was the least potent (IC_{50} ~ 94 μM). The ***in vivo*** inhibition of CYP 2D6 mediated metabolism of primaquine was also assessed ***in vivo*** using a primaquine pharmacokinetic study. The pharmacokinetic profile of primaquine was assessed alone or after co-administration of paroxetine. Co-administration of paroxetine with primaquine significantly increased liver concentrations, and area under the curve values for primaquine. This can likely be attributed to decreased CYP 2D metabolism as reflected by the decreased clearance (CL/F) for primaquine when co-administered with paroxetine. The results indicate that caution should be exercised with concomitant use of primaquine with SSRI/SNRI antidepressants and/or other CYP 2D6 inhibitors as the clinical implications in the context of anti-malarial activity for these interactions are unknown.

256

HIT TO LEAD OPTIMIZATION OF THE APICOPLAST-TARGETING ANTIMALARIAL AGENT MMV008138

Zhong-Ke Yao, Priscilla M. Krai, Emilio F. Merino, Morgan E. Simpson, Carla Slebodnick, Maria B. Cassera, **Paul R. Carlier**

Virginia Tech, Blacksburg, VA, United States

Compounds that target isoprenoid biosynthesis in ***Plasmodium falciparum*** could be a welcome addition to malaria chemotherapy, since the methylerythritol phosphate (MEP) pathway used by the parasite is not present in humans. Through a phenotypic rescue screen of 400 compounds in the publicly available Malaria Box, we determined that only one of the compounds (MMV008138) is toxic to ***P. falciparum*** by inhibiting isoprenoid biosynthesis. Since the relative and absolute stereochemistry of this compound was not known, we prepared all four stereoisomers. The active stereoisomer of MMV008138 was found to be (1R,3S)-; none of the other stereoisomers had significant growth inhibitory activity. Structure variation was then carried out to interrogate the effect of D-ring substitution and isosteric replacement of the carboxylic acid group, resulting in compounds possessing improved drug-like character.

257

PHARMACOKINETICS AND PROPHYLACTIC EFFICACY OF NANO- AND MICRO-PARTICLE DECOQUINATE SUSPENSION FOLLOWING SINGLE INTRAMUSCULAR INJECTION IN MICE

Qigui Li, Lisa Xie, Diana Caridha, Qiang Zeng, Jing Zhang, Ping Zhang, Chau Vuong, Brittney Potter, Jason Sousa, Sean Marcsisin, Lisa T. Read, Mark R. Hickman

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Prophylactic efficacy and pharmacokinetics (PK) were examined following single intramuscular (IM) depot formulation of decoquinate (DQ) suspension injected into mice infected with ***Plasmodium berghei*** sporozoites. DQ nano- and micro-particles suspended in an oily vehicle to retard drug release is suitable for long-term malaria prophylaxis. PK studies in normal animals and antimalarial efficacy in liver-stage malaria mice were conducted at various IM-DQ doses for 2, 4, 6, or 8 weeks prior to infection with ***P. berghei*** sporozoites. The liver stage efficacy evaluation was monitored by using an ***in vivo*** imaging system (IVIS). Full causal prophylaxis was shown in mice with a single IM dose of nanoparticle DQ (0.42 µm) at 120 mg/kg for 2-3 weeks and with microparticle DQ (8.31 µm) at 120 mg/kg lasted 8 weeks prior to inoculation. The 120 mg/kg IM dose with the two formulations was shown to be the minimal prophylactic dose required to provide full causal prophylaxis of malaria sufficient for a period of 2-8 weeks. A significant increase in the elimination half-life of the microparticle DQ formulation (1,447 hrs.) was achieved compared to that of the nanoparticle DQ (524 hrs.). Similarly, the AUC of the microparticle IM-DQ formulation in plasma was observed to be 17,609 ng·h/ml, which is double the AUC observed for the nanoparticle IM-DQ (8,465 ng·h/ml) at the same single 120 mg/kg dose administered to both animal groups. Body clearance results indicated that the CL/F in the animals treated with nanoparticle DQ was14.28 L/hr/kg, which is twice as fast as the clearance observed in animals treated with the microparticle DQ formulation (6.82 L/hr/kg). PK/PD evaluations have demonstrated the minimal inhibitory concentration (MIC) of DQ to provide full causal prophylaxis in mice infected with ***P. berghei*** sporozoites is 5.12 ng/mL. The microparticle IM-DQ formulation provided a longer and more constant DQ release in the plasma, which resulted in a 2.4 fold longer drug exposure time above MIC. The prophylactic effect of the microparticle formulation observed in mice was shown to be 3-4 times longer than the nanoparticle DQ.

258

PLASMODIUM FALCIPARUM EQUILIBRATIVE NUCLEOSIDE TRANSPORTER 1 INHIBITORS KILL MALARIA PARASITES IN CULTURE

Roman Deniskin, Yvett Sosa, Deborah Egbo, IJ Frame, Avish Arora, **Myles H. Akabas**

Albert Einstein College of Medicine, Bronx, NY, United States

The ***Plasmodium falciparum*** Equilibrative Nucleoside Transporter Type 1 (PfENT1) was hypothesized to be a potential target for novel antimalarial drugs. Malaria parasites are purine auxotrophs, incapable of ***de novo*** purine biosynthesis. They import purine precursors from the host and modify them through the purine salvage pathway to generate the purine nucleotides needed for RNA and DNA synthesis and other cellular metabolic processes. PfENT1 is the primary purine import transporter. Previous studies showed that PfENT1-knockout parasites are not viable in culture at purine concentrations found in human blood (< 10 µM). Based on these results, we and others had hypothesized that PfENT1 inhibitors might represent therapeutic leads for the development of novel antimalarial drugs. We developed a robust yeast-based high throughput screen to identify PfENT1 inhibitors. We screened a 64,500 compound library and identified 171 hits. Nine of the best hits, representing five distinct chemotypes, inhibited [^{3}H]adenosine uptake by PfENT1-expressing yeast and by red blood cell free trophozoite stage parasites with IC_{50} values in the 5-50 nM concentration range. These nine compounds inhibited parasite proliferation in culture in the 5-50 µM concentration range, but were not cytotoxic for yeast (Frame, Deniskin et al., (2015) ACS Chem Biol. 10(3):775-83). We now show that these nine compounds are highly selective for PfENT1 compared to the human ENT1 and human facilitated nucleobase transporter. The compounds are parasitocidal after 24 hours of exposure in culture. The compounds also inhibit the ***P. vivax*** ENT1 transporter and known non-synonomous single nucleotide polymorphisms from field isolates of PfENT1 and PvENT1. These results support the hypothesis that PfENT1 is a promising potential target for the development of novel antimalarial medicines. The compounds we have identified are potential therapeutic leads for antimalarial drug development.

259

TRANSLATIONAL PLATFORMS TO INVESTIGATE ANTIMALARIAL DRUG COMBINATIONS

John N. Haselden, Francisco-Javier Gamo

GlaxoSmithKline, Tres Cantos (Madrid), Spain

During recent years there has been considerable success in the identification and progression through to early clinical testing, of novel antimalarial drug candidates. Accordingly there is an increasing need to evaluate clinically a burgeoning portfolio of potential drugs that could ultimately be used to eradicate malaria. Given that historically most new treatments sooner or later are overcome by the ability of the parasite to develop resistance, the concept of a combination therapy of complementary drugs as a treatment regimen is becoming increasingly attractive. Such an approach affords a new antimalarial, protection against the emergence of resistance thereby ensuring continued utility in the broader population potentially for many more years. The strategic direction proposed here is the alignment of the readouts from ***in vitro*** and ***ex vivo*** assays with correlative data from our mouse model of ***Plasmodium falciparum*** malaria, which already has proven clinical translational ability. To that end we are establishing quantitative readouts of drug-treated parasites to monitor accurately effects on both the viability of parasites and clearance by the host. This system can be implemented with different ***P. falciparum*** strains to study precisely the effect of combinations, not only in standard strains but also in parasites with well-characterized resistance to parent drugs. We anticipate that information generated across these platforms will create the foundations upon which future antimalarial combination regimens will be based, and provide an

opportunity for the evaluation of clinically-relevant combination regimens as alternative route for clinical progression. Details on the strategy as well as preliminary results of initial stages will be presented.

260

COMPARATIVE EMBRYOTOXICITY OF DIVERSE ANTI-MALARIAL COMPOUNDS USING RAT WHOLE EMBRYO CULTURE AND THE APPLICATION OF THE SCREEN IN LEAD IDENTIFICATION FOR DISEASES OF THE DEVELOPING WORLD MOLECULES

Pablo Castaneda-Casado[1], Elena Jimenez-Navarro[1], Alison James[2], John Haselden[1], Stephanie Gresham[3], Sharon Robinson[3], Paul Bushdid[2]

[1]GlaxoSmithKline R&D, Tres Cantos, Spain, [2]GlaxoSmithKline R&D, Philadelphia, PA, United States, [3]GlaxoSmithKline R&D, Ware, United Kingdom

Malaria is a major health problem and a serious global health threat. In 2008, there were 247 million cases of malaria and nearly 1 million deaths (World Health Organization, 2011). The frequency and severity of infection is greatest in pregnant women. The increased susceptibility creates a problem as many of the anti-malarial drugs available on the market today are teratogenic. TB is second only to HIV as the leading infectious killer of adults worldwide. It is among the three greatest causes of death of women aged 15-44 and is the leading infectious cause of death among people with HIV/AIDS. Kinetoplastid diseases are a group of infections caused by different parasites: sleeping sickness (caused by Trypanosoma brucei), leishmaniasis (caused by Leishmania spp) and Chagas (caused by Trypanosoma cruzi). Over 30 million people get infected resulting in over 120,000 deaths world-wide annually.GSK is striving to develop new medicines for Diseases of the Developing World with reduced risk for adverse embryo-foetal outcomes. The early screening of potential candidate molecules using rat whole embryo culture (rWEC) will allow for an informed selection of compounds for further development. To support this strategy six marketed anti-malarials were assessed for their potential to induce teratogenicity. The results demonstrated that the rWEC can detect development defects induced by marketed anti-malarials and is a suitable platform for screening compounds in discovery. It has subsequently been used to support the candidate selection of molecules across the disease areas and clarified if the findings were related to target or chemical structure and supported the preclinical study plan to support inclusion of WCBP in clinical studies.

CHARACTERIZATION OF *PLASMODIUM FALCIPARUM*-INFECTED ERYTHROCYTE ADHESION TO HOST RECEPTORS AND IDENTIFICATION OF EFFECTIVE ANTI-ADHESION MOLECULES TO PREVENT THIS INTERACTION USING ATOMIC FORCE MICROSCOPY

Olga Chesnokov, Shalondria Sears, Ewa P. Wojcikiewicz, **Andrew V. Oleinikov**

Florida Atlantic University, Boca Raton, FL, United States

Anti-adhesion adjunct therapy aimed at preventing ***P. falciparum***-infected erythrocyte (IE) adhesion to host receptors might be of great benefit in the effective treatment of severe malaria. Currently, adhesion of IE to host receptors ***in vitro*** is often characterized using static plate adhesion assays. While useful at identifying interactions, these assays do not provide insight into the biophysical properties that underlie the IE/host receptor interactions. These can differ significantly among host receptors, thus their characterization is integral toward the development of tailored anti-adhesion therapy. We demonstrate here that single cell force spectroscopy (SCFS) can be used to measure detachment force and work required for de-adhesion between individual living IE cells and host receptors. In addition, this approach can be utilized to characterize various anti-adhesion molecules, including antibodies and small molecules, which effectively disrupt IE/host receptor interactions. We have recently identified a number of anti-adhesion molecules using a two-step high throughput approach , as reported previously. In this work we confirmed and characterized their anti-adhesion activity using SCFS. Our results demonstrate that SCFS can be effectively used for detailed biophysical characterization of the IE-host receptor interactions including effects of anti-adhesion molecules at the single-cell level.

262

IN VIVO EFFICACY OF JPC-3210 AND PARTNER DRUGS FOR MALARIA ERADICATION USING THE RODENT-*PLASMODIUM BERGHEI* MODIFIED THOMPSON TEST WITH AN EXTENDED FOLLOW-UP PERIOD

Arba L. Ager[1], Merita Aviles[1], Richard Boodoo[1], John W. Anderson[2], Gavin D. Heffernan[2], Peter E. Krasucki[2], Kurt W. Saionz[2], Guy A. Schiehser[2], Hong-Ming Shieh[2], Wenyi Zhao[2], Geoffrey W. Birrell[3], Marina Chavchich[3], Michael D. Edstein[3], G. Dennis Shanks[3], Laura R. Jacobus[2], David P. Jacobus[2]

[1]University of Miami Miller School of Medicine, Miami, FL, United States, [2]Jacobus Pharmaceutical Co., Inc., Princeton, NJ, United States, [3]Australian Army Malaria Institute, Enoggera, Australia

The aminomethylphenol, JPC-3210 is being developed as a potent long acting schizontocide to be used in combination with other antimalarial agents for the treatment of malaria infections and possibly to support malaria elimination programs. In the modified Thompson test using a three day twice daily administration, the lowest dose required to obtain 100% cure at day 30 was 2 mg/kg/day for JPC-3210, 4 mg/kg/day for pyronaridine and 16 mg/kg/day for piperaquine. The blood elimination half-lives of JPC-3210, pyronaridine and piperaquine in mice are relatively lengthy at 125 h, 79 h and 197 h, respectively. When the modified Thompson test was extended by an additional 30 days, parasites reappeared in both JPC-3210 and piperaquine treated groups. Most of the parasites observed were male or female gametes. The pyronaridine group remained slide negative out to day 60. Subinoculation studies with blood from all three treatment groups at day 60 into naïve mice are currently ongoing to evaluate the development of recrudescent infections. When JPC-3210 was co-administered with the gametocytocidal drug primaquine, the reappearance of parasites out to day 60 day was prevented despite the short elimination half-life of primaquine (1.8 h) in mice. Additionally, we plan to evaluate whether artesunate, dihydroartemisinin, or methylene blue will influence the development of late parasitemia. The 60 day test systems will also be extended to include lumefantrine and mefloquine. Our conclusion is that the modified Thompson test with a 60 day follow-up period should be used to assist in the selection of new antimalarial drug combinations for the treatment and elimination of malaria.

263

RICE FARMERS' WILLINGNESS TO PAY FOR MALARIAL VECTOR LARVAL SOURCE MANAGEMENT: THE CASE OF RUHUHA COMMUNITY IN EASTERN RWANDA

Alexis Rulisa[1], Chantal Ingabire[1], Emmanuel Hakizimana[1], Fred Kaatera[1], Michele Van Vugt[2], Leon Mutesa[3], Luuk Van Kempen[4]

[1]Rwanda Biomedical Center, Kigali, Rwanda, [2]University of Amsterdam, Amsterdam, Netherlands, [3]University of Rwanda, Kigali, Rwanda, [4]Radboud University Nijmegen, Nijmegen, Netherlands

This study is part of an action research project that aims to eliminate malaria in the community of Ruhuha in southeastern Rwanda. A study component has recently established that rice farming in the area creates significant malaria risk, which is in line with earlier work that documents this link in various settings. So far, none of the interventions that have been proven to be effective in tackling rice farming-induced mosquito breeding sites have been implemented in Ruhuha. Therefore, the project

has decided to use external funds to supports a larviciding intervention with Bacillus thuringiensis israelensis (Bti), but for just one rice cultivation season (semester). Future interventions will thus depend on co-payment of rice farmers and the wider community. The present study, conducted prior to Bti application, aims to assess the willingness to pay (WTP) for larviciding. Out of 1,914 rice farmers organized into four cooperatives, 320 farmers were randomly selected to participate in a cross-sectional study conducted in January 2015. The maximum WTP was elicitated through a contingent valuation exercise using the bidding game method. Focus group discussions were held with farmers. The mean WTP was US$ 2.2 and US$ 0.5 per farmer per season for lumpsum and per are, respectively. The median WTP revelead that 50% of the participants were willing to pay at least US$ 1.4 and US$ 0.3 for lumpsum deduction and per are, respectively. A multivariate analysis showed that more income from rice, a higher starting bid and being cued first on a lumpsum rather than a progressive deduction, were significantly associated with higher WTP (p<0,05). While acceptability of the intervention appears generally high, as witnessed for instance by a stated willingness to invest (non-compensated) labor time in applying Bti once it is established that it is effective in reducing malaria incidence, the WTP levels reported can only cover one fourth (1/4) of the full intervention cost (US$ 9 for lumpsum and US $ 1,8 per are). To fill this gap, financing models need to be developed to support rice farmers and their communities to increase the sustainability of the intervention.

264

MOLECULAR EPIDEMIOLOGY OF MALARIA TRANSMISSION IN VHEMBE DISTRICT, LIMPOPO PROVINCE, SOUTH AFRICA

Shehu S. Awandu[1], Jaishree Raman[2], Jandeli Niemand[1], Philip Kruger[3], Taneshka Kruger[1], Braam Louw[1], Lyn-Marie Birkholtz[1]

[1]University of Pretoria, Centre for Sustainable Malaria Control, Pretoria, South Africa, [2]National Institute for Communicable Diseases, Johannesburg, South Africa, [3]Limpopo Malaria Control Program, Limpopo, South Africa

Malaria remains one of the most devastating parasitic infections, contributing to mortality and morbidity on the African continent. However, for the past decade, massive international efforts have resulted in reducing the number of annual malaria deaths globally. Certain countries have moved from malaria control to attempt to achieve elimination of the disease within their borders. Malaria transmission in South Africa is seasonal with low transmission densities (<1/1000 risk population). This, in addition to well-managed malaria control programmes, led to the shift in focus towards implementation of malaria elimination strategies, aimed at achieving zero cases of malaria transmission by 2018. However, currently, only malaria incidence data in terms of blood stage parasite load is readily available for South Africa, with data on the transmissible gametocyte forms of these parasites and its carriage in the population limited. Whilst the first is important in malaria control strategies, in the situation of aiming towards malaria elimination, it is imperative that data on transmittable forms of the parasite is available. This will guide, monitor and assess the success of elimination strategies. This study is therefore quantifying the ***Plasmodium*** species and gametocyte carriage in the population through cross sectional surveys at health facilities, communities and farms using sensitive molecular technologies. The study has a four-tiered analysis profile, including molecular detection of parasite infections (and simultaneous speciation thereof), analysis of molecular markers for drug resistance of all positive samples followed by genetic barcoding as an indication of clonality and origin of infection. The findings of this study will help in identifying the source of persistent malaria transmissions and informing evidence based policy changes involving the deployment of e.g. primaquine and targeted interventions in South Africa in support of the malaria elimination agenda.

265

COMPARATIVELY ASSESSMENT OF THE EFFICACY OF DIFFERENT FORMATS OF DISPENSING THE IFAKARA SYNTHETIC MOSQUITO LURE AGAINST MALARIA VECTORS IN THE SEMI FIELD SYSTEM

Nancy S. Matowo[1], Salum Mapua[2], Halfan Ngowo[2], Fredros Okumu[1]

[1]Ifakara Health Institute/University of the Witwatersrand, Dar-es Salaam/ Johannesburg, United Republic of Tanzania, [2]Ifakara Health Institute, Dar-es Salaam, United Republic of Tanzania

The Ifakara odour blend was originally developed and tested by Okumu et al. The odour mixture was formulated from various synthetic chemicals that mimic the odour from human body emanations including sweat and breath that elicit mosquito host-seeking behavior. The Ifakara lure has been proven more attractive than actual human odour when placed apart but when a human is placed next to the lure, the human remain more or squarely attractive to mosquitoes. The initial dispensing mechanism of Ifakara blend involved the use of nylon strips (made of 15 denier microfibers) that are commonly available. The present study involved a semi-field experimental evaluation of different formats of dispensing Ifakara synthetic lure against host-seeking mosquitoes. The new Ifakara synthetic lure in pellets format, packaged in sachets by Biogents (BG) Ltd (Germany), was comparatively evaluated with the nylon strips as a means of dispensing the mosquito chemical attractants. The impregnated pellets were packed at the required concentrations, either with 4 group of compounds (4C) combined or the 9 compounds of separate pellets (9C). While the lure in nylon strips was formulated following the original procedures by Okumu et al. Carbon dioxide gas generated from yeast and molasses fermentation was used to augment the attractiveness of the synthetic lure. The evaluation was done using BG-sentinel traps developed by (Biogents, Germany). When the BG sentinel trap was baited with impregnated pellets (4C), it caught significantly higher number of Anopheles arabiensis (RR = 333.15 [149.57-742.08], P < 0.001) than un-baited BG trap. Similarly, the significantly number An. arabiensis (RR = 329.84 [148.08-734.70], P <0.001) were caught from the BG baited with pellets in 9C than un-baited trap. In addition, the BG-trap baited with nylon strips caught significantly more number of An. arabiensis (RR = 292.66 [131.36-652.00]. We conclude that the new formulation of Ifakara lure in pellets (4C/9C formats) may offer a simple and long-lasting dispensing mechanism of mosquito odorants to be used in attracting and killing, mass trapping or surveillance of mosquito vectors.

266

DEVELOPMENT OF RECYCLE-BASED HOMEMADE SUGAR BAITS AGAINST *ANOPHELES ARABIENSIS*

Frank S. Tenywa[1], Adam Saddler[2], Marta F. Maia[3], Athoman Kambagha[1]

[1]Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, [2]Ifakara Health Institute, Bagamoyo, Tanzania, Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland, Bagamoyo, Basel, United Republic of Tanzania, [3]Ifakara Health Institute, Swiss Tropical and Public Health Institute, Basel, Switzerland, University of Basel, Basel, Switzerland, Bagamoyo, United Republic of Tanzania

Innovative vector control approaches are needed to reach malaria elimination. Ivermectin (IVM) has been proven to kill mosquitoes post blood-feeding on treated humans. In this study IVM was incorporated into an attractive sugar bait (ASB) made from household waste and other recycled materials. The KD90 of IVM in 10% sugar solution against ***Anopheles arabiensis*** was determined as well as the most attractive fruit bait concoction. Floral baits, different prototype designs as well as best deployment site for the ASB within a household are under study in Bagamoyo, Tanzania. Dose response experiments to determine KD90 of IVM against Anopheles arabiensis were done in laboratory conditions.

Serial dilutions of IVM in sugar solution were investigated in separate cages (30x30x30 cm) . Mosqutoes mortality was observed after 3, 6, 24 and 48 hours post introduction of the treatments. Fruit bait attractivity of 7 different fresh fruit juices were investigated inside 6 large cages (1,20x1,20x1,20 cm) placed inside a tunnel. Solutions were marked with specific food colouring and the occurence of sugar feeding was recorded after 24 hours by squeezing the mosquito abdomens and observing the presence or absence of food colouring. Ivermectin proved to be toxic against malaria vectors in very low concentrations. Over 90% of ***An. arabiensis*** were knocked down 48 hours post sugar feeding on sucrose solutions containing at least 1‰ IVM. Results from sugar feeding preference on different fruits show that An. arabiensis will feed on a variety of fruit solutions as well as just water and sugar. No fruit concotion proved to be particulary more attractant with mosquitoes prefering orange, watermelon and guava over papaya, tomato, mango or banana. Further research is on-going with aim of designing a homemade recycled-based ASB using the knowledge gathered so far.

267

ESTABLISHING NEW LINE OF *PLASMODIUM FALCIPARUM* EXPERIMENTAL CHALLENGE INFECTION CLONAL STRAINS IN SUPPORT CONTROLLED HUMAN MALARIA INFECTION STUDIES

Redemptah Yeda

Walter Reed Project, Kisumu, Kenya

Malaria remains a significant global health threat to the world's population. With resistance having developed for all classes of drugs and no licensed vaccine, there are efforts to develop new and/or improved antimalarial drugs and vaccines. The controlled human malaria infection (CHMI) model, which is alternate to Phase IIb field studies, is used for testing safety and efficacy of new antimalarial drugs and vaccines. However, these experimental infections and challenges are mostly done using limited number of clones obtained > 30 years ago. This limits data interpretation because correlation of experimental and natural infections might not be obvious because field parasites are highly genetically and phenotypically diverse. This study set out to expand the genetic and phenotypic diversity of ***Plasmodium falciparum*** available for CHMI by developing clonal strains from recently obtained field isolates. Forty field isolates from different regions in Kenya underwent limiting dilution to generate single clones. For each of the 40 parent parasite, 3-10 clones were obtained generating a total of 212 clones. For genetic characterization, 12 microsatellites and 300 SNPs distributed across the ***P. falciparum*** genome were analyzed. Of the 212 clones, 80 were true single clones based on MS and SNPs analysis. Phylogenetic analysis revealed close kinship within multiple-genotype from each parasite infection. Multi-locus analysis showed matching genotypes within individuals up to seven loci combinations, indicating that although clones from the same parent have close kinship, they are not identical but have diverse genetics. To determine the parasite phenotypic characteristics, establishment of IC50 for 18 antimalarials is underway. The infectiousness of each clonal line will be established by assessing gametogenesis and oocyst/sporozoites production in mosquito. A CHMI study will be conducted to assess the ability of these clones to infect human. Highly characterized (genetic, ***in vitro*** and ***in vivo***) parasites will be deposited with Malaria Research and Reference Reagent Resource Center.

SEVEN YEAR TRENDS OF MALARIA IN ZANZIBAR, 2008-2014: A PRE-ELIMINATION SETTING

Issa Ally Garimo[1], Abdul-wahid Al-mafazy[2], Abdullah Ali[2], Jackie Cook[3], Fabrizio Molteni[4], Osia Mwaipape[1], Salum O. Masoud[2], Mohamed Ali[2], Wahida Hassan[2], Mwinyi Msellem[2], Mahdi M. Ramsan[1], Humprey Mkali[1], Lynn Paxton[5], Peter McElroy[6], Naomi Kapar[7], George Greer[7], Jessica M. Kafuko[8], Shabbir Lalji[1], Rajeev Colaco[9], Richard Reithinger[9], Jeremiah M. Ngondi[1]

[1]Research Triangle Institute, Dar es Salaam, United Republic of Tanzania, [2]Zanzibar Malaria Elimination Program, Zanzibar, United Republic of Tanzania, [3]Zanzibar Malaria Research Unit-Karolinska University, Zanzibar, United Republic of Tanzania, [4]Swiss Tropical and Public Health Institute, Dar es Salaam, United Republic of Tanzania, [5]Malaria Branch, and President's Malaria Initiative/Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania, [6]Malaria Branch, and President's Malaria Initiative/Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]President's Malaria Initiative/United States Agency for International Development, Dar es Salaam, United Republic of Tanzania, [8]United States Agency for International Development, Abuja, Nigeria, [9]Research Triangle Institute, Washington, DC, United States

Over the last decade, Zanzibar has experienced substantial declines in malaria burden. Surveillance of malaria cases can assist with programmatic decision making by helping to monitor seasonality, detect hotspots of transmission, and identify outbreaks of malaria. This study reports seven-year trends of passively detected malaria cases in Zanzibar. Weekly malaria data were collected through the malaria early epidemic detection system (MEEDS) which transmits aggregate malaria case data via mobile phone from public health facilities to a web-based server. Data for patient attendance and malaria diagnostic testing results from 2008 to 2014 were analysed to investigate trends in malaria burden in a pre-elimination area. Between 2008 and 2013, incidence of cases had dropped by 29% in Unguja (2,238 vs.1,598) and 50% in Pemba (918 vs. 419), with the largest reduction seen in children under 5 years (70% in both Unguja and Pemba). Case reports indicate that transmission has changed from perennial to highly seasonal, with peak case numbers in May and June. Rainfall was associated with increases in malaria cases in Unguja ($p<0.001$), although not Pemba. In Unguja, several stable hotspots of transmission were detected in 2010, 2011 and 2013. These hotspots appeared only following the long rains. Rainfall was associated with increases in malaria cases in Unguja ($p<0.001$), although not Pemba. Surveillance systems have identified substantial decline in malaria burden, changing transmission patterns and stable hotspots of transmission, which can now be more specifically targeted with intensified interventions.

269

STRATIFYING AND MAPPING MALARIA RISK TO INFORM SUB-NATIONAL MALARIA ELIMINATION IN ETHIOPIA

Hiwot S. Taffese[1], Henok Kebede[2], Seife Bashaye[1], Dereje Muluneh[3], Sheleme Chibsa[4], Jimee Hwang[5], Joseph Malone[6], Gunawardena Dissanayake[4]

[1]Federal Ministry of Health, Ethiopia, Addis Ababa, Ethiopia, [2]World Health Organization, Addis Ababa, Ethiopia, [3]United Nations Children's Fund, Addis Ababa, Ethiopia, [4]President's Malaria Initiative, United States Agency for International Development, Addis Ababa, Ethiopia, [5]President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States, [6]President's Malaria Initiative, Centers for Disease Control and Prevention, Addis Ababa, Ethiopia

Although much of Ethiopia remains at risk of malaria, routine surveillance data from the last decade have noted declining malaria outpatient morbidity and inpatient mortality. Based on this progress, Ethiopia has set a new strategic goal of eliminating malaria in select low transmission areas by 2020. The annual micro-planning exercise conducted by district malaria health officers compiles malaria data from nearly 100% of the 16,013

public health facilities. The creation of large numbers of additional primary health care facilities, including 13,000 health posts in rural communities, was temporally associated with improved access to prompt malaria case management, including parasitological confirmation and improved surveillance system completeness between 2005 and 2014. Of the 11,950,186 fever cases reported nationally from July 2012 to June 2013, 93% underwent laboratory testing. Of the 5,011,418 total malaria cases, 84% were parasitologically confirmed. Of the confirmed cases, 70% were due to ***Plasmodium larviciding intervention falciparum*** and 30% due to ***P. vivax***. District level annual parasite incidence per 1000 population (API) from 835 districts was used to stratify the country into four distinct API strata: <1, 1-4.99, 5-99.99, and ≥100. Of the total 84.2 million Ethiopians, 33.6 million live in areas considered malaria free (API <1) and are not targeted for malaria vector control measures. About 50 million (60%) live in malaria transmission risk areas (API>1), generally located at elevations below 2,000 meters. Of those living in malaria risk areas, 14.3 million people (29%) live in high transmission areas (API≥100), 26.5 million (53%) live in moderate transmission areas (API 5-99.99) and 9.2 million (18%) in low transmission areas (API 1-4.99). High transmission areas were largely on the western border with South Sudan and Sudan, whereas large clusters of low transmission areas were concentrated in Somali and Oromia Regions. Identification of districts with API between 1-4.99 and mapping of these districts will inform the selection of low transmission districts or clusters of districts appropriate for additional pre-elimination and elimination activities.

270

A CLUSTER-RANDOMIZED TRIAL OF TARGETED CONTROL TO ELIMINATE MALARIA IN CENTRAL SENEGAL: MAIN RESULTS IN YEAR 2

Abdoulaye Diallo[1], Badara Cisse[1], Fassiatou Tairou[1], Elhadji Ba[2], Jules Gomis[1], Ousmane Sy[1], Cheikh Sokhna[2], Jean Gaudart[3], Clare Flach[4], Ousmane Faye[1], Oumar Gaye[1], Paul Milligan[4]

[1]University Cheikh Anta Diop, Dakar, Senegal, [2]Institut de Recherche pour le Developpement, Dakar, Senegal, [3]Université Aix-Marseille, UMR 912 SESTIM, Marseille, France, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Targetting ***foci*** of malaria transmission may be more effective in reducing transmission than if the same effort is expended in blanket control measures, and has the potential advantage of limiting selection for resistance. The purpose of this trial was to evaluate the extent to which a targetted malaria control strategy combining vector control with indoor residual spraying (IRS) and chemotherapy, delivered by district health staff to hotspot villages, can reduce the transmission of malaria in low endemic areas. The trial will also determine whether, as part of this strategy, chemotherapy should be delivered to all members of targetted communities (MDA, Mass Drug Administration) or only those who have been tested and are known to be infected (MSAT, Mass Screening and Treatment). In 30 clusters, all households in hotspot villages were targetted to receive IRS with Actellic 300CS in July, followed, in 15 clusters, by MDA with dihydroartemisinin-piperaquine (DHA-PQ) administered to all persons in the household in September and again in October. In the other 15 clusters, instead of MDA, all persons in the household were screened using a malaria RDT and those who tested positive treated with DHA-PQ. 10 clusters served as controls. Interventions were delivered over two years (2013 and 2014), and the primary outcomes were the incidence of malaria, and the prevalence of parasitaemia just after the main peak period of transmission, in year 2. In each intervention arm, about 80,000 persons were enrolled each month in each year. In 2014, parasite prevalence was 1% in September (cluster range: 0.05% to 5%), and 0.99% in October (cluster range: 0.03% to 5.2%). A survey was done four days after MDA and MSAT to assess adherence and to ask about side-effects. Side-effects were reported by 20% (117/599) in September and 15% (91/598) in October, but with excellent adherence to the regimen. Indirect effects of the interventions on transmission will be assessed by comparing between the trial arms the incidence of malaria in non-targetted areas in each cluster. Total effects (direct + indirect) will be evaluated by comparing overall incidence.

271

THE COSTS AND COST-EFFECTIVENESS OF TWO SPATIALLY TARGETED, MULTI-COMPONENT MALARIA ELIMINATION STRATEGIES: RESULTS OF A LARGE THREE-ARM CLUSTER-RANDOMIZED TRIAL IN RURAL SENEGAL

Fassiatou Tairou[1], El Hadj Konko Circe Ba[2], Abdoulaye Diallo[1], Ousmane Sy[1], Badara Cisse[1], Jules Francois Gomis[1], Omar Gaye[1], Paul Milligan[3], Catherine Pitt[3]

[1]University Cheikh Anta Diop, Dakar, Senegal, [2]Institute de Recherche Pour le Developpment, Dakar, Senegal, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

In areas of low and patchy transmission, it is hypothesized that targeting residual hotspots can cost-effectively eliminate malaria. We conducted a three-arm, cluster-randomized controlled trial in an area of low, patchy, and highly seasonal transmission in rural Senegal over two malaria seasons in 2013-14. Health posts (n=46) serving approximately 320,000 people were randomized into 40 clusters: one of two multi-component hotspot strategies (n=15 clusters each) or control (n=10 clusters). In both intervention strategies, hotspot villages were identified and community health workers (CHWs) offered residents indoor residual spraying (IRS) in July each year. In September and October, CHWs again conducted door-to-door visits in hotspot villages in the intervention arms; in one arm, they offered mass screening and treatment (MSAT) with rapid diagnostic tests (RDTs) and dihydroartemisinin-piperaquine (DHA-PQ) and in the second arm, they offered mass drug administration (MDA) with DHA-PQ. In all three arms, health promotion encouraged care seeking for fever and health posts provided enhanced case management, including RDT testing and for positive cases, treatment with antimalarials and provision of a long-lasting insecticide-treated bed net. Based on detailed micro-costing, we report the incremental financial and economic cost per recipient of each of the 6 intervention components: hotspot identification, promotion of care-seeking, IRS, MDA, MSAT, and enhanced case management. We use a decision analytical model to assess the cost-effectiveness of each of the three strategies from a societal perspective based on intention-to-treat including hotspot and non-hotspot villages and present the incremental cost per malaria case averted and per disability-adjusted life-year averted. We explore uncertainty with univariate and probabilistic sensitivity analysis illustrated with cost-effectiveness acceptability curves and the cost-effectiveness plane. The relative costs of the six malaria interventions and the efficiency of alternative elimination strategies constitute important considerations for policy makers.

272

EFFICACY OF ACTELLIC® 300 CS (PIRIMIPHOS-METHYL) AFTER TWO YEARS OF INDOOR RESIDUAL SPRAYING IN SENEGAL

Ousmane Sy[1], Badara Cissé[1], Abdoulaye Diallo[1], Fassiath Tairou[1], Elhadji Konco Ciré Ba[2], Jean Louis Abdourahim Ndiaye[1], Lassana Konaté[1], Oumar Gaye[1], Paul Milligan[3], Ousmane Faye[1]

[1]University Cheikh Anta Diop, Dakar, Senegal, [2]Institut de Recherche pour le Developpement, Dakar, Senegal, [3]London School of Hygiene & Tropical Medicine, Dakar, Senegal

In central-western Senegal, scaling-up of control measures has been effective in reducing malaria incidence, but additional measures are now required to eliminate the disease. However, widespread resistance to currently used insecticides threatens the effectiveness of bednet and IRS (Indoor Residual Spraying) programmes. In 2013 and 2014, as part of a large-scale cluster randomized trial of a targetted control strategy, we evaluated the duration of efficacy of Actellic® 300CS, a capsular

formulation of pirimiphos methyl, when used for IRS. IRS with pirimiphos methyl was delivered to all households in malaria hotspot villages by spray-teams of community health workers (CHWs) who were trained and supervised by staff of the Public Health department. Each year, efficacy was assessed over 7 months in 5 villages. In each village, 5 treated rooms were selected and untreated rooms used as controls. Bioassays were performed on each of 3 walls in each room, to measure knock-down and 24-hour mortality of lab-reared ***Anopheles gambiae*** and of locally-caught wild strains. In 2014 steps were taken to improve the training and supervision of CHW sprayers and the duration of efficacy measured in the same way as in 2013. In 2013, 24-hour mortality (adjusted for control mortality using Abbott's formula), two months after spraying, was 92% , decreasing to 72% after 3 months, and 37% after 4 months. Mortality at 7 months was 48%. In 2014, the 24-hour mortality was 97%, 97%, 82%, 76% after one, two, four and seven months respectively. In all villages, vectors were highly sensitive to carbamates (bendiocarb) and organophosphates (pirimiphos-methyl) in both years (24-hour mortality rates 98% and 100%). These results showed that IRS with Actellic® 300CS was highly effective but the duration of efficacy depends on the quality of spraying.

273

SOCIAL AND CULTURAL FACTORS INFLUENCING PREGNANT WOMEN'S ADHERENCE TO ANTIMALARIAL TREATMENT IN RURAL GAMBIA

Fatou Jaiteh

Medical Research Council, The Gambia, Banjul, Gambia

Non-adherence to antimalarial treatment in pregnancy has been identified as a major barrier to malaria control efforts. There is limited evidence on the cultural and contextual factors that influence adherence to anti-malarial treatments in pregnancy. This study aims to understand these factors by exploring community perceptions on pregnant women's adherence to their antimalarial treatment in a rural area of The Gambia.A qualitative ethnographic study was conducted in three villages in the Upper River Region of The Gambia from June to July 2014. Data collection included semi-structured interviews and participant observation, which included informal conversations . Interview transcripts and field notes were entered, coded and analysed using NVivo Version10. In-depth semi-structured interviews were conducted with 30 participants, which included women of reproductive age (n=15), mothers-in-law (n=5), husbands (n=4) and health workers (n=6). Adolescent girls and older women were more likely to delay revealing their pregnancies to health workers. For adolescents, delayed disclosure of pregnancy was linked to feelings of awkwardness and social shyness. For older mothers, delayed disclosure of pregnancy was associated with their social role and position. Delayed disclosure of pregnancy was indicated as an influence on women's views regarding the importance of treatment adherence. In general, women indicated having insufficient information on treatment efficacy and the possible side effects of antimalarial medication. Mothers in-laws were identified as influencing pregnant women's non-adherence to malaria medication. Husbands were regarded as potential reinforcers to pregnant women complying with antimalarial treatment regimens. Culturally adapted community-based health information and treatment should be targeted at adolescent and older pregnant women who are at risk of being isolated from health facility-based education and treatment for malaria in pregnancy. Additionally, mothers-in-law and husbands should be included in facility and community based health promotion programs targeted at pregnant women.

THE BIOPHYSICAL CHARACTERIZATION OF HRP2 REVEALS INSIGHTS TOWARD IMPROVED DIAGNOSTICS FOR *PLASMODIUM FALCIPARUM* MALARIA ELIMINATION

Robert A. Burton[1], Ihn Kyung Jang[1], Rebecca S. Barney[1], David J. Sullivan[2], Christine Markwalter[3], David W. Wright[3], Paul LaBarre[1]

[1]PATH, Seattle, WA, United States, [2]Johns Hopkins Malaria Research Institute, Baltimore, MD, United States, [3]Vanderbilt University, Nashville, TN, United States

Malaria programs aimed at eliminating ***Plasmodium falciparum*** (***Pf***) seek to incorporate active infection detection strategies to target low density infections that could drive low prevalence transmission. Currently available immunoassays lack the sensitivity required for active infection detection strategies; the limit of detection (LOD) of these rapid diagnostic tests (RDTs) is too high to identify all transmissible infections. Malaria infection detection tests (IDTs) with a significantly improved LOD would enable more effective elimination interventions while retaining the critical advantages of low cost, ease of use, and rural deployment. The ***Pf*** specific histidine-rich protein 2 (HRP2) is a useful biomarker for clinical diagnostics because it is specific to current or recent ***Pf*** infection, and may be equally effective even in the absence of circulating parasites. Thus, improved HRP2 tests are of particular significance for stratification of focal mass drug administration (FMDA) and focal test and treat (FTAT) malaria elimination tactics. However, further characterization of the HRP2 protein is necessary before we can fully exploit its potential. Our aim is to facilitate the development of improved malaria HRP2 IDTs by thoroughly investigating HRP2 structure-function relationships and their impact on epitope-antibody interactions. The highly polymorphic, low amino acid complexity, and unstructured nature of the HRP2 protein makes quantification, optimization, and standardization of RDTs challenging. Current HRP2-detecting RDT immunoreagents primarily target the Type 2 (AHHAHHAAD) and Type 7 (AHHAAD) tandem repeat motifs that comprise the most prevalent antigen epitope, AHHAADAHHA. Amino acid sequence analysis and biophysical characterization of native and recombinant HRP2 constructs including quantitative ELISA, biolayer interferometry, and circular dichroism under a variety of physiological and clinical test media reveal the impact of sequence variations on immunoreagent binding and are useful to guide design parameters of highly sensitive ***Pf*** malaria HRP2-based IDTs under development.

275

UNNEEDED DEATHS: ABOUT MALARIA IN MADAGASCAR

Milijaona Randrianarivelojosia[1], Djordje Gikic[2], Pascal Rajaonarison[3]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]PIVOT Project, Ifanadiana, Madagascar, [3]Former Ministry of Public Health, Antananarivo, Madagascar

Since 2005, the Malagasy Government has planned to achieve malaria elimination in Madagascar. ACT is recommended for treating uncomplicated malaria; and insecticide treated bed nets for prevention purposes. Financial support from international organizations such as the Global Fund to Fight AIDS, Tuberculosis and Malaria; the President Malaria Initiatives, UNITAID; UNICEF have given some hope to insuring availability and affordability of ACTs. But that has been illusory. The whole strategy to combat malaria was never implemented properly in a continuous manner. Above all, the Global Fund episodically interrupted funding likely following the proven misuse of the funds. In the last five years, tens of devastating tropical cyclones hit the country. Political turmoil and instability do not allow good management of the public health policies. Fatal malaria epidemics occur. We carried out the investigation in the dry South; the wetter North-West region both in May 2012 and the rainy South-Western in June 2011. Malaria prevalence among villagers was 25% to 55%. The epidemiological data clearly shows that the number of malaria cases is still increasing up to today although some health officials

have questioned this increase at that period. Surprisingly, many people believe that malaria (locally called tazo) does not kill; but that it is actually unknown pathologies with high fever and convulsion that occur and kill. So they seek "spiritual care" from traditional healers. Therefore, people die of malaria; and also of other infectious diseases. Actually, antimalarial drugs are not available in several health centers in rural area. Fighting malaria means fighting mortality and morbidity. The number of death related to malaria in Madagascar is underreported for many reasons. The government support in funding of malaria control is necessary in order to increase patients' access to life-saving intervention to lower the rates of malaria and the unneeded deaths related to malaria. We will present more data to the alarmingly increasing malaria epidemics in Madagascar, as the aftermath due to the failure of the system in this combat against malaria.

276

NON-CHEMICAL TECHNOLOGY FOR INSTANTLY KILLING SUSCEPTIBLE AND RESISTANT MALARIA VECTORS THAT BITE HUMANS OUTDOORS IN TANZANIA

Salum A. Mapua, Nancy Stephen Matowo, Fredros Oketch Okumu

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Long lasting insecticidal net, indoor residual spraying and larval source management have been the successful frontline interventions against malaria for decades with a major reduction in malaria mortality by 47% globally and 54% in Africa. Unfortunately, the major malaria vectors have now developed biochemical, physiological and behavioral resistance towards most of insecticide related interventions, thus, posing a skeptical query on the human protection from the existing insecticidal interventions in the near future. A 3 X 3 Latin square comparative study was conducted against wild mosquitoes in the Lupiro village located in the south eastern part of the rural Tanzania. Three solar-powered mosquito landing boxes (MLB) were fitted with modified low-cost commercially available mosquito zappers as electrocuting grids. One MLB was fitted with one electrocuting grid on one side, second MLB was fitted with two electrocuting grids on two sides and third MLB was fitted with three electrocuting grids on three sides. The MLBs were baited with synthetic human lure (Ifakara lure) and the entire electric system was controlled by water proof light sensor, in which the system turns on at dusk and shut off at dawn, thus improving the battery life span and providing minimal human supervision. A significantly number of mosquitoes were killed by the MLB with two or three grids, relative to MLB with one grid ($P<0.05$). The malaria vector An.arabiensis were killed in higher number compared to any other species, though the non malaria vectors (i.e. Culex and Mansonia species) number also increased as the grid number increase. The non blood fed mosquitoes were 99% thus suggesting host seeking status. These findings suggest that the biochemical and physiological resistance of outdoor malaria vectors can now be tackled in a way that does not augment environmental concerns and chances of resistance development. Moreover, a mosquito landing box fitted with electrocuting grids can effectively complement the existing front line interventions against malaria

277

DEVELOPMENT ASSISTANCE AND GOVERNMENT EXPENDITURE FOR MALARIA ELIMINATION

Joseph L. Dieleman, Lavanya Singh, Maxwell Birger, Elizabeth Johnson, Annie Haakenstad

Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States

In 2010, malaria was the fifth-largest cause of years of life lost globally, with approximately 1.2 million deaths attributed to the disease. In parts of sub-Saharan Africa, where malaria burden is highest, it is the leading cause of death. Despite this ongoing impact, remarkable progress is being made towards reducing the incidence and prevalence of malaria. To date, 111 countries have eliminated malaria, while another 34 countries, including China, South Africa, and Argentina, are realistically moving toward elimination. However, little is known about how much governments and donors spend on the prevention and treatment of malaria in these countries. We tracked development assistance for health (DAH) and government health expenditure (GHE) for the prevention and treatment of malaria. For DAH, we tracked resources from source to channel to recipient country or region, focusing on 34 malaria elimination countries from 1990 to 2012 and generated projections of malaria DAH from 2013 to 2017. For GHE, we use macro-economic, socioeconomic, and epidemiological data, as well as expenditure information from the World Malaria Reports to estimate the share of domestic government health budgets spent on malaria for 1995 through 2012 for 34 countries. Analyzing these trends in expenditure exposes which countries and donors are prioritizing the elimination of malaria, as well as how funding for elimination has evolved over time. A strategic input for ongoing efforts to eliminate malaria in the 34 elimination countries, these funding trends form the basis for understanding how these and other countries can realistically move towards elimination.

278

THE IMPACT OF TARGETED MASS DRUG ADMINISTRATION USING DIHYDROARTEMISININ-PIPERAQUINE IN SOUTHERN PROVINCE ZAMBIA: INITIAL FINDINGS

Thomas P. Eisele[1], Adam Bennett[2], Kafula Silumbe[3], Timothy Finn[1], Victor Chalwe[4], Mukalwa Kamuliwo[5], Busiku Hamainza[5], Josh Yukich[1], Joe Keating[1], Richard W. Steketee[6], John M. Miller[7]

[1]Tulane University, New Orleans, LA, United States, [2]University of California San Francisco, San Francisco, CA, United States, [3]PATH-Malaria Control and Elimination Partnership in Africa, Luaka, Zimbabwe, [4]University Teaching Hospital, Lusaka, Zambia, [5]National Malaria Control Centre, Lusaka, Zambia, [6]PATH-Malaria Control and Elimination Partnership in Africa, Seattle, WA, United States, [7]PATH-Malaria Control and Elimination Partnership in Africa, Lusaka, Zambia

With the recent call for malaria elimination, there is renewed interest in mass treatment with highly effective antimalarials to clear parasites from the human reservoir to break malaria transmission. A community randomized controlled trial of 60 health facility catchment areas was used to quantify the effectiveness of 2 rounds of mass drug administration (MDA) or focal MDA (fMDA) using dihydroartemisinin + piperaquine (DHAp), versus a control of routine prevention and care but no mass treatment, in Southern Province, Zambia, an area of endemic malaria transmission with high vector control coverage. The study was stratified by malaria transmission above and below 10% parasite prevalence. All eligible participants in the intervention rounds were tested for ***P. falciparum*** using an HRP2 rapid diagnostic test (RDT). MDA consisted of treating all eligible residents with DHAp in each round (Dec 2014 just prior to the rains and Feb 2015 at the beginning of the rainy season), irrespective of RDT result. fMDA, conducted simultaneously to the MDA rounds, consisted of treating all eligible household members with DHAp where anyone in the house tested positive by RDT. Primary outcomes included malaria parasite prevalence measured by pre and post cross-sectional surveys at the end of high transmission season (April-May), and malaria infection incidence measured in a cohort of 2,100 individuals followed monthly for 12 months; infection status was determined by RDT and PCR. The study was powered to detect a 50% reduction in these outcomes compared to the control group. The baseline survey showed malaria prevalence in children <6 years old to be 8.9% (95% CI: 5.6 - 12.2%) and 49.9% (95% CI: 40.3 - 59.5%) in low and high transmission areas, respectively. The 2 MDA and fMDA rounds reached 287,145 people, combined, over both rounds (coverage of eligible respondents was approximately 80-85%); parasite prevalence decreased from 8.3% to 4.6% between rounds at a time when transmission normally rises dramatically. The impact of the MDA/fMDA rounds will be presented using data from the follow-up survey and from the first 6 months of the infection incidence cohort study.

279

SCHOOL-BASED TREATMENT WITH ACT TO REDUCE TRANSMISSION' (START-IPT): EVALUATION OF THE COMMUNITY IMPACT OF INTERMITTENT PREVENTIVE TREATMENT FOR MALARIA IN UGANDAN CHILDREN

Catherine Maiteki[1], Samuel Gonahasa[1], Simon Peter Kigozi[1], Christopher Drakeley[2], Andrea M. Rehman[2], Clare Ir Chandler[2], Grant Dorsey[3], Moses R. Kamya[4], Sarah G. Staedke[2]

[1]Infectious Disease Research Collaboraton, Kampala, Uganda, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]University of California San Fransisco, San Francisco, CA, United States, [4]School of Medicine, Makerere University College of Health Sciences, Kampala, Uganda

Intermittent preventive treatment (IPT) for malaria in schoolchildren has been shown to benefit individual children, and has the potential to decrease malaria transmission at the community level. This cluster-randomized trial assessed the impact of IPT of malaria in schoolchildren with dihydroartemisinin-piperaquine (DP) on community-level clinical outcomes and malaria transmission in Jinja, Uganda. A total of 84 clusters were randomised equally between intervention and control. A total of 10,746 children were enrolled in the intervention. Monthly IPT with DP was delivered from June-Dec 2014, and up to 6 rounds of DP (dosed by weight, 3-day course) were delivered to participants. The impact of the intervention was measured by comparing parasitological outcomes in community and school surveys pre- and post-intervention, and from continuous entomology surveillance. Safety monitoring was also conducted. The baseline community survey was carried out from Feb-June 2014; 10,033 participants from randomly selected households in the 84 clusters were enrolled. Parasite prevalence by microscopy was high in community residents (25%), particularly in school-aged children (35%), which was confirmed by the baseline school survey (43%). The final community survey was conducted in Jan-April 2015, and microscopy of samples is ongoing at the time of abstract submission. The final school survey was conducted in Nov-Dec 2014; 1092 students were enrolled, including 13 students randomly selected from each of the 84 schools, and preliminary microscopy results suggest that parasite prevalence was much lower in the intervention arm (9%) than in the control (44%), crude odds ratio 0.09 (95% CI:0.05-0.17). The entomology survey includes 200 households, 5 randomly selected from 40 clusters, and was conducted for one year, ending in April 2014. Mosquitoes were collected from each house monthly using CDC light traps, and will be analysed to estimate sporozoite rate for an effect of the intervention on transmission. Full results of the study will be presented and discussed in light of implementation challenges to inform chemoprevention and control of malaria.

280

QUANTITATIVE G6PD TESTING FOR SAFE TREATMENT OF *PLASMODIUM VIVAX* MALARIA WITH 8-AMINOQUINOLINES: A POINT-OF-CARE ELECTROCHEMICAL DEVICE

Sampa Pal[1], Nicole LaRue[1], Maria Kahn[1], Pooja Bansil[1], Sarah McGray[1], Gary Hewett[2], Matthew Musho[3], Micheal Benecky[4], Gonzalo Domingo[1]

[1]PATH, Seattle, WA, United States, [2]G6DX Inc, Hayward, CA, United States, [3]Conductive Technologies, York, PA, United States, [4]GlaxoSmithKline, Raleigh, NC, United States

Currently the only class of drugs that can completely cure a patient of ***Plasmodium vivax*** parasites (radical cure), thus reducing the risk of relapse, are the 8 aminoquinoquinolines such as the registered drug primaquine. This class of drugs presents a safety risk to subjects with glucose-6-phosphate dehydrogenase (G6PD) deficiency. G6PD deficiency is an X-linked disorder that affects more than 400 million people worldwide. Moderate to severe, life-threatening hemolytic anemia episodes can develop if G6PD-deficient individuals are treated with 8-aminoquinoline drugs. This risk represents a major barrier to wide-scale adoption of radical cure. Therefore, determination of a malaria patient's G6PD activity level is critically important before 8-aminoquinoline drug therapy. The G6DX Diagnostic System uses an electrochemical sensor to make a simultaneous quantitative measurement of red blood cell G6PD and hemoglobin in whole blood in a point-of-care setting with results available in a minute. We describe the proof-of-feasibility of such a test, presenting analytical performance data over the critical G6PD activity dynamic range, usability, and acceptability data collected in several ***P. vivax*** endemic countries. The G6DX Diagnostic System is in the research prototype stage and is not yet commercially available.

281

RECOMBINANT HUMAN G6PD FOR QUALITY CONTROL AND QUALITY ASSURANCE: RESOURCE FOR ROBUST G6PD TESTING IN *PLASMODIUM VIVAX* RADICAL CURE

Maria Khan[1], Nicole LaRue[1], Marcus Estrada[1], Sampa Pal[1], Lynn Barrett[2], Steve Nakazawa Hewitt[2], Mitchell Dumais[2], Wesley C. Van Voorhis[2], Gregory Crowther[2], Gonzalo Domingo[1]

[1]PATH, Seattle, WA, United States, [2]University of Washington, Seattle, WA, United States

Primaquine is an 8-aminoquinoline based drug that has been available for malaria radical cure since the 1950s and currently is used with or without glucose-6-phosphate dehydrogenase (G6PD) testing. Good medical practice requires that people know their G6PD status prior to receiving an 8-aminoquinoline drug. Robust G6PD tests are currently under development to meet the needs for radical cure of ***Plasmodium vivax*** with 8-aminoquionlines. A large gap for the support of point-of-care G6PD testing is the availability of reagents to support quality control (QC) of G6PD products along the supply chain from the manufacturer to the end user. While there are reagents and systems to support QC of laboratory screening tests, they are not configured in terms of shelf life and volumes to support quality assurance (QA) programs for point-of-care G6PD tests. Feasibility to lyophilize recombinant human G6PD as a QC reagent is demonstrated. For calibration of G6PD assays, a standard reagent of G6PD was used to create a panel of normal, intermediate and severe deficiency, representing 100%, 30% and 10% activity respectively, as well as a no-enzyme control. Recombinant G6PD was expressed in ***E.coli*** and purified and stored at -80°C. Aliquots were thawed and combined with mannitol and sucrose in single use tubes and lyophilized. After lyophilization, enzyme activity was not altered. Results are presented from real time and accelerated stability studies of the lyophilized G6PD enzyme. These reagents could support a framework for a sustainable QC/QA system to support robust point-of-care G6PD testing for ***Plasmodium vivax*** radical cure.

282

FACTORS THAT ARE ASSOCIATED WITH THE RISK OF ACQUIRING *PLASMODIUM KNOWLESI* MALARIA IN SABAH, MALAYSIA: A CASE-CONTROL STUDY

Matthew J. Grigg[1], Timothy William[1], Chris Drakeley[2], Jenarun Jelip[3], Lorenz von Seidlein[4], Bridget E. Barber[4], Kimberly M. Fornace[2], Nicholas M. Anstey[4], Tsin W. Yeo[4], Jonathan Cox[2]

[1]Queen Elizabeth Hospital, Kota Kinabalu, Sabah, Malaysia, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Sabah Ministry of Health, Kota Kinabalu, Sabah, Malaysia, [4]Menzies School of Health Research, Darwin, Australia

Plasmodium knowlesi has long been present in Malaysia, and is now an emerging cause of zoonotic human malaria. Cases have been confirmed throughout South-East Asia where the ranges of its natural macaque hosts and Anopheles leucosphyrus group vectors overlap. The majority of cases are from Eastern Malaysia, with increasing total public health notifications despite a concurrent reduction in ***P. falciparum*** and ***P. vivax***

malaria. The public health implications are concerning given ***P. knowlesi*** has the highest risk of severe and fatal disease of all ***Plasmodium spp*** in Malaysia. Current patterns of risk and disease vary based on vector type and competence, with individual exposure risks related to forest and forest-edge activities still poorly defined. Clustering of cases has not yet been systematically evaluated despite reports of peri-domestic transmission and known vector competence for human-to-human transmission. A population-based case–control study was conducted from December 2012 to January 2015 at two adjacent districts in north-west Sabah, Malaysia. 228 ***P. knowlesi*** PCR-confirmed malaria cases presenting to the district hospital sites meeting relevant inclusion criteria were enrolled, with three community controls matched to the same village as the case selected randomly. Study procedures included blood sampling and administration of household and individual questionnaires to evaluate potential exposure risks associated with acquisition of ***P. knowlesi*** malaria. Results from the primary per protocol analysis will be presented, with adjusted ORs for exposure risks between cases and controls calculated using conditional multiple logistic regression models. Secondary outcomes will include differences in exposure variables between ***P. knowlesi*** and other ***Plasmodium*** species, risk of severe ***P. knowlesi*** malaria, and evaluation of ***P. knowlesi*** case clustering.

283

MEASURING SOCIOECONOMIC INEQUALITIES IN MALARIA RISK IN RURAL UGANDA

Lucy S. Tusting[1], John C. Rek[2], Emmanuel Arinaitwe[2], Sarah G. Staedke[1], Moses Kamya[3], Christian Bottomley[1], Deborah Johnston[4], Grant Dorsey[5], Steve Lindsay[6]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Makerere University College of Health Science, Kampala, Uganda, [4]School of Oriental and African Sciences, London, United Kingdom, [5]University of California, San Francisco, San Francisco, CA, United States, [6]Durham University, Durham, United Kingdom

Relative wealth is an important risk factor for malaria. However, there is little consensus on how to measure wealth in malaria studies in rural African communities. We evaluated the agreement between six indicators of socioeconomic position and assessed their relative performance in detecting socioeconomic inequalities in malaria in Nagongera, eastern Uganda. Socioeconomic information was collected for all children aged six months to ten years living in 100 households, who were followed for 36 months. Parasite prevalence was measured every three months and malaria incidence was determined by passive case detection. Mosquito density was measured using monthly light trap collection. Socioeconomic position was determined using (1) two wealth indices derived from Principal Component Analysis, (2) income, (3) occupation, (4) food security, (5) vulnerability and (6) education. Indicators were assessed in terms of (1) relative agreement and (2) sensitivity to malaria inequalities. We will present the relative agreement between indicators and the association between each indicator and human biting rate, malaria infection and clinical malaria. We will discuss the most appropriate indicators for measuring relative wealth in this setting and the implications for future study design.

284

PREVALENCE OF MALARIAL INFECTION AMONG PRIMARY SCHOOL CHILDREN IN AN URBAN SETTING IN UGANDA

Ronald Mulebeke[1], Adoke Yeka[2], Ambrose O. Talisuna[3], Bob W. Snow[3]

[1]School of Public Health, College of Health Sciences, Makerere University, Kampala, Uganda, [2]School of Public Health, College of Health Sciences Makerere University, Kampala, Uganda, [3]Malaria Public Health Department, University of Oxford-KEMRI-Wellcome Trust Programme, Nairobi, Kenya

This study was undertaken to estimate the prevalence and distribution of ***Plasmodium*** infection and identify local risk factors among school children in Kampala the main urban setting in Uganda in order to contribute to the national updating of the malaria epidemiology profile. Urban malaria is still a problem in Sub-Saharan Africa, contributing up to 25% of the global burden of malaria among urban dwellers. In Uganda, urban malaria is still predicted with least certainty. The prevalence of malaria parasitemia in Kampala the biggest urban setting in Uganda was 5% in 2009. There has been a scale up in malaria control interventions since however information is lacking to capture the transitioning epidemiology. We conducted school based surveys in Kampala between June and August 2014 to estimate the prevalence and distribution of ***Plasmodium*** infection and identify local risk factors among school children in Kampala the capital city of Uganda. A finger-prick blood sample was collected for a thick and thin blood smear and children with fever had a malaria rapid diagnostic test performed using Para Check-Pf device. Participating schools were mapped using hand-held GPS receivers. The survey was conducted in 20 primary schools and a total of 2,069 children aged 5 to 16 years were randomly enrolled. Malarial parasite prevalence was 3.04% (95% CI: 0.962-0.977) with ***P. falciparum*** as the main species. About 42.10% of the children slept under an ITN the previous night and 8.36% lived in houses sprayed with IRS in the last twelve months. There were no significant predictors of malaria parasitemia identified. In conclusion, malarial parasite prevalence has remained low in this urban setting. Inexpensive school surveys can be used to monitor malaria prevalence to inform transitioning malaria epidemiology.

285

ADAPTIVE GEOSTATISTICAL DESIGNS: OPTIMIZING SAMPLING IN DISEASE PREVALENCE MAPPING TO SUPPORT TARGETED INTERVENTION STRATEGIES

Michael G. Chipeta[1], Dianne J. Terlouw[2], Robert McCann[3], Kamija Phiri[4], Peter J. Diggle[5]

[1]University of Malawi - College of Medicine and University of Liverpool, Liverpool, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Wageningen University, Wageningen, Netherlands, [4]University of Malawi - College of Medicine, Blantyre, Malawi, [5]Lancaster Medical School, Lancaster University, Lancaster, United Kingdom

Geostatistical methods are being used increasingly to support disease control efforts and analyse disease prevalence. Adaptive geostatistical designs (AGD) allow collection of exposure and outcome data over time to depend on information obtained from previously collected data to optimise data collection towards the analysis objective. AGDs are especially useful in poor resource settings where uniformly precise mapping may be unrealistically costly and the priority is often to identify critical areas where interventions can have the most health impact. If successfully implemented, AGDs should outperform current standard sampling by improving on predictive performance and hotspots identification. AGDs are timely and could be instrumental in monitoring/accelerating disease transmission reduction. We developed two main classes: singleton and batch sampling. In singleton sampling, locations xi are chosen one at a time, so that each new location xk+1 can depend on data obtained at previously sampled locations x1,...,xk. In batch sampling, locations are

chosen in batches of size b>1, allowing new batch, {x(kb+1),...,x(k+1) b}, to depend on data obtained at locations x1,...,xkb. Batch sampling can't be more efficient theoretically than singleton, but is more realistic in practice. Using simulated data, we have evaluated batch sampling designs and assessed their efficiency relative to their singleton adaptive and non-adaptive counterparts by comparing their average prediction variance. We will present simulation results and describe an application to a multi-year rolling cross-sectional Malaria Indicator Survey that is being conducted within a 5-year malaria transmission reduction project in communities living around Majete Game Reserve, Malawi. Aims of this application are to: describe local variation in malaria infection in children below 5 years; identify hotspots that could guide more targeted disease control efforts; and investigate association of prevalence with environmental and social risk-factors, using a combination of survey data and publicly available, remotely sensed climate and environmental information.

286

THE GEOGRAPHY OF IMPORTED MALARIA TO NON-ENDEMIC COUNTRIES

Peng Jia[1], Dariya Ordanovich[2], Andrew Tatem[2]

[1]*Louisiana State University, Baton Rouge, LA, United States,* [2]*University of Southampton, Southampton, United Kingdom*

Despite over fifty countries having achieved malaria elimination over the past century, the disease remains a problem to many 'malaria-free' countries through cases imported from endemic regions each year. Imported cases to non-endemic countries remain difficult to diagnose, expensive to treat and can occasionally spark secondary local transmission, while the movement of malaria between endemic countries is driving the spread of drug resistance. Quantifying the international movements of malaria can aid in improving our understanding of these phenomena and facilitate the design of mitigation strategies, providing insights into the epidemiology of malaria in regions where reliable surveillance data are lacking. We describe the assembly of a database of all publicly-available nationally reported statistics on imported malaria over the past 15 years, covering over 50,000 individual cases, and assessments of the geographical variations seen were undertaken. Results highlight the clear geographical differences that exist between non-endemic countries and regions in terms of imported malaria case numbers, origins and species composition, as well as the variations in composition for the countries where cases originate. Infection movements are strongly skewed towards a small number of high traffic routes, with the geographical distribution of cases correlating strongly with existing data on transmission intensities. The mapping of communities of countries linked strongly by imported case movements reveals clear groupings that are a result of historical, language and travel ties. Finally, examination of the species composition of origin cases provides a unique insight into the distribution, prevalence and acquisition risk of each of the malaria parasites.

287

RISK FACTORS ASSOCIATED WITH OCCURRENCE OF PLACENTA MALARIA IN A POPULATION OF PARTURIENTS IN ABEOKUTA OGUN STATE, NIGERIA

Olufunmilayo A. Idowu, Ayodele S. Babalola

Federal University of Agriculture, Abeokuta, Nigeria

Placental malaria has long been acknowledged as a complication of malaria in pregnancy and has been associated with poor pregnancy outcome in malaria endemic areas. This study was conducted to determine the risk factors associated with occurrence of placenta malaria in a population of parturients in Abeokuta Ogun State. Maternal and placenta blood and relevant maternal demographic information were obtained from 211 parturients. Chi-square tests and regression model were computed to measure risk using SPSS version 16.0. Overall, 40.1% (86 of 211) of the parturients had malaria at delivery, with 19.0% (40 of 211) having placenta malaria. Age range 18-22 years (OR= 4.4, 95% CI = (1.1 - 17.4), p= 0.046), primigravidae (OR= 2.1, 95% CI = (0.9 - 5.1), p= 0.028) and living in a congested apartment (OR= 1.6, 95% CI = (0.4 - 6.0), p= 0.029) as a significant risk factor for placenta malaria. Non usage of Intermittent Preventive Treatment (IPT) (OR= 2.6, 95% CI = (1.2 - 5.4), p= 0.018), Long Lasting Insecticidal Nets (LLINs) (OR= 2.7, 95% CI = (1.3 - 5.5), p= 0.005) were also risk factors for placenta malaria. In Abeokuta, approximately one of every five parturients had placenta malaria at delivery, with 55% having parasite densities between (501-5000 parasites/µl of blood). Proper use of LLIN and IPT for pregnant women is hereby recommended.

288

TRANSMISSION OF MALARIA AMONG INTRAVENOUS DRUG USERS IN THE UNITED STATES: A SHIFT FROM ENDOGENOUS TO EXOGENOUS CASES, 1929-1975

David Adams[1], Daniel Mauck[2]

[1]*ASU/Medical College of Georgia, Savannah, GA, United States,* [2]*ASU, Savannah, GA, United States*

Malaria remains a major health issue in developing countries. It is often overlooked in the industrial world unless there is a history of travel to a malarial zone. An especially overlooked issue, however, is malaria transmission between intravenous drug addicts. The sharing of needles among heroin users who are malaria-positive may well spark cases of this disease. Analysis of peer-reviewed literature in PubMed and PubMed Central from 1900 to 1975 was undertakebn. . The spread of malaria through shared equipment for injecting intravenous drugs was first reported in 1929 in Egypt. Since that time, several cases of induced malaria among heroin users have been identified. Beginning in the early 1930s, reports of malaria transmitted between IV drug users began to appear in the eastern United States, typically among individuals who reported no history of foreign travel. This trend continued until the late 1960s and early 1970s, the years of the Vietnam War, during which time cases were imported to California and New York after the Vietnam War. In each of these cases, transmission of the malaria parasite was due to sharing of needles among addicts. Usually, the index case had recently traveled to a malaria zone such as Southeast Asia and had contracted malaria. There has been a shift from domestic cases of malaria to imported cases during the latter part of the 20th century. Conclusions: Malaria among intravenous drug users remains an important, if not overlooked, public health issue. The number of heroin users is believed to be growing, and the potential for more cases of induced malaria remains high in the United States. Malaria among drug addicts remains a clinical problem of which physicians should be aware. The diagnosis of malaria should be considered in all intravenous drug users with fever and chills. This issue is hardly a new one and remains a potential public health issue in the early 21st century.

289

IMPACT OF TARGETED MALARIA TREATMENT ON THE TRANSMISSION OF *PLASMODIUM FALCIPARUM* ALONG THE THAI-MYANMAR BORDER

Victor Chaumeau[1], Phabele Phatharakokordbun[2], Nithipa Kwansomboon[3], Céline Montazeau[1], Bénédicte Fustec[1], Chiara Andolina[2], Phubet Ya-Umphan[1], Dominique Cerqueira[2], Theeraphap Chareonviriyaphap[3], Vincent Corbel[1]

[1]*Institut de Recherche pour le Développement, Maladies Infectieuses et Vecteurs, Ecologie, Génétique, Evolution et Contrôle, Montpellier, France,* [2]*Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot, Thailand,* [3]*Department of Entomology, Faculty of Agriculture, Kasetsart University, Bangkok, Thailand*

The emergence and spread of artemisinin resitance in ***Plasmodium falciparum*** (Pf) is challenging the efforts of malaria control and

elimination in South East Asia. The Shoklo Malaria Research Unit through the support of the Welcome Trust and the Bill & Melinda Gates Foundation has implemented a pilot study in four villages along the Thai Myanmar border to assess whether Targeted Malaria Treatment (TMT) can eliminate the parasite reservoir and contain artemisinin-resistance. Entomological surveys using human landing catch technique were conducted in parallel to parasitological surveys to address the Pf-malaria transmission before and after intervention. One thousand two hundred and eighty two malaria vectors belonging to the Minimus, Maculatus and Dirus Groups were collected during baseline surveys (before TMT, during the rainy season). Bites of malaria vectors occur all night long but An. maculatus s.l. and An. dirus s.l. exhibit a peak in their biting behaviour during the early evening and a higher tendency to exophagy. An average of 267 bites of malaria vectors was received per person and per month (95% CI 226-309). Pf-sporozoitic index was 2.2 ‰ (95% CI 0.0-4.4, n=1,782 mosquitoes inspected) and we estimated that each person received an average of 0.6 (95% CI 0.02-1.18) Pf-infective bites per month. Half of the transmission occurred outside the premise (2 on 4 infective bites) and half of the transmission occurred between 5:00 and 06:00 a.m. (2 on 4 infective bites). Data on the impact of TMT on Pf transmission will be presented during the meeting. In conclusion, malaria transmission in the studied area involves early feeding and exophagic vectors that could maintain residual transmission (i.e. transmission that is not controlled by full coverage of the population with long lasting insecticide-treated bed-nets) after TMT. Therefore the development and evaluation of vector control tools adapted to malaria transmission settings in South-East Asia are needed in order to act in synergy with TMT and achieve artemisinin-resistance containment.

290

HIGH PREVALENCE OF FALCIPARUM MALARIA IN ASYMPTOMATIC INDIVIDUALS AND NO PFMDR1 AMPLIFICATION IDENTIFIED IN DEMOCRATIC REPUBLIC OF CONGO

Dieudonné M. Mvumbi[1], Jean-Marie N. Kayembe[2], Thierry L. Bobanga[3], Hippolyte N-T. Situakibanza[3], Célestin N. Nsibu[4], Georges L. Mvumbi[1], Patrick De Mol[5], Marie-Pierre Hayette[5]

[1]*Biochemistry and Molecular Biology Unit, Department of Basic Sciences, School of Medicine, Kinshasa, Democratic Republic of the Congo,* [2]*Department of Internal Medicine, School of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [3]*Department of Tropical Medicine and Infectious Disease, School of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [4]*Department of Pediatrics, School of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [5]*Department of Clinical Microbiology, University Hospital of Liège, Liège, Belgium*

Malaria remains a major public health problem in Democratic Republic of Congo (DRC) with 14 million cases reported by the WHO malaria report in 2014. These figures only include patent malaria cases that were detectable by microscopy or by RDT. Asymptomatic malaria cases are known to be prevalent in endemic areas and are generally untreated, resulting in a significant source of gametocytes that may serve as reservoir of disease transmission. Considering that microscopy certainly underestimates the prevalence of ***Plasmodium*** infections within asymptomatic carriers and that PCR assays are currently recognized as the most sensitive methods for ***Plasmodium*** identification, this study was conducted to weigh the asymptomatic carriage in DRC by a molecular method. We additionally assessed the pfmdr1 gene amplification, that is related to many antimalarial drugs' resistance. Globally, almost half of the samples collected in the 6 provinces on the asymptomatic individuals (280/600; 46.6%) had ***Plasmodium*** infections and the most species identified was ***P. falciparum*** (97.8%) alone or combined with P. malariae. The lesser prevalence was found in Nord-Kivu province (22%) nearly at 1800 meter altitude. No pfmdr1 amplification > 2 copies was found. The high prevalence reported in our study should interpellate the bodies involved in malaria control in DRC to take in account asymptomatic carriers in actions taken and consider asymptomatic malaria as a major hurdle for malaria elimination. This study was the first to assess pfmdr1 amplification in DRC.

291

DOES STRESS PROVOKE *PLASMODIUM FALCIPARUM* RECRUDESCENCE?

G. Dennis Shanks

Army Malaria Institute, Enoggera, Australia

Plasmodium falciparum, unlike ***P. vivax***, must maintain infection in the blood/bone marrow over many months/years in order to bridge periods between transmission periods. Asymptomatic parasitemia at very low concentrations is now known to be quite common due to molecular detection methods. Old tropical medicine texts commonly list many stressful events stated to provoke recrudescent falciparum parasitemia such as fatigue, heat/chill, trauma/surgery, famine/war, transit between areas and other febrile illness. The older literature is reviewed to discover the factual basis of such varied reports since they have not been recently confirmed. Surgery / trauma studies have variably shown falciparum recrudescence in areas with high rates of infection and drug suppression. Travel particularly during times of war or famine has been noted to induce recrudescence likely contributing to complex public health emergencies. Provocative tests such as infections of epinephrine or endotoxin to aid diagnosis of cryptic infections could not be shown to induce falciparum recrudescence. It seems likely that human stress sometimes induces falciparum recrudescence of an otherwise asymptomatic infection. Reproducing such observations today has been radically altered as malaria chemotherapy has evolved from suppressive quinine to curative artemisinin combinations. Host stress provoked recrudescence may be part of ***P. falciparum's*** survival strategy.

292

HOST FACTORS IMPACTING UPON THE FUTURE USE OF PRIMAQUINE IN MALARIA-ENDEMIC SOUTHWESTERN UGANDA

Michelle Roh[1], Caesar Oyet[2], Gertrude Kiwanuka[2], Juliet Mwanga-Amumpaire[3], Yap Boum II[3], Sunil Parikh[1]

[1]*Yale School of Public Health, New Haven, CT, United States,* [2]*Mbarara University of Science and Technology, Mbarara, Uganda,* [3]*Epicentre Mbarara Research Centre, Mbarara, Uganda*

As malaria transmission continues to decline in southwestern Uganda, aggressive strategies, such as the addition of primaquine (PQ) to artemisinin-combination therapies (ACTs), are being considered. Despite the potential benefit of PQ in reducing transmission, concerns over its safety and efficacy have hampered its deployment. In particular, those with glucose-6-phosphate dehydrogenase (G6PD) deficiency are at a higher risk of hemolytic toxicity, and recent metabolic variants of CYP2D6 have the potential to impact upon PQ efficacy. To better assess the prevalence of host factors that may impact PQ use in southwestern Uganda, we conducted a stratified, two-stage cluster sampling cross sectional survey among 631 children under five years of age. Blood samples were collected to determine the following: (1) quantitative G6PD deficiency by spectrophotometric assay (Trinity Biotech®) and (2) qualitative G6PD deficiency assay by rapid diagnostic test (CareStart™ G6PD RDT). In addition, DNA was isolated to conduct (1) genotyping of the G6PD A- allele (RFLP analysis to detect the 202A/376G mutation), and (2) CYP2D6 genotyping to identify poor and ultrarapid metabolizers. Using the spectrophotometric assay as the gold-standard, the prevalence of mild G6PD deficiency (defined as 10-60% of normal activity) was 13.8% (95% CI: 11.1-16.5) as compared with 8.6% (95% CI: 6.4-10.8) by RDT. No children in our study were classified as being severely deficient (<10% enzyme activity). Of the 577/631 children with normal G6PD status by RDT, 37 were mildly deficient by quantitative assay. Of the 54 children found to be G6PD deficient by RDT, 4 were quantitatively normal. Performance

characteristics of the CareStart™ G6PD RDT as compared with the Trinity Biotech® spectrophotometric assay revealed low/moderate sensitivity and high specificity (57.5% and 99.3%, respectively). Further comparison of G6PD qualitative and quantitative assays to molecular results is underway and will be presented. In addition, CYP2D6 prevalence estimates will also be presented. Our preliminary results suggest the need for improved point-of-care G6PD screening methods.

293

RISK FACTORS FOR MALARIA INFECTIONS IN FEVER HOTSPOTS AND COLDSPOTS IN A HIGH TRANSMISSION REGION IN WESTERN KENYA

Judith Nekesa Mangeni[1], Andrew Obala[1], Wendy Prudhomme O'Maera[2]

[1]*Moi University, Eldoret, Kenya,* [2]*Moi University, Duke University, USA, Eldoret, Kenya*

Identifying and understanding the risk factors for malaria infections in regions with high transmission is important for targeting control measures to the local situation. We sought to determine malaria indices in fever hotspots and coldspots. We conducted a prospective cohort study in Bungoma East sub-County, a region with persistently high malaria. A total of 400 participants in randomly selected households in six sentinel villages were followed up longitudinally and tested for malaria using malaria rapid diagnostic tests at quarterly intervals for a period of one year. Multivariate logistic regression analysis with generalized estimating equations was used to estimate the risk of malaria infections. A total of 870 malaria vectors were captured out of which 73.6% (no=640) were identified as members of ***Anopheles gambiae*** group. The member species of ***An. gambiae*** group were identified by polymerase chain reaction as follows; 24.5% (no=117) were ***An. arabiensis*** while ***An. gambiae*** ss consisted of 75.5% (no=483) of the total collection. Parasite prevalence by RDT in the fever cold spot was 19.2%, 12.3%, 7.5%, 9.4% and 17.4% per survey respectively. In the fever hotspot, parasite prevalence was 22%, 8.5%, 5%.4%, 9.7% and 32.4% per survey respectively. The person-time incidence rate of malaria was not significantly different between the two regions. However, incidence significantly varied between the villages and was significantly correlated with entomological risk factors in some of the villages. Risk factors for malaria infections are; children below five years, (O.R 3.7; P: 0.02), Not sleeping under the net the previous night (O.R. 1.7; P: 0.01), Asymptomatic infected individuals (O.R. 9.5; P: 0.004), the type of wall for the house (O.R 0.3, $P < 0.001$), the village one lives (OR 0.3; $P < 0.001$).There is a slightly higher risk of malaria infection for individuals living in the fever hotspots although this does not reach significance level. There is heterogeneity in malaria transmission among the villages. This study has identified factors defining the local situation in Western Kenya and should be targeted if malaria is to be eliminated in this region.

294

LARGE RESERVOIR OF ASYMPTOMATIC *PLASMODIUM VIVAX* IN A MESOENDEMIC AREA OF BELU REGENCY, WEST TIMOR

Ayleen A. Kosasih

Universitas Indonesia, Depok, Indonesia

With the call for malaria elimination in Indonesia, ***Plasmodium vivax*** and the asymptomatic infection resevoir are considered particularly important as submicroscopic infections escape diagnostic tools, thereby confounding elimination efforts. Microscopy was compared to Real-Time PCR to identify submicroscopic infections from subjects (n=1013) living in Kabupaten Belu, West Timor. Microscopy detected parasites in 10.6% (107/1013) subjects, while PCR resulted in a 29.8% (302/1013) infection rate. Of the PCR diagnosed samples, 65.2% (197/302) were submicroscopic (negative by microscopy). Eighty four percent (166/197) of submicroscopic infections were ***P. vivax*** with lower number of ***P. falciparum*** (25/197) and P. malariae (1/197). Submicroscopic ***P. vivax*** infection predominated all age groups. Few mixed submicroscopic infections were found (3 Pf + Pv; 2 Pv + Pm). In conclusion, the presence of 3x more malaria infections detected by PCR (29.8% prevalence) when compared to microscopy demonstrates the large number of submicroscopic infections, of which 84% were ***P. vivax***, indicating that this area will be challenging for malaria elimination. This more sensitive diagnostic mechanism (Real-Time PCR), combined with other tools will have to be implemented if elimination is to be considered in this area.

295

IN VITRO ANTIPLASMODIAL ACTIVITY OF BIOSYNTHESIZED SILVER NANOPARTICLES USING *PSYCHOTRIA NILGIRIENSIS* LEAF EXTRACT AGAINST *PLASMODIUM FALCIPARUM*

Kovendan Kalimuthu[1], Murugan Kadarkarai[1], Vincent Savariar[2]

[1]*Bharathiar University, Coimbatore, India,* [2]*Loyola College, Chennai, India*

The utilization of various plant resources for the biosynthesis of metallic nanoparticles is called green nanotechnology, and it does not utilize any harmful chemical protocols. The present study reports the plant mediated synthesis of silver nanoparticles using the plant leaf extract of ***Psychotria nilgiriensis***, which acts as a reducing and capping agent. The obtained nanoparticles were characterized using UV-visible spectroscopy; EDX (energy-dispersive X-ray), SEM (Scanning electron microscope), XRD (X-ray diffraction) and Fourier transform infrared (FTIR) analysis. The efficacy of green synthesized AgNPs at different concentrations (25, 50, 75 and 100µg/ml) were tested on ***Plasmodium falciparum***. Synthesized AgNPs particles were confirmed by analysing the excitation of surface plasmon resonance (SPR) using UV-vis spectrophotometer at 422 nm.The scanning electron micrograph showed structures of spherical, cubic shape, and the size range was found to be 40-60 nm. The EDX spectra showed the purity of the material and the complete chemical composition of the synthesized AgNPs. XRD study shows that the particles are crystalline in nature with face centered cubic geometry. The FTIR analysis of the nanoparticles indicated the presence of proteins, which may be acting as capping agents around the nanoparticles. Biosynthesis of nanoparticles may be triggered by several compounds such as carbonyl groups, terpenoids, phenolics, flavonones, amides, proteins, alkaloids and other reducing agents present in the biological extract. The parasitic inhibition was dose-dependent. The synthesized AgNPs showed significant anti-plasmodial activity when compared to aqueous leaf extract of P. nilgiriensis. The maximum efficacy was observed in synthesized AgNPs against ***P. falciparum*** (IC_{50}=100 µg/ml; 100%) respectively. This method is considered as a new approach to control the malarial parasite, ***P. falciparum***. Therefore, this study provides first report on the anti-plasmodial activity of synthesized AgNPs using ***P. nilgiriensis*** against ***P. falciparum.***

296

ESTIMATING THE GLOBAL CLINICAL BURDEN OF *PLASMODIUM VIVAX* MALARIA

Katherine E. Battle, Ewan Cameron, Samir Bhatt, Rosalind E. Howes, Peter W. Gething, Simon I. Hay

Spatial Ecology and Epidemiology Group, University of Oxford, Oxford, United Kingdom

Accurate burden of disease estimates are essential to assess the relative impact of a disease, generate targets for control and measure progress towards elimination, and have been identified as a key knowledge gap in ***Plasmodium vivax*** research. Annual clinical incidence must be measured to estimate the burden of ***P. vivax*** malaria. However, accurate incidence data is relatively rare. Incidence must be obtained through longitudinal studies, making it costly and time consuming to collect. Prevalence data, on the other hand, is widely available from cross-sectional surveys. A model defining the relationship between ***P. vivax*** infection prevalence and incidence of clinical disease was developed to address this disparity in data availability. The model accommodated the unique biology and epidemiology of ***P. vivax*** and provided separate prevalence-incidence

relationships for areas known to have different patterns of relapse. The model, combined with an updated map of ***P. vivax*** endemicity based on prevalence survey data through 2014, provided global annual case numbers with associated measures of uncertainty. These results highlight regions where ***P. vivax*** morbidity burden is greatest and where improved survey coverage is needed to increase the certainty of outputs generated.

297

MALARIA PARASITEMIA AMONG RESIDENTS SEEKING CLINICAL CARE IN AN URBAN INFORMAL SETTLEMENT AREA IN NAIROBI, KENYA

Henry N. Njuguna[1], Joel M. Montgomery[1], Leonard Cosmas[1], Newton Wamola[2], Joseph O. Oundo[1], Meghna Desai[1], Ann M. Buff[1], Robert F. Breiman[1]

[1]*Centers for Disease Control and Prevention Kenya, Nairobi, Kenya,* [2]*KEMRI, Nairobi, Kenya*

Although Nairobi, Kenya--with an altitude of approximately 1,600 meters and low seasonal temperatures--is considered low-risk for malaria transmission, malaria is frequently diagnosed throughout Nairobi. We investigated the epidemiology of malaria among patients presenting to a study clinic in a population-based surveillance system located in the densely-populated, informal settlement of Kibera, Nairobi, over a 5-year period (01 January 2007 to 31 December 2011). We describe the epidemiological and clinical characteristics of febrile patients and malaria cases in Kibera, Nairobi. During the 5-year study period, 105,960 patient visits occurred at the study clinic, and 17% (n=18,183) had a measured temperature of ≥37.4°C. A total of 11,825 (65%) febrile patients had a microscopy test performed for malaria; 2,630 (22%) were positive. Malaria parasitemia was detected throughout the year with peaks generally in January, May and September. Children ages 5-14 years old had the highest proportion (29%) of positive malaria blood slide results followed by children ages 1-4 years (23%) old. Sixty-three percent (3% unknown travel status) of malaria cases reported travelling outside of Nairobi in the previous month; 79% reported travel to just three counties (7%, 3/46) in western Kenya. History of recent travel was strongly associated with malaria parasitemia (OR: 8.9; 95% CI: 8.0-9.9). Malaria parasitemia was frequently observed among febrile patients at a health facility in Kibera, Nairobi. The majority of patients had travelled to counties in western Kenya, which have the highest rates of parasitemia in the country. However, over one-third 34% reported no travel history, which raises the possibility of local transmission of malaria in this densely-populated, urban setting. Reducing/eliminating malaria transmission in western Kenya and communicating and implementing effective malaria prevention strategies to travelers is likely to reduce the malaria burden in Kibera, Nairobi.

298

NEW STRATEGIES FOR ESTIMATING MALARIA TRANSMISSION: USING SEROLOGY TO ESTIMATE INDIVIDUAL LEVEL EXPOSURE

Gillian H. Stresman[1], Nuno Sepúlveda[1], Michael White[2], Teun Bousema[1], Chris Drakeley[1]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Imperial College London, London, United Kingdom*

Current metrics of malaria transmission are restricted to population level estimates limiting their utility for understanding the more granular, individual level heterogeneities inherent in ***Plasmodium falciparum*** epidemiology. Age specific serological profiles in a population, and particularly the seroconversion rate, are useful proxy metrics for transmission intensity. However, assuming a homogenous population, a person of the same age with comparable exposure history should have a similar antibody profile suggesting that obtaining an analogous individual level metric for exposure is possible. To test this hypothesis we extended the standard reverse catalytic model to incorporate determinants of exposure including elevation and use of mosquito control using a Bayesian framework to predict each individuals' probability of being seropositive, an analogous measure to the force of infection. Data from a large cross-sectional survey in the western Kenyan highlands was used to train the model, and was subsequently validated on available datasets from the same study site as well as other sites with a range of transmission intensities. Initial results suggest that the predicted probability of being seropositive per year of age were strongly correlated (r=0.96) to the true seroprevalence and showed similar spatial patterns. When applying the model to other data from the same site, there was good discriminatory capacity (AUC: 0.76) for seropositivity. The predicted values resulted in a slight underestimation of the true seroprevalence per year of age however there was still a good correlation (r=0.79). These findings show that obtaining individual estimates of malaria exposure are possible and have important implications for understanding and controlling for intrinsic heterogeneity in malaria exposure.

299

AN INVESTIGATION INTO THE RISK FACTORS OF MALARIA IN A PRE-ELIMINATION RURAL AND PERI-URBAN SETTING OF NORTHERN NAMIBIA

Erastus H. Haindongo[1], Davis R. Mumbengegwi[1], Ronnie Bock[1], Hugh Sturrock[2], Roly Gosling[2]

[1]*University of Namibia, Windhoek, Namibia,* [2]*University of California, San Francisco, CA, United States*

A remarkable over 75% reduction of cases has been achieved, with case numbers dropping as low as 1,546 in August of 2013, from 537 115. With the reduction of malaria transmission, Namibia has moved from a control phase to a pre-elimination phase. Although malaria cases have been on the decline, a plateau has been reached since 2008. This plateau provides direct evidence that, the existing tools used in the control phase cannot be used to achieve the elimination phase. This also suggest that there are perhaps other risk factors that are not known and thus poses challenges to elimination. This risk factors may be the presence of breeding sites within households, net ownership and usage, Indoor Residual Spraying, whether people slept inside or outside, and their travel history. There is a gap in knowledge on what intervention tools should be used in order to achieve the elimination phase. Malaria risk factors therefore need to be established by conducting surveillance, and thus provide evidence on how to mitigate against any failing interventions. Re-Active Case Detection (RACD) was used to investigate cases reported at health facilities. Control Houses were randomly selected from the National Census Enumeration points for inclusion in the study. A combination of an open and closed ended questionnaire was administered to all members living in the same house as a reported case or a chosen control. A total of 944 individuals were recruited. There were 408 and 536 individuals from 51 case and 87 control households respectively. It was found that 71% of the case households are found close to breeding sites, whilst only 58% of the control households are found close to breeding sites. Individuals in case households also slept outside more than those in control households. Unexpectedly, net ownership and usage was higher in control households by a factor of 1.13. Spraying was also higher in control households, with only 12% of the case households spray and 18% of the control households. Reactive case detection can be implemented as a tool to identify common behavioral risk factors in individuals within households.

300

PREVALENCE OF MALARIA BY AGE AND GENDER IN KABERAMAIDO, LWALA AND DOKOLO DISTRICTS IN THE EASTERN UGANDA

Joel C. Mouatcho[1], Leo Braack[1], Michael Okia[2]

[1]*University of Pretoria, Pretoria, South Africa,* [2]*National Malaria Control Program, Kampala, Uganda*

Malaria is a major health concern in affected developing countries. It is endemic in Uganda with 34 million people at high risk accounting for

7,277 malaria attributed death in 2013. There are limited data on gender and age distribution of malaria cases in hospital and outpatients' settings. This study assessed malaria case records between January 2006 and April 2013 in the Kaberamaido, Lwala and Dokolo health districts in Northern Uganda. A total of 346,769 outpatients and 75,955 inpatient children were examined for malaria. Of these, 183,849 (53.05 %) outpatients and 31,459 (41.42 %) inpatients were clinically diagnosed with malaria with 28,954 (70.52%) testing positive on 41,058 (19.07%) blood smears examined in both groups. Covering both genders, 56.02% and 46.32% clinically diagnosed malaria cases were below and above 5 years of age, respectively. Females were the most affected. The proportions of positive malaria cases per health district were 47.9%, 46.1% and 51.8% for Kaberamaido, Lwala and Dokolo, respectively. In 2009, over 8000 malaria cases principally in children above age 5 were recorded in Dokolo. Overall, Dokolo was the most affected malaria district, followed by Kaberamaido. In conclusion, malaria prevalence remains very high in study sites in Northern Uganda. Children under the age of 5 were the most affected with girls more susceptible than boys. Due to the shortage of microscopes and qualified microscopists, malaria remains poorly diagnosed in Uganda with the majority of diagnoses still made clinically.

301

THE ASYMPTOMATIC MALARIA RESERVOIR IN A REGION OF DECLINING MALARIA TRANSMISSION IN SOUTHERN PROVINCE, ZAMBIA: DEMOGRAPHIC CHARACTERISTICS AND ASSOCIATED RISK FACTORS

Natasha M. Laban[1], Tamaki Kobayashi[2], Harry Hamapumbu[1], Kelly Searle[2], Phil Thuma[1], William J. Moss[2]

[1]*Macha Research Trust, Choma, Zambia,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Asymptomatic malaria has been reported in areas of declining transmission among individuals with partial immunity acquired from previous exposure. Undetected and untreated asymptomatic individuals can act as parasite reservoirs posing a threat to further control and their active detection and characterization is important to achieve elimination. To better understand this threat, demographic characteristics as well as seasonal and spatial distributions of asymptomatic malaria infections were assessed in an area of declining transmission in Southern Province, Zambia. Cross-sectional surveys were conducted between 2009 and 2013 when annual parasite prevalence was ≤ 1.5% by rapid diagnostic test (RDT). Households were randomly selected based on satellite imagery and all residents were eligible for enrollment. Blood was collected by finger prick for microscopy, RDT and as dried blood spots for nested PCR for cytochrome b gene of human ***Plasmodium*** species. Questionnaires were administered to collect information on age, sex, recent history of malaria symptoms and antimalarial use. Asymptomatic cases among positive individuals were determined based on absence of fever, chills and headache both within 48hrs and a fortnight prior to screening and without a recent history of malaria medication. Seasonal and spatial distributions of asymptomatic individuals were based on sample collection dates and geo-coordinates of households respectively. Of 3,555 participants tested by all three methods, 53 were positive for ***Plasmodium*** by nested PCR. Fifty-two participants had complete survey data available, 19 (36.5%) of whom were asymptomatic. Participants aged between 5 and 20 years were more likely to have asymptomatic parasitemia identified by PCR during both rainy and dry seasons. Identifying asymptomatic parasitemia among school-aged children in both wet and dry seasons suggests the potential for school-based strategies to eliminate the parasite reservoir. Submicroscopic asymptomatic parasite reservoir detected by PCR highlights the need for more sensitive diagnostic tools in low transmission settings moving towards elimination.

302

THE EPIDEMIOLOGY OF RELAPSING *PLASMODIUM VIVAX* MALARIA IN WESTERN MADAGASCAR

Thierry Franchard[1], Tovonahary Rakotomanga[1], Brune Ramiranirina[1], Tiana Ramanatiaray[1], Arsene Ratsimbasoa[1], David Serre[2], David Serre[2], Rosalind E. Howes[3], Peter A. Zimmerman[4]

[1]*National Malaria Control Programme of Madagascar, Antananarivo, Madagascar,* [2]*Genomic Medicine Institute, Cleveland Clinic, Cleveland, OH, United States,* [3]*Department of Zoology, University of Oxford, Oxford, United Kingdom,* [4]*Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States*

Malaria is a major health problem in Madagascar. While cases have dropped since 2003, malaria was still the second leading cause of death among children under five years in 2011. The epidemiology varies considerably between different regions of the country, but the entire population is considered to be at risk of infection by four ***Plasmodium*** species, with ***P. falciparum*** responsible for 90% of cases. Prevalence of ***P. vivax*** is highest in the western highlands, where the climate is dry and hot. The dormant hypnozoites of the ***P. vivax*** life-cycle make it more challenging to control than ***P. falciparum***. As a first step towards assessing the importance of relapse infections and the significance of the invisible reservoir of ***P. vivax*** hypnozoites, it is important to determine the relapse periodicity of the ***P. vivax*** strains causing infection in Madagascar. Molecular analysis can also allow insight into the population structure of the parasites and help estimate the relative contribution of hypnozoites to the burden of clinical cases. To investigate these objectives, a longitudinal study was initiated in an area of Madagascar endemic with ***P. vivax*** where all individuals reporting to clinics with fevers were tested for infection with rapid tests, microscopy and molecular diagnostics. All ***P. vivax*** positive patients were monitored with active monthly follow-up and PCR-based diagnosis of blood-stage infection. Up for four repeated clinical ***P. vivax*** episodes were observed in patients monitored during the first year of the study, and genetic SNP analysis provides insight into the evolution of the parasite strains during the course of the follow-up. Madagascar plans to advance from malaria control to pre-elimination status. However, the complexities and heavy contribution of apparent relapses to the ***P. vivax*** burden will continue to represent an important barrier to successful elimination unless access to safe radical cure therapy is made available.

303

HETEROGENEITY IN MALARIA TRANSMISSION IN THE PERUVIAN AMAZON: RAPID ASSESSMENT THROUGH A PARASITOLOGICAL AND SEROLOGICAL SURVEY

Angel Rosas[1], Niko Speybroeck[2], Alejandro Llanos-Cuentas[1], Anna Rosanas-Urgell[3], Gabriel Carrasco-Escobar[1], Hugo Rodriguez[4], Umberto D'Alessandro[5], Annette Erhart[3]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Université Catholique de Louvain, Brussels, Belgium,* [3]*Institute of Tropical Medicine, Antwerp, Belgium,* [4]*Region de Salud Loreto, Loreto, Peru,* [5]*Disease Control and Elimination, Medical Research Council, Fajara, Gambia*

Where malaria endemicity is low and markedly seasonal, sensitive tools are needed for better stratifying risk of infection and targeting interventions. A cross-sectional survey was conducted in 3 endemic sites of the Peruvian Amazon to characterize the current malaria transmission patterns, identify hotspots, and detect recent changes in transmission using parasitological and serological measures. After full census of the study population in Nov 2012, a total of 651 survey participants were examined and a blood sample taken for the detection of malaria parasites (microscopy, PCR) and antibodies to ***Plasmodium vivax*** (PvMSP119,PvAMA1) and P.falciparum (PfGLURP,PfAMA1) antigens by ELISA. Risk factors malaria infection (species-specific positive PCR) and malaria exposure (seropositivity to any of two species-specific antigens) by species were assessed by survey logistic regression models. Age-specific seroprevalence was analyzed using a reversible catalytic conversion model for generating seroconversion

rates(SCR). SaTScan using a Bernoulli model was used to detect spatial clusters of serology-positive individuals within each site. The overall parasite prevalence by PCR was low, i.e. 3.9% for ***P. vivax*** and 6.7% for ***P. falciparum***, while the seroprevalence was much higher, 33.6% for ***P. vivax*** and 22.0% for ***P. falciparum***, with substantial differences between study sites. Age and location were significantly associated with ***P. vivax*** exposure; while location, age and outdoor occupation were associated with ***P. falciparum*** exposure. ***P. falciparum*** seroprevalence curves showed a stable transmission throughout time, while for ***P. vivax*** transmission curves were better described by a model with two SCRs. The spatial analysis identified well-defined clusters of ***P. falciparum*** seropositive individuals in two sites, while it detected only a very small cluster of ***P. vivax*** exposure. The use of a single parasitological and serological malaria survey has proven to be an efficient and accurate method to characterize the species specific heterogeneity in malaria transmission at micro-geographical level as well as to identify recent changes in transmission.

304

ESTIMATING THE PROPORTION THE DISTRIBUTION OF *PLASMODIUM FALCIPARUM* MALARIA-ATTRIBUTABLE FEVERS THE ASYMPTOMATIC INFECTION IN AFRICA

Ursula Dalrymple, Ewan Cameron, Samir Bhatt, Daniel J. Weiss, Bonnie Mappin, Donal Bisanzio, Peter W. Gething

University of Oxford, Oxford, United Kingdom

In order to accurately assess the infectivity of populations endemic with ***P. falciparum*** malaria, asymptomatic infections must be accounted for, as these are not detected by passive case detection but still contribute to onwards transmission. The effect that geographic heterogeneity of malaria endemicity and environmental confounders have on the proportion of infections that are asymptomatic has not yet been well characterised. Additionally, the importance of the asymptomatic reservoir in terms of prospects for elimination is not yet fully understood. In areas where ***P. falciparum*** remains highly endemic, most individuals host parasites at a diagnostic detectable level throughout the year. As such, nearly all fevers in these populations will be accompanied by a parasite infection, but malaria may rarely be the fever's causal mechanism. Modelling the spatiotemporal distribution of this malaria-attributable fraction of fevers will allow insight into the true contribution of malaria compared to other causes of febrile illness. Here, we fit observed field data from large-scale routine surveillance of diagnostic outcome and individual fever history to established mechanistic models of malaria infection, in order to estimate the proportion of asymptomatic infection and malaria-attributable fevers geographically through time, and investigate a number of environmental and sociodemographic factors that affect these proportions.

305

MODELED COUNTERFACTUAL OF PREDICTED MALARIA CASE INCIDENCE USING A DIFFERENCE-IN-DIFFERENCE ANALYSIS, UNGUJA AND PEMBA ISLANDS, ZANZIBAR, 1999-2010

Adam Bennett[1], **Achuyt Bhattarai**[2], Abdul-wahid Al-mafazy[3], Ali K. Abass[3], Mwinyi I. Msellem[3], S. Patrick Kachur[4], Steven S. Yoon[2], Abdullah S. Ali[3], Thomas P. Eisele[5]

[1]*Global Health Group, University of California, San Francisco, San Francisco, CA, United States,* [2]*Malaria Branch, President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*Zanzibar Malaria Elimination Programme, Ministry of Health, Zanzibar, United Republic of Tanzania,* [4]*Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [5]*Center for Applied Malaria Research and Evaluation, Tulane University School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, United States*

Malaria morbidity and mortality fell in Zanzibar (Unguja and Pemba islands) following introduction of artemisinin-based combination therapy for uncomplicated malaria in late 2003 and long-lasting insecticidal nets and indoor residual spraying in 2006. The impact of such public health interventions, scaled-up in short successions, is challenging to quantify without a contemporaneous counterfactual to understand what would have happened in the absence of these interventions. We modeled the impact of malaria control interventions scale-up using a counterfactual of confirmed malaria case incidence per 1,000 population (cMCI) predicted from a generalized linear autoregressive model fitting the relationship between cMCI, climate and other relevant pre-scale-up (1999-2003) data. The full prediction model included district, month, rainfall, and minimum and maximum temperature, standardized by district population estimates over time. The full model then predicted a counterfactual with malaria control interventions scale-up between 2004-2010. The impact of malaria control interventions scale-up on cMCI was then estimated using the difference-in-difference estimator, while controlling for district malaria diagnostic testing rate. We estimated 0.61 (95%CI, 0.43-0.79; p<0.001) lower monthly cMCI in the scale-up period in Zanzibar. The impact was larger in Pemba (0.73, 95%CI 0.39-1.08; p<0.001) than in Unguja (0.52, 95%CI, 0.33-0.72; P<0.001). A modeled counterfactual of predicted cMCI using a difference-in-difference analysis showed malaria control interventions scale-up significantly reduced cMCI from what it would have been in the absence of interventions scale-up in Zanzibar islands.

306

THE EFFECTIVENESS OF NON-PYRETHROID INSECTICIDE-TREATED DURABLE WALL LINERS AS A METHOD FOR MALARIA CONTROL IN ENDEMIC RURAL TANZANIA: A CLUSTER RANDOMIZED TRIAL IN NORTHERN EASTERN TANZANIA: RESULTS OF THE BASELINE SURVEY

Joseph Mugasa[1], Robert Malima[1], George Mtove[1], Peter Mangesho[1], Said Magogo[1], Geofrey Makenga[1], Abubakary Mziray[1], Ramadhani Hashim[2], Donald Shepard[3], Meera Venkatesan[4], Laura C. Norris[4], Frank Mosha[5], William Kisinza[1]

Non-pyrethroid insecticide-treated durable wall lining (DL) is a new method of vector control that releases insecticides and kill vectors that rest on its surface, and are expected to be efficacious for 3-4 years. To determine whether the combined use of LLINs and DL provides additional benefit over LLINs alone, a two arm cluster randomized controlled trial is underway in Muheza district, Tanzania. We present baseline epidemiological and entomological parameters from the study site prior to study implementation. After mapping and doing a census of the area, 60 clusters were created, and 15-20 houses from the core areas were randomly selected for a survey conducted in January-February 2015. All consenting household members completed household and demographic questionnaires, and blood samples were drawn for malaria diagnosis, anemia testing, and immunochromographic testing (ICT) for ***Wuchereria bancrofti***. A total of 2,513 people from 932 households were sampled. Malaria parasitemia by mRDT was 23.6 % (95% CI: 20.4 -26.9%); 4.2% (95% CI: 2.9-5.5%) had positive ICTs. Malaria parasitemia was more common in children 5-12 years (34.5%; 95% CI 28.5- 40.6%) compared with children 12 years, (19.0%; 95% CI: 16.4-21.6%). Anemia (haemoglobin <8g/dL) prevalence in children <5 years was 5.1% (95% CI: 1.5-8.7%). To determine the biting rate Indoor host-seeking mosquitoes were sampled using CDC light traps in 8 randomly selected houses with open eaves and children under five years of age in the core sampling area of all sixty clusters between May and September 2014. Pooled estimates of human biting rate/person/night for the two malaria vectors (An. gambiae s.l and An. funestus) during the wet and dry seasons were 24 and 22, respectively. The biting rate for ***W. bancrofti*** vector ***Culex***

quinquefasciatus during the two seasons was 18 and 6, respectively. The DL and LLIN interventions are scheduled to begin in July 2015. The results of this study will provide important information to help guide vector control strategies within national malaria control programs.

307

ADHERENCE TO NATIONAL GUIDELINES FOR THE DIAGNOSIS AND MANAGEMENT OF SEVERE MALARIA, MALAWI 2012

Monica P. Shah[1], Melissa Briggs[1], Jobiba Chinkhumba[2], Andy Bauleni[2], Alfred Chalira[3], Dubulao Moyo[3], Wilfred Dodoli[4], Julie Gutman[1], Misheck Luhanga[3], John Sande[3], Doreen Ali[3], Don P. Mathanga[2]

[1]*Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Malawi College of Medicine, Malaria Alert Center, Blantyre, Malawi,* [3]*Malawi Ministry of Health, National Malaria Control Program, Lilongwe, Malawi,* [4]*World Health Organization, Lilongwe, Malawi*

Severe malaria has a case fatality rate of 10-20%. Given the complexity of evaluating multi-faceted components of health systems, few studies have addressed the quality of severe malaria case management. In July-August 2012, a nationwide, cross-sectional survey of severe malaria management was conducted in 36 health facilities (HFs) selected with equal probability from a list of all public sector HFs in Malawi that admit patients with severe malaria. Patient care records from all admissions during October 2011 (low season) and April 2012 (high season) with an admission diagnosis of malaria or prescription of an antimalarial were eligible. Up to 8 charts were randomly sampled within each age (<5 and ≥5 years) and month stratum. Severe malaria was defined by a) admission diagnosis or b) documentation of any signs of severe malaria. Treatment with at least one dose of an intravenous antimalarial was considered correct. A total of 906 records with complete data from 35 HFs were included; one HF had no patient records. Patients were 3 months to 81 years old; 55% were female. Overall, 387 patients (42%) had an admission diagnosis of severe malaria. A severe sign was documented in 464 records (51%). Patients <5 years were significantly more likely to be diagnosed with severe malaria than those ≥5 years either by admission diagnosis or documented severe sign; risk ratio (RR) 1.3 (95% confidence interval [CI], 1.1-1.6) and 1.6 (95% CI, 1.4-1.8), respectively. Correct treatment was more common for patients identified by admission diagnosis (79%) than by documented severe sign (68%) (p <0.001). Notably, 14% of severe malaria patients by admission diagnosis and 20% with a documented severe sign were treated exclusively with an oral antimalarial and 8% and 13%, respectively, did not receive any effective antimalarial, with no significant differences by age. Case management of severe malaria remains a challenge. Despite the high proportion of severe malaria patients receiving recommended treatment, it is concerning that 8-13% received no effective therapy. Challenges to adhering to national guidelines should be identified and addressed to improve quality of care.

308

MALARIA AND ILLEGAL GOLD MINES IN A HIGH INCOME COUNTRY: FIRST DESCRIPTION OF THE DISEASE BURDEN

Maylis Douine[1], Antoine Adenis[1], Lise Musset[2], Magalie Demar[3], Felix Djossou[4], Paul Brousse[5], Hedley Cairo[6], Stephen Vreden[6], Mathieu Nacher[1]

[1]*Centre d'investigation Antilles-Guyane (Inserm/DGOS CIE*[1424]*), Centre Hospitalier Andrée Rosemon, Cayenne, French Guiana,* [2]*Laboratoire de Parasitologie, Centre National de référence du Paludisme, Institut Pasteur Guyane, Cayenne, French Guiana,* [3]*Laboratoire Hospitalo-Universitaire de Parasitologie, Centre Hospitalier Andrée Rosemon, Cayenne, French Guiana,* [4]*Unité des Maladies Infectieuses et Tropicales, Centre Hospitalier Andrée Rosemon, Cayenne, French Guiana,* [5]*Centres Délocalisés de Prévention et de Soins, Centre Hospitalier Andrée Rosemon, Cayenne, French Guiana,* [6]*Bureau of Public Health, Ministry of Health, Paramaribo, Suriname*

Malaria is endemic on the Guiana Shield. In French Guiana, a French overseas territory, although the number of cases has decreased since 2005, ***foci*** of infection still remain, particularly within illegal gold mines. There, malaria patients often self-medicate, resulting in a risk of resistance to anti-malarial treatments, notably to artemisinine. The mobility of gold miners increases the risk of spreading both malaria and the resistance to antimalarials, and puts the population at risk of new outbreaks despite the great efforts put into anti-malarial policy in this region. This study aims to estimate and map the prevalence of ***Plasmodium*** carriers and to determine knowledge attitudes and practices concerning malaria in illegal gold miners. Inclusions were carried out from January to March 2015 (continued until June 2015) at the resting sites along the Maroni river. Illegal gold mine workers periodically go to these sites for rest, supplies, or medical care. People working on gold mining sites in French Guiana and being on the resting site for less than 7 days were included. A malaria-RDT, thick and thin blood smear, molecular diagnosis by PCR were performed. Persons also answered a questionnaire and had a medical examination. Informed consent was obtained. On the 03/01/2015, 128 persons were included of the 360 expected for the complete study duration. On PCR, 25 (19.5%) were positive for malaria, with 11 ***P. vivax*** (44%), 10 ***P. falciparum*** (40%), 3 mixed faciparum+vivax (12%) and 1 P. malariae (4%). Seventeen (65.4%) were asymptomatic. The last time they had malaria, 37% did a test, and 64% declared regularly using self-medication containing artemisinine. This first study about the epidemiology of malaria in illegal gold miners in French Guiana shows a very high prevalence of malaria along with a high proportion of asymptomatic carriers. Therefore control of malaria in French Guiana must take into account illegal gold miners, the main but hidden reservoir of malaria endemicity. These results should help French Health Agencies to implement adapted measures to deal with malaria in this population and hope to avoid the emergence of artemisinine resistance.

309

THE RISE OF VECTOR RESISTANCE AND INSECTICIDE COSTS: AN ASSESSMENT OF INSECTICIDE CHANGE FOR INDOOR RESIDUAL SPRAYING AND MALARIA BURDEN IN ZIMBABWE

Beth A. Brennan[1], Ben Johns[1], Hieronymo Masendu[2], Shadreck Sande[3], Andrew Tangwena[3]

[1]*Abt Associates, Bethesda, MD, United States,* [2]*Abt Associates, Harare, Zimbabwe,* [3]*Abt Associates, Zimbabwe, Zimbabwe*

Indoor residual spraying (IRS) has been implemented since the 1940s in Zimbabwe and has protected millions of people from malaria. However, long-term insecticide exposure leads to vector resistance. While entomological studies have shown increasing resistance to PYs in mosquitoes, the population-level effects of changing insecticides is not well understood. In November 2014 the President's Malaria Initiative-supported (PMI) Africa Indoor Residual Spraying (AIRS) project in Zimbabwe started using organophosphate-based insecticides (OPs) in

four high malaria burden districts (Chimanimani, Mutare, Mutasa, and Nyanga) in Manicaland Province. Previously, these areas were sprayed with pyrethroid-based insecticides (PYs). OPs are substantially more expensive than PYs; they cost approximately ten times more per area sprayed than PYs, according to a 2013 AIRS Costing Study. Thus, as programs expand and require more expensive insecticide, the number of beneficiaries an IRS campaign can protect is dependent on the type of insecticide used. With Health Management Information System (HMIS) and entomological data through transmission season (May-June 2015), we will: 1) compare the number of confirmed malaria cases in health facilities in four districts in 2011-2013 (under PYs) to the same districts in 2014-2015 (under OPs); and (2) compare the number of confirmed malaria cases in health facilities in the four OP districts in 2014-2015 to four comparison PY districts in the same time period. We will strengthen our analysis by comparing mosquito densities from our routine entomological monitoring before and after using OPs for IRS. Although not randomized-controlled, the analysis provides a relatively inexpensive method to suggest the most effective pesticide for reducing malaria burden in these districts, while considering rising insecticide costs and program budget limitations. Preliminary results are not available at the time of abstract submission as malaria season in the target districts continues through May-June 2015. We will present our methodology and the results of our analysis, if selected.

310

SHOULD INTERMITTENT PREVENTIVE TREATMENT DURING PREGNANCY BE MAINTAINED IN AREAS OF LOW TRANSMISSION: ANALYSIS OF BIRTHWEIGHT, INTERVENTION COVERAGE, AND EPIDEMIOLOGIC STRATUM IN SENEGAL

Moustapha Cisse[1], Medoune Ndiop[1], Ibrahima Diallo[1], Mame Birame Diouf[2], Mady Ba[1]

[1]*National Malaria Control Programme, Dakar, Senegal,* [2]*United States Agency for International Development/President's Malaria Initiative, Dakar, Senegal*

Intermittent preventive treatment during pregnancy (IPTp) with at least two doses of sulfadoxine-pyrimethamine (SP) is recommended for prevention of malaria during pregnancy, along with use of insecticide treated nets (ITNs), to reduce low birthweight and miscarriages. In 2006, Senegal adopted IPTp with SP free of charge for pregnant women, along with training and point of delivery equipment for directly observed therapy. The prevalence of markers of resistance to SP is monitored. Introduction of IPTp coincided with the intensification of other malaria control interventions including ITNs and artemisinin-based combination therapy, and parasite prevalence among children under 5 years fell from 6% in 2008 to 1.2% in 2014, with near zero prevalence in the north. Many question the applicability of continuing IPTp in the north of Senegal. We analyzed data from Senegal's continuous Demographic and Health Survey from 2013 to examine the benefit of the coverage of two doses of SP on low birth weight, by epidemiologic stratum. We compared IPTp coverage and prevalence of low birthweight in the zones of low, moderate, and high transmission in Senegal to test the hypothesis that IPTp would have a decreased effect in zones of low transmission, given the Senegalese context of intense seasonality and epidemiologic stratification. Nationally, IPTp coverage is 41.3% and the rate of low birth weight (LBW) is 13.0%. The zone of moderate transmission has the lowest rate of LBW at 10.2%, while having the lowest coverage of IPTp (36%). The rate of LBW is similar in the low transmission zone (14.7%) and the high transmission zone (13.7%), despite the highest IPTp coverage in the low transmission zone (48%) compared to 40% in the high transmission zone. As there was no clear relationship between IPTp coverage and rate of low birthweight when stratified by epidemiologic strata, further analysis is ongoing to consider factors such as number of doses, use of LLINs, season, parity, nutrition, and socio-economic status. While national survey data may shed light on this question, a prospective study should be conducted to ascertain the contribution of IPTp in northern Senegal.

311

TRACKING THE IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON MORBIDITY AND MORTALITY OF CHILDREN IN SENEGAL THROUGH THE ROUTINE HEALTH INFORMATION SYSTEM

Medoune Ndiop[1], Ibrahima Diallo[1], Julie Thwing[2], Seynabou Gaye[1], Alioune Badara Gueye[1], Moustapha Cisse[1], Mame Birame Diouf[3], Mamadou Lamine Diouf[1], Mady Ba[1]

[1]*National Malaria Control Program, Dakar, Senegal,* [2]*Centers for Disease Control and Prevention/President's Malaria Initiative United States Agency for International Development, Dakar, Senegal,* [3]*United States Agency for International Development/President's Malaria Initiative, Dakar, Senegal*

The World Health Organization recommends seasonal malaria chemoprevention (SMC), a monthly treatment course of anti-malarial, for up to four months during malaria transmission season for children 3-60 months of age, in regions with highly seasonal transmission. In 2014, the Senegal National Malaria Control Program (NMCP) implemented SMC in the four regions of Senegal that meet WHO criteria, with a target of 624,139 children 3 - 120 months, increasing the age range given data showing a displacement of burden of malaria toward older children. SMC campaigns were conducted in August, September, and October, with administrative coverage rates of 98.6% 97.9%, and 98.0%, respectively. We examined routine information collected from malaria sentinel sites, the public health system, and reference hospitals to determine the impact of SMC on morbidity and mortality. Twenty sentinel sites, four in regions targeted for SMC, report the weekly number of total consultations, suspected malaria cases, patients tested, and confirmed malaria cases. Morbidity data from the sentinel sites were examined during the period covered by the campaign (epi week 35-48) in 2013 (baseline) and 2014. The number of confirmed cases among children < 5 and among children 5-10 at the four sites decreased 50% and 60%, respectively, from 2013 to 2014. The proportion of confirmed malaria cases among children 0-120 months among all confirmed malaria cases declined from 39% in 2013 to 23% in 2014. The incidence of all confirmed malaria cases reported by all the public health facilities in the SMC regions decreased from 81/1000 in 2013 to 60/1000 in 2014, a 26% reduction. The number of hospitalized malaria cases among children < 5 years recorded at health facilities in the four regions decreased 50% (1,384 in 2013 to 688 in 2014). The number of deaths due to confirmed malaria among children < 5 years recorded at reference hospitals in the four regions decreased 61% (135 in 2013 to 53 in 2014). Data from sentinel sites confirmed data from the routine health system, and enabled understanding of burden reduction by age group. With these very encouraging results the NMCP will continue SMC in 2015 and 2016.

312

MALARIA: BURDEN, PREVENTION, AND TREATMENT SEEKING PRACTICES AMONG NOMADIC PASTORALISTS IN SENEGAL

Julie I. Thwing[1], Mame C. Seck[2], Fatou B. Fall[3], Jules F. Gomis[2], Awa B. Deme[2], Yaye D. Ndiaye[2], Rachel Daniels[4], Sarah Volkman[4], Medpune Ndiop[3], Mady Ba[3], Daouda Ndiaye[2]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Cheikh Anta Diop University, Dakar, Senegal,* [3]*National Malaria Control Program, Dakar, Senegal,* [4]*Harvard School of Public Health, Boston, MA, United States*

Senegal has had remarkable declines in malaria in the last decade. In the north, annual incidence is now less than 5 confirmed cases per 1000 people. Senegal is home to nomadic pastoralists who travel south to high malaria transmission zones during dry season, returning north when the rains start. There was concern that the migration of pastoralists at the start of the rains might sustain malaria transmission in the north. Nomadic and migrant populations present a challenge for public health, as they

may be located in remote areas, have less access to prevention and care, suffer stigmatization, and be more at risk for disease. We conducted a modified snowball sampling survey of nomadic pastoralists at 6 sites in northern Senegal. We enrolled 1800 people 6 months and older, and collected data regarding demographics, access to care and preventive measures, and a blood sample for rapid diagnostic test (RDT), blood smear, and PCR. Of these, 31.5% were under 15 years, and 38.7% were female. Literacy among adults was 12%, and 16% had heard messages about malaria in the last three months, 94% of these by radio. Of the 55% who knew at least one preventive measure against malaria, 84% cited bednets. Though 64% had a net, only 29% had received a net from a mass distribution campaign, and 26% reported using a net every night. Of the 21% with a family member with fever in the last month, 23% sought care. The primary reason for not seeking care (26%) was distance. However, parasite prevalence by PCR was 0.5%, similar to the remainder of the north. Sensitivity and specificity of RDT compared to PCR was 100% and 99%, respectively. All of the molecular barcodes identified among the migrants were novel in Senegal, providing no evidence that these strains had originated in the south, though 96% had been in the district two weeks or less at the time of the survey. While nomadic pastoralists have poor access to prevention and care of malaria, parasite prevalence is low, and they do not appear to be a source of ongoing transmission. Efforts are being made to include them for insecticidal net distribution and to train health volunteers among them to provide diagnosis, treatment, and health messages.

313

MEASURING THE PREVALENCE OF MALARIA PARASITEMIA USING LAMP IN A HIGH-TRANSMISSION COMMUNITY IN UGANDA

Shereen Katrak[1], Nathan Day[2], Emmanuel Ssemmondo[3], Dalsone Kwarisiima[4], Moses Kamya[5], Diane Havlir[6], Grant Dorsey[1]

[1]*University of California, San Francisco, San Francisco, CA, United States,* [2]*Vanderbilt University, Nashville, TN, United States,* [3]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [4]*Mulago-Mbarara Joint AIDS Program, Kampala, Uganda,* [5]*Makerere University, Kampala, Uganda,* [6]*Division of HIV/AIDS, San Francisco General Hospital, University of California San Francisco, San Francisco, CA, United States*

The epidemiology of malaria parasitemia, particularly in older children, adults, and HIV-infected persons, is poorly understood. Knowledge gaps regarding parasitemia hinder elimination efforts in high transmission areas, where large segments of the population are asymptomatic carriers of malaria parasites, but retain the ability to transmit disease. We performed a cross-sectional analysis of community residents (n=10,875) in Nankoma, Uganda, in which we collected 9,629 dried blood spots (DBS), representing 89% sampling of the population. In order to describe population-level parasitemia, we tested a random subset of 4,000 HIV-negative samples and all 147 HIV-positive samples for malaria parasitemia using loop mediated isothermal amplification (LAMP). We estimated population-level prevalence using a weighted proportion, and fit a multivariate logistic regression model to identify independent predictors of malaria parasitemia. We found an overall prevalence of parasitemia in the community of 82.1% (95% CI, 81.3 - 83.0%). Age-specific prevalence increased steadily among children until age 9, peaking at 92.3% in children under 10 years old, then decreased until age 35, with a prevalence of 61.3% in those older than 35 years. When controlling for age, we found male sex to be independently associated with malaria parasitemia (aOR =1.27, 95% CI, 1.05 - 1.53, p=0.01), while self-reported insecticide-treated bed net (ITN) use the prior evening was not. HIV-infected individuals had a lower odds of parasitemia when compared to uninfected persons (aOR=0.09, 95% CI 0.06-0.15, p=<0.01), likely representing this group's use of trimethoprim-sulfamethoxazole prophylaxis. Among HIV-infected adults, a CD4 count of less than 200 was associated with parasitemia (aOR = 7.00, 95% CI 1.18 - 41.39, p=0.03), while antiretroviral use was not. These data show extremely high levels of parasitemia at all ages in a highly endemic community in Uganda, including an overall prevalence of 82.1% and a greater than 60% prevalence in adults. Successful malaria elimination efforts need to address high-level parasitemia across all age strata.

314

EPIDEMIOLOGY OF MALARIA IN NON-AMAZONIAN COLOMBIAN REGIONS: IMPORTANCE OF ASYMPTOMATIC SUBJECTS AS TRANSMISSION *FOCI*

Juan M. Vásquez-Jiménez[1], Cristhian Morales-Plaza[1], Sergio A. Ochoa-Orozco[1], Nora Martínez[1], John García[1], Andrés F. Vallejo[1], Yoldy Benavides[1], Angélica Castellanos[1], Juliana Henao-Giraldo[1], Myriam Arévalo-Herrera[2], Sócrates Herrera[1]

[1]*Caucaseco Scientific Research Center, Cali, Colombia,* [2]*Caucaseco Scientific Research Center and School of Health, Universidad del Valle, Cali, Colombia*

Despite major progress towards Malaria Control in Colombia and Latin America, it still remains as an important public health problem. However, control and elimination programs still rely on methods incapable of detecting most of asymptomatic subjects, which endure untreated as potential reservoirs for transmission. Here we describe the epidemiology of malaria in non-Amazonian Colombian endemic regions throughout a three year follow-up, and discuss the importance of asymptomatic subjects and their persistence for malaria elimination. We conducted a series of cross-sectional surveys in eleven sentinel sites (SS) of Buenaventura, Tierralta and Tumaco, Colombia in 2011, 2013 and 2014, in which a census was taken and a random sample of houses drawn from each SS. People from the selected houses were asked to complete a questionnaire about clinical, epidemiological and demographic information and provide a blood sample for diagnosis of malaria by thick blood smear microscopy (TBS) and real time polymerase chain reaction (qPCR). Additionally, cases were georeferenced. A total of 3,046 samples were taken from all the SS whereof 58% were women. A total prevalence of 9.7, 7.3 and 3.5% was found in 2011, 2013 and 2014 respectively by qPCR. Only 2% of the cases detected by qPCR were detectable by TBS and 73% of all infected subjects were asymptomatic. Whereas Buenaventura and Tierralta presented a consistent prevalence decrease along these years, Tumaco had a rise of malaria cases in 2013 but then decreased in 2014. ***P. vivax*** accounted for the majority of cases in Tierralta and Buenaventura but only 33-50% of the cases in Tumaco. During two consecutive cross-sectional surveys conducted, two people remained positive and asymptomatic for malaria. In this study we found an important prevalence of malaria in endemic regions considered to be of low and moderate transmission. The fact that only 2% of the cases were detectable by TBS, which is the most widely used diagnostic method by National Malaria Control Programs, highlights the importance of considering the introduction of molecular methods for the diagnosis of malaria as a public health tool.

315

PREVALENCE AND FACTORS ASSOCIATED WITH MALARIA IN PREGNANCY IN RURAL RWANDAN HEALTH FACILITIES: A CROSS-SECTIONAL STUDY

Corine Karema[1], **William R. Brieger**[2], Irenee Umulisa[3], Aline Uwimana[3], Jeremie Zoungrana[4], Beata Mukarugwiro[4], Rachel Favero[4], Elaine Roman[4], Barbara Rawline[4], Tharcisse Munyaneza[5], Fidele Ngabo[6], David Sullivan[2], Jean Baptiste Mazarati[5], Rukundo Alphonse[3], Agnes Binagwaho[7]

[1]*Malaria and Other Parasitic Diseases Division, Rwanda Biomedical Centre, Ministry of Health Biomedical Services, Ministry of Health, Kigali, Rwanda,* [2]*Johns Hopkins University, Baltimore, MD, United States,* [3]*Malaria and Other Parasitic Diseases Division, Rwanda Biomedical Centre, Ministry of Health, Kigali, Rwanda,* [4]*Jhpiego, Baltimore, MD, United States,* [5]*Biomedical Services, RBC, Ministry of Health, Kigali, Rwanda,* [6]*Maternal and Child Health Program, Ministry of Health, Kigali, Rwanda,* [7]*Ministry of Health, Kigali, Rwanda*

Malaria in pregnancy (MIP) is a serious health risk for the pregnant woman and fetus and associated with mortality in the perinatal period. In Rwanda there has been no accurate national estimate of malaria prevalence among pregnant women. In 2011, a cross-sectional study of 6 districts in 3 malaria transmission zones (low, medium and high) in Rwanda was conducted to estimate the prevalence of peripheral parasitemia in pregnant women. Data were collected from consenting women presenting to antenatal clinics (ANC) for the first time in their current pregnancy including age, parity, gestation, ITN availability and use. Blood was obtained for malaria testing using microscopy, rapid diagnosis tests and polymerase chain reaction (PCR). A total of 4,037 pregnant women were recruited with median age of 27 years, and 3,781 (93.7%) had usable PCR samples. The prevalence of MIP by PCR was 5.6%. Nearly 20% of women's families did not have a net, and 8.7% of these tested positive compared to 4.9% of women whose family owned an ITN. For those who did not sleep under an ITN the previous night, 8.1% tested positive compared with 4.8% who slept under an ITN. Malaria prevalence by parity ranged from 5.5% (parity 0-1), to 5.4% (parity 2-3), and 6.5% (parity 4 or more). The two districts that bordered highly endemic countries had MIP prevalence rates of 10% and above. Those testing positive were treated according to national guidelines. Despite a significant decline of 86% in malaria prevalence in the general population from 2005 to 2011, MIP prevalence remains high, especially in border districts. Our study also showed that ITN ownership and use among these pregnant women is below the national target. In order to address this gap, ITN distribution to achieve universal access, and educational campaign targeted at pregnant women on the use of ITN are recommended. Furthermore, early detection and treatment of MIP at ANC and regional collaboration to reduce cross-border malaria transmission should be prioritized.

UNUSUAL HIGH GENETIC DIVERSITY OF *PLASMODIUM FALCIPARUM* POPULATION IN BANGLADESH

Mohammad Shafiul Alam[1], Rubayet Elahi[2], Abu Naser Mohon[3], Hasan Mohammad Al-Amin[1], Mohammad Golam Kibria[1], Wasif A. Khan[1], Rashidul Haque[1]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [2]*Department of Biochemistry, Virginia Tech, Blacksburg, VA, United States,* [3]*Department of Microbiology and Infectious Disease, Cumming School of Medicine, University of Calgary, Calgary, AB, Canada*

More than 90% of malaria cases of Bangladesh are caused by ***Plasmodium falciparum***. Despite the recommendation for the use of msp1, msp2, and glurp as markers in drug efficacy studies by WHO and their limited use in Bangladesh, still the circulating ***P. falciparum*** population genetic structure has not been assessed systematically in the country. The present study is the first comprehensive report of the circulating ***P. falciparum*** population structure based on msp1, msp2, and glurp in seven most malaria endemic districts out of thirteen malaria endemic districts of Bangladesh. Among the 130 pretreatment ***P. falciparum*** field isolates, 14, 20, and 13 distinct genotypes were observed for msp1, msp2, and glurp, respectively. We found 94.62% polyclonal infections, which is almost similar to some holoendmic areas of Sub-saharan Africa. The heterozygosity for msp1, msp2, and glurp was 0.89, 0.93, and 0.83, respectively. These MOI's fall within the range of MOI's reported in hypoendemic areas of Southeast Asia. Even though Bangladesh is a malaria hypoendemic country, the prevalence of polyclonal infection and the genetic diversity in ***P. falciparum*** do not represent hypoendemicity.

317

POPULATION STRUCTURE: THE PHYLO-DYNAMICS OF *PLASMODIUM FALCIPARUM* IN PAPUA NEW GUINEA

Abby G. Harrison[1], Natacha Tessier[1], Stuart Lee[1], Livingstone Tavul[2], Roberto Amato[3], Magnus Manske[4], Olivo Miotto[3], Dominic Kwiatkowski[3], Inoni Betuela[2], Peter Siba[2], Katherine Smith[1], Ivo Mueller[1], Melanie Bahlo[1], Alyssa Barry[1]

[1]*Population Health & Immunity Division, Walter and Eliza Hall Institute, Melbourne, Australia,* [2]*Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea,* [3]*MRC Centre for Genomics and Global Health, University of Oxford, Oxford, United Kingdom,* [4]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom*

Papua New Guinea (PNG) has the highest burden of malaria outside of Africa with intense year round transmission ranging from hyper- to holo-endemic in the lowland and coastal areas to largely absent in the highlands. The country's extremely diverse biogeography contributes to variable parasite population dynamics and transmission, even across the highly endemic areas. Recently, we have shown that the population structure of ***Plasmodium falciparum*** on the north coast of Papua New Guinea (PNG) is fragmented. Should such population fragmentation and structure be observed throughout PNG then mapping of this geographical diversity will enable the monitoring of changes in populations, the identification of routes of migration, predict the spread of drug resistance, and pinpoint the source of outbreaks. Such knowledge will be valuable for the success of malaria elimination and control programmes as it will enable informed choices to be made. Using microsatellite markers, mitochondrial sequences, and genome wide SNP data, from three geographically distinct populations within PNG, we are investigating ***P. falciparum***'s genome dynamic nature, and demographic structure. Exploring fundamental biological questions regarding the genetic history. In addition, we are working towards defining a high-resolution map of parasite population networks and migration patterns throughout PNG. Using state-of-the-art Fluidigm Integrated Fluidic Circuit SNP genotyping, a panel of geographically informative single nucleotide polymorphisms (SNPs), and a national cross-sectional ***P. falciparum*** dataset of isolates covering all endemic areas of PNG. These results will have direct translational benefits by identifying isolated populations that may be targeted for elimination, and will provide a database of genotypes to map the origins of imported infections and outbreaks in areas where malaria is normally absent.

A -1447 A>G POLYMORPHISM IN THE HUMAN CXCL10 GENE PROMOTER IS ASSOCIATED WITH CHILDHOOD MALARIA

Felix A. Botchway[1], Nana Wilson[2], Adel Driss[2], Micheal Wilson[3], Andrew A. Adjei[1], Jonathan Stiles[2]

[1]*University of Ghana Medical School, Accra, Ghana,* [2]*Morehouse School of Medicine, Atlanta, GA, United States,* [3]*University of Ghana, Accra, Ghana*

Background The risk factors for severity of malaria pathogenesis and the wide variation in clinical manifestations of malaria are poorly understood. Recent studies indicate that interferon gamma inducible chemokine, CXCL10, is a predictor of both human and experimental cerebral malaria severity. In addition, polymorphisms in the CXCL10 gene promoter has

been associated with increased CXCL10 production, which is linked to severity of malaria in Indian malaria patients. In the present study, we hypothesized that in a subset of Ghanaian malaria patients, susceptibility to malaria is associated with different variants of the CXCL10 gene. Method: We assessed basic demographics that may impact our assessment including age, gender, hemoglobin levels, sickle cell status CXCL10 plasma levels and CXCL10 polymorphism. We determined whether polymorphisms in the CXCL10 gene are associated with the clinical status of malaria patients. We tested several known polymorphisms and identified one reported single nucleotide polymorphism in the CXCL10 promoter (-1447A>G [rs4508917]) and compared 382 malaria and 115 non malaria cases using PCR-restriction fragment length polymorphism method. Results: The median age for malaria patients was 4 years and that for non-malaria patients was 13 years. There was significant difference with regards to hemoglobin, hematocrit, wbcs level, CXCL10 plasma levels between malaria patients and non-malaria patients, p=0.001. The -1447A>G genotype of the CXCL10 gene was significantly associated with malaria (adjusted odds ratio =2.55, 95% CI=1.13-5.74, p=0.024).). In addition, individuals with the 21447(A/G) genotype had significantly higher plasma CXCL10 levels than individuals with the 21447(A/A) genotype. Stratifying patients according to gender, the observed association of malaria with over expression of CXCL10 were more pronounced in females than in male patients (AOR = 5.47, 95% CI = 1.34-22.29, p = 0.018. Conclusion: These results suggest that the -1447A>G polymorphism in CXCL10 gene promoter could be partly responsible for malaria outcomes in Ghanaian malaria children.

319

SURVEILLANCE OF MOLECULAR MARKER OF ANTIMALARIAL DRUG RESISTANCE IN SENEGAL BY USING MALARIA RAPID DIAGNOSTIC TEST (RDTS)

Magatte Ndiaye[1], Sidsel Nag[2], Doudou Sow[1], Khadyme Sylla[1], Babacar Faye[1], Jean Louis Ndiaye[1], Roger Tine[1], Michael Alifrangis[2], Oumar Gaye[1]

[1]*University Cheikh Anta Diop, Senegal, Senegal,* [2]*University of Copenhagen, Center for Medical Parasitology, Denmark*

In Senegal, strategies such as Intermittent Preventive Treatment in pregnancy (IPTp) (SP) and Seasonal Malaria Chemoprevention (SMC) using sulfadoxine-pyrimethamine (SP) and SP plus amodiaquine, respectively have been implemented while artemisinin-based combination therapies are used to treat uncomplicated malaria. These strategies have largely contributed to the decrease of malaria morbidity and mortality in the country. However, the successful control of malaria is highly dependent on continued effectiveness of these drugs which may be compromised by the spread of drug resistance. Therefore surveillance of drug resistance in the malaria parasites is essential. The objective of this study was to test the feasibility of routinely sampled malaria rapid diagnostic tests (RDTs) at a national scale to assess the temporal changes in the molecular profiles of antimalarial drug resistance markers of ***P. falciparum*** parasites. A low-cost sampling procedure of RDTs was established at 14 malaria sentinel sites across the country. Overall 4339 RDT positives were collected during 2014 out of which, a subset of 700 RDTs (50 RDTs per site) was randomly selected for initial SNPs analysis of the Pfcrt gene by PCR-SSOP ELISA methodology. Among the 700 selected and extracted RDTs, 598 (85.4%) was confirmed ***P. falciparum*** positive by Pfcrt PCR. The prevalence of the Pfcrt wild type CVMNK haplotype was above 75% in the North-eastern regions including Dakar while a lower prevalence at 65% and 56% was observed in the Central and South regions, respectively. In conclusion, this study showed that routine sampled positive RDTs can be successfully amplified by PCR and used for routine surveillance of antimalarial drug resistance. Further sampling of RDTs and analysis of other markers of drug resistance (e.g. Pfmdr, Pfdhfr, Pfdhps, K13) are ongoing which will provide temporal trends of these markers and potentially aid drug policy makers in timely decisions regarding choice of antimalarial drugs.

320

TRANSCRIPTION PROFILING OF MALARIA-NAÏVE AND SEMI-IMMUNE COLOMBIAN VOLUNTEERS IN A *PLASMODIUM VIVAX* SPOROZOITE CHALLENGE

Monica L. Rojas-Peña[1], Andrés Vallejo[2], Sócrates Herrera[3], Myriam Arévalo-Herrera[2], Greg Gibson[1]

[1]*Center for Integrative Genomics, School of Biology, Georgia Institute of Technology, Atlanta, GA, United States,* [2]*Caucaseco Scientific Research Center, Cali, Colombia,* [3]*Malaria Vaccine and Drug Development Center, Cali, Colombia*

In endemic regions the continued exposure to the malaria parasite induces significant levels of clinical immunity in individuals who develop lower morbidity and almost no mortality. This immunity is very complex and slow processes, but little is known about the immunological response to ***Plasmodium vivax*** in early infections and how the immune system may be boosted during vaccination. This study hypothesizes that the partial clinical immunity observed in semi-immune volunteers from Buenaventura (high prevalence) compared to naïve individuals from Cali (no transmission) is associated with altered peripheral blood gene expression. To explore the difference in gene expression between semi-immune and naïve individuals experimentally exposed to viable ***P. vivax*** sporozoites, we describe a transcript profile analysis in these volunteers using nanofluidic Fluidigm quantitative RT-PCR arrays and RNASeq. Previous malaria experience has a relatively minor variation effect, although it does separate the two clusters in the overall profiles of expression among the samples. There is little evidence for transcriptional changes prior to the appearance of blood stage parasite at diagnosis day (day 12 or 13). At the parasitemia onset, there is a strong interferon response reflected in up-regulation of co-regulated transcripts, while unexpectedly we also see down-regulation of transcripts related to TLR signaling and innate immunity. This differential expression was confirmed with the RNASeq, which also suggested differential expression of reticulocytes and a subset of T cell function. No obvious difference in the transcriptomes of naïve and semi-immune volunteers was seen, however several hundred genes were up-regulated in naïve individuals. Interaction analysis showed 175 genes with a significant Time-by-Population effect at $p<0.05$, most of these genes are more strongly up- or down-regulated in the naïve individuals. This study shows that gene expression is strong in naïve volunteers in comparison to semi-immune at the time of diagnosis. Gene expression of lymphocytes can thus be used to establish how semi-immune exposure modifies their activation.

321

CHARACTERIZATION OF CIRCUMSPOROZOITE PROTEIN VARIANTS (VK210, VK247 AND *PLASMODIUM VIVAX*-LIKE) IN *P. VIVAX* ISOLATES WITH DIFFERENT PROFILES OF SENSITIVITY TO ANTIMALARIAL DRUGS

Lilian R. Pratt-Riccio[1], Leonardo J. Carvalho[1], Cesare Bianco-Junior[1], Daiana S. Perce-da-Silva[1], Vanessa R. Torres[1], Barbara O. Baptista[1], Gustavo Cassiano[2], Luciane S. Mello[2], Ricardo L. Machado[3], Dalma M. Banic[1], Claudio T. Daniel-Ribeiro[1]

[1]*Fundação Oswaldo Cruz, Rio de Janeiro, Brazil,* [2]*FAMERP, São Paulo, Brazil,* [3]*IEC, Pará, Brazil*

The ***Plasmodium vivax*** Circumsporozoite Protein (CSP) is the most abundant polypeptide present in the sporozoite covering. Based on csp gene, two variants, VK247 and ***P. vivax***-like, have been described that differ from the classical form (VK210) by sequence variations in the central region of the gene. The distribution of these variants seems to be universal and an important issue is the possibility of differential response to treatment is depending on the genotype of the parasite. Here, we characterized the CSP variants circulating in Brazilian malaria-endemic area and associated the presence of these variants with different profiles of sensitivity to chloroquine and mefloquine. The ***P. vivax*** isolates were

collected in Manaus, Amazonas. The determination of CSP variants was performed by PCR-RFLP or PCR-sequencing and sensitivity to chloroquine and mefloquine was determined by the colorimetric DELI-test. VK210 was the most prevalent, detected in 92% of samples while VK247 variant was observed in 14.7% of samples. Single infection with VK210 was observed in 85.2% of samples, single infection with variant VK247 was observed in 7.9% of the samples and mixed infection (VK210 + VK247) was observed in 6.8% of samples. The mean IC_{50} in the presence of chloroquine were 61nM, 25nM and 21nM for VK210, VK247 and VK210+VK247, respectively. The mean IC50 in the presence of mefloquine were 24nM, 32nM and 10nM for VK210, VK247 and VK210 + VK247, respectively. No association was derived in the resistance or susceptibility profile or in the IC_{50} values in presence of chloroquine or mefloquine determined by DELI-test and the presence of the CS variants of ***P. vivax***. Conclusions: the classical form VK210 is more prevalent in the studied area and that the presence of VK210 appears not to be associated with susceptibility or resistance to chloroquine and mefloquine in the studied area.

322

DECREASE OF HEMOGLOBIN LEVELS IN AFRICAN CHILDREN WITH SEVERE MALARIA ASSOCIATED WITH GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY RATHER THAN HEMOGLOBINOPATHIES

Christian N. Nguetse[1], Peter G. Kremsner[2], Thirumalaisamy P. Velavan[1]

[1]*Institute of Tropical Medicine - University of Tuebingen, Tuebingen, Germany,* [2]*Institute of Tropical Medicine - University of Tuebingen; Centre de Recherches Médicales de Lambaréné, Tuebingen; Lambaréné, Germany*

Red blood cell polymorphisms, including glucose-6-phosphate dehydrogenase (G6PD) deficiency and hemoglobinopathies confer relative protection from severe malaria. However, their true impact on clinical parameters during severe malaria remains poorly understood. In this study we determined the frequencies of accountable genetic variants and investigated their effects on baseline parasitemia and hemoglobin levels in African children with severe malaria. A total of 278 children aged 6 to 120 months with severe malaria were enrolled into this study. G6PD deficiency (G202A and A376G) and hemoglobin variants (HbC and HbS) were determined by direct sequencing of the genome regions harboring the variants. The overall prevalence of G6PD deficiency (G6PD*A-) was 12.9%; 14.4% of children were female heterozygous (G6PD*A), while 72.7% were G6PD normal (G6PD*B). 87.9%, 3.6% and 8.2% of children had the HbAA, HbAC and HbAS genotypes, respectively. Only one female child was homozygous for HbSS. HbCC and HbSC variants were absent. Using a multivariate regression analysis, G6PD variants were associated with decreased hemoglobin concentrations of 2.7 g/dL in G6PD heterozygous (P<0.0001) and 1 g/dL in G6PD deficient (P=0.009) children. However, there was no effect on adjusted log mean parasite densities (P=0.287). We found a significant association between the hemoglobin variants and the mean temperature (P=0.015). In fact, on admission, HbAS children had a higher temperature (37.8 ± 1.2°C), while lower temperatures (15.3 ± 4.4°C) were found in HbAC individuals. There was no effect of hemoglobin variants on parasitemia and hemoglobin levels. In addition, G6PD and hemoglobin variants did not have any association with severe malaria anemia. G6PD polymorphisms contribute to the reduction of hemoglobin levels in African children with severe malaria without leading to severe malarial anemia. This study confers further knowledge to help understand the effect of G6PD deficiency and hemoglobinopathies during malaria infection in endemic countries.

PLASMODIUM FALCIPARUM ATOVAQUONE SUSCEPTIBILITY REMAINS INTACT IN NORTHERN CAMBODIA BASED ON *EX VIVO* THE MOLECULAR EVIDENCE

Panita Gosi[1], Chanthap Lon[2], Suwanna Chaorattanakawee[1], Michele D Spring[1], Nitima Chanarat[1], Soklyda Chann[2], Piyaporn Sia-ngam[1], Sok Somethy[3], Rathvicheth Bun[4], Siratchana Sundrakes[1], Saowaluk Wonarunkotchakorn[1], Chaiyaporn Chaisathit[1], Mali Ittiverakul[1], Char Meng Chuor[4], Satharath Prom[3], Charlotte A Lanteri[1], David L Saunders[1]

[1]*U.S. Army Medical Component-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand,* [2]*U.S. Army Medical Component-Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia,* [3]*Royal Cambodian Armed Forces, Ministry of National Defense, Phnom Penh, Cambodia,* [4]*National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia*

Multidrug resistant ***P. falciparum*** (MDR Pf) malaria is a critical issue in Cambodia, with multiple artemisinin combination therapies losing their effectiveness in recent years. Atovaquone, in combination with proguanil (MalaroneTM) has been used in limited areas of Cambodia to treat MDR Pf. In a recent trial showing clinical failure of DHA-piperaquine, we evaluated ***in vitro*** atovaquone susceptibility and looked for point mutations in the Pf cytochrome bc1 gene, known to confer atovaquone resistance. Parasites from the last 62 of 101 adult patients treated with DHA-piperaquine in Northern Cambodia were genotyped for mutations at codon 268 in the cytochrome bc1 gene. A high resolution melting RT-PCR assay (HRM-RTPCR) offering faster turn-around times was compared to conventional DNA sequencing. ***In vitro*** drug sensitivity was assayed using an HRP-2 assay with W2 and C2B ***P. falciparum*** reference clones used as susceptible and resistant controls, respectively. The geometric mean atovaquone IC50 was 5.0nM for the sensitive W2 clone, 6.6 nM for 62 Cambodian isolates (no difference from W2) and 11,000 nM for the resistant C2B reference clone. None of the 62 isolates had cytb codon 268 mutations by either HRM-RTPCR or DNA sequencing. Despite recent ACT failures in the area, there does not appear to be significant atovaquone-proguanil resistance at this time. Although use as a first line agent is not recommended, atovaquone-proguanil remains a safe and effective alternative therapy for MDR Pf in northern Cambodia, and may serve as a stop-gap measure until more effective therapies are developed.

324

ASSOCIATION BETWEEN GENETIC POLYMORPHIMS OF TCR RECEPTOR THE MALARIA VIVAX IN BRAZIL

Marcela Petrolini Capobianco[1], Adriana Antônia Furini[2], Gustavo Capatti Cassiano[1], Valeria Daltibari Fraga[2], Luciana Moran Conceição[2], Claudia Regina Bonini-Domingos[1], Ricardo Luiz Machado[3]

[1]*Universidade Estadual Paulista- Unesp, São José do Rio Preto, Brazil,* [2]*Famerp- Faculdade de Medicina, São José do Rio Preto, Brazil,* [3]*Instituto Evandro Chagas, Ananindeua, Brazil*

In Brazil, the ***Plasmodium vivax*** has been the most prevalent species, accounting for approximately 88% of malaria cases in the Brazilian Amazon region. Polymorphism in genes of molecules involved in immune response may influence the response and consequently the establishment of the parasite. The polymorphism TCRBV3S1 (C/T) has been widely investigated because it seems to significantly affect the repertoire of T cell receptors for modifying the development capacity of an imune response. The aim of this study was to identify the polymorphism, estimate the allele and genotype frequencies and associate these polymorphisms with parasitaemia of the individual.We analyzed 83 blood samples from patients from Goianesia, Para State, Brazil, with vivax malaria diagnosed by molecular biology and thick drop test. DNA samples were amplified by PCR and the resulting amplification fragments were 431bp, subsequently, were digested with the Pvu. Homozygous individuals were identified by the

presence of a single fragment of 431 bp. However, mutants homozygotes for the other allele were identified by the presence of a fragment of 352 bp and the heterozygotes by the presence of two fragments of 352 and 431 bp. All statistical analysis was performed using the R program v 2.11.1 (http://www.r-project.org). Differences in median parasitaemia in relation to genotypes were evaluated using the nonparametric Mann-Whitney test. P values < 0.05 were considered significant. The results for the polymorphism in TCRBV3S1 demonstrate that the most frequente genotype was the TC (45.8%) and the most frequent allele was C (82.5%). Polymorphism tested were in Hard-Weinberg Equilibrium. The parasitaemia ranged from 15 to 70,000 with a mediam of 1,500 parasites per microliter of blood. There was no difference in parasitaemia in relation to TCRBV3S1 genotypes (p = 0.19). No significant association was found between the polymorphisms tested and vivax malaria. The results suggest that genetic variant analyzed in gene segment of the TCR do not affect the functionality of the molecules so that it can interfere with parasitaemia of malaria caused by ***P. vivax***.

325

GENOME SEQUENCING OF *PLASMODIUM OVALE WALLIKERI*

Mary C. Oguike[1], Ifeyinwa Aniebo[2], Ernest D. Bienevente[3], Suzana Campino[4], Taane G. Clark[3], Ozan Gundogdu[3], Colin J. Sutherland[2]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Immunology and Infection Department, London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Department of Pathogen Molecular Biology, London School of Hygiene & Tropical Medicine, London, United Kingdom,* [4]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom*

Plasmodium ovale curtisi and ***P. ovale wallikeri*** are distinct malaria parasites both known to cause liver relapse as seen with ***P. vivax***. This ability to reside in the liver as hypnozoites provides a reservoir for continuous transmission of the parasite which is a threat to malaria control. Although ***P. ovale*** spp often occur in very low parasitaemias and as mixed infections with ***P. falciparum***, they contribute to the malaria burden. Recent evidence suggests that these two ovale parasites are very closely related yet genetically distinct. There is also a clear phenotypic difference between them related to the duration of pre-erythrocytic latency, and as such represents an ideal system in which to identify candidate genes linked to hypnozoisis. We hypothesized that if genome data were available for both both ovale parasite species, new insights into the species barrier between them could be gained using a comparative genomic approach. We attempted the first genome sequence of a ***P. ovale wallikeri*** isolate, derived from an imported case of ovale malaria in the UK, using an Illumina Miseq platform in-house at LSHTM. We generated the first ever partial genome sequence for ***P. ovale wallikeri***, which we will compare with partial published data for ***P. ovale curtisi***. The multicopy extra-chromosomal genomes of the apicoplast and mitochondrion were particularly well represented. These were compared against genome sequence data from other ***Plasmodium*** species, including ***P. falciparum***, ***P. knowlesi*** and ***P. vivax***.

326

ASSOCIATIONS OF ANTIBODY RESPONSES THE PROTECTION FROM CLINICAL MALARIA IN A HIGHLAND KENYA AREA OF LOW TRANSMISSION

Karen E. Hamre[1], Bartholomew Ondigo[2], George Ayodo[2], John Vulule[2], Chandy C. John[3]

[1]*University of Minnesota, Minneapolis, MN, United States,* [2]*Kenya Medical Research Institute, Kisumu, Kenya,* [3]*University of Minnesota, Minneapoils, MN, United States*

Establishing markers of protection in low transmission settings is important in determining how to assess risk in these less-immune populations. It is inherently difficult to predict correlates of protection in low transmission settings due to the limited number of cases, but our longitudinal prospective study allowed for this testing of antibody responses to multiple antigens over a time period of 6 years. We performed a nested case-control study with 3 controls matched to every case on village and age. Plasma samples from a blood collection that targeted the entire cohort performed from April-June 2007 were used to test antibody responses to 11 antigens (10 using Multiplex assay, 1 using enzyme-linked immunosorbant assay). Cases were identified as having a measured fever or reported fever or headache in the presence of ***Plasmodium falciparum*** malaria detected by microscopy from the Ministry of Health dispensary-based surveillance performed from June 2007-June 2013. Controls were followed for the same time period as cases without detection of clinical malaria. Conditional logistic regression performed on laboratory results of 620 plasma samples (155 cases, 465 controls) identified 2 antigens where a positive antibody response, defined as >= 1 arbitrary unit, was statistically significantly associated with protection from clinical malaria over a 6 year period in a highland Kenya area with unstable malaria transmission. Specifically, subjects whom elicit a positive response to GLURP-R2 have a 42% decrease in odds of developing clinical malaria compared to subjects who do not elicit a positive response over this time period (OR = 0.58, 95% CI: 0.37, 0.90, p=0.016). Similarly, subjects whom elicit a positive response to LSA-NRC have a 42% decrease in odds of developing clinical malaria (OR= 0.58, 95% CI: 0.38, 0.89, p=0.013). Identifying markers of protection in less-immune individuals are important for future vaccine development as malaria control efforts continue to increase, transmission will continue to decrease, leaving many populations living in transmission settings similar to our highland cohort.

327

MEMORY CD4 T CELL ACTIVATION IN CHRONIC MALARIA INFECTION

Samad Ibitokou, Brian E. Dillon, Michael M. Opata, Robin Stephens

University of Texas Medical Branch, Galveston, TX, United States

Development of long-lived memory T cells is the cellular basis for vaccination. However, the potential for survival of protective effector memory T cells (Tem) in malaria is not well understood. It is well-documented that activated effector cells (Teff) increase glycolysis for proliferation while quiescent memory T cells predominantly rely on fatty acid oxidation for energy generation during homeostatic proliferation. However, Tem don't do homeostatic proliferation and the mechanisms allowing Tem to survive to the memory phase, and yet maintain their protective effector functions, is unknown. To understand the metabolic status regulating survival in Tem during chronic malaria infection, we compared gene expression profiles of ***Plasmodium chabaudi*** MSP-1-specific B5 TCR transgenic Teff and Tmem. Strikingly, we observed up-regulation of the genes involved in lipid biosynthesis, without concomitant upregulation of fatty acid oxidation, in Tem compared to Teff. These data were supported by high lipid content in Tem compared to Teff using Bodipy 409/502 staining by flow cytometry, and by electron microscopy, which nevertheless showed lipid droplets next to active mitochondria. However, the increase in fatty acid synthesis here was not coupled with an increase in mitochondria, suggesting a novel function of fatty acid in effector memory cells other than fatty acid oxidation. To assess whether fatty acid biosynthesis is required for Tem generation or maintenance in chronic malaria infection, we analyze activation and memory cell formation in malaria-specific T cells throughout infection in animals treated with drugs that inhibit fatty acid biosynthesis. Blocking fatty acid synthesis pathway reduces memory T cell survival. These findings will help to understand the metabolic pathways that control generation and maintenance of protective Tem during chronic malaria infection and may suggest new generation metabolic adjuvants for malaria vaccine development.

328

IMPACT OF SEASONAL MALARIA CHEMOPREVENTION IN THE PRODUCTION OF MSP1 THE AMA1 ANTIBODIES IN SENEGAL

Annie W. Abiola

UCAD, Dakar, Senegal

Malaria remains a major disease in many African countries, caused an estimated 243 million cases of clinical malaria and 863 thousand deaths globally 2008. The acquisition of immunity to clinical malaria is usually acquired the first five years of life depending on the intensity of malaria transmission. Nowadays, many strategies such as IPTic /SP are used for prevention in children. Intermittent Preventive Treatment for children (IPTc) against ***Plasmodium falciparum*** malaria is administered at defined intervals curative doses independently of the presence of parasites or symptoms. IPTc could however delay the acquisition of the antibodies which are managed against the malaria to this group of children. In this optics we want to understand the impact of this strategy in kinetics of specific antibodies against malaria on the acquisition of antibody in children living in zone of unstable transmission. This study measure the kinetics of antibodies MSP-119 and AMA-1 by ELISA, which are recombinantes proteins specifically managed against the membrane of ***Plasmodium falciparum***. To evaluate the impact of IPTic /SP on antigenic variation in rural areas of three districts, all children aged 11mths-10years, in Senegal. Our results show that young children under 5 years are the ones who produce most antibodies and this production increases significantly with age (p=0, 0001). Production of AMA-1 antibody is more important (27, 09 %) than MSP-119 antibody (13, 69 %). Control zone produce more antibodies than intervention zone, the PSP is a factor which can modifies the production of antibody. Seroepidemiology can provide key information on malaria transmission for control programmes, when parasite rates are low.

329

LONGITUDINAL CHANGES IN ΓΔ T CELL POPULATIONS FOLLOWING ACUTE MALARIA INFECTION AMONG CHILDREN IN A MALARIA ENDEMIC REGION

Fredrick Lutwama[1], Mayimuna Nalubega[2], Samuel Wamala[2], Lila Farrington[3], Ann Auma[2], Kate Naluwu[2], Kenneth Musinguzi[1], Esther Sikyomu[2], John Rek[2], Michelle Boyle[3], Grant Dorsey[3], Moses Kamya[4], Prasanna Jaganathan[3], Margaret E. Feeney[5]

[1]*Infectious Diseases Institute, Makerere University College of Health Sciences and Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*Department of Medicine, San Francisco General Hospital, University of California, San Francisco, CA, United States,* [4]*Infectious Diseases Research Collaboration and Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda,* [5]*Department of Medicine, San Francisco General Hospital, University of California, and Department of Pediatrics, University of California, San Francisco, CA, United States*

Immune dysregulation caused by ***Plasmodium falciparum*** (Pf) infection may impair the control of malaria infection, but may on the other hand contribute to the clinical immunity that is observed to develop with increasing age. Although others have shown robust expansion of the malaria-responsive Vδ2 subset of γδ T cells during acute infection in previously naïve individuals, we have shown that heavy malaria exposure is associated with loss and dysfunction of these cells, and that this process is associated with tolerance to subsequent Pf infection. Our aim was to investigate the impact of age on changes in the absolute numbers of peripheral blood γδ T cells following an acute malaria episode in Tororo, Uganda, a setting of high malaria endemicity. Children in 3 age groups (1-3yrs, 4-6yrs, 7-10yrs) who presented with acute febrile malaria were enrolled from a larger cohort study, and a blood sample was drawn at enrollment. Participants were treated for malaria and follow-up blood draws were performed at 3, 6, and 9 weeks. Cells were stained with antibodies to CD3, CD4, Vδ2, and Vγ9, and acquired on a BD Accuri flow cytometer. To date, 41 children have been enrolled in this study (1-<4 yrs, n=12; 4-<7 yrs, n=15; 7-10 yrs, n=14). Overall, we observed a significant increase in the absolute count of Vδ2 (p=0.001), Vγ9 (p<0.001) and Vδ2+Vγ9+ T cells (p=0.004) between the acute malaria episode and at 3 weeks follow-up. However, we observed significantly greater induction of Vδ2+ T cells among children aged 1-<4 compared with children 7-10 years of age (P<0.001 utilizing repeated measures generalized estimating equations controlling for age and Day 0 parasite density.) This suggests that Vδ2 T cells significantly expand in the peripheral circulation following acute malaria infection, but there are age-associated differences in this expansion in heavily exposed children. These data are consistent with the hypothesis that alterations in Vδ2 T cell function may play a role in the development of clinical immunity to malaria.

MECHANISMS UNDERLYING THE INDUCTION OF IL-27-PRODUCING CD4⁺ T CELLS DURING IMMUNE RESPONSES AGAINST INTRACELLULAR PATHOGENS

Henrietta Terko Doe, Daisuke Kimura, Mana Miyakoda, Masoud Akbari, Kazumi Kimura, Katsuyuki Yui

Nagasaki University, Nagasaki, Japan

CD4⁺ T cells play critical roles in protection against blood-stage malaria. During malaria infection, there is a coordinated upregulation of the integrins CD11a and CD49d. The upregulation these integrins can be used as surrogate markers to directly identify ***Plasmodium***-specific CD4⁺ T cells responding to blood stage infection. We have reported that during ***Plasmodium berghei*** ANKA (PbA) infection, a subpopulation of malaria-specific CD4⁺ T cells produce IL-27, a heterodimeric regulatory cytokine of the IL-12 family composed of p28 and EBI3. These IL-27-producing CD4⁺ T cells, which we have designated as Tr27 cells, inhibit IL-2 production as well as clonal expansion of effector CD4⁺ T cells, and express the T cell inhibitory receptors LAG-3 and PD-1. In this study, we investigated the conditions under which Tr27 cells are induced. First, we infected C57BL/6 mice with various malaria strains such as ***P. yoelii***, ***P. chabaudi***, ***P. vinckei***, as well as ***Listeria monocytogenes***. Specific CD4⁺ T cells responses during infection were investigated using $CD11a^{hi}CD49d^{hi}$ as markers for specific T cells by flow cytometry. Specific CD4⁺ T cells from all the ***Plasmodium***-infected mice expressed the inhibitory receptors LAG-3 and PD-1, whereas those from ***Listeria***-infected mice did not. ELISA results revealed that IL27p28 was produced by CD4⁺ T cells from ***Plasmodium***-infected mice but not by CD4⁺ T cells from ***Listeria***-infected mice, suggesting that Tr27 cells are induced in only ***Plasmodium*** species. MyD88 and TRIF are critical adaptor molecules in toll-like receptor (TLR) signalling. So we examined whether TLR signaling is critical for the induction of Tr27 cells. CD4⁺ T cells from both MyD88 KO and TRIF KO mice infected with PbA produced IL-27. Finally, we examined the involvement of LAG-3 and PD-1 signalling in induction of Tr27 cells. CD4⁺ T cells from mice treated with anti-PDL-1 and anti-LAG-3 mAbs produced IL-27p28 at levels lower than untreated mice during infection with PbA. Taken together, our results suggest that Tr27 cells develop during infection with ***Plasmodium*** species in a manner independent of TLR signalling but possibly dependent on LAG-3/PD-1 signalling.

331

THE EFFECT OF *IN UTERO* EXPOSURE THE *PLASMODIUM FALCIPARUM* MALARIA ON CORD BLOOD T REGULATORY CELLS THE CYTOKINES IN KENYAN INFANTS

Sidney O. Ogolla[1], Ibrahim I. Daud[1], Stephen Amolo Asito[2], Carie Coleman[3], Peter O. Sumba[4], Kenneth Simbiri[3], Collins Ouma[5], Robert Ploutz-Snyder[6], Arlene Dent[7], Rosemary Rochford[3]

[1]*SUNY Upstate/Kemri, Kisumu, Kenya,* [2]*Jarmogi Oginga Odinga University of Science and Technology, Bondo, Kenya,* [3]*SUNY Upstate Medical University, Syracuse, NY, United States,* [4]*Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya,* [5]*Maseno University, Maseno, Kenya,* [6]*Universities Space Research Association, Houston, TX, United States,* [7]*Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States*

It is well documented that infants born to mothers with placental malaria are more susceptible to ***Plasmodium falciparum*** malaria infections, other infections during infancy as well as impaired immune responses to vaccines. Immunologic differences are also evident in children born to mothers with placental malaria such as increased frequency of regulatory CD4+ T-cells (Tregs) in cord blood and alterations in cord blood cytokine levels. However, these previous studies evaluated malaria exposure based on placental malaria infection at parturition. In this study, we asked whether malaria exposure during pregnancy altered the cord blood cellular immune profiles. Clinical and parasitological data were collected from the expectant women during all their ANC visits and at delivery to determine their malaria histories during gestation. Immediately after delivery, cord blood was collected and processed immediately. CBMC were stained using a panel of monoclonal antibodies to identify ***ex vivo*** Treg cells by flow cytometry. The concentrations of circulating pro-inflammatory and anti-inflammatory cytokines and chemokines were evaluated in cord blood plasma by Luminex bead based assay. The frequency of CD4+ Treg cells was increased in cord blood of malaria exposed infants compared to unexposed infants. These Treg cells mainly expressed the naïve phenotype (CD45RA+). No difference in the frequency of CD4+ Treg cells in cord blood of infants who were exposed to malaria either early or late in gestation was observed. Cord blood from Kenyan infants had increased levels of pro-inflammatory cytokines TNF-α, IL-8, IL-2R and chemokines RANTES and MIP-1β compared to North American cord blood. Exposure to malaria ***in utero*** also results in the expansion of CD4+Treg cells in cord blood and may contribute to the increased susceptibility to infections as observed in children born to mothers with placental malaria.

332

IMPACT OF *IN UTERO* EXPOSURE THE MALARIA ON VΔ2 T CELL RESPONSES

Ann Auma[1], Fredrick Lutwama[1], Mary Prahl[2], Tara McIntyre[2], Sam Wamala[1], Kate Naluwu[1], Mayimuna Nalubega[1], Kenneth Musinguzi[1], Esther Sikyomu[1], Moses Kamya[1], Grant Dorsey[2], Prasanna Jagannathan[2], Margaret E. Feeney[2]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*University of California, San Francisco, San Francisco, CA, United States*

Placental malaria remains a major cause of maternal and child morbidity in sub-Saharan Africa, and there is evidence that ***in utero*** exposure to malarial antigens leads to increased susceptibility to malaria in early childhood. The Vδ2 subset of $\gamma\delta$ T cells possess intrinsic reactivity to malaria antigens and may represent an important anti-malarial effector mechanism, but we have shown that repeated exposure to malaria in early childhood is associated with loss and dysfunction of this subset. Our aim was to investigate the impact of ***in utero*** exposure to malaria on Vδ2 T cells at birth, leveraging samples from a recently initiated double-blind placebo-controlled trial of antimalarial chemoprevention during pregnancy in Tororo, Uganda, a high endemicity setting. 300 pregnant women were enrolled at 12-20 weeks gestation and randomized to 1) 3-dose sulfadoxine-pyrimethamine (SP) (standard of care, given at 20, 28, and 36 gestational weeks); 2) 3-dose dihydroartemisinin-piperaquine (DP). 3) Monthly DP. Upon delivery, maternal peripheral blood, placental blood, and placental tissue were obtained to classify current or prior ***in utero*** exposure, and absolute counts of cord blood Vδ2 T cells were enumerated using flow cytometry. To date, 143 women have delivered; all women will have delivered by May 2015. Of 138 deliveries after 28 weeks gestation, 5.8% had either a positive placental (n=7) and/or maternal peripheral blood smear (n=6), with placental histopathologic diagnosis currently being performed. Compared to children born to mothers without a positive peripheral or placental blood smear at the time of delivery, malaria-exposed infants had significantly higher absolute counts of CD3+ Vδ2 cells in cord blood (21.69 vs 78.32 Vδ2 cells/μl, $p<0.001$) at birth. This suggests that ***in utero*** exposure to malaria may lead to expansion of Vδ2 T cells at birth. Results will be updated upon completion of the trial and will include chemoprevention assignments and histopathologic diagnoses.

333

ANTIBODY RESPONSES THE *PLASMODIUM FALCIPARUM* AND *P. VIVAX* AND PROSPECTIVE RISK OF *PLASMODIUM* INFECTION POSTPARTUM

Alistair McLean[1], Machteld Boel[2], Rose McGready[2], Julie Simpson[3], David Narum[4], Takafumi Tsbuoi[5], James Beeson[1], Francois Nosten[2], Freya Fowkes[1]

[1]*Burnet Institute, Melbourne, Victoria, Australia,* [2]*Shoklo Malaria Research Unit, Mae Sot Tak, Thailand,* [3]*Centre for Epidemiology and Biostatistics, University of Melbourne, Melbourne, Victoria, Australia,* [4]*Malaria Vaccine Development Branch, National Institute of Allergy and Infectious Diseases/ National Institutes of Health, Rockville, MD, United States,* [5]*Malaria Research Unit, Cell-Free Science and Technology Research Centre, Ehime University, Ehime, Japan*

Pregnant women are more susceptible to malaria due to alterations in the immune response and the appearance of pregnancy-specific parasites, but how these immunological changes influence malaria risk in the postpartum period is unknown. A cohort study at the Thai-Myanmar border, found that postpartum women experienced less ***Plasmodium falciparum*** infections, but more ***P. vivax*** infections, compared to non-pregnant controls. To investigate the immunological basis behind these observations we measured IgG levels to ***P. falciparum*** antigens (PfVAR2CSA-DBL5, PfAMA1, PfEBA-140, PfEBA-175, PfMSP2, PfRh2, PfCSP, PfDBL-alpha) and ***P. vivax*** antigens (PvAMA1, PvMSP1-19, PvDBP, PvCSP) at enrolment (delivery date for postpartum women) and every four weeks thereafter over 12 weeks in 201 postpartum and 201 non-pregnant individuals paired by residence, age and enrolment date. To investigate the association between postpartum status, antibody levels and the time to the first microscopically confirmed species-specific infection, a Cox-proportional hazards regression was performed, modelling antibodies as time varying exposures. Higher levels of antibodies against most ***P. falciparum*** targets were associated with increased risk of ***P. falciparum*** infection in postpartum women (Hazard Ratio (HR) range 1.55-2.83; p range <0.001-0.043) suggesting that antibodies are indicative of a history of exposure. In contrast antibodies against ***P. vivax*** targets were not associated with an increased risk of ***P. vivax*** infection in postpartum women (HR range 1.06-1.18; p range 0.03-0.63). Similar associations were seen in control women suggesting that antibodies do not play a role in the differential susceptibility to malaria in the postpartum period in this population. This study provides a comprehensive analysis of antibodies towards two ***Plasmodium*** spp. and contributes to our understanding of the association between antibodies and risk of infection postpartum. Further investigations examining antibody-independent mechanisms of the differential susceptibility of malaria in the postpartum period are warranted.

334

NATURALLY ACQUIRED IMMUNE RESPONSE TO THE ICAM1 BINDING PF11_0521_DBL2B IS ASSOCIATED WITH REDUCED RISK OF HIGH DENSITY *PLASMODIUM FALCIPARUM* MALARIA IN YOUNG PAPUA NEW GUINEAN CHILDREN

Sofonias K. Tessema[1], Digjaya Utama[1], Anthony N. Hodder[1], Clara S. Lin[1], Enmoore Lin[2], Benson Kiniboro[2], Peter M. Siba[2], Andrew Oleinikov[3], Ivo Mueller[1], Alyssa E.[1]

[1]*The Walter and Eliza Hall Institute, Parkville, Australia,* [2]*Vector Borne Diseases Unit, Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea,* [3]*Charles E. Schmidt College of Medicine, Florida Atlantic University, Boca Raton, FL, United States*

Cerebral malaria is characterized by adhesion of ***Plasmodium falciparum*** infected erythrocytes to the cerebral microvasculature. ICAM-1 has been proposed as the key host adhesion receptor in the brain for infected erythrocytes causing cerebral malaria. The PfEMP1 variant PF11_0521_DBL2β has been shown to bind host ICAM1 receptor. We examined the association of IgG responses to PF11_0521_DBL2β with subsequent risk of ***P. falciparum*** malaria at enrolment in 187 children, aged 1-3 years, compared to that for four domains from two distinct PfEMP1 variants (PF13_0003_NTS-DBL1; PF13_0003_CIDRγ; PFL1955w_NTS-DBL and PFL1955w_CIDR). Overall, there was a low prevalence of antibodies to all PfEMP1 proteins analysed in this study (9-32%) likely due to the young age of the participants. Seroprevalence for the NTSDBL and CIDR domains of the group B/C variant, PFL1955w was particularly low in these young children (10% and 9% respectively). However, seroprevalence of NTSDBLα1 and CIDRγ domains of the group A variant PF13_0003 was relatively higher (24% and 28% respectively), as was the seroprevalence of the ICAM1 ligand PF11_0521_DBL2β (32%). Antibodies to the three group A variant domains were positively associated with concurrent ***P. falciparum*** infection. Antibodies specific to PF11_0521_DBL2β were associated with protection against high-density (≥10000 parasites/μl) ***P. falciparum*** malaria (IRR = 0.63, $p = 0.007$) independent of age and exposure. These results indicate that PF11_0521_DBL2β antibodies provide functional immunity against high-density malaria in young PNG children. The results highlight the importance of parallel comparisons of multiple PfEMP1 domains in identifying serological markers of protection and support the further development of this antigen as a malaria vaccine candidate.

IMPORTANCE OF VAR2CSA ANTIBODIES TO *PLASMODIUM FALCIPARUM* IN A LOW TRANSMISSION AREA

Yukie M. Lloyd[1], Naveen Bobbili[1], Vanda Koko[1], Elise P. Ngati[1], Rui Fang[1], John J. Chen[1], Ali Salanti[2], Rose Leke[3], Diane W. Taylor[1]

[1]*University of Hawaii at Manoa, Honolulu, HI, United States,* [2]*University of Copenhagen, Copenhagen, Denmark,* [3]*University of Yaoundé* [1]*, Yaoundé, Cameroon*

In areas where ***Plasmodium falciparum*** is transmitted, infected erythrocytes (IE) accumulates in the placenta causing placental malaria (PM), thus increasing the risk of maternal anemia and low birth-weight (BW) babies. Maternal antibodies (Ab) to VAR2CSA have been shown to play a key role in reducing the severity of PM in high-transmission areas. However, their importance in reducing PM in low-transmission areas is less clear. In this study, plasma samples collected at delivery from 1, 377 women in Yaoundé, Cameroon (low transmission) with (PM+) and without PM (PM-) were measured by Luminex for Ab against full-length VAR2CSA (FV2) and its 6 DBL domains. Samples were collected prior to implementation of intermittent preventative treatment (IPT) and insecticide-treated bed nets (ITN), allowing us to study natural acquisition of Ab to VAR2CSA. Ab levels to FV2 and each of the domains were determined and correlated with presence of PM, baby weight, and anemia. Furthermore, repertoire of Ab to the 6 DBL domains was compared with gravidity and by PM status. In this low transmission area, results showed an association between PM+ and lower BW ($p<0.0001$) and increased anemia ($p<0.0001$), but presence of Ab to FV2 did not improve the outcome. PM+ women produced more Ab against FV2 than PM- women ($p<0.0001$). Ab levels increased approximately two-fold with gravidity (G1-G6+). Moreover, the number of DBL domains recognized by Ab was consistently higher in PM+ (G1=3.2 domains to ≥G6 = 4.2 domains) than PM- women (G1=1.6 domains to ≥G6 =2.9 domains). Therefore, a larger DBL repertoire was found in PM+ than PM- women. Thus, Ab levels to FV2 and the breadth of Ab response to DBL domains was associated with infection rather than protection from PM. These results differ significantly from those reported for high transmission areas and need be taken into consideration in vaccine development and creating prediction models based on Ab levels.

336

PROTEOMIC PREDICTORS OF *PLASMODIUM FALCIPARUM* SPECIFIC IGG ANTIBODY RESPONSES IN AN AREA OF INTENSE SEASONAL MALARIA TRANSMISSION

Eugene Liu[1], Jeff Skinner[1], Aissata Ongoiba[2], Boubacar Traore[2], Philip L. Felgner[3], Peter Crompton[1]

[1]*National Institutes of Health, Bethesda, MD, United States,* [2]*Mali International Center of Excellence in Research, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [3]*University of California, Irvine, Irvine, CA, United States*

During an infection some antigens of the infecting pathogen elicit higher antibody responses than others, but the factors underlying this heterogeneity are unclear. In this study we sought to understand the factors underlying differential antibody reactivity to natural ***Plasmodium falciparum*** infections. Using a protein microarray containing 1087 ***P. falciparum*** proteins, we profiled ***P. falciparum***-specific IgG responses in plasma samples collected from 267 Malian subjects aged 3 months to 25 years exposed to intense seasonal malaria transmission every year. We examined the relationship between the level of ***P. falciparum*** antigen-specific IgG levels and a number of features of the antigens on the array including their subcellular location, presence of MHC class II epitopes, protein abundance, molecular weight, presence of human orthologs, and degree of polymorphism. We found that IgG reactivity was significantly higher to extracellular and plasma membrane proteins, proteins with MHC class II epitopes, highly abundant proteins and highly polymorphic proteins; whereas IgG reactivity was significantly lower to proteins with human orthologs. Multiple regression analysis revealed that extracellular location independently predicted higher IgG reactivity, whereas location in the plasma membrane predicted low IgG reactivity in highly conserved membranes, and conversely high reactivity in highly polymorphic membranes. We observed the same findings in our cohort the following malaria season. These results provide insights into the proteomic features of antigens that underlie the variation in antibody responses during a natural infection, information that could inform vaccine strategies.

337

MEROZOITE SURFACE PROTEIN-1 FROM *PLASMODIUM FALCIPARUM* IS A MAJOR TARGET OF OPSONIZING ANTIBODIES IN INDIVIDUALS WITH ACQUIRED IMMUNITY AGAINST MALARIA

Anja S. Jäschke[1], Boubacar Coulibaly[2], Edmond J. Remarque[3], Hermann Bujard[4], Christian Epp[1]

[1]*Centre for Infectious Diseases - Parasitology, University Hospital Heidelberg and German Centre for Infectious Diseases, Heidelberg, Germany,* [2]*Centre de Recherche en Santé de Nouna, Nouna, Burkina Faso,* [3]*Biomedical Primate Research Centre, Department of Parasitology, Rijswijk, Netherlands,* [4]*Zentrum für Molekulare Biologie der Universität Heidelberg, Heidelberg, Germany*

Malaria, in particular when caused by ***Plasmodium falciparum***, represents a huge medical problem in many countries. Individuals living in malaria endemic regions can acquire immunity against this often deadly disease with increasing numbers of survived infections. This premunition is evidently mediated by serum antibodies controlling levels of blood stage parasites. Antibodies against various ***P. falciparum*** antigens were shown to interfere with parasite growth by inhibiting red blood cell invasion. In addition, increasing evidence points towards an important role of opsonizing antibodies, which bind to the cell-free merozoites and recruit immune effector cells such as macrophages or neutrophil granulocytes. The merozoite surface protein-1 (MSP-1) is a target of antibodies acquired during natural infection. Antibodies to MSP-1 can inhibit parasite growth and have been associated with protection against malaria in several epidemiological studies, making MSP-1 a promising vaccine candidate. Here we use the antibody-dependent respiratory burst (ADRB) assay to characterize serum antibodies from semi-immune individuals from Burkina Faso. While a few sera were identified, which directly inhibit growth of ***P. falciparum*** blood stage parasites ***in vitro,*** IgG from almost all individuals clearly mediated the activation of neutrophils. The level of neutrophil activation correlates with antibody levels to MSP-1 and affinity-purified MSP-1 antibodies mediate ADRB activity. Furthermore, immunization of non-human primates with recombinant full-length MSP-1 induces antibodies, which efficiently opsonize ***P. falciparum*** merozoites. Reversing the function by pre-incubation with recombinant antigens allows us to quantify the contribution of MSP-1 to the anti-parasitic effect of serum antibodies and to map MSP-1 subunits primarily recognized by opsonizing antibodies. Our data suggest that MSP-1 is an important target of opsonizing antibodies acquired during natural exposure to malaria. Induction of opsonizing antibodies might be a crucial effector mechanism for malaria vaccines based on full-length MSP-1.

338

TACI IS NEEDED THE CONTROL *PLASMODIUM YOELII* PARASITEMIA THE ANTI-*P. YOELII* IGG3 ANTIBODY PRODUCTION

Marcela Parra, Xia Liu, Amy Yang, Windy Allman, Sheldon Morris, Mustafa Akkoyunlu

Food and Drug Administration, Silver Spring, MD, United States

The transmembrane activator and calcium-modulator and cyclophilin ligand receptor (TACI) is involved in B-cell survival, antibody switching and plasma cell generation. TACI expression is severely impaired in murine and human newborns as compared to adults. To assess the role of TACI in murine malaria infections, TACI-KO and the wild type (WT) C57BL/6 mice were infected (i.p) with 1 million ***Plasmodium yoelii*** (Py) parasites. After the infection, the parasitemia levels were significantly elevated in TACI-KO mice (61.8% at day 18) compared to WT mice (11.1% at day 11), and parasitemia clearance was substantially delayed in the TACI-KO (27 days) relative to WT control (18 days). In addition, to investigate the impact of TACI on anti-Py antibody production, sera from WT and TACI-KO mice were tested by ELISA and Western Blot (WB) assay. The ELISA results showed that the TACI-KO mice produce less anti-Py IgG-antibodies than the WT mice, and the WB results showed that TACI-KO mice were impaired in the anti-Py IgG3 production but not the WT mice. Several IgG3 specific bands (49, 70-190 kDa) detected in the sera of Py infected WT mice were absent in the sera of infected TACI-KO mice. (IgG3 levels following infection have been associated with clinical immunity to malaria). Importantly, measurement of the levels of the B cell activating factor (BAFF- a TACI ligand) revealed that serum BAFF concentrations were higher in TACI-KO mice than the WT mice after Py infection. Conclusion: The TACI receptor plays a key role in the control of Py NL infections, and it may mediate anti-Py antibody isotype production and BAFF secretion

339

RESPONSES THE GAMETOCYTE-SPECIFIC *PLASMODIUM FALCIPARUM* ANTIGENS DETECTED BY PROTEIN MICROARRAY MAY IDENTIFY MARKERS OF GAMETOCYTE EXPOSURE

Jeff Skinner[1], Chiung-Yu Huang[2], Michael Waisberg[3], Philip L. Felgner[4], Ogobara K. Doumbo[5], Boubacar Traore[5], Peter D. Crompton[1], Kim C. Williamson[6]

[1]*National Institutes of Health, Rockville, MD, United States,* [2]*Johns Hopkins University, Baltimore, MD, United States,* [3]*University of Virginia, Charlottesville, VA, United States,* [4]*University of California Irvine, Irvine, CA, United States,* [5]*University of Bamako, Bamako, Mali,* [6]*Loyola University, Chicago, IL, United States*

Malaria elimination efforts would benefit from vaccines that block transmission of ***Plasmodium falciparum*** gametocytes from humans to mosquitos. A clear understanding of gametocyte-specific antibody responses in exposed populations could help determine if transmission-blocking vaccines (TBV) would be boosted by natural gametocyte exposure, and could also inform the development of serologic tools to monitor gametocyte exposure in populations targeted for malaria elimination. We reanalyzed previously published data from microarrays containing 1,204 ***P. falciparum*** proteins and probed with plasma from Malian children and adults collected before and after the 6-month malaria season. Using publicly available proteomic data we identified 91 proteins as gametocyte-specific and 69 proteins not expressed by gametocytes. The overall breadth and magnitude of gametocyte-specific IgG responses increased during the malaria season, although they were consistently lower than IgG responses to non-gametoctye antigens. Notably, IgG specific for the TBV candidates Pfs48/45 and Pfs230 increased during the malaria season. Additionally, IgG specific for the gametocyte proteins Pfmdv1, Pfs16, PF3D7_1346400 and PF3D7_1024800 were detected in nearly all subjects, suggesting that seroconversion to these proteins may be a sensitive marker of gametocyte exposure. These findings suggest that TBV-induced immunity would be boosted through natural gametocyte exposure, and that antibody responses to particular antigens may reliably indicate gametocyte exposure.

340

POLYMORPHISMS IN CYTOKINE GENES CAN INFLUENCE ON ANTIBODY PRODUCTION AGAINST PVDBP IN BRAZILIAN PATIENTS WITH MALARIA VIVAX?

Adriana A. Furini[1], Gustavo C. Cassiano[2], Marcella P. Capobiano[2], Marinete M. Povoa[3], Luzia H. Carvalho[4], Flora S. Cano[4], Valeria D. Fraga[1], Luciana M. Conceicao[1], Ricardo L. Machado[3]

[1]*Faculdade de Medicina, São José do Rio Preto, Brazil,* [2]*Universidade Estadual Paulista, São José do Rio Preto, Brazil,* [3]*Instituto Evandro Chagas, Ananindeua, Brazil,* [4]*Instituto Rene Rachoud, Fiocruz/MG, Belo Horizonte, Brazil*

In Brazil, the ***Plasmodium vivax*** has been the most prevalent species, accounting for approximately 88% of malaria cases in the Brazilian

Amazon region. A DBP (Duffy Binding Protein) appears to be a strong vaccine candidate. The aim of this study were evaluate SNPS of the TNF-α gene, in the IL-10 and IFN-γ can interfere with blood levels of antibodies to PvDBP. We analyzed 84 samples from patients from Goianésia of Pará city, Pará State, Brazil, with vivax malaria by microscopy and confirmed by molecular analysis. Three SNPs in the promoter region of the TNF-α gene (-238 G / A, -308 G / A and -1031 T / C) and two IL-10 (-819C/T and - 592C/A), one IFN-γ (+874A/T) gene were genotyped by PCR-RFLP e ASO-PCR. Standardized ELISA protocol was used to measure IgG total against PvDBP. The nonparametric Kruskal-Wallis test was used to determine the differences in the antibody levels in relation to the genotypes. Sixty two (73,8%) patients produced IgG antibodies against PvDBP. All polymorphisms tested were in Hardy-Weinberg equilibrium (p-value > 0.05). For the polymorphism at position - 1031 TT in the TNF-α gene, the TT genotype had the highest frequency (51%), at position -308GG, the genotype GG (80,6%) and position -238 was GG (88,7%) in the patients with antibody titers against PvDBP. For the same group, the most common genotypes of SNPs in the IL-10 were CT (56,5%) to the position-819, e and CA (56,5%) to - 592. The most common genotypes of SNPs in the IFN-γ +874 were AA (52,8%).No significant differences were observed in the frequencies of genotypes among individuals who were positive or negative for IgG antibodies against PvAMA-1.However, it was significant association (p = 0.03) for individuals with CGG haplotype of the TNF- α (-1031, -308, -208). This study indicated that individuals with a TNF-α CGG haplotype are more likely to possess antibodies to PvDBP and genetic polymorphisms may play a relevant role in the regulation of the antibody response in this population. Although no association observed in this study may not entirely exclude their possible link with malaria disease pathogenicity/severity.

PERIPHERAL THE PLACENTAL BIOMARKERS IN WOMEN WITH PLACENTAL MALARIA: A SYSTEMATIC REVIEW

Esmée Ruizendaal[1], Elisabeth van Leeuwen[2], Henk D. Schallig[1], Petra F. Mens[1]

[1]*KIT Biomedical Research, Royal Tropical Institute, Amsterdam, Netherlands,* [2]*Academic Medical Centre, Gynaecology and Obstetrics, Amsterdam, Netherlands*

Placental malaria (PM) causes significant morbidity in mothers and infants. Diagnosis of PM during pregnancy is problematic due to placental sequestration of parasites. To circumvent this problem, the immunological response in pregnant women to a malaria infection could potentially serve as an indicator of ongoing PM. We aimed to identify potential host biomarkers that can indicate PM infection caused by ***Plasmodium falciparum*** by performing a systematic review of the literature. The databases of PubMed, Embase and the Cochrane Library were searched using specific search terms. This search resulted in 2424 records, of which 47 were relevant. Both studies on peripheral and placental markers were included in our review. Most studies measured biomarkers at time of delivery and most focused on inflammatory markers. A trend was observed for increased peripheral levels of IL-10 and TNF-α in PM positive women at delivery, but due to heterogeneity a meta-analysis could not be performed. Although many other biomarkers were studied, of which several showed significant differences between PM positives and negatives, a few were considered to be of greater interest. These were inflammatory markers TNF-R2, CXCL-13, C5a, and suPAR, a lipid metabolism marker APO-B and a marker of angiogenesis sFlt-1; each of these had additional proof of an association with (placental) malaria or its detrimental effects. Although differences in design and test methods limited firm conclusions on potential biomarkers, it is unlikely that a single biomarker will result in a high enough sensitivity and specificity to detect PM. Therefore, it is proposed to study combinations of multiple biomarkers involved in different pathophysiological pathways of PM. Furthermore, as the majority of published studies tested biomarker levels only at delivery, more longitudinal cohort studies will be necessary to inform on the natural course of biomarker levels in pregnant women, as well as fluctuations during PM.

342

ASSESSING SEROLOGICAL RESPONSES THE MOSQUITO SALIVARY GLAND GSG6 PROTEIN AS A MARKER OF EXPOSURE THE MALARIA VECTORS IN A REGION OF DECLINING TRANSMISSION IN SOUTHERN ZAMBIA

Ben Katowa[1], Tamaki Kobayashi[2], Harry Hamapumbu[1], Jennifer Stevenson[1], Douglas Norris[2], Bruno Arca[3], Raffaele Ronca[4], Philip E. Thuma[1], David Sullivan[2], Clive Shiff[2], William J. Moss[2]

[1]*Macha Research Trust, Choma, Zambia,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Sapienza University, Rome, Italy,* [4]*Federico II University, Naples, Italy*

Various methods for measuring exposure to malaria vectors are available. Human landing catches are the gold standard for quantifying vector exposure but are less accurate for estimating the entomological inoculation rate (EIR) in low transmission settings because of the large sample size required to obtain precise estimates. Serologic responses to mosquito salivary proteins may provide an alternative method to estimate vector exposure in low transmission settings. An enzyme immunoassay (EIA) to measure IgG antibodies to ***Anopheles gambiae*** salivary protein gSG6 was performed using both gSG6-1P peptide and recombinant gSG6 protein in a region of declining malaria transmission in Choma District, Southern Province Zambia. In this setting, a single rainy season, lasting from approximately December through March, is followed by a cool, dry season from April to July, and a hot, dry season from August to November. The malaria vector population, consisting of Anopheles arabiensis, peaks during the rainy season. The parasite prevalence as measured by active case detection using a rapid diagnostic test was <1% between 2009 and 2013. 152 blood samples were collected from 92 individuals participating in a longitudinal cohort study in June 2013, December 2013 and June 2014. The median age was 23 years (IQR: 4, 74) and 47% were female. The assay using recombinant protein performed better than the assay based on gSG6 peptides. When restricted to 16 participants with complete visits at three time points, the mean EIA optical density (OD) values were 0.193, 0.159 and 0.191 at June 2013, December 2013 and June 2014 respectively. The EIA OD in December 2013 was significantly lower than the EIA OD value in June 2013 (p=0.005). The higher OD values observed in June suggest increased exposure to anopheline mosquitoes during the prior rainy season, with a reduction in detectable antibodies by the end of the dry season. These results suggest that the EIA using recombinant gSG6 protein can be used to assess exposure to malaria vectors in a low transmission setting approaching malaria elimination.

343

NEW ANSWERS THE HOW IMMUNITY IN MALARIA IS FORMED: DEVELOPMENT OF *PLASMODIUM FALCIPARUM* SPECIFIC B-CELLS DURING THE FIRST YEAR OF LIFE

Allan Lugaajju[1], Reddy Sreenivasulu B[2], Caroline Rönnberg[2], Mats Wahlgren[2], Fred Kironde[1], Kristina E. Persson[3]

[1]*School of Biomedical Sciences, College of Health Sciences, Makerere University, Kampala, Uganda,* [2]*Microbiology, Tumor, and Cell Biology, Karolinska Institutet, Stockholm, Sweden,* [3]*Microbiology, Tumor, and Cell Biology, Karolinska Institutet and Department of Laboratory Medicine, Lund University, Stockholm, Sweden*

Plasmodium falciparum malaria is still a major health threat in endemic areas especially for young children. While it is recognized that antibody immunity plays an important role in controlling the disease, knowledge of the mechanisms of sustenance and natural boosting of immunity is very limited. Before, it has not been possible to investigate malaria specific B-cells in flow cytometry, making it difficult to know how much of a B-cell

response is due to malaria, or how much is due to other immunological stimulators. In this study, we have developed a new technique using quantum dots to be able to investigate ***P. falciparum*** specific B-cells directly in fresh/frozen PBMC samples, something that has not been done before. To start with, we compared immune and non-immune individuals and found around 20% of the CD19-positive cells to be specific for ***P. falciparum*** in immune samples, with the highest levels in ongoing infections. We then used this technique to study the development of malaria immunity during infancy from the time of delivery with repeated sampling up to 10 months of age, in combination with studies of the response in the mothers, in a study performed in 150 mother-baby pairs in Uganda. We see large differences in development of immunity correlating with changes in CD27-positive and FCRL4-positive ***P. falciparum*** specific cells. This gives new insights into how immunity against malaria is formed, something that is important to know for creation of a vaccine or in forming new medications.

344

DIRECT COST OF SEVERE MALARIA MANAGEMENT IN PEDIATRIC HOSPITAL OF MBUJIMAYI, DEMOCRATIC REPUBLIC OF CONGO

Oshwa B. Mbalabu[1], Thierry L. Bobanga[2], Solange B. Umesumbu[3], Jean Caurent Mantshumba[4], Evariste K. Tshibangu[5]

[1]*University of Mbujimayi, Pediatric Department, Faculty of Medicine, Mbuji-Mayi, Democratic Republic of the Congo,* [2]*University's Clinics of Kinshasa, Tropical Medicine Department, Kinshasa, Democratic Republic of the Congo,* [3]*Operational Research Service, National Malaria Control Policies, Kinshasa, Democratic Republic of the Congo,* [4]*National Program Organisation-Malaria/World Health Organization, Kinshasa, Democratic Republic of the Congo,* [5]*Faculty of Medicine, University of Mbujimayi, Mbuji-Mayi, Democratic Republic of the Congo*

Leading cause of morbidity and mortality of the Congolese child, malaria especially severe is so much a source of the economic losses, both direct (related to curative treatment or prevention) and indirect (due to absenteeism or the decrease of productivity), non-negligible for Mbujimayi's population whose the majority lives below the poverty line. We conducted a prospective study of the cases admitted in observation and hospitalization from July 01, 2012 to June 30, 2013 in the Pediatric Department of the Provincial Hospital Dipumba in Mbujimayi, in order to determine the direct cost of the in-hospital hold in charge of severe malaria among children of 6 to 59 months as well as the factors influencing it. Epi info 2008 version 3.5.1 was used to analyze data. Severe malaria represented 70.9% of admissions (534 of 753) whose 45.5% and 36% of cases were respectively secondary to untreated or poorly treated malaria. The majority of the households concerned (81.5%) were very poor because earned less than $ 30/month. Each household contained an average 2.2 subjects of under five years. The mean direct cost of the hold in charge of a severe malaria episode rose to $ 38.6±11.2 (range $ 8.5-79.94 US) either 34740±10636 Fc (Congolese money) of which 78.3% were bound to medication, 10.7% to consultation, 8.3% to hospitalization and 7.1% to laboratory tests. The average direct cost was high in case of healing ($40.83±10.95), bad quality of treatment before admission, therapeutic failure notion, severe anemia and high gravity of the case at admission. Malaria is a costly disease in relation to the standard of living of our population. It is therefore necessary to reinforce the management capabilities of the cases correctly and early so much at home that in hospital and to streamline the prescriptions in order to reduce the costs led by malaria.

345

REFERRAL PRACTICES AND MANAGEMENT OF SEVERE MALARIA IN CHILDREN: A RETROSPECTIVE STUDY OF PATIENTS MANAGED IN A CHILDREN EMERGENCY UNIT IN A TERTIARY HOSPITAL IN SOUTHWEST NIGERIA

Esther O. Ayandipo[1], Babatunde Ogunbosi[2], Bolatito Aiyenigba[3], Yemi Labaeka[2], Oluwole Adeusi[3], Ahmed Babatunde[1]

[1]*FHI360, Ibadan, Nigeria,* [2]*University College Hospital, Department of Pediatrics, Ibadan, Nigeria,* [3]*FHI360, Abuja, Nigeria*

Severe malaria is a disease known to be fatal in children and a major cause of admission into emergency units in Nigeria. The Nigerian treatment guidelines for the management of severe malaria recommend laboratory diagnosis and treatment with injection artesunate. Majority of children with severe malaria are referred to secondary and tertiary centers for management. Pre referral treatment with rectal artesunate or injection arthemeter is always encouraged. The objective of this study was to assess the use of pre referral treatment, pattern of management and treatment outcome in children with severe malaria This study assessed the use of rectal artesunate and arthemeter injection as pre referral treatment and management practices of severe malaria a teaching hospital in south western Nigeria. Children managed in Otunba Tunwase Children emergency unit between April and September 2014 were recruited. A total number of 134 children with a diagnosis of severe malaria were seen during the period. Referral, demographic, laboratory, treatment and outcome data were collected using semi structured questionnaire. Analysis was done using SPSS version 17. 134 children were managed over a period of 6 months. Majority of children were >5years (52.2%) while 64(47.7%) were <5years. More males (50.7%) than females (49.2%) were seen. Some (21, 8%) were referred to the hospital from other health facilities while 78.2% were admitted directly into the emergency unit. None of those referred got the recommended pre referral treatment before referral. Laboratory diagnosis was made in 83.6% of cases while clinical diagnosis was made in 16.4%. The treatment regimen used was injection artesunate in 97.8% of patients while oral ACT was commenced in 80.6% of patients. Majority (91%) improved and were discharged while 11(8.2%) died and 1 (0.75%) absconded. In conclusion, despite largely complying with treatment guidelines, a high mortality rate was still recorded during the period under study. Referral system should be strengthened to ensure patients receive pre referral treatment.

346

EXPANDING ACCESS TO MALARIA DIAGNOSIS AND TREATMENT IN LAO PDR WITH A PUBLIC-PRIVATE MIX PROGRAM

Bouasy Hongvanthong[1], Phoutnalong Vilay[1], Odai Sichanthongtip[1], Kelly Phouyaphone[2], David Sintasath[3]

[1]*Center for Malariology, Parasitology, and Entomology, Vientiane, Lao People's Democratic Republic,* [2]*Clinton Health Access Initiative, Vientiane, Lao People's Democratic Republic,* [3]*United States Agency for International Development, Vientiane, Lao People's Democratic Republic*

As the Lao People's Democratic Republic transitions toward malaria elimination and attempts to limit the spread of artemisinin resistance, one of the country's primary objectives is to improve access to and quality of diagnosis and treatment services. To increase the coverage of case management services and ensure the availability of quality antimalarials, the Center for Malariology, Parasitology, and Entomology (CMPE) implemented a Public-Private Mix (PPM) program to integrate private sector providers into national malaria interventions. As part of the PPM program, private healthcare providers are trained to use rapid diagnostic tests kits (RDTs) for malaria diagnosis and ACTs treatment of uncomplicated malaria, while agreeing to adhere to national guidelines and surveillance protocols. The PPM program was initially piloted in 2008 in eight districts across four provinces with a total of 98 private pharmacies

and 10 physicians from private clinics. By 2015, the PPM program has been expanded to include 17 clinics and 242 private pharmacies across 22 districts in eight provinces in Lao PDR. Over a 66 month period of implementation, the PPM program accounted for 19.2% (22,060) of total patients testing positive for uncomplicated malaria in the areas where the program exists. While public health facilities still test and report the majority of positive uncomplicated malaria cases in those areas (80.8%; 93,232), it is clear that private providers have made a significant contribution in providing access to life-saving health interventions. Overall, the PPM partnership has improved compliance with national guidelines and the quality of malaria services available within the private sector as well as increased the robustness of malaria data received throughout the country, which will be necessary for achieving the goal of elimination.

347

EFFECTS OF ARTEMETHER ON HEMATOLOGICAL PARAMETERS OF PATIENTS PRESENTING WITH UNCOMPLICATED MALARIA IN KISUMU COUNTY WESTERN KENYA

Irene A. Onyango, Elazia Majid, Jack Ogony, Hosea Akala, Ben Andagalu, Edwin Kamau

KEMRI-Walter Reed Project, Kisumu, Kenya

Malaria is still the leaing cause of morbidity in sub sahah Africa.Artemether is an antimalarial used for the treatment of multiple drug resistant strains of ***Plasmodium falciparum*** malaria.Artemether has been shown to affect the hematological parameters of healthy animal models.Neutropenia has been reported following use of artemether in patients with uncomplicated malaria. In a clinical efficacy study conducted among patients presenting with uncomplicated malaria in Kisumu County, Western Kenya, 118 Subjects were enrolled and randomized to receive either artemether lumefantrine or artesunate mefloquine.These subjects were then admitted in the ward for thee days and thereafter discharged upon receipt of two consecutive negative malaria blood films.Data from AL arm were analyzed. Complete blood counts were done daily while subjects had positive malaria blood films and thereafter weekly till Day 42. ACT Diff 5 coulter machine was used to run the complete blood counts.All parameters were observed to decrease in the first 48-72hrs.Interestingly in the White blood cont differential count, only decreased in neutrophil count was observed while the other parameters were either not changed or actually increased. These findings confirm what others have found.It is therefore important to closely monitor hematological parameters especially haemoglobin levels in patients using artemether based artemisinin combination therapies.

348

MALARIA PARASITEMIA, ANEMIA THE MALNUTRITION PREVALENCES THE INTERACTIONS AMONG PRESCHOOL-AGED CHILDREN IN RURAL RWANDA - A COMMUNITY-BASED SURVEY

Fredrick Karambizi Kateera

Rwanda Biomedical Centre, Kampala, Rwanda

Malaria, anemia and malnutrition are 3 highly prevalent and frequently co-existing diseases that, individually, are associated with high morbidity and mortality. We measured the burden of, and assessed for interactions between, malaria, anemia and malnutrition among community based preschool-aged children. Analysis of data collected as part of a community-wide cross sectional survey was performed. Altogether, 1,882 children aged 6-59 months with complete data on outcomes of malaria slide positivity, anemia (Hb levels of lt 90g/L) and stunting, wasting and underweight were included. Multivariate logistic regression analysis was performed. The prevalences of malaria, anemia and stunting were 5.9%, 7.0% and 41.3% respectively. Malaria parasitemia risk was associated with age groups gt 24 months (odds ratio (OR) 3.3; P=0.014, OR 3.5; P=0.008 and OR 3.7; P=0.005 for age-groups 24-35, 36-47 and 48-60 months respectively), whilst a reduced risk was observed among children living in household of high socio-economic status (SES) (OR 0.37; P = 0.029). Risk of anemia was higher among children gt or equal to 12 months and those with malaria parasitemia (OR = 3.86; P = lt 0.0001). Underweight was associated with stunting (OR = 20.41; P = lt 0.0001) and wasting (OR 59.14; P = lt 0.0001), stunting was associated with underweight (OR = 20.26; P = lt 0.0001) while wasting was associated with underweight (OR = 60.71; P = lt0.0001). The risk of stunting was high among children with a fever history (OR = 1.33; P = 0.01) but low among children living in household of high SES (OR = 0.79; P = 008) and in household with gt or equal to 1 bednet (OR = 0.55; P = 0.017). Study findings showed high proportions of stunting and anemia but not malaria in the study group. A strong association between malaria and anemia with children aged gt or equal to 12 months at significantly high risk of anemia and malaria. Integrated rather than vertical programs providing nutritional rehabilitation, comprehensive malaria control, improvements in household SES and investments in better house structures are needed to optimize health outcomes among children lt 5 years.

DEVELOPMENT OF MALARIA PARASITES PURIFICATION BY ANTIBODY IMMOBILIZED MAGNETIC NANOPARTICLES

Tienrat Tangchaikeeree[1], Duangporn Polpanich[2], Pramuan Tangboriboonrat[3], Kulachart Jangpatarapongsa[1]

[1]*Faculty of Medical Technology, Mahidol University, Nakhon Pathom, Thailand,* [2]*National Nanotechnology Center, National Science and Technology Development Agency, Pathumthani, Thailand,* [3]*Department of Chemistry, Faculty of Science, Mahidol University, Bangkok, Thailand*

Malaria is the most important parasitic infectious disease that many researchers are interested. Due to its harmful, malaria researches are still ongoing to combat the disease in several fields including the progression on drug and vaccine. In this regard, intact malaria parasites are required material for the research experiment. Conventional method for malaria separation is gradient centrifugation which is complex, time consuming, and specific to only mature stage of the parasite. This study aimed to develop a novel technique for malaria purification with rapid and high specificity by using magnetic nanoparticles (MNPs). The MNPs with specific functionalized surface were modified by immobilization of anti-malarial antibodies, which were purified from acutely ***P. falciparum*** infected plasma. Afterwards, antibody immobilized MNPs (Ab-MNPs) was incubated with ***P. falciparum***-infected erythrocytes. Complexes of Ab-MNPs and infected erythrocytes were then selectively purified from normal red blood cells by magnetic force. The malaria parasites were smeared, stained, and examined under optical microscopic examination. The result of microscopic examination showed that all stages of the parasite were separated by Ab-MNPs with high purity. Moreover, we showed result of scanning electron microscopy that the high specificity between Ab-MNPs and malaria infected erythrocytes was observed. This developed technique would be potentially used in malaria research and also adapted in diagnostic field.

ALTERED ANGIOGENESIS THE ADVERSE BIRTH OUTCOMES IN EXPERIMENTAL PLACENTAL MALARIA

Vanessa Tran[1], Ana Cabrera[1], Kevin C. Kain[2]

[1]*Sandra Rotman Centre for Global Health, Toronto General Research Institute, University Health Network, Toronto, ON, Canada,* [2]*Sandra Rotman Centre for Global Health, Toronto General Research Institute, University Health Network; Tropical Disease Unit, Division of Infectious Diseases Department of Medicine, University of Toronto, Toronto, ON, Canada*

Each year ~125 million pregnant women are at risk of malaria infection. Placental malaria (PM) has a profound impact on maternal and child health, increasing the risk of stillbirth (SB) and low birth weight (LBW), and results in ~200 000 infant deaths per year. We have shown that

PM-mediated LBW is associated with dysregulated angiogenesis through the angiopoietin (Ang)-Tie2 axis; however, it is unknown whether these alterations are a cause or consequence of poor birth outcomes. We hypothesize that altered levels of Ang1/Ang2 during PM impairs placental vascular remodeling, directly resulting in poor birth outcomes. To test this, we used the ***Plasmodium berghei*** ANKA (PbA) mouse model of experimental PM (EPM) and found that levels of angiogenic (Ang1, Ang2, PlGF, VEGF) and inflammatory (sICAM-1, C5a) markers were altered with PbA infection. Further, an elevated ratio of Ang2/Ang1 in both maternal serum and placental mRNA was associated with PM-mediated LBW. To further interrogate the Ang-Tie2 pathway in PM, we compared Ang1+/- to WT mice and found that pups from infected Ang1-deficient dams were significantly smaller and had decreased viability compared to pups from PbA-infected WT mice, irrespective of pup genotype. This suggests that maternal Ang1 deficiency exacerbates SB and LBW associated with PM and that supplementing with recombinant Ang1 (rAng1) could potentially rescue these phenotypes. Combined with the genetic approach, the ability of rAng1 to prevent SB/LBW would establish a causal role for Ang1 in PM-associated adverse birth outcomes. To determine the impact of Ang1 deficiency on fetoplacental vasculature, we are employing microCT 3D imaging to compare placentas from PbA-infected Ang1+/- and WT mice to examine the number of vessels and degree of vascular remodeling. Overall, these studies will provide novel insights into mechanisms underlying malaria-complicated pregnancies and may identify novel interventions to prevent poor birth outcomes in PM. Further, our findings may have broad implications for other causes of adverse pregnancy outcomes associated with vasculopathy including preeclampsia and gestational diabetes.

351

ASSESSMENT OF THE SUSCEPTIBILITY OF LABORATORY BRED *ANOPHELES GAMBIAE* M/S HYBRID MOSQUITOES TO *PLASMODIUM FALCIPARUM*

Jacqueline Akuamoah[1], Ruth C. Brenya[2], Michael F. Ofori[1], Joseph W. Diclaro[3], Samuel Dadzie[1], Mba Mossore[1], Joseph Chabi[1]

[1]*Noguchi Memorial Institute for Medical Research, Accra, Ghana,* [2]*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [3]*Naval Medical Research Unit - 3, Cairo, Egypt*

Malaria is caused by the ***Plasmodium*** haemo-protozoan and transmitted by Anopheline mosquitoes***. The Anopheles complex*** comprises seven species out of which ***An. gambiae*** is the most effective vector in Sub Saharan Africa. This species is divided into two main forms based on chromosomal polymorphisms. These are: the Mopti (M) form and Savanna (S) form. Both forms exhibit high and equivalent levels of susceptibility to ***P. falciparum*** and malaria transmission potential. Currently, there are increasing reports of naturally occurring M/S hybrids in West Africa and further studies nullify assumptions that there cannot be hybridisation of M and S forms by demonstrating a significant level of gene flow between the two. Unfortunately, no profiling has been done on M/S hybrids with regards to malaria transmission despite the fact that both forms exist in sympatry in Central and West Africa and even in Ghana. The primary purpose of this study therefore, is to investigate the susceptibility of ***An. gambiae*** M/S hybrids to ***P. falciparum.*** This novel investigation would provide information on the malaria transmission potential of M/S hybrids which could be useful in vector control programmes and serve as a basis upon which further research may be performed. The study will be conducted at the Noguchi Memorial Institute for Medical Research, Accra. ***An. gambiae*** M and S forms would be bred under standard insectary conditions and mated to ensure fertilisation and production of viable eggs. 2- 5 day old naïve adult hybrid female mosquitoes would then be infected with mature stage 5 gametocytes (NF54 lab strain). Infection would be done with a membrane feeder using high and low gametocytaemia parasite cultures. Control cages would be fed with uninfected blood and 10% sugar solution. DNA extraction and PCR tools would be used to determine the presence of parasites in the salivary glands of mosquitoes 18–20 days post infection. It is expected that the susceptibility profile of the ***An. gambiae*** M/S hybrid would be known and from this, conclusive information can be drawn on the malaria transmission potential of ***An. gambiae*** M/S hybrids.

352

ESTABLISHMENT OF A PBMC REPOSITORY FOR IDENTIFYING BIOMARKERS OF PROTECTION AND ASSOCIATED TARGET ANTIGENS FOR MALARIA

Joanne Lumsden[1], Harini Ganeshan[1], Sharina Reyes[1], Jun Huang[1], Jo Glenna Banania[1], Maria Belmonte[1], Arnel Belmonte[1], Esteban Abot[1], Yolanda Alcorta[1], Alicia Simmons[1], Charlotte Fedders[1], Anatalio Reyes[1], Carlos Vasquez[1], Santina Maiolatesi[1], Nimfa Teneza-Mora[1], Alexandra Singer[1], Cindy Tamminga[1], Megan Dowler[2], Lindsey Garver[2], Silas Davidson[2], Thomas Richie[3], Eileen Villasante[1], Judith Epstein[1], Martha Sedegah[1], Bradley Hickey[1]

[1]*Naval Medical Research Center, Silver Spring, MD, United States,* [2]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [3]*Sanaria Inc., Rockville, MD, United States*

Studies in the 1970s demonstrated that immunization with radiation-attenuated ***P. falciparum*** sporozoites (***Pf***RAS) via mosquito bite confers protection against malaria in human subjects. However, neither the mechanisms of protection nor the targeted antigens have been clearly identified. The BMGF is supporting a clinical trial (Immunization via Mosquito bite with Radiation-Attenuated Sporozoites, or IMRAS) in which up to 24 subjects will receive bites from ***Pf***RAS-infected mosquitoes (true-immunized) and 8 subjects will receive bites from irradiated, uninfected mosquitoes (mock-immunized). These subjects, plus infectivity controls, will undergo controlled human malaria infection (CHMI). To maximize statistical power, the trial is designed to generate approximately 50% protection in the true-immunized group by using two cohorts, where Cohort 1 will be conducted prior to Cohort 2. Samples collected throughout the trial using routine venipuncture for whole blood and leukapheresis for large numbers of PBMCs will be used to: discover biomarkers and correlates of protection using a range of approaches, including systems biology; and identify pre-erythrocytic ***Pf*** antigens associated with protection using agnostic and candidate approaches. Leukapheresis was performed on 14 subjects in Cohort 1 who completed a series of 5 true (n=11) or mock (n=3) immunizations and CHMI. Leukopaks were collected pre-immunization (n=14), day 14 post 3rd immunization (n=8), day 5 or 6 post-CHMI (n=12) and 4 months post-CHMI (n=9). PBMC were isolated by Ficoll-Hypaque density gradient separation, and cryopreserved at 20 million PBMCs/vial. The average yield per leukopak was 4.5 billion PBMCs (range 1.6-10 billion). Conduct of Cohort 2 is ongoing and will be completed in early 2016. The IMRAS Committee for Samples and Immunoassays has been established to prioritize the allocation of samples to maximize scientific benefit. This PBMC repository will be an invaluable resource for identifying biomarkers of protection and associated target antigens for malaria vaccine development.

353

PRE-REFERRAL TREATMENT PROCESS OF SEVERE MALARIA CASES IN AREAS SOUTHEAST OF SENEGAL

Alioune Gueye[1], Seynabou Gaye[1], Medoune Ndiop[1], Fatou Ba[1], Lamine Diouf[1], Julie Twing[2], Moussa Ndour[1], Mame Birame Diouf[2], Ibrahima Diallo[1], Moustapha Cisse[1], Mady Ba[1]

[1]*National Malaria Control Program, Dakar, Senegal,* [2]*United States Agency for International Development, Dakar, Senegal*

The new guidelines of the NMCP recommended by WHO includes the Pre-referral treatment of severe malaria cases with the use of rectal artesunate capsules .This strategy which mainly targets children under 5 years has been scaled up in all the health posts of the country especially in the South East districts where malaria mortality in this age group makes up about 40% of national mortality. So after drawing up the document for the implementation and management tools, we launched and held the

trainings in the targeted medical areas in February 2014. These trainings helped guide 63 agents on the strategy in the regions of Tambacounda, Kolda, Sedhiou and Kedougou between 14 and 26 March 2014;. This program enabled us to train 405 providers. The NMCP also includes a community component in Salemata and Saraya districts in the region of Kedougou to reduce the delay of managing severe cases in areas where access is difficult; So after 8 days of theoretical and practical sessions, 50 community health workers were trained. After that, the districts with the support of the NMCP proceeded to the establishment of the capsules Artesunate and the management tools in the health posts and community sites. The 1st national monitoring conducted from 22 to 23 October, 2014 showed 100% functionality of Home-based management (HBM) sites and health nuts. For the same period, the routine data showed that 24 severe malaria were referred to the health centers (including 6 cases from the community level) with 60% of cases who received pre-referral artesunate-based treatment; which have contributed to the reporting of severe malaria cases in children under 5 years and their early treatment to prevent a fatal outcome; However, the impact of both seasonal malaria chemoprevention (SMC) and HBM along with a more active screening of cases have certainly reduced the incidence of severe cases in these highly endemic malaria areas. Looking ahead, the NMCP contemplates doing an overall assessment of the strategy in May 2015 in order to share this experience and expand the strategy to other districts with high malaria mortality and thus further reduce malaria death risk in this vulnerable age group.

354

MATERNAL HOST FACTORS INFLUENCE NEONATAL MALARIA IN SOUTHEASTERN NIGERIA

Uchechukwu Madukaku Chukwuocha, **Ikechukwu Nosike Simplicius Dozie**, Agwu Nkwa Amadi, Geoffrey Chima Nwakwuo, Adanna Nneoma Chukwuocha, Christopher Peres Ekiyor

Department of Public Health Technology, Federal University of Technology, Owerri, Nigeria

This study aims at documenting the maternal host factors influencing the prevalence of malaria in neonates in South Eastern Nigeria. Fifty-seven neonates who had a positive blood smear for the malaria parasite were included in the study and their socio-demographic and clinical correlates reviewed. The prevalence of neonatal malaria in this study is 35.67% and 77.3% of children with neonatal malaria presented fever. 99 (42.9%) and 132 (57.6%) of the mothers had parasitaemia in maternal peripheral blood and placental blood respectively. Obstetrics factors like parity was found to have a significant association ($\chi 2=7.30$, p=0.026) with neonatal malaria. Neonatal malaria was more likely to occur in babies of primigavid mothers and those mothers who attended ANC outside the tertiary health facilities ($\chi 2=6.75$, p=0.009). Neonatal malaria is not as rare as was previously thought and its morbidity and mortality in Sub-Saharan Africa is increasing and thus, there is need for educating of pregnant mothers on the necessity of early care-seeking for newborns.

355

DHFR MUTATIONS IN *PLASMODIUM KNOWLESI* DO NOT APPEAR LINKED TO SELECTIVE DRUG PRESSURE FROM PUTATIVE HUMAN-TO-HUMAN TRANSMISSION IN SABAH, MALAYSIA

Matthew J. Grigg[1], **Bridget E. Barber**[1], Jutta Marfurt[1], Mallika Imwong[2], Timothy William[3], Usa Boonyuen[4], Kim Piera[1], Ammar Aziz[1], Sarah Auburn[1], Jonathon Cox[5], Chris J. Drakely[5], Nick White[6], Qin Cheng[7], Tsin W. Yeo[1], Nicholas M. Anstey[1]

[1]*Menzies School of Health Research and Charles Darwin University, Darwin, Northern Territory, Australia,* [2]*Mahidol Oxford Research Unit, Mahidol University, Bangkok, Thailand,* [3]*Infectious Diseases Unit, Queen Elizabeth Hospital, Kota Kinabalu, Sabah, Malaysia,* [4]*Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand,* [5]*Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom,* [6]*Centre for Tropical Medicine, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom,* [7]*Australian Army Malaria Institute, Brisbane, Australia*

Malaria due to zoonotic ***Plasmodium knowlesi*** is increasing in Eastern Malaysia. Despite demonstrated vector competency, it is unknown whether human-to-human transmission is occurring naturally. We sought evidence of drug selection pressure from the antimalarial sulfadoxine-pyrimethamine (SP) as a potential marker of human-to-human transmission. The ***P. knowlesi*** dihydrofolate-reductase (pkdhfr) gene was sequenced from 449 ***P. knowlesi*** malaria cases from Sabah (Malaysian Borneo) and genotypes evaluated for association with clinical and epidemiological factors. Homology modelling using the pvdhfr template was used to assess the effect of pkdhfr mutations on the pyrimethamine binding pocket. Fourteen non-synonymous pkdhfr mutations were detected, with the most common being at codon T91P (10.2%) and R34L (10.0%), resulting in 21 different genotypes, including the wild-type, 14 single mutants, and six double mutants. Whereas 145 (32%) of patients had pkdhfr single mutants, 14 patients harboured double-mutants. In contrast, among the 47 ***P. falciparum*** isolates sequenced, three pfdhfr genotypes were found, with the double mutant 108N+59R being fixed and the triple mutants 108N+59R+51I and 108N+59R+164L occurring with frequencies of 4% and 8%, respectively. Two non-random spatio-temporal clusters were identified with pkdhfr genotypes. There was no association between pkdhfr mutations and hyperparasitaemia or severe disease, both hypothesized to be indicators of H-H transmission. The orthologous loci associated with resistance in ***P. falciparum*** were not mutated in pkdhfr. Subsequent homology modelling of pkdhfr revealed gene loci 13, 53, 120, and 173 as being critical for pyrimethamine binding, however, there were no mutations at these sites among the 449 knowlesi isolates. Although common, the pkdhfr mutations in Sabah do not appear due to selective drug pressure. While not providing evidence for naturally-occurring human-to-human transmission, this mode of transmission is not excluded.

356

STRATEGIC PROCUREMENT MANAGES THE CHALLENGE POSED BY THE ACCUMULATING OF LONG-LASTING INSECTICIDE-TREATED BED NETS (LLIN) PACKAGING WASTE

Chris Warren

United States Agency for International Development | DELIVER PROJECT, John Snow, Inc., Arlington, VA, United States

Long-lasting insecticide-treated bed nets (LLINs) can successfully prevent the transmission of malaria worldwide, but for some recipient communities, one unwanted result of this success has been the accumulation of used LLIN packaging. If managed incorrectly, this used packaging can expose local populations to toxic substances. Three procurement options are available to help donors, programs, and the

malaria prevention community respond to this challenge: 1. not specifying any particular type of LLIN packaging; 2. procuring LLINs in individual bags, but stating that a specific packaging be used; 3. procuring LLINs that are packaged in bulk instead of individual bags. With each option, programs and stakeholders should review the potential ramifications and contextual issues before deciding on the best solution. Ultimately, any decision that will contribute to a well-managed LLIN packaging waste plan will contribute to an improved malaria prevention program and a reduced risk of contaminating the environment.

357

LESSONS FOR INTEGRATING INTERMITTENT PREVENTIVE TREATMENT FOR MALARIA IN SCHOOL SYSTEMS IN LOW INCOME SETTINGS: EXPERIENCES FROM UGANDA

Susan Nayiga[1], Christine Nabirye[1], Sarah Staedke[2], Clare I.R. Chandler[2]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Evaluations of mass drug administration suggest that these programmes are not always well received by communities. Concerns regarding side-effects and the time and effort required to implement programmes, and doubts over the intentions of such programmes, have been raised. Discourses of foreigners harming local residents are often called into play in making sense of such initiatives that involve standardized treatment of asymptomatic people with drugs that are viewed as a precious commodity. The START-IPT trial was conducted in primary schools in Jinja district to assess if treating schoolchildren with dihydroartemisinin-piperaquine monthly to prevent malaria could improve the health of children and reduce the burden of malaria in the community. A qualitative study was conducted alongside the main trial to investigate the potential feasibility for integrating this intervention into routine health services and school systems. Ethnographic observations were conducted of the sensitization and consenting process at selected schools for one day each. During the roll-out of the intervention, the same schools that had been observed during the sensitization and consenting process were observed for the first three days of treatment distribution. A total of 19 in-depth interviews were held with district and national stakeholders, teachers, health workers and Village Health Team members. Three focus group discussions were held with study staff. We will present the findings of the qualitative study highlighting: 1) considerations for integration of health programmes into schools; and 2) potential supporting intervention methods and content of messages for IPT through schools. Key themes emerging in this context related the IPT programme to post-colonial concerns, economies of opportunity and operational issues. We situate these findings with those of others identified through a systematic literature review to provide considerations relevant to those planning to conduct mass treatment in schools in Africa.

EFFICACY OF ARTEMETHER-LUMEFANTRINE OR ARTESUNATE-AMODIAQUINE FOR UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA-MALAWI, 2014

Magdalena Paczkowski[1], Dyson Mwandama[2], Daniel Marthey[3], Madalitso Luka[2], Georgina Makuta[2], John Sande[4], Doreen Ali[4], Peter Troell[1], Don Mathanga[2], Julie Gutman[1]

Malaria remains a major public health problem in Malawi, with an estimated 4 million cases in 2013. The first- and second-line treatments for uncomplicated malaria are artemether-lumefantrine (AL) and artesunate-amodiaquine (ASAQ), respectively. Globally, emerging antimalarial drug resistance threatens treatment efficacy. We evaluated the efficacy of AL and ASAQ for the treatment of uncomplicated malaria in Malawi. During March-July 2014, febrile children aged 6-59 months with microscopy-confirmed uncomplicated ***Plasmodium falciparum*** malaria (1,000-200,000 parasites/μL) were enrolled in an ***in vivo*** efficacy trial at 3 sites, 1 each in northern, central and southern Malawi. Children were randomized 3:1 to AL or ASAQ arms. Sample size was sufficient to estimate site-specific efficacy for AL and overall efficacy for ASAQ. Blood was collected for malaria diagnosis by microscopy and malaria parasite molecular testing on days 0-3, 7, 14, 21, and 28. If treatment failure occurred, polymerase chain reaction (PCR) was used to differentiate recrudescence from reinfection; in PCR corrected analyses, reinfections were censored on the day they occurred. The primary outcome was the proportion of children with PCR-corrected adequate clinical and parasitological response (ACPR) on day 28. We enrolled 453 children; 307/338 (90.8%) and 102/115 (88.7%) reached a study endpoint in the AL and ASAQ arms, respectively, with no treatment failures on or before day 3. PCR uncorrected ACPR was 97% (95% confidence interval [CI]: 92-99%) for ASAQ and 77% (95% CI: 72-82%) for AL (84% [95% CI: 76-91%], 69% [95% CI: 59-78%], and 78% [95% CI: 68-86%] in the northern, central, and southern regions, respectively). PCR-corrected ACPR was 99% (95% CI: 95-99.9%) in the ASAQ arm and 99% (95% CI: 98-99.9%) in the AL arm, with 99-100% efficacy in each of the sites. Both AL and ASAQ remain efficacious treatments for uncomplicated malaria in Malawi. Recurrent parasitemia, primarily a result of reinfection, was significantly lower with ASAQ than with AL. This is expected given the shorter half-life of lumefantrine (3-6 days) compared to amodiaquine (9-18 days).

359

HOW TO ACCOUNT FOR SEASONALITY WHEN PLANNING NATIONAL-LEVEL MALARIA ORDERS FOR COUNTRIES

Naomi Printz, Loren Bausell

United States Agency for International Development | DELIVER PROJECT, John Snow, Inc., Arlington, VA, United States

Learning objectives: Participants will understand how to account for seasonality when planning orders for malaria products. Quantification is the process of estimating the quantities and costs of the products required for a specific health program, and determining when the products should be delivered to ensure an uninterrupted supply for the program. The process includes both a forecasting and a supply planning step. A supply plan is based on forecast consumption, quantities on order, stocks on hand, and program minimum and maximum stock levels. The supply plan is the final output of the quantification; it lists in detail the quantities, costs, and arrival dates of the shipments. The traditional approach to supply planning is to calculate the annual forecast consumption and divide by 12, which yields an average monthly consumption (AMC). Shipments are scheduled to arrive when national stocks are at a minimum; stocks are then increased to the maximum level. Using a standard AMC for shipment scheduling for seasonal products can cause overstocks in the dry season and stockouts in the rainy season. An alternative is to develop a seasonality index to apply to forecast consumption_this will produce a monthly consumption that accounts for seasonal variation. Shipments can be planned accordingly. To develop a seasonality index, a random month is first selected as a reference month. Then, historical consumption for each month is divided into the consumption for the reference month. This yields monthly ratios, which capture the general shape of the annual consumption pattern, and show the relationship of consumption in a particular month to that of the reference month. For example, a peak malaria month may show consumption that is 2.5 times higher than a non-peak month; or consumption during a month of the dry season may be less than half the consumption in a rainy season month. After developing the seasonality index, these ratios are applied to the total forecast consumption for one year, which will yield an estimate of monthly consumption. When supply plans are developed, shipments should be scheduled to arrive prior to the peaks in consumption.

FOOD INSECURITY AND THE COST OF MALARIA ILLNESS IN RURAL TANZANIA

Donald S. Shepard[1], Yara A. Halasa[1], Robert Mpagala Kihomo[1], Clara Makerere[1], Aggrey Kihombo[1], Peter Mangesho[2], Joseph Mugasa[2], Ruth Mnzava[2], Mohamed Seif[2], Filemoni Tenu[2], Robert Malima[2], George Mtove[2], Frank Mosha[3], William Kisinza[2]

[1]*Brandeis University, Waltham, MA, United States,* [2]*The National Institute for Medical Research, Tanga, United Republic of Tanzania,* [3]*Kilimanjaro Christian Medical Center, Moshi, United Republic of Tanzania*

Understanding the impact of malaria on endemic rural African communities can assist governments and donors in developing appropriate and sustainable malaria control strategies. In Muheza, Tanzania, a cluster randomized trial is assessing the cost and effectiveness of non-pyrethroid insecticide-treated durable wall lining (DL). To project savings from DL, we estimated the current expenditures on malaria treatment in conjunction with a cross-sectional epidemiological household survey. We mapped and enumerated households and invited 4,200 randomly selected residents aged>6 months from 60 village clusters to participate in 3 rounds of epidemiological surveys. We asked the subset of respondents randomly selected for a parasitemia test (mRDT) and who reported a malaria episode within prior 30 days to respond to socio-economic surveys which focused on care seeking behavior, household expenditures on malaria care, and catastrophic expenditures and food insecurity. We complemented the surveys with macro-costing analysis implemented at district hospital to project the economic cost of care. Of the 89 respondents in the latest round of the socio-economic survey (Jan-Feb 2015), 55% were children, 53% reported some impact of the illness episode on food security in their household (7% to a great extent), 8% were hospitalized, 88% sought care in an ambulatory setting, and 4% were treated at home. On average, household direct medical expenditures on a malaria episode, including private sector, averaged $3.95 ($3.77 child, $4.17 adult) for ambulatory cases, $75.81 ($29.11 child, $94.42 adult) for hospitalized cases, and zero for home cases. The corresponding economic costs, including government financing, were $5.38 ($5.17 child, $5.63 adult) for ambulatory, $89.17 ($78.13 child, $93.58 adult) for hospitalized, and zero for home cases. The direct non-medical cost (transportation, food and lodging) averaged $1.93 for ambulatory and $23.51 for hospitalized cases. Malaria's impacts on household food security and finances are substantial. Additional preventive programs would generate important cost offsets.

361

IMMUNE RESPONSES AGAINST TRANSMISSION BLOCKING TARGET ANTIGENS IN CHILDREN TREATED FOR SCHISTOSOMIASIS FROM A MALARIA MODERATE TRANSMISSION REGION IN ZIMBABWE

Noah H. Paul[1], Nicholas Midzi[2], Dibyadyuti Datta[3], James Chipeta[4], Geetha Bansal[3], Takafira Mduluza[5], Nirbhay Kumar[3]

[1]*Scientific and Industrial Research and Development Centre. Zimbabwe, Harare, Zimbabwe,* [2]*University of Zimbabwe, Department of Community Medicine, College of Health Sciences, Parirenyatwa, Harare, Zimbabwe,* [3]*Department of Tropical Medicine , School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, United States,* [4]*University of Zambia, University Teaching Hospital, Lusaka, Zambia,* [5]*University of Zimbabwe, Biochemistry Department, Mount Pleasant, Harare, Zimbabwe*

Malaria remains a leading killer in sub-Saharan Africa with the most vulnerable group being children under 5 years. Although there has been successful decline in the malaria cases, the focus so far has mainly been on control. Eradication of malaria is still a long term goal and the development of effective vaccines remains to be achieved. Transmission blocking vaccines (TBV) represent a valuable approach to malaria elimination. Several antigens (Pfs230, Pfs49/45 and Pfs25) expressed in the sexual stages have been identified as target antigens and pre-clinical studies on TBVs have shown marked efficacy, 96-100%. The study was carried out in school-going children (7-16 years age, N=150) in Makoni, District, Zimbabwe, undergoing MDA for schistosomiasis. The prevalence of malaria diagnosed by microscopy and rapid diagnostic kit (Paracheck) TM was 1.2 % and 30.3 %, respectively and infected children received CoartemTM.treatment. We wished to assess presence of naturally occurring transmission-blocking immune responses. Serum samples were used for ELISA and in membrane feeding assays (MFA) to assess functional malaria transmission blocking immunity, and whole blood samples were used for PCR detection of ***Plasmodium falciparum*** malaria. Analysis of serum samples by ELISA revealed >90% sero-positivity using crude asexual lysates. Most significantly, 66 % and 63% samples showed ELISA reactivity to the recombinant Pfs48/45 and Pfs47 proteins, respectively. A few randomly selected sera samples were also tested in MFA. The MFA demonstrated measurable transmission blocking ability- 4 out of 20 sera revealed 56 to 84% transmission reducing activity. The results provide evidence for the presence of transmission blocking antibodies in these children co-infected with malaria and schistosomiasis. A TBV vaccine induced immunity further boosted by natural immunity may play significant role in the elimination of malaria transmission even in people co-infected with other helminthes.

Malaria is a major global health burden, causing approximately 584, 000 deaths annually, especially in children under the age of five. There are five ***Plasmodium*** species that infects humans, of which ***Plasmodium falciparum*** (P.f.) and ***P. vivax*** (P.v.) are the two most prevalent. Currently, no effective vaccine against malaria exists, hence the global effort aim to develop a vaccine to prevent infection, limit disease and interrupt mosquito transmission for all ***Plasmodium*** species. Glycosylphosphatidylinositol (GPI) is a potential target as it is a conserved glycolipid anchor of many essential parasite proteins found across most differentiated stages and ***Plasmodium*** species. Additionally, GPI is also a toxin that causes immuno-pathological symptoms of malaria. Previously, we proved that vaccination against GPI protects mice against severe malarial disease. This study further investigates the potential of the synthetic anti-GPI vaccine in preventing infection and blocking parasite transmission into the mosquito vector in a pre-clinical rodent malaria model, ***P. berghei*** (P.b.). The vaccine showed significant efficacy in reducing liver burden following sporozoite challenge, blood stage infection and parasite transmission to the mosquito. This was further validated by passively immunizing mice with anti-GPI antibodies prior to mosquito infection. When assessed over a complete life-cycle, i.e. sporozoite challenge followed by blood stage infection and mosquito feeding, sustained reduction in oocyst numbers were observed. Thus the anti-GPI vaccine shows pre-clinical efficacy against sporozoite, blood stage and sexual stages of malaria.

Despite the decline in the global burden of malaria cases and deaths, an effective malaria vaccine is still crucial to complement existing control strategies against the devastating effect of malaria: approximately 584,000 deaths occur annually, mostly in young children. We report here the interim findings of evaluation of co-administration of malaria vectored vaccines with EPI vaccines in Gambian infants and neonates. Sixty-five healthy infants and neonates aged 16 weeks, 8 weeks and 1 week were sequentially enrolled and randomized to vaccine or control (EPI vaccines only) arm. Participants in the vaccine arm received high dose ChAd63 ME-TRAP prime vaccination, followed by administration of MVA ME-TRAP boost vaccination eight weeks later. Each vaccination was accompanied by administration of EPI vaccines appropriate for the participants' ages. Safety of the vaccines was assessed by the description of adverse events related to vaccinations ascertained through clinical assessment, biochemical and haematological tests. Immunogenicity was evaluated by interferon-gamma ELISPOT, and intra-cellular cytokine staining and flow cytometry. Antibody testing was performed to assess possible interference of the candidate vaccines with the EPI vaccines. The median haemoglobin, white cell counts, alanine transaminases and creatinine at pre and post-vaccination visits in the vaccine and control arms were within the acceptable ranges. Frequently observed adverse events that appeared related to the vaccinations included fever and induration at injection sites. Overall, the vaccination regimes were very well tolerated. High level antigen-specific T cell responses were generated and sustained beyond Day 168 among infants in the malaria vaccine arm. Prime-boost effects were also observed with significant increase in geometric mean T-cell responses at Days 21 and 63. In conclusion, our findings suggest that administration of ChAd63-MVA ME-TRAP together with EPI vaccines continue to exhibit satisfactory safety and potent T-cell immunogenicity in very young infants living in a malaria-endemic area.

364

FACING THE CHALLENGE OF VOLUNTEER RECRUITMENT IN PHASE I MALARIA CLINICAL TRIALS: EXPERIENCE FROM BAGAMOYO CLINICAL TRIAL UNIT, TANZANIA

Kamaka R. Kassim

Ifakara Health Institute, Bagamoyo, United Republic of Tanzania

As a way to speed up clinical development program of investigational products such as vaccines to the community in need. The need to establish phase I clinical trial facilities in Africa has been realized, now that several research sites in Africa are capable to conduct early phase one clinical trial, Ifakara Health Institute is one among those sites. In the past three years, Ifakara Health Institute was able to conduct different three Phase I clinical trials to assess for the safety and immunogenicity of two promising malaria vaccine candidates. Volunteers for these trials were recruited from higher learning institutions in Dar es Salaam based on the pre-defined inclusion and exclusion criteria. Considering the fact that, such trials were for the first time conducted, there were challenges associated with the execution of these trials, which over time, a research team have learnt how to overcome them. One of those challenges associated with process of volunteer recruitment and encountered by establishment of volunteer database to assure easy and timely recruitment. Volunteers were invited in the series of sanitization meetings and those who met initial inclusion criteria attended screening at BCTU. Out of 702 volunteers who attended first sensitization meeting, 524 (74.6%) attended the second sensitization meeting. Almost three quarters 384 (73.3%) of the volunteers who attended second sensitization meeting met initial inclusion criteria and invited to the screening at BCTU. Out of 384 underwent both clinical and laboratory screenings at BTCU, 242(63%) were declared eligible and their contact address entered in the volunteer database ready for PfSPZ and P27A malaria clinical trials. So far, the screening of PfSPZ and P27A malaria phase I trials screening has utilized 153 (63.2%) volunteers from the existing volunteer database. Consequently, volunteer's data base has ensured the timely recruitment and enrollment, although there was a delay in getting approval from ethical committees and regulatory authority.

365

CONSTRUCTION OF TRANSGENIC *PLASMODIUM BERGHEI* TO EVALUATE THE TRANSMISSION BLOCKING VACCINES BASED ON *P. VIVAX* TARGET ANTIGEN PVS48/45

Yi Cao[1], Geetha P. Bansal[2], Nirbhay Kumar[1]

[1]*Department of Tropical Medicine, School of Public Health and Tropical Medicine and Vector-Borne Infectious Diseases Research Center, Tulane University, New Orleans, LA, United States,* [2]*Department of Tropical Medicine, School of Public Health and Tropical Medicine and Vector-Borne Infectious Diseases Research Center, Tulane University, New Orleans, LA, United States*

Plasmodium vivax is geographically widely distributed species of human malaria parasite, with nearly 40% of the world population at risk. Because of the lack of a continuous ***in vitro*** culture system, research on ***P. vivax*** parasites has relied on access to blood from infected patients or primates, resulting in relatively fewer vaccine studies in comparison to ***P. falciparum***. Transmission blocking vaccine (TBV) specifically targeting the sexual development of the malaria parasite in the mosquito vector offers an effective way to reduce or stop malaria transmission. Known TBV target antigens in ***P. falciparum*** include Pfs230 and Pfs48/45 expressed prior to fertilization of gametes and Pfs25 expressed after fertilization. Targeted gene disruption studies with P48/45 have also shown that it plays a critical role in male gamete fertility. The long-term goal of our research is to evaluate Pvs48/45 (***P. vivax*** homologue of Pfs48/45) as a TBV candidate. We focused our studies to generate transgenic ***P. berghei*** parasites by replacing the endogenous Pbs48/45 gene with Pvs48/45. In one transgenic parasite line we replaced the full length Pbs48/45 with Pvs48/45 gene sequence. In the second line we replaced Pbs48/45 sequence with chimeric sequence that consist of the signal and anchor sequences from Pbs48/45 and the middle section from Pvs48/45. Both transgenic parasites showed similar asexual blood-stage growth kinetics to the wide type ***P. berghei*** parasite in mice. More importantly, these transgenic parasites were found to be transmission competent and resulted in complete transmission success through ***Anopheles*** vector. These studies demonstrated the functional conservation of P48/45 proteins in evolutionarily distant species of ***Plasmodium*** with about 60% identity at the protein level between ***P. vivax*** and ***P. berghei***. We are now characterizing stage specificity of transgene expression by RT-PCR, Western blotting and IFA. In the next step, these transgenic parasites will be employed to evaluate transmission blocking activity based on the Pvs48/45 recombinant antigen, monoclonal antibodies and vaccine formulations being developed in our lab.

366

A NOVEL SIMIAN ADENOVIRUS VECTOR IS ABLE TO ELICIT HUMORAL AND CELLULAR RESPONSES PROTECTIVE AGAINST AN EXPERIMENTAL *PLASMODIUM* CHALLENGE

Jessica N. McCaffery[1], Jairo A. Fonseca[1], Monica Cabrera-Mora[1], Igor Dmitriev[2], David Curiel[2], Alberto Moreno[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Washington University School of Medicine, St. Louis, MO, United States*

Malaria remains a public health burden despite efforts to improve infection control. In 2013 there were an estimated 198 million cases and 584,000 deaths, 78% of which occurred in children under 5 years, making malaria a leading cause of death in children of this age. Although malaria is treatable with ACT, reports indicate that less than 26% of children with malaria received ACT in 2013. A malaria vaccine is needed to reduce the burden of this disease in the areas where access to medication is logistically demanding. The development of an effective malaria vaccine has proven challenging. Although inoculation of volunteers with radiation attenuated sporozoites is capable of producing sterilizing immunity through induction of targeted antibody and CD4 and CD8 T cell responses, this method remains impractical for widespread use. Furthermore, clinical trials with the leading vaccine candidate RTS,S have failed to produce long lived efficacy, likely due to its inability to induce strong CD8 T cell responses. We have reported the design of a fusion protein based on chimeric ***Plasmodium yoelii*** CSP and MSP1 antigens designated PyLPC-RMC. This construct is able to induce robust antibody and CD4 T cell responses. Based on the evidence that viral vectors increase CD8 T cell mediated immunity we tested heterologous prime-boost immunization regimens that include human adenovirus serotype 5 vectors (Ad5). While Ad5 remains a popular vector for vaccine studies, the high prevalence of pre-existing immunity to Ad5 severely compromises its utility. The use of non-human Ad species is an alternative to Ad5-based vaccination. Here we use simian adenovirus 36 (SAd36) as candidate for a vectored malaria vaccine since there is little to no pre-existing immunity to this virus in human populations. Our studies show the induction of specific CD8 T cell response and similar antibody titers when compared to a prime-boost immunization regimen that includes Ad5PyLPC-RMC. This robust immune responses induced by SAd36PyLPC-RMC are translated into a lower parasite load and higher hemoglobin levels after a ***P. yoelii*** challenge when compared to naïve and mice immunized with Ad5PyLPC-RMC.

367

ENHANCING THE PROTECTIVE EFFICACY OF A CHIMERIC MULTI-STAGE RECOMBINANT MALARIA VACCINE WITH THE USE OF ADENOVIRAL VECTORS IN HETEROLOGOUS PRIME-BOOST IMMUNIZATION REGIMENS

Jairo A. Fonseca[1], Monica Cabrera-Mora[1], Igor Dmitriev[2], David Curiel[2], Jerry Blackwell[2], Alberto Moreno[1]

[1]*Emory Vaccine Center, Atlanta, GA, United States,* [2]*Washington University School of Medicine, St. Louis, MO, United States*

Although significant improvements in malaria control have occurred in the past few years, an effective vaccine is needed to control the disease. Given the complexity of the parasite, an ideal malaria vaccine should target several stages of the parasite life cycle. A major challenge for the development of an effective multi-stage vaccine is to induce balanced and robust cellular and humoral immune responses. However, a regimen able to induce such responses is not available. We have reported ***Plasmodium yoelii*** chimeric recombinant proteins derived from CSP and MSP-1 that express cognate promiscuous T cell epitopes. These vaccines have superior efficacy compared to non-chimeric vaccine constructs. Based on the reported chimeric proteins, we developed a single fusion protein called PyLPC-RMC. This protein was able to induce multi-stage immune responses mediated by CD4 T cells and neutralizing antibodies. With the aim of eliciting effective CD8 T cell responses, we produced recombinant adenovirus (Ad) vectors expressing PyLPC-RMC as a transgene and tested several prime-boost immunization regimens with the reported fusion protein in an effort to improve protective efficacy. A major concern in the use of the Ad5 vector is the high prevalence of anti-vector neutralizing antibodies against capsid proteins following natural infection in humans which limits the immunogenic potential of the vector. To overcome this limitation, we developed a chimeric Ad5/3 vector where the Ad5 knob region was replaced with the orthologous region from the rare Ad3 human serotype, allowing the vector to circumvent preexisting anti-Ad5 immunity. Comparative experiments demonstrated that the breadth of the immune responses elicited by immunization with Ad5 or recombinant Ad5/3 were comparable. Our data highlights that immunization with the recombinant Ad5/3 vector induces a protective immune response against ***P. yoelii*** infection that depends on antibodies, CD4 and CD8 T cells. To our knowledge this is the first time that the chimeric Ad5/3 vector has been used for malaria vaccine development. The proposed immunization regimen and correlates of protection will be discussed.

368

PHASE 2A/B PROTECTIVE EFFICACY OF *PLASMODIUM VIVAX* CS DERIVED PROTEIN FORMULATED WITH MONTANIDE ISA 51

Michelle Larmat

Nora Cespedes Malaria Vaccine and Drug Development Center, Cali, Colombia

Plasmodium vivax is one of the most widely distributed malaria parasites, generating a global burden estimated in 75-85 million cases every year, which represents a great public health problem, particularly in the Asian and American continents. Malaria vaccine is considered the most economical and best strategy that may contribute to accelerate the reduction or elimination of malaria in high to low areas of transmission. Despite the traditional shortage of funding for ***P. vivax*** malaria research, significant efforts are being invested in the development of ***P. vivax*** vaccines and several phase I clinical trials have been conducted in recent years involving two different parasite antigens, the circumsporozoite (CS) protein and the oocyst/ookinete Pvs25 protein. The MVDC has invested efforts in the development of a ***P. vivax*** vaccine program and successfully assessed the safety, tolerability, and immunogenicity of a mixture of three long synthetic peptides (LSP) derived from the ***P. vivax*** CS protein in two phase 1a/b clinical trials, in addition, to the establishment of the ***P. vivax*** sporozoite infectious challenge. The protective efficacy of the ***P. vivax*** CS LSP formulated in Montanide ISA 51 adjuvant is being assessed in a phase 2a/b randomized, double-blind, controlled trial. Sixteen malaria naïve volunteers and sixteen previously exposed volunteers (pre-immune) were included. Ten and six volunteers from each group were randomly assigned to the experimental (E) and control group (C), respectively. E volunteers will receive three doses of the mixture of LSP (150 µg) and C volunteers a placebo at months 0, 2 and 6. Thirty days after the last immunization all volunteers will be challenged with viable ***P. vivax*** sporozoites. Currently the first two immunizations have shown to be safe and well tolerated and no serious adverse events have occurred, however a local self-limited adverse event and a few self-limited systemic adverse events such as fever, headache, chills, malaise and diarrhea have developed in some volunteers within the first three days. Results of the immune response as well as the protective efficacy will be presented.

369

FROM LAB TO FIELD: PRACTICAL CHALLENGES TO PERFORMING SMFA WITH LOW MEAN OOCYSTS IN THE CONTROL

Kazutoyo Miura[1], Bruce Swihart[2], Bingbing Deng[1], Luwen Zhou[1], Thao P. Pham[1], Ababacar Diouf[1], Timothy Burton[1], Michael P. Fay[2], Carole A. Long[1]

[1]*Laboratory of Malaria and Vector Research/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States,* [2]*Biostatistics Research Branch/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States*

The standard membrane-feeding assay (SMFA) is one of few functional assays in which the transmission blocking activity (TBA) of test antibodies is evaluated in pre-clinical and clinical studies. There are two different readouts to express SMFA results: % inhibition in oocyst intensity (transmission reducing activity, TRA) and % inhibition in prevalence (transmission-blocking activity, TBA). Our lab and others have shown that TBA results from different assays depend on the mean number of oocysts in the controls. Therefore, if one wants to use TBA data directly from SMFA to estimate efficacy in the field, the SMFA should be performed with a similar mean number of oocysts in the control, i.e, means of more than 0 but less than 4-5, as is usually seen in mosquitoes in the field. However, at present it is very challenging to target the mean number of oocysts in the control within a certain restricted range (e.g., the mean number of oocysts is within 1-4, which we call "restricted SMFA"). Based on our SMFA data, we have compared TBA estimates from "restricted SMFA" and model-based TBA estimates. The "restricted SMFA" should have a pre-specified target mean number of oocysts in the control (e.g., 2.5, the midpoint of the restricted range), while the model-based TBA was calculated with observed TRA using any (i.e., non-restricted) controls. Our simulations show that the "restricted SMFA" required more feeding experiments compared with the model-based approach to achieve the same level of accuracy in TBA estimates. These results suggest that it might be more practical to estimate TBA based on the model rather than performing "restricted SMFA".

370

PROFILING OF ANTIBODY RESPONSES AGAINST *PLASMODIUM FALCIPARUM* PROTEIN ARRAY IN UGANDAN CHILDREN FOR IDENTIFICATION OF NOVEL BLOOD-STAGE VACCINE CANDIDATES

Bernard N. Kanoi[1], Eizo Takashima[1], Masayuki Morita[1], Edward H. Ntege[1], Betty Balikagala[1], Nirianne M. Palacpac[2], Thomas G. Egwang[3], Toshihiro Horii[2], Takafumi Tsuboi[1]

[1]*Division of Malaria Research, Proteo-Science Center, Ehime University, Matsuyama, Japan,* [2]*Department of Molecular Protozoology, Research Institute for Microbial Diseases, Osaka University, Osaka, Japan,* [3]*Medical Biotechnology Laboratories, Kampala, Uganda*

Immunity to ***Plasmodium falciparum*** malaria can be acquired albeit slowly and after repeated infections. Parasite specific antibodies are considered to play a critical role in this immunity. Despite malaria being an enormous global health burden, the key targets of protective antibodies remain largely unknown. Identification of these targets could accelerate development of much-needed malaria vaccine. In this study, we attempted to profile antibody responses to 1848 recombinant proteins representing ~35% of the ***P. falciparum*** entire proteome, to identify novel blood-stage malaria vaccine candidates. The recombinant proteins were expressed by wheat germ cell-free system; a robust eukaryotic protein expression system that allows synthesis of natively folded plasmodial proteins as compared to prokaryotic expression system. Serum samples were obtained from children and young adults (n=66) who are indigenous residents of Lira, a malaria holoendemic region in Northern Uganda. They were enrolled at the start of the rainy season and prospectively monitored for clinical malaria episodes for a year. Antibody (IgG) responses against the 1848 ***P. falciparum*** protein array were measured by modified AlphaScreen® system, a homogeneous assay in solution which has the advantage of retaining antigens in natural conformations. As an outcome, levels of 195 antigen-specific antibodies were significantly associated with protection from clinical malaria (Hazard ratio <1, P<0.05). Of these, 78 antigens were predicted to have signal peptide and/or transmembrane domain(s) suggesting expression on parasite surface hence viable targets of protective immunity. Overall, 32% (25/78) of selected antigens were previously uncharacterized hence considered novel blood-stage vaccine candidates. Our data offers new and wide options for malaria blood-stage vaccine candidate discovery.

The RTS,S/AS01 vaccine targets the circumsporozoite (CS) protein of ***Plasmodium falciparum*** and confers partial protective efficacy against clinical and severe malaria disease in infants and children for 12 months post vaccination (NCT00866619). We investigated whether vaccine efficacy was specific to parasite genotypes at CS. We employed PCR-based next-generation sequencing of DNA extracted from 4985 participant samples to survey polymorphisms in CS. We evaluated the impact of polymorphic CS positions and several haplotypic regions on vaccine efficacy (VE) against first or only episodes of clinical malaria within a year of vaccination. VE was significantly greater against clinical malaria with infections matching the vaccine strain in several haplotype regions and individual amino acid positions of the CS C terminus in the 5-17 month old per-protocol category of 4557 RTS,S/AS01 vaccinated and 2328 control vaccinated participants. For matched versus mismatched malaria based on the entire CS C-terminus, VE based on a hazard ratio was 62.7% (95% CI, 51.6 to 71.3) versus 54.2% (95% CI, 49.9 to 58.1), P = 0.06; and 1-year cumulative VE after vaccination was 50.3% (95% confidence interval [CI], 34.6 to 62.3) versus 33.4% (95% CI, 29.3 to 37.2), P = 0.04 for differential VE. In the 6-12 week old category, VE against matched and mismatched malaria was similar. Given the low frequency of parasites matching the vaccine strain at many of the study sites, these results suggest that parasite genotype contributes to the partial nature of protection conferred by RTS,S/AS01 vaccination in 5-17 month old children.

372

NOROVIRUS-VLPS EXPRESSING MALARIA ANTIGENS INDUCE FUNCTIONAL IMMUNITY AGAINST *PLASMODIUM* PARASITES

Elke Bergmann-Leitner[1], Mehran Pazirandeh[2], Julien Fey[2], Elizabeth H. Duncan[1], Heather E. Hosie[1], Carl Batt[3], **Evelina Angov**[1]

[1]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [2]*Agave BioSystems, Inc., Ithaca, NY, United States,* [3]*Cornell University, Ithaca, NY, United States*

Despite the development of novel prophylactic anti-malarial drugs and practices to prevent infection, malaria remains a major health concern in tropical regions. Preclinical testing of novel malaria vaccine strategies achieved through rational antigen selection and novel particle-based delivery platforms is yielding encouraging results in preclinical models. Self-assembling virus-like particles (VLP) and capsid-like particles (CLP) are safer than attenuated live viruses, and have been approved as vaccination tools by the FDA. Moreover, a theoretical potential for a dual-application vaccine, against both the vector particle and the heterologous insert, could greatly impact public health. Here we explore the use of Norovirus sub-viral particles that lack the natural shell (S) domain forming the interior shell but retain the protruding (P) structures of the natural virus as vaccine vector. Epitope selection and their combination into multiple epitope presentations may focus antigen specific immune responses to crucial epitopes. Several recombinant P-particles displaying epitopes from two protective malaria antigens, namely CelTOS and CSP, were evaluated for immunogenicity and their ability to confer protection in murine challenge models. Immune responses induced in mice resulted either in sterile protection (particles displaying PfCelTOS epitopes) or in antibodies with functional activity against sporozoites (particles displaying PfCSP epitopes) as measured by an ***in vitro*** liver-stage development assay (ILSDA). These results are encouraging and support further evaluation of this platform as a vaccine delivery system for malaria antigens.

373

HOW TO ADDRESS THE METHODOLOGICAL AND LOGISTICAL CHALLENGES OF PERFORMING MALARIA VACCINE EFFECTIVENESS STUDIES IN THE SUB-SAHARAN COUNTRIES

Judith Vandepitte

GlaxoSmithKline Vaccines, Wavre, Belgium

RTS,S/AS01 is the most advanced candidate vaccine and might be the first to be introduced for children living in sub-Saharan Africa (SSA). A Phase III pivotal trial (NCT00866619) demonstrated a partial vaccine efficacy against uncomplicated and severe malaria due to ***Plasmodium falciparum***. Pre- (NCT02374450) and post-licensure safety studies are planned in five SSA countries with a Health and Demographic Surveillance System in place. The effectiveness and impact of the vaccine, when used in addition to other malaria control interventions, needs to be assessed in a larger population setting. We have explored the optimal study design for SSA settings to estimate effectiveness and impact of RTS,S/AS01 against malaria disease. A methodological assessment of possible study designs was conducted, taking into account post-licensure uncertainties regarding recommended age groups and booster dose requirement. To account for effect modifiers and potential confounding factors, other determinants (such as malaria endemicity, vaccine coverage and field feasibility) were also considered. A stepped wedge cluster trial was considered unsuitable as simulations demonstrated that this design requires long study duration to account for malaria seasonality and a high number of clusters, which might be logistically complex to achieve in the field. A self-controlled case series design was considered inappropriate because of possible natural immunity against malaria existing before vaccination and the difficulty of identifying a control period during the same malaria season. Case-control design increases the risk confounding and does not allow for estimation of vaccine impact effects. The optimal design was considered to be a cohort study, this would allow calculation of vaccine effectiveness and vaccine attributable rate reductions, and could assess these measures for a variety of outcomes. Therefore, the effectiveness and impact of the RTS,S/AS01 vaccine will be first assessed through a cohort study embedded in and taking advantage of the infrastructure developed for the safety study in 5 SSA countries.

One of the constraints in the development of malaria vaccines is the limited availability of experimental models that can be correlates of protection. Randomized, controlled trials remain as the gold standard in providing scientific evidence regarding the efficacy of a malaria vaccine candidate. In clinical trials, several factors interplay with regards to interactions of the pathogen and host immune response. An evidence-based approach would expedite the development of a specific candidate. Here, we present the experiences we have encountered during our phase 1b clinical trial and follow-up study using the SE36 antigen from the blood stage ***Plasmodium falciparum*** malaria parasite. SE36 antigen was formulated with aluminum hydroxyl gel (BK-SE36). An age de-escalation (age cohorts: Stage 1: 21-40y; Stage 2: 16-20y, 11-15y, 6-10y) trial, tested BK-SE36 in participants after 2 vaccinations, 21 days apart. The vaccine was found to be safe and well tolerated. In our attempts to obtain additional data on the possible promise of BK-SE36, stage2 subjects were age-matched to 50 control individuals to compare malaria episodes 130–365 days post-second vaccination. In our assessment, we used a wide range of clinical outcomes from infection: using comparisons of risks, rates or hazards, depending on various endpoints. Each endpoint has its own advantages and disadvantages but gives important information for the developmental pathway of BK-SE36. Our longitudinal data constitute a first description of a blood-stage vaccine candidate that gave statistically significant level of protection up to one-year post-vaccination.

375

INITIAL EVALUATION OF PFS25-EPA AND PFS230-EPA CONJUGATES ADJUVANTED WITH ALHYDROGEL®

Daming Zhu, Yimin Wu, Weili Dai, Holly McClellan, Sarah Brockley, Lynn Lambert, Kelly Rausch, David Narum, Patrick E. Duffy

Laboratory of Malaria Immunology and Vaccinology, Rockville, MD, United States

Both Pfs25 and Pfs230 proteins of ***Plasmodium falciparum*** are leading malaria transmission-blocking vaccine candidates. Pfs25 is a surface protein expressed on the zygotes and ookinete stages in the infected mosquito and Pfs230 is expressed in gametocytes in the human host and on the surface of gametes in the mosquito host. To enhance immunogenicity, recombinant Pfs25 and Pfs230 domain 1 (identified as Pfs25M and Pfs230D1M, respectively) were chemically conjugated to recombinant nontoxic Pseudomonas aeruginosa ExoProtein A (rEPA) in conformance with current good manufacturing practices (cGMP). The clinical grade conjugates were formulated following cGMP on Alhydrogel at 78 µg/mL of Pfs25M and 50 µg/mL of Pfs230D1M, respectively. In order to meet the regulatory requirements for a phase 1 human

clinical trial, these drug products were extensively evaluated. The initial characterization performed on the clinical lots included appearance, endotoxin content, sterility, general safety, strength (protein content tested by o-Phthaldialdehyde (OPA) assay and aluminum content determined by atomic absorption), identity (SDS-PAGE and Western blot after extraction of antigen from Alhydrogel), integrity (pH, percent protein bound to Alhydrogel, SDS-PAGE, Intrinsic Fluorescence CD, Direct Alhydrogel Formulation Immunoassay), and efficacy (mouse potency assay). Our results showed that the Drug Products Pfs25M-EPA and Pfs230D1M-EPA formulated on Alhydrogel are in conformance with the regulatory specifications and are considered suitabe for human clinical trials.

376

DEVELOPMENT OF SELF-ADJUVANTED SELF ASSEMBLING NANOPARTICLES FOR USE AS MALARIA VACCINE CANDIDATES

Christopher Karch[1], David Lanar[2], Peter Burkhard[1]

[1]*University of Connecticut, Storrs, CT, United States,* [2]*Walter Reed Army Institute of Research, Silver Spring, MD, United States*

The need for a safe, effective, and affordable malaria vaccine is currently one of the most critical global public health concerns. Currently, no malaria vaccine candidate meets all of these criteria. RTS,S, the most successful candidate to date, induces protection, but these levels quickly fall; particularly in the most vulnerable population young children. In light of this situation there is a pressing need for new vaccine technologies to induce higher and longer lasting levels of protection. Our lab has developed the Self Assembling Protein Nanoparticle (SAPN) technology. Our SAPNs are rationally designed from coiled coil folding motifs to be similar in size and shape to small icosahedral viruses. Each SAPN is decorated on its surface with 60 copies of the antigen of choice. Currently, we have multiple malaria SAPNs in all stages of development from preclinical to clinical trials. One important aspect of vaccine development is adjuvant formulation. We have begun to expand upon our SAPN design to generate self-adjuvanted particles. These self-adjuvanted SAPNs contain a fragment of ***Salmonella enterica*** flagellin, a known TLR5 agonist, as well as a malaria antigen. Previous studies have indicated that TLR5 activation by flagellin has the potential to function as a successful adjuvant by activating cells in both the innate and adaptive immune system. This activation leads to a strong adaptive immune response and ultimately memory. ***In vitro*** studies in a model cell culture system indicate that SAPNs containing flagellin stimulate TLR5 in a concentration dependent manner. Initial animal studies are ongoing to determine the effect on protection against sporozoite challenge. Our self-adjuvanted SAPNs are viable new malaria vaccine candidates that may potentially eliminate the need to contain a separate adjuvant in the vaccine formulation.

HIGH-THROUGHPUT AUTOMATED ASSAYS FOR ANTIBODY BINDING AND INHIBITION OF SPOROZOITE INVASION

Sumana Chakravarty[1], Natasha KC[1], Patricia Dranchak[2], James Inglese[2], Stephen L. Hoffman[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*Chemical Genomics Center, National Center for Advancing Translational Sciences , National Institutes of Health, Rockville, MD, United States*

In recent trials, Sanaria® ***Plasmodium falciparum*** (Pf) sporozoites(PfSPZ)-based vaccines, composed of aseptic, purified, cryopreserved, radiation attenuated PfSPZ Vaccine, or non-attenuated PfSPZ with chloroquine (PfSPZ-CVac) were safe and highly protective. PfSPZ Vaccine protected 100% and 92% of non-immune individuals after 5 doses and 87% after 3 doses in 2 independent trials and provided durable and heterologous (75%) strain protection. PfSPZ-CVac was 100% efficacious in non immunes. Under natural exposure settings in Africa, PfSPZ Vaccine provided ~50% protection of semi-immune individuals over 6 months. Analysis of the humoral immune responses induced in these volunteers has uncovered a striking correlation between anti-PfCSP antibodies measured by ELISA and their protective status. Because the activity of antibodies in response to PfSPZ is believed to target SPZ before they enter hepatocytes, we assessed 2 additional measures of antibody function: the capacity to bind PfSPZ (anti-whole PfSPZ Immunofluorescence Assay or IFA) and the ability to prevent invasion into HC-04 cells (inhibition of Sporozoite Invasion or ISI). Initially IFA was performed by manual inspection of antibody-stained dried PfSPZ preparations. We have enhanced the throughput of this assay coating sporozoites in 96-well format and using an Acumen eX3 laser cytometer for fluorescence detection and quantification. The IFA readouts are highly correlated (75%-90%) with anti-PfCSP responses.The ISI assay is similarly performed with HC 04 cells grown in 96-well plates followed by a 3-hour invasion of PfSPZ. Both assays are reproducible over multiple iterations with specificity, sensitivity and statistical significance to predict clinical outcome in non-immune volunteers. Analysis of semi-immune individuals is ongoing. The miniaturized IFA and ISI assays are also useful screening tools in human monoclonal antibody development. They are expected to provide the malaria community with antigen-unbiased assays to interrogate antibody responses across diverse pre-erythrocytic vaccine platforms in an automated high-throughput format.

378

DIFFERENTIAL ANTIBODY RESPONSE TO THE *ANOPHELES STEPHENSI* AAPP AND *PLASMODIUM* ANTIGENS IN INDIVIDUALS NATURALLY EXPOSED TO BITES OF AFROTROPICAL MALARIA VECTORS

Mitsuhiro Iyori[1], Risa Fujiyoshi[1], Din Syafrudin[2], Shigeto Yoshida[1]

[1]*Kanazawa University, Kanazawa, Japan,* [2]*Eijkman Institute of Molocular Biology, Jakarta, Indonesia*

To identify the efficacy of control efforts of intervention trials against malaria transmission, the development of sensitive tools for evaluation of malaria risk and frequency of the vector exposure is required. During the exposure to the anopheles mosquitoes, antibodies against some of the salivary gland proteins are raised in the hosts. Recently, we have identified that anopheles mosquitoes expressed anopheline anti-platelet protein (AAPP), a one of the major component of the salivary protein, and the anti-AAPP antibody was well induced in mice frequently bitten by the mosquitoes. To examine the possibility of anti-AAPP antibody as a new tool for the evaluation system of malaria risks, recombinant AAPP as well as a series of malaria antigen were purified, and ELISA was conducted for the sera of residents of Sumba Island, Indonesia. Throughout the rainy season we examined, anti-malaria antibodies such as anti-PfCSP IgG and anti-PfMSP1 IgG were significantly increased in the individuals infected with ***Plasmodium*** as compared with normal hosts. In contrast, IgG responses to AAPP were increased after the exposure to the mosquitoes during the rainy season, and those with high titer of anti-AAPP antibody was significantly correlated with infection with ***Plasmodium*** spp. Geographical variations of mosquitoes number were associated with the anti-AAPP IgG responses, further supporting that anti-AAPP antibody response was depended on the variation of vector exposure. Taken together, anti-AAPP IgG can be a suitable marker for the evaluation of the vector exposure and malaria risks.

379

MALARIA CONTROL WITH SOLAR-POWERED MOSQUITO TRAPPING SYSTEMS: SOCIO-ECONOMIC AND PERCEIVED HEALTH OUTCOMES OF HOUSE LIGHTING IN RUSINGA ISLAND, WESTERN KENYA

Prisca A. Oria[1], Cees Leeuwis[1], Alexandra Hiscox[1], Daniel Masiga[2], Willem Takken[1], Jane Alaii[2]

[1]*Wageningen University and Research Centre, Wageningen, Netherlands,* [2]*International Centre for Insect Physiology and Ecology, Nairobi, Kenya*

In 2012, a proof of principle study was launched to eradicate malaria from Rusinga Island using solar-powered mosquito trapping systems (SMoTS). In addition to the mosquito trap, two light bulbs and a mobile telephone charging port were provided for use in each homestead in which a SMoTS was installed. Prior to receiving SMoTS, residents mainly used kerosene tin lamps for lighting. The effectiveness of new preventive health interventions is enhanced if, in addition to clinical efficacy, they are socially and culturally acceptable, and are widely adhered to in the longer-term. Social science studies on the project aim to understand socio-cultural and behavioural aspects of adherence to use and maintenance of SMoTS. We assessed socio-economic and perceived health outcomes of house lighting using in-depth interviews and focus group discussions with selected early recipients of SMoTS. The main economic benefit of solar lighting was reduced or eliminated expenditure on kerosene. Additionally, some residents charged mobile telephones for neighbours without SMoTS for pay. Kerosene traders, however, attracted fewer customers which led some to abandon the trade. Electricity reportedly reduced risks of respiratory infections, fire outbreaks from tin lamps, and physical accidents prone to poor house lighting. However, bright lights reportedly attracted mosquitoes into houses. Social outcomes included improvements in spousal relations due to reduced squabbles over expenditure on kerosene, while extended lighting periods facilitated unhurried social networking in the evenings, and night-time studying. Respondents also perceived improved social status as a result of owning a SMoTS. Negative social outcomes were strained relationships among women in polygamous households and envy from households that did not receive SMoTS. Although data on malaria prevention is not yet complete, there is evidence of enhanced socio-economic and emotional well-being of study participants which may increase the desire of community members to sustain the intervention beyond the research period.

380

CONTROLLING MALARIA VECTORS IN EASTERN RWANDA THROUGH A COMMUNITY-BASED LARVAL SOURCE CONTROL APPLICATION OF BTI

Chantal M. Ingabire[1], Emmanuel Hakizimana[1], Constantianus JM Koenraadt[2], Alexis Rulisa[3], Fredrick Kateera[1], Leon Mutesa[4], Michelle Van Vugt[5], Jane Alaii[6], Bart Van Den Borne[7]

[1]*Rwanda Biomedical Center, Kigali, Rwanda,* [2]*Wageningen University, Wageningen, Netherlands,* [3]*Rwanda Social Security Board, Kigali, Rwanda,* [4]*University of Rwanda, Kigali, Rwanda,* [5]*Academic Medical Center, Amsterdam, Netherlands,* [6]*Context Factor Solutions, Nairobi, Kenya,* [7]*Maastricht University, Maastricht, Netherlands*

Larval source management (LSM) with existing vector control strategies such as insecticide treated nets (LLINs) and indoor residual spraying (IRS) are expected to contribute to further malaria reduction. We evaluate the process of a community-led LSM using bacillus thuringiensis israelensis (Bti). The research is being conducted in Ruhuha sector, a malaria endemic zone of the eastern province of Rwanda, geographically surrounded by marshlands and mainly occupied by rice farming. Since January 2015, four main steps were achieved; baseline studies involving entomological and socio economic aspects, training of larval control and mosquito surveillance teams; larval control implementation and lastly self-assessment using designed toolkits. Overall, 90% of rice farmers highlighted stagnant water/irrigation ditches as common mosquito breeding sites and 92% cited rice fields as significantly contributing to larval habitats. Only 12% had ever heard about LSM. However, 90% and 88% of the rice farmers were confident of the safety of the intervention to rice consumers and farmers, respectively. Nearly all were confident that the intervention would reduce the number of mosquitos and thereby reduce malaria transmission. Weekly application of Bti in marshlands resulted in a decrease of late stage mosquito larvae as compared to the baseline data. A self-assessment done using checklists coupled with weekly meetings highlighted contextual aspects and challenges to the implementation of the intervention and resulted in adjustment of self-assessment tools. The community-based LSM was found highly acceptable in the area. Newly identified open water sources have had implications on the amount of product to be used as well as the general timeframe allocated to the intervention. In conclusion, this novel approach is deemed to contribute to significant malaria reduction in the area and is expected to strengthen community know-how and promote local (1) ownership, (2) sustainability and (3) long term application.

381

NO DIFFERENCE IN THE INCIDENCE OF MALARIA IN HUMAN-LANDING MOSQUITO CATCH COLLECTORS AND NON-COLLECTORS IN A SENEGALESE VILLAGE WITH ENDEMIC MALARIA

Amélé N. Wotodjo[1], Jean-François Trape[1], Vincent Richard[2], Souleymane Doucouré[1], Nafissatou Diagne[1], Adama Tall[2], Ousmane Ndiath[3], Ngor Faye[4], Jean Gaudart[5], Christophe Rogier[6], Cheikh Sokhna[1]

[1]*Institut de Recherche pour le Développement, Dakar, Senegal,* [2]*Institut Pasteur de Dakar, Dakar, Senegal,* [3]*Institut Pasteur International Network, Bangui, Central African Republic,* [4]*Université Cheikh Anta Diop de Dakar, Dakar, Senegal,* [5]*Aix-Marseille Université, Marseille, France,* [6]*Institut Pasteur de Madagascar, Antananarivo, Madagascar*

To study the various vectors that transmit malaria and estimate their aggressiveness, most entomological studies opt to capture mosquitoes using human landing catches (HLC), which remains the gold standard method. However, this method has raised safety concerns due to a possible increased risk of malaria or other mosquito-borne diseases among the mosquito collectors. The aim of this study was to evaluate the incidence of malaria attacks among mosquito collectors and to compare these results with those of non-collectors living in a Senegalese village. From July 1990 to December 2011, a longitudinal malaria study involving adult mosquito collectors and non-collectors was performed in Dielmo village, Senegal. During the study period, 4 drugs were successively used to treat clinical malaria, and long-lasting insecticide-treated nets were offered to all villagers in July 2008. No malaria chemoprophylaxis was given to mosquito collectors. Incidence of uncomplicated clinical malaria and asymptomatic malaria infection were analyzed among these two groups while controlling for confounding factors associated with malaria risk in random effects negative binomial and logistic regression models, respectively. A total of 3,812 person-trimester observations of 199 adults at least 15 years of age were analyzed. Clinical malaria attacks accounted for 6.3% both in collectors and non-collectors, and asymptomatic malaria infections accounted for 21% and 20% in collectors and non-collectors. A non-significant lower risk of malaria was observed in the collector group in comparison with the non-collector group after adjusting for other risk factors of malaria and endemicity level (clinical malaria: adjusted incidence rate ratio = 0.89; 95% confidence interval [95%CI] = 0.65-1.22; p= 0.47). Being a mosquito collector in Dielmo was not significantly associated with an increased risk of malaria both under holoendemic, mesoendemic and hypoendemic conditions of malaria epidemiology. This result supports the view that HLC, the most accurate method for evaluating malaria transmission, can be used in areas with endemic malaria without ethical concern.

382

USING MACHINE-LEARNING FEATURE SELECTION APPLIED TO NEAR INFRARED SPECTRA TO CHARACTERIZE AGES OF MALARIA VECTORS

Masabho P. Milali

Marquette University, Milwaukee, WI, United States

One way to evaluate the degree of risk of a particular mosquito population on malaria transmission is by determining its age and species composition. Currently, mosquito age-grading is best done by hand-dissection of ovaries to identify mosquitoes that have previously laid eggs (i.e., likely to be old and potentially infectious), and those that have not previously laid eggs (likely to be young and non-infectious). Studies show that the minimum age of mosquitoes to lay eggs is three days. Such a mosquito cannot be infectious, as the malaria parasite needs 10-14 days in mosquitoes to complete its development. A mosquito has to be at least 10 days old to be infectious. This means knowing a mosquito's egg laying status is not enough information to tell whether it is infectious. This implies a need for a new method to age grade a particular mosquito population to determine its infectiousness. Studies have shown that Near-Infrared Spectroscopy (NIRS), a low-cost high-throughput method, is 95% accurate on age-grading laboratory-reared mosquitoes. Based on calibration from lab-reared mosquitoes, NIRS classified 95% of 1740 wild samples to be <10 days old and 5% to be at least 10 days old. Despite of these promising results on age grading wild mosquitoes, its application still needs validation of its accuracy. Once hand dissection of ovaries were thought to be a means of validating accuracy of NIRS, but dissection does not provide chronological age needed to validate NIRS inferred ages. Identifying specific spectral feature associated with age is one way of validating these results. Using supervised machine learning (samples used have labels), we applied feature extraction techniques to characterize patterns associated with age from spectra collected from lab-reared mosquitoes. Machine learning feature extraction uses computer tools to develop features from a huge data set. 700 spectra collected from lab-reared mosquitoes with different known ages were used in this analytical study. It was found that there are features in spectra that support classification of lab-reared mosquitoes by age, a step toward validation of NIRS for age-grading of wild mosquitoes.

383

WHAT IS THREATENING THE EFFECTIVENESS OF ITNS? A COMPARISON OF PHYSICAL, BEHAVIORAL, ENTOMOLOGICAL AND ENVIRONMENTAL FACTORS

Wendy Prudhomme O'Meara[1], Judith Mangeni[2], Alyssa Platt[1], Lucy Abel[3], Jane Namae[2], Andrew Obala[2]

[1]Duke University, Durham, NC, United States, [2]Moi University, Eldoret, Kenya, [3]AMPATH, Eldoret, Kenya

Insecticide-treated nets are the cornerstone of global malaria control and have been shown to reduce malaria morbidity by 50-60%. However, some areas are experiencing a resurgence in malaria following successful control. We enrolled 442 children hospitalized with malaria in an endemic area of western Kenya where coverage with ITNs is high. We paired them with age, time, village and gender-matched controls. We completed comprehensive household and neighborhood assessments including entomological surveillance. The variables were grouped into five domains - ITN ownership, compliance, physical integrity, vector susceptibility and facilitating factors. After variable selection, case-control data were analyzed using conditional logistic regression models and mosquito data were analyzed using negative binomial regression. Measures of ITN coverage and physical integrity were not correlated with infection in our study . However, ITN compliance(AOR=0.23, 95%CI:0.12-0.43) presence of nearby larval sites (AOR=1.43, 95%CI:1.05-1.95), and specific types of crops were significantly correlated with infection amongst children who owned an ITN. The odds of infection increased nearly three-fold when one other household member had symptomatic malaria infection (AOR=2.76, 95%CI:1.83-4.18). Overall, perfect household adherence could reduce the probability of infection to less than 30% and reducing environmental risk factors could reduce the probability of infection to less than 20%. We conclude that availability of ITNs is not the bottleneck for malaria prevention in this community. Behavior change interventions to improve compliance and environmental management of mosquito breeding habitats may greatly enhance ITN efficacy. A better understanding of the relationship between agriculture and mosquito survival and feeding success is needed.

384

EFFECTIVENESS OF CONTINUOUS DISTRIBUTION IN SUSTAINING ACCESS TO LONG-LASTING ITNS: RESULTS FROM FIVE COUNTRIES

Angela Acosta[1], Albert Kilian[2], Celine Zegers de Beyl[3], Emmanuel Obi[4], Ato Selby[3], Andrea Brown[1], Mohamad Sy-Ar[1], Hannah Koenker[1], Matthew Lynch[1]

[1]Johns Hopkins University School of Public Health, Baltimore, MD, United States, [2]Tropical Health, LLP, Montagut, Spain, [3]Malaria Consortium, London, United Kingdom, [4]Malaria Consortium, Abuja, Nigeria

Sustained universal coverage with ITNs is essential to malaria control. While mass campaigns which deliver nets in a single time-limited operation, continuous distribution systems (CD) use existing infrastructure such as clinics, schools, religious leaders and community-based workers to deliver nets continuously over time. To assess the effectiveness of CD, the NetWorks project piloted different models in five settings: Cross River State, Nigeria (schools and ANC), Nasarawa State, Nigeria (community and ANC), Ghana (multiple: schools, ANC and child clinics), Madagascar (community) and South Sudan (community). The number of nets distributed ranged from 26,686 to 150,000 per pilot. Pre-post representative cross-sectional household surveys were carried out in Nigeria, Ghana and South Sudan; in Madagascar, the study was a post-only design. Results showed improvements or, for Madagascar, continuation of high rates across several key indicators such as ownership of at least 1 ITN (Cross River 51% to 77%, Nasarawa 17% to 37%, Ghana 81% to 88%, Madagascar 97% and South Sudan 66% to 82%) and population access to an ITN (Cross River 34% to 55%, Nasarawa 16% to 34%, Ghana 57% to 67%, Madagascar 84% and South Sudan 38% to 66%). For the proportion of households with at least 1 ITN per 2 people, improvements were mixed with positive outcomes in Cross River (17% to 30%) Madagascar (62%) and South Sudan (31% to 63%) and slight declines in Nasarawa (25% to 17%) and Ghana (50% to 40%). Few households were oversupplied with nets and there was little overlap in source of nets. However, in Nasarawa, which had the lowest coverage outcomes at endline, gains were constrained by stock-outs, insufficient awareness of the program (only 32% of households knew about the program), and misconceptions among providers. Regardless, overall results suggest that CD contributes to sustained ownership levels and household access to ITNs over time. The quality of implementation contributed measurably to redemption rates for community distribution. Pilots with strong partnerships, sensitization, and supervision systems were successful.

385

HEALTH SYSTEMS STRENGTHENING: IMPROVING QUALITY OF SERVICES FOR PREVENTION OF MALARIA IN PREGNANCY THROUGH THE STANDARDS-BASED MANAGEMENT AND REWARD APPROACH IN KENYA

Augustine M. Ngindu[1], Gathari Ndirangu[2], Sanyu N. Kigondu[2], Isaac M. Malonza[3]

[1]United States Agency for International Development-MCSP, Kisumu, Kenya, [2]United States Agency for International Development-MCSP, Nairobi, Kenya, [3]Jhpiego Kenya, Nairobi, Kenya

Performance quality improvement (PQI) is one of Jhpiego's 9 health systems strengthening components in provision of health services towards improvement of maternal health including better pregnancy outcomes. The Standards-Based Management and Reward (SBM-R) approach has been used in improving as well as assessing the quality of services provided at health facilities. Kenya developed 15 malaria in pregnancy (MIP) SBM-R standards for use by service providers in provision of MIP services and is also used by supervisors to assess the quality of services provided at service delivery points. Facility incharges were trained on the 15 MIP SBM-R performance standards and they oriented service providers in their facilities on use of the performance standards. A baseline on SBM-R practices was done in all facilities before orientation in Kakamega east and Kakamega central subcounties and 1st assessment on practices done after three months of practice. A total of 30 health facility incharges from the two malaria endemic subcounties ***(Kakamega east 16 Kakamega central 14)*** were trained on the 15 MIP SBM-R performance standards. The facility incharges oriented 291 service providers ***(127 Kakamega east, 164 Kakamega central)*** on use of SBM-R performance standards in provision of MIP services in health facilities. Baseline assessment had an average score of 57% for Kakamega east and 58% for Kakamega central. 1st assessments were conducted after three months of practice and showed an average score of 76% for Kakamega east and 64% for Kakamega central giving an overall increase in score of 19% and 13% between baseline and 1st assessment for Kakamega east in Kakamega central respectively. Use of MIP SBM-R performance standards ensures services provided at health facility level are in line with WHO recommendations and national guidelines. Establishment of PQI as a health systems strengthening component is feasible and is an approach that would make available quality MIP services at facility level. Provision of quality MIP services ensures protection of pregnant women against the effects of malaria in pregnancy.

[1]RTI International, Dar es Salaam, United Republic of Tanzania, [2]National Malaria Control Programme, Dar es Salaam, United Republic of Tanzania, [3]President's Malaria Initiative/United States Agency for International Development, Dar es Salaam, United Republic of Tanzania, [4]Swiss Tropical and Public Health Institute, Dar es Salaam, United Republic of Tanzania, [5]Tanzania Red Cross Society, Dar es Salaam, United Republic of Tanzania, [6]Johns Hopkins University-Center for Communication Programs, Dar es Salaam, United Republic of Tanzania, [7]RTI International, Durham, NC, United States, [8]RTI International, Washington DC, United States

Tanzania has been successful in implementing mass distribution of nets through a number of campaigns conducted to scale up the coverage of insecticide-treated nets (ITNs) in the country. In order to sustain these gains, the government has adopted a school-based approach as a Keep-up Strategy for the continuous distribution of long-lasting insecticidal nets (LLINs). In 2013, it piloted a school net project (SNP1) for distribution of LLINs in the Southern Zone. A second round of school net project (SNP2) was undertaken to maintain high access to LLINs. This study reports on the design, implementation and outcomes of the SNP2 project to sustain high LLIN coverage in Southern Tanzania. The SNP was conducted in Lindi, Mtwara and Ruvuma regions of Tanzania to distribute nets to students and teachers of primary and secondary schools (Standard 1, 3, 5 and 7 and Forms 2 and 4). In Lindi region, two additional classes (class 2 and 4) were targeted for net distribution. Each student from the selected classes received one LLIN for his/her household. In addition, a net was issued to each of the primary and secondary school teachers in the three regions. Training and sensitization activities, planning of logistics, data quantifications and revision of tools and manuals from SNP1, took place prior to net distribution. We designed a database that used an android software application for collection, entry and management of SNP2 data. A total of 487 trainers and 4,583 implementers were trained for distribution of the nets to schools. A total of 2,337 schools, 473,700 students and 25,269 school teachers participated in SNP2. A total of 507,775 LLIN were distributed to schools. A total of 464,893 (98.0% of registered) students and 24,206 (95.8% of registered) school teachers received LLIN. After net distribution was over, 18,676 (3.8% of those distributed) LLIN remained. The SNP2 reached 98% of registered eligible students. LLIN ownership and use in the community can be expected to increase and therefore reduce the burden of malaria in the three SNP regions.

387

COVERAGE, USE AND MAINTENANCE OF BED NETS AND RELATED INFLUENCE FACTORS IN KACHIN SPECIAL REGION II, NORTHEASTERN MYANMAR

Hui Liu

Yunnan Institute of Parasitic Diseases, Simao, Puer, China

Myanmar is one of the 31 highest burden malaria countries worldwide. The study combined a quantitative household questionnaire survey and qualitative direct observation of households to investiagte the extent to which bed nets were used and which factors influence bed net use among the population in Kachin Special Region II, Northeastern Myanmar. The results of study showed that the bed net to person ratio was 1:1.96 (i.e., more than one net for every two people). The long lasting insecticidal net (LLIN) to person ratio was 1: 2.52. Also, the percentage of households that owned at least one bed net was 99.7% (666/688). 3262 (97.3%) residents slept under bed nets the prior night, 2551(76.1%) of which slept under ITNs/LLINs the prior night (SUITNPN). The poorest families (OR: 4.67, 95% CI: 3.59 to 9.12; P<0.0001), those with thatched roofing (OR: 1.57, 95% CI: 1.33, 2.24; P<0.0001), those who use agriculture as their main source of family income (OR: 1.66, 95% CI: 1.45, 2.70; P<0.0001), household heads who knew that mosquitoes transmit malaria (OR: 1.88, 95% CI:1.45-3.47; P<0.0001) and those who used bed nets to prevent malaria (OR: 1.56, 95% CI: 22, 2.67; P=0.0003) were significantly more likely to be in the SUITNPN group. However, residents in lowlands and foothills were significantly less likely to be SUITNPNs (OR: 0.63, 95% CI: 0.44, 0.71; P<0.0001). Finally, head of household attitude towards fixing bed nets influenced MCHI (F=8.09, P=0.0046). The coverage and usage rates of bed nets were high, especially among children and pregnant women. Family wealth index, geographical zones, household roofing, source of family income, household head's knowledge of malaria transmission and of using bed nets as tools for malaria prevention are independent factors which influence use of ITNs/LLINs in KR2. The attitudes of household heads toward mending bed nets influenced the intactness of bed nets. Maintaining high coverage and use rate of bed nets should be a priority for the war-torn population of KR2 to ensure equity and human rights.

388

A LONGITUDINAL STUDY OF THE DURABILITY OF LONG-LASTING INSECTICIDAL NETS IN ZAMBIA

Kathrine R. Tan[1], Jane Coleman[2], Barbara Smith[3], Busiku Hamainza[4], Cecilia Katebe-Sakala[5], Casey Kean[6], Ashley Kowal[7], Jodi L. Vanden Eng[1], Stephen C. Smith[1], Tiffany K. Parris[1], Carla T. Mapp[1], Robert A. Wirtz[1], Mulakwa Kamuliwo[4], Allen S. Craig[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Jhpiego an affiliate of Johns Hopkins University, Washington, DC, United States, [3]Peace Corps, West Coast Region, San Francisco, CA, United States, [4]Zambia National Malaria Control Centre, Lusaka, Zambia, [5]Bayer (Pty) Ltd, Isando, South Africa, [6]Success Academy Charter Schools, New York, NY, United States, [7]Society for Family Health, Lusaka, Zambia

Universal access to long-lasting insecticidal nets (LLINs) is key to malaria control. Quantifying how many nets are needed to achieve and maintain universal coverage requires knowing when to replace worn nets. Net lifespan is often thought to be 3 years. We aimed to describe attrition, physical integrity, and insecticide persistence of LLINs over time to better estimate net lifespan. In 2 highly endemic provinces in Zambia, LLINs randomly selected from distribution records were followed every 6 months from 12-30 months of age. Net owners were surveyed on net care and reasons for attrition. Holes were counted and sizes estimated (< thumb =1.23 cm^2, ≥thumb but <fist =28.28 cm^2, ≥fist but < head=240.56 cm^2, and ≥head=706.95 cm^2). Proportional hole index (pHI) was calculated by dividing hole area by 1.23 cm^2 (smallest hole area). Functional survival (FS) was defined as nets present at follow up with a pHI <643 (WHO working group definition). Generalized estimating equation models of log transformed pHI and survival analysis on nets with endpoints of attrition and pHI≥643 were done. At 12 and 24 months old, a subset of nets was studied for insecticidal activity and concentration using bioassay and chemical analysis. We enrolled 999 LLINs; 505 PermaNet and 494 Olyset nets. Of these, 74 were removed for insecticide studies, and 925 had full follow-up. At 30 months old 325 (33%) nets remained. Attrition at 12-30 months old was primarily due to disposal (29%). Olyset nets, repairs and use over a reed mat were associated with larger log pHIs. Only 56% of remaining nets met FS criteria. FS was shorter in nets with repair ($p<0.05$), but longer in nets used the night before ($p<0.05$) and never washed ($p<0.05$). At 30 months, nets had a 34% chance of functionally surviving. Median survival was longer in PermaNets than Olysets ($p<0.05$). Insecticide activity and content was lower at 12 months old. Bioassay and chemical results were poorly correlated, likely due to small sample size. Replacing nets every 3 years may not be enough to maintain high level coverage with LLINs in this setting. A better measure of net survival incorporating insecticidal effectiveness is needed.

389

TYPHOID TRANSMISSION: A HISTORICAL PERSPECTIVE ON MATHEMATICAL MODEL DEVELOPMENT

Iurii Bakach[1], Matthew R. Just[1], Manoj Gambhir[2], Isaac Chun-Hai Fung[1]

[1]Georgia Southern University, Statesboro, GA, United States, [2]Monash University, Melbourne, Australia

Mathematical models of typhoid transmission have been developed for nearly half a century. To facilitate a better understanding of the historical development of this field, we reviewed mathematical models of typhoid and summarized their structures and limitations. Eleven models, published in 1971 to 2014, were reviewed. While models of typhoid vaccination are well developed, we highlight the need to better incorporate water, sanitation and hygiene interventions into models of typhoid and other foodborne and waterborne diseases. Mathematical modeling is a powerful tool to test and compare different intervention strategies which is important in the world of limited resources. By working collaboratively, epidemiologists and mathematicians can build better mathematical models of typhoid transmission that will be useful in epidemiological practice.

390

A SYSTEMATIC REVIEW OF DIARRHEAL DISEASE: ITS DIFFERENTIAL BURDEN BETWEEN GENDERS AND THE ROLE OF WOMEN IN THE ABATEMENT OF THIS EPIDEMIC?

Varadan Sevilimedu[1], Keisha Pressley[1], Kassandra Snook[1], Jamesa Hogges[1], Maria Politis[1], Kelly Baker[2], Manoj Gambhir[3], Isaac Chun-Hai Fung[1]

[1]Georgia Southern University, Statesboro, GA, United States, [2]University of Iowa, Iowa City, IA, United States, [3]Monash University, Melbourne, Australia

Even though research on diarrheal diseases has been done in the past, some aspects have remained unexplored. One of these aspects is the differential disease burden and vulnerability to disease between males and females. We try to shed light on this important issue by performing a systematic review of relevant articles chosen from the literature. We searched PubMed for peer-reviewed articles, and included grey literature from the World Health Organization, Water and Sanitation for the Urban Poor and Water Supply and Sanitation Collaborative Council. All articles that dealt with the public health relevance of diarrheal disease, focused on access to clean water and care taker role in access to clean water, role of gender in sanitation, helminth infections and differential gender burden were included in this study. Articles which do not address diarrheal diseases and the role of sanitation and WASH interventions in the amelioration of diarrheal diseases and helminth infections, articles that are not epidemiologically linked or articles that deal with rare pathogens or diseases, therapeutic regimens or drug resistance were excluded from the study. All articles that dealt with respondents 6 years of age and older were included in the study. From our systematic review, we concluded that the burden of diarrheal disease falls more on females qualitatively than males. Women empowerment in making household and community level decisions with regard to sanitation may be of greater benefit to the well-being of society in developing countries. Some limitations of our study are: The study participants in most of the studies belonged to the 6-18 year age group, which could have resulted in age bias. Secondly, because of the large quantity of articles that were retrieved, there is a small but very unlikely chance that some relevant articles might have been missed. Lastly, we provide qualitative evidence of differential burden of diarrheal disease between genders. A meta-analysis will be performed to consolidate our current findings.

391

AUTOMATED VS. NON-AUTOMATED ANTIBIOTIC SUSCEPTIBILITY TESTING: A COMPARATIVE ANALYSIS OF METHODS FOR ASSESSING RESISTANCE IN *SHIGELLA* AND *ESCHERICHIA COLI*

Elizabeth Odundo[1], Janet Ndonye[1], Ronald Kirera[1], Brett E. Swierczewski[2], Christine Hulseberg[1]

[1]KEMRI/United States Army Medical Research Unit - Kenya/Walter Reed Project, Nairobi/Kericho, Kenya, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Substantial milestones have been achieved in automation of microbiology assays for identification and antimicrobial susceptibility testing of bacterial pathogens. However, non-automated methods are still widely utilized across the globe. Both automated and non-automated ***in vitro*** methods are available in Kenya to determine the minimum inhibitory concentrations (MIC) for multiple antibiotics against bacterial pathogens. A comparison study was performed using 60 common diarrheal clinical isolates of ***Shigella*** spp (30) and E. coli (30) on two representative methods: the Etest® (Biomérieux), a non-automated gradient diffusion test, and the Negative Breakpoint Combo 34 panel (NBPC 34) for the MicroScan (Siemens), a micro broth dilution-based automated platform. The resistance patterns for these isolates against five commonly used antibiotics in Kenya were interpreted according to the Clinical and

Laboratories Standards International (CLSI M07-09-2012) guideline. The resistance patterns measured by both MicroScan and Etest® were highest to Tetracycline (90%) and Trimethoprim/Sulphamethoxazole (> 80%) for both pathogenic E. coli and ***Shigella*** spp. Resistance patterns were much higher for E.coli for the following anibiotics by MicroScan and Etest® respectively: Ampicillin/Sulbactam: 60% and 50% and Ampicillin: 90% and 80% as compared to ***Shigella*** spp: Ampicillin/Sulbactam: 3% and 33% and Ampicillin: 53% and 50%. Resistant patterns among E. coli pathotypes were similar while among ***Shigella*** spp, S. flexneri exhibited higher resistance than S. sonnei to three out of the five antibiotics tested. Ciprofloxacin, whose use in treatment for acute diarrhea is increasing in Kenya, was more than 100% effective against E. coli and 90% against ***Shigella*** spp. There was significant correlation of the results obtained between the two methods ($p < 0.01$). Therefore, either of these methods can be used for reliable ***in vitro*** antimicrobial susceptibility testing for clinical or research purposes.

392

IDENTIFICATION OF *SALMONELLA ENTERICA* SEROVAR PARATYPHI A ANTIGENS EXPRESSED DURING CHRONIC BILIARY PARATYPHOID CARRIAGE

Geoffrey Gonzalez-Escobedo[1], Farhana Khanam[2], Mohammad Murshid Alam[2], Stephen Calderwood[1], Stephen Baker[3], Firdausi Qadri[2], Edward T. Ryan[1], Richelle Charles[1]

[1]Massachusetts General Hospital, Boston, MA, United States, [2]International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh, [3]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam

Enteric fever, caused by ***Salmonella enterica*** serovar Typhi (***S.*** Typhi) and serovar Paratyphi (***S.*** Paratyphi) A, B, or C, is a life-threatening systemic disease, responsible for significant morbidity and mortality worldwide. A subset of individuals infected with enteric fever become asymptomatic chronic carriers, with the gallbladder and biliary ducts being primary sites of chronic colonization. Because ***S.*** Typhi and ***S.*** Paratyphi are human-restricted pathogens, asymptomatic carriers can act as critical reservoirs for further spread of enteric fever. We have previously used ***in vivo***-induced antigen technology (IVIAT) to identify potential bacterial biomarkers unique to ***S.*** Typhi chronic carriers. Here, we report a similar approach to identify bacterial antigens expressed in humans with ***S***. Paratyphi A isolated from cholecystectomy specimens in Kathmandu, Nepal. In brief, we pooled sera from ***S.*** Paratyphi A carriers and adsorbed it against ***in vitro***-grown ***Escherichia coli.*** We then used this sera to screen a genomic inducible expression library of ***S.*** Paratyphi A (500-1500 bp fragments) in ***E. coli*** BL21DE3. We identified 70 clones (representing 133 genes of interest) that were reactive with the sera from paratyphoid A carriers but not against sera from Bangladeshi healthy controls or patients convalescing from acute paratyphoid A infection. Thus far, we have subcloned 98 of the 133 genes of interest, and identified 48 proteins with higher immunoreactivity in chronic paratyphoid A carriers compared to healthy individuals from a typhoid endemic area (Dhaka, Bangladesh). Many of the genes encode proteins involved in carbohydrate transport/metabolism and antimicrobial peptide resistance, whereas others encode uncharacterized proteins which may play an important role in surviving in the nutrient-limited biliary environment or in the formation of biofilms. Further assessment of these proteins may lead to the discovery of diagnostic biomarkers of ***S.*** Paratyphi A carriers, and may lead to improved understanding of the survival adaptations of ***Salmonella*** in biliary tissue.

393

CHARACTERIZATION BY PCR-RFLP OF STRAINS OF *CAMPYLOBACTER JEJUNI* IN CHILDREN FROM 0- 5 YEARS WITH DIARRHEA IN THE PERUVIAN AMAZON

Rosa Burga[1], Cesar Banda[2], Maribel Paredes[2], Margaret Kosek[3], Nathanael Reynolds[1], Drake H. Tilley[1], Mark P. Simons[1]

[1]U.S. Naval Medical Research Unit-6, Lima, Peru, [2]Asociacion Benefica PRISMA, Iquitos, Peru, [3]Department of International Health, Johns Hopkins Bloomberg School of Public Health., Baltimore, MD, United States

Campylobacter is one of the most common causes of bacterial gastroenteritis in children living in developing countries. To date, 18 species of ***Campylobacter*** have been described, with C. jejuni being the most common cause of gastrointestinal infections in most settings. Molecular biology provides a wide variety of techniques for genotypic sub–typing of ***Campylobacter*** spp. The use of the polymerase chain reaction (PCR)–restriction fragment length polymorphisms (RFLP) technique allows for the higher resolution of pathogen identification to assist in source tracing and outbreak investigation. Application of the PCR–RFLP assay of Fla A gen was performed to determine the genetic diversity of ***Campylobacter*** spp. found circulating in the Amazonian jungle community of Santa Clara, Peru between 2002 to 2006 in stool samples of children from 0–5 years of age.***Campylobacter***–specific restriction fragment length polymorphisms (RFLP) were described in asymptomatic, dysenteric and non–dysenteric diarrhea stools. Specific RFLP patterns showed a high level of diversity among isolates and specific RFLP patterns were highly associated with the having clinical dysentery, as opposed to watery diarrhea or no diarrhea. The utility and feasibility of the realization of molecular techniques in this remote region at low cost demonstrates that this test to be incorporated in epidemiological studies to improve the understanding of disease transmission of ***Campylobacter*** in children under five in endemic areas.

394

ANTIBIOTIC RESISTANCE IN *CAMPYLOBACTER* AND *SHIGELLA* SPECIES ISOLATED FROM AMAZONIAN CHILDREN UNDER FIVE YEARS BETWEEN 2010-2014

Ricardo E. Abadie[1], Claudio Rocha[1], Rosa Burga[1], Maribel Paredes[2], Cesar Ramal[3], Graciela Meza[4], Nathanael D. Reynolds[1], Mark P. Simons[1], Margaret Kosek[5]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]Asociación Benéfica PRISMA, Iquitos, Peru, [3]Hospital Regional de Loreto, Iquitos, Peru, [4]Direccion Regional de Salud Loreto, Iquitos, Peru, [5]Department of International Health, Johns Hopkins School of Public Health, Baltimore, MD, United States

Campylobacter and ***Shigella*** species are common cause of diarrhea in children from developing countries. Due to the emergence of antimicrobial resistance in these species, therapeutic options have dramatically reduced causing considerable morbidity and mortality in children from developing countries. In this study, we cultured 12,304 stool samples and analyzed the antibiotic resistance profiles of 875 ***Campylobacter*** and 218 ***Shigella*** species isolated between 2010-14 from children under five years old near the Peruvian Amazon city of Iquitos. Fecal samples were cultured on standard growth media plates for bacterial identification and antibiotic susceptibility determined on ***Campylobacter*** and ***Shigella*** isolates by disk diffusion. Of the ***Campylobacter*** isolates, C. jejuni was most prevalent (64%) followed by C. coli (34%), whereas S. flexneri was most prevalent (69%) ***Shigella*** spp. isolate followed by S. sonnei (20%), S. boydii (10%) and S. dysenteriae (1%). Of the ***Campylobacter*** isolates, 84% were resistant to trimethoprim/sulfamethoxazole, followed by ciprofloxacin (77%), nalidixic acid (67%), ampicillin (53%), tetracycline (50%) and 12% to azithromycin and erythromycin each. Of all tested ***Shigella*** species, the highest resistance rate was found against tetracycline (89.5%), followed by trimethoprim/sulfamethoxazole (86.2%), ampicillin (76%), erythromycin

(72.5%). Only 5% of ***Shigella*** species were resistant to azithromycin, while 16.5% exhibited intermediate resistance profiles. Similarly, nalidixic acid resistance in ***Shigella*** was detected in 3% of the isolates and 11% showed intermediate resistance, with none of the isolates resistant to ciprofloxacin (0%) and only 0.9% demonstrating intermediate resistance. These high antibiotic resistance rates in ***Campylobacter*** and ***Shigella*** represent a serious public health concern for children living in the Amazon, especially in remote regions where trimethoprim/sulfamethoxazole remains the first line of therapy against dysentery. Based on these results, strategies for treatment of diarrheal diseases in this region should be adjusted to reflect emergence of resistance.

395

RECOMBINASE POLYMERASE AMPLIFICATION AS A DIAGNOSTIC FOR TOXIN PRODUCING *CLOSTRIDIUM DIFFICILE* IN POINT-OF-CARE SETTINGS

Hayley N. Sparks[1], Diana M. Quilaguy[2], Alex G. Peniche[1], Kevin W. Garey[3], Sara M. Dann[1], Alejandro Castellanos-Gonzalez[1]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Fundación Universitaria del Area Andina, Bogota, Colombia, [3]University of Houston College of Pharmacy, Houston, TX, United States

Clostridium difficile Infection (CDI) has become a significant global health concern over recent years. With the emergence of highly virulent strains and continuing spread throughout the world, innovations in CDI detection and treatment are severely needed. The most accurate current methods for diagnosis are costly and use equipment not currently available in clinical labs worldwide. Recombinase Polymerase Amplification (RPA) is an isothermal method for DNA amplification. Unlike PCR, the reagents for RPA are thermostable and do not require expensive thermal cyclers for amplification; which allows the entire RPA reaction to be ran on the bench top at point-of-care facilities. The detection of the resulting amplicon can be made using the novel process of lateral flow analyses (LF). This detection method requires a very short amount of time and is graded using the naked eye, advancing the value of this method. The goal of this project is to utilize our RPA-Lateral Flow (RPA-LF) protocol to detect ***C. difficile*** in DNA samples and to further identify if the sample contained DNA coding for toxin A or B, a critical diagnostic determination. We accomplished this by designing specific primers for the toxin A and B genomes which were then paired with a specific genetic probe that allows for detection via the lateral flow strips. By the RPA-LF method, we have detected 10^3 toxin A producing bacteria and 10^4 toxin B producing bacteria. Further exploration has demonstrated the specificity of RPA when testing ***C. difficile*** samples alongside other enteric pathogens; ***C. difficile*** was positively identified while non-***C. difficile*** samples were continuously negative. The RPA-LF protocol was successfully utilized to identify the presence of ***C. difficile*** in the stools of infected mice. RPA-LF is currently being tested against PCR results from human stool samples. If successful, this data will further strengthen the potential of RPA-LF as a future, vital point-of-care diagnostic. Induction of this protocol as an acceptable method for CDI detection would also aid in the advancement of a global monitoring system for the spread of ***C. difficile***.

396

REDUCTION IN DIARRHEAL RATES THROUGH INTERVENTIONS THAT PREVENT UNNECESSARY ANTIBIOTIC EXPOSURE EARLY IN LIFE

Elizabeth T. Rogawski[1], Steven R. Meshnick[1], Sylvia Becker-Dreps[1], Linda S. Adair[1], Robert S. Sandler[1], Rajiv Sarkar[2], Deepthi Kattula[2], Honorine D. Ward[3], Gagandeep Kang[2], Daniel J. Westreich[1]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Christian Medical College, Vellore, Vellore, India, [3]Tufts Medical Center, Boston, MA, United States

Antibiotic treatment of common childhood illnesses, such as acute gastroenteritis and upper respiratory infections, is generally not indicated. Antibiotic exposure before 6 months of age has also recently been associated with increased rates of subsequent diarrhea. However, because the treatment of some illnesses with antibiotics is necessary, we cannot prevent all antibiotic exposures early in life. Here, we estimated the impact of realistic interventions that would prevent only unnecessary antibiotic exposures on childhood diarrheal rates. In data from a prospective observational cohort study conducted in Vellore, India, we used the parametric g-formula to model diarrheal incidence rate differences contrasting the observed incidence of diarrhea to the incidence expected under hypothetical interventions. The interventions prevented antibiotic treatments for non-bloody diarrhea, vomiting, and upper respiratory infections before 6 months of age. More than half of all antibiotic exposures before 6 months (58.9%) were likely unnecessary. The incidence rate difference associated with removing unnecessary antibiotic use before 6 months of age was -0.28 (95% confidence interval: -0.47, -0.11) episodes per 30 child-months. This implies that preventing unnecessary antibiotic exposures in just 4 children would reduce the incidence of diarrhea by one from 6 months to 3 years of age. When targeted only to children who had stopped exclusive breastfeeding, the impact of the interventions was smaller because many antibiotic exposures occurred during exclusive breastfeeding. These results suggest that a general intervention applied to all children before 6 months of age would be most effective. This work provides an example application of statistical methods which can further the aim of presenting epidemiologic findings that are relevant to public health practice. Interventions to reduce unnecessary antibiotic use among young children could result in an important reduction in diarrheal rates.

397

A CONJUGATE VACCINE FOR CHOLERA CONTAINING THE O-SPECIFIC POLYSACCHARIDE (OSP) OF *VIBRIO CHOLERAE* O1 INABA AND A RECOMBINANT FRAGMENT OF TETANUS TOXIN HEAVY CHAIN (OSP:RTTHC) INDUCES SERUM, MEMORY AND LAMINA PROPRIAL RESPONSES AGAINST OSP, AND PROTECTION AGAINST WILD TYPE CHOLERA CHALLENGE IN MICE

Md. Abu Sayeed[1], Meagan K. Bufano[2], Peng Xu[3], Grace Eckhoff[4], Richelle C. Charles[2], Md. Murshid Alam[1], Tania Sultana[1], Md. Rasheduzzaman Rashu[1], Amanda Berger[2], Geoffrey Gonzalez-Escobedo[2], Anjali Mandlik[2], Taufiqur R. Bhuiyan[1], Daniel T. Leung[2], Regina C. LaRocque[2], Jason B. Harris[2], Stephen B. Calderwood[2], Firdausi Qadri[1], W. F. Vann[5], Pavol Kováč[3], **Edward T. Ryan**[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Massachusetts General Hospital, Boston, MA, United States, [3]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD, United States, [4]Harvard Medical School, Boston, MA, United States, [5]CBER, Food and Drug Administration, Laboratory of Bacterial Toxins, Bethesda, MD, United States

Vibrio cholerae is the cause of cholera, a severe watery diarrhea. Protection against cholera is serogroup specific. Serogroup specificity

is defined by the O-specific polysaccharide (OSP) component of lipopolysaccharide (LPS). Here we describe a conjugate vaccine for cholera prepared via squaric acid chemistry from the OSP of V. cholerae O1 Inaba strain PIC018 and a recombinant heavy chain fragment of tetanus toxin (OSP:rTTHc). Immunized mice developed prominent anti-OSP and anti-TT serum IgG responses, as well as vibriocidal antibody and memory B cell responses following intramuscular or intradermal vaccination. Mice did not develop anti-squarate responses. Intestinal lamina proprial IgA responses targeting OSP occurred following intradermal vaccination. We assessed a range of vaccine doses based on the OSP content of the vaccine (10-50 µg), and vaccine compositions varying by molar loading ratio of OSP to rTTHc (3:1, 5:1, 10:1). In general, we found comparable immune responses in mice immunized with these variations, although memory B cell and vibriocidal responses were blunted in mice receiving the highest dose of vaccine (50 µg). We found no appreciable change in immune responses when the conjugate vaccine was administered in the presence or absence of immunoadjuvant alum. Administration of OSP:rTTHc resulted in 55% protective efficacy in a mouse survival cholera challenge model. Development of an effective cholera conjugate vaccine that induces high level and long-term immune responses against OSP would be beneficial, especially in young children who respond poorly to polysaccharide antigens.

398

HIGHLIGHTING THE ESSENTIAL SECONDARY METABOLITES OF THREE OYSTER MUSHROOMS RESPONSIBLE FOR ANTIMICROBIAL ACTIVITIES AGAINST MULTIDRUG RESISTANT *SHIGELLA* SPP.

Debasmita Chatterjee[1], Dipankar Halder[1], Satadal Das[2]

[1]Jadavpur University, Kolkata, India, [2]Peerless Hospital and B.K. Roy Research Centre, Kolkata, India

Growing resistance to available antibiotics is becoming a serious issue now and thus exploring all natural resources to find an effective antimicrobial agent is of paramount importance. Shigellosis, a highly prevalent diarrheal disease in developing countries is presently associated with multidrug resistance (85%) ***Shigella*** isolates having higher MIC values against commonly used antimicrobials, isolated from fresh stools and rectal swab samples of infected persons. Although antimicrobial activities of edible mushrooms are well known against common pathogens like ***Staphylococcus***, ***E. coli*** etc. the antimicrobial activities of edible mushrooms against ***Shigella*** spp. is largely unknown. Thus the present study was aimed to evaluate the ***in-vitro*** antibacterial activities of ethanol and aqueous extracts (hot) of three oyster edible mushrooms namely ***Pleurotus ostreatus, Pleurotus eous*** and ***Pleurotus florida*** against ***Shigella flexneri*** type 4a, ***Shigella sonnei***, ***Shigella boydii*** and multidrug resistant ***Shigella flexneri*** type 2a. Methodologies adopted were agar disc diffusion assay and minimum inhibitory concentration (MIC) assay along with phytochemical screening assay (PSA) was performed for the detection and estimation of specific antimicrobial components. All the ethanol based crude mushroom extracts showed inhibitory activities against all the ***Shigella*** spp. especially upon the multidrug resistant strain. Presence of essential secondary metabolites such as phenol, flavonoid, terpenoid, steroid and saponin were confirmed in the tested mushrooms. Significant difference (ANOVA, P value < 0.0001) in the phenol and flavonoid content of the mushrooms were correlated for their differences in antimicrobial activities. Therefore, this study revealed anti-shigellosis potency of edible mushrooms highlighting specific essential secondary metabolites of them which may be responsible for such activities.

AGGREGATIVE ADHERENCE AND INTESTINAL COLONIZATION BY ENTEROAGGREGATIVE *ESCHERICHIA COLI* ARE PRODUCED BY INTERACTIONS AMONG MULTIPLE SURFACE FACTORS

Alexander Lafrance, Laura V. Blanton, Lawrence T. Wang, Joshua W. DuBow, Stephen Kwak, Levi J. Bowers, Jennifer Hwang, Iruka N. Okeke

Haverford College, Haverford, PA, United States

Enteroaggregative ***Escherichia coli*** (EAEC) are important diarrheal pathogens worldwide, and particularly in developing countries. EAEC are exceptional colonizers that are defined by the characteristic stacked-brick pattern they produce on epithelial cells. This defining phenotype is convergent. Strains exhibiting it typically express one of several varieties of Aggregative Adherence Fimbriae (AAF). Research in our laboratory has revealed that a non-structural adhesin, the integral outer membrane Heat-Resistant Agglutinin 1 (Hra1), is sufficient to produce aggregative adherence and is encoded on many EAEC chromosomes. Hra1, like AAF, confers autoaggregation and biofilm formation ***in vitro***. An hra1 mutant of EAEC strain 042 adheres but is deficient in true stacked-brick formation and ***in vivo*** colonization but shows no defects in the ***in vitro*** phenotypes. We hypothesized that Hra1 is sterically masked by one or more other surface factors and unveiled only when required for host colonization. Physically or genetically removing fimbriae from EAEC strain 042 reveals that the AAF/II fimbriae do not mask Hra1. By contrast, deletion of the gene encoding a secreted antiaggregation protein (Aap) resulted in enhanced ***in vitro*** colonization-associated phenotypes and ***in vivo*** clumping in a Caenorhabditis elegans colonization model. Hyper-autoaggregation by aap mutants was previously attributed to loss of Aap-AAF interactions. We demonstrate that enhanced autoaggregation and biofilm formation by aap mutants is unrelated to the presence of AAF/II but is Hra1-dependent. The data suggest that Aap masks Hra1 ***in vitro*** and that the aggregative adherence phenotype is a complex one mediated by multiple surface factors.

CARRIAGE OF NASAL *STAPHYLOCOCCUS AUREUS* AND RHINOVIRUSES AMONG HEALTHY INDIVIDUALS IN THREE RURAL AREAS OF GHANA

Michael Owusu, Ellis Owusu-Dabo, Augustina Annan, Yaw Adu-Sarkodie

Kwame Nkrumah University of Science and Technology, Kumasi, Ghana

Colonisation of the nares with ***Staphylococcus aureus*** is known to be associated with skin and soft tissue infections. Data on its occurrence is however limited in many developing countries including Ghana. This study therefore sought to describe the burden of Staphylococcus aureus, risk factors for infection and co-colonisation with rhinoviruses. We conducted a cross-sectional study among healthy individuals in three rural areas of Ghana. Nasal swabs were collected from study participants and tested for the presence of methicillin resistant Staphylococcus aureus (MRSA), methicillin susceptible ***Staphylococcus aureus*** (MSSA) and coagulase negative staphylococci (CoNS) bacteria using conventional bacteriological techniques. Nasopharyngeal swabs were also collected and tested for the presence of rhinoviruses using Reverse Transcriptase Real-Time Polymerase Chain Reaction. Staphylococci bacteria were identified in 91 (25.4%; 95% CI = 21% - 30.3%) out of the 358 study subjects enrolled. Of all bacteria isolated, 51 (56.0%) were MSSA, 32 (35.2%) were CoNS, 6 (6.6%) were MRSA and 2 (2.2%) were methicillin resistant coagulase negative staphylococci (MR-CoNS). The overall prevalence of MSSA was 14.2% (95% CI; 10.8% - 18.3%) and that of MRSA was 1.7% (95% CI; 0.6% - 3.6%). Of the total 205 samples, 78 (38.0%; 95% CI = 31.4% - 45.1%) tested positive for rhinoviruses. Nine (4%) were positive for both MSSA and rhinoviruses while one (1) was positive each for MRSA and MR-

CoNS. There was no association between human rhinovirus detection and MSSA (p = 0.52) or MRSA colonisation. In conclusion, the present study has further corroborated other findings that MSSA and MRSA are still significant reservoirs of human nasopharynx in rural areas of Ghana. There is a need to look at the disease transmission dynamics and a further strong public health education on practices that reduce the transmission of these pathogens within communities.

IDENTIFICATION OF NEW ANTIGEN CANDIDATES OF *BARTONELLA BACILLIFORMIS*

Claudia Gomes[1], Noemi Palma[1], Carmen Tinco[2], Isabel Sandoval[3], Carlos Gutarra[3], Juana del Valle[2], Joaquim Ruiz[1], Mayumi Kubota[4], Health Center Tunal[5], Health Center Los Ranchos[5], Health Center Guayaquiles[5], Health Center Mayland[5], Health Center Huancabamba[5]

[1]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [2]Laboratorio de Biología Molecular y Celular. Centro de Investigación de la Facultad de Ciencias de la Salud. Universidad Peruana de Ciencias Aplicadas (UPC), Lima, Peru, [3]Red de Salud de Morropon Chulucanas, Piura, Peru, [4]National Institute of Infectious Diseases, Tokyo, Japan, [5]Health Centers of Tunal, Los Ranchos, Guayaquiles, Mayland and Huancabamba, Piura, Peru

Bartonella bacilliformis is a fastidious Gram-negative bacterium associated with Carrion disease, a neglected illness endemic in Peru. In the acute phase of the disease, ***B. bacilliformis*** invades erythrocytes and mortality rates are 44-88% in absence of adequate treatment. A relevant problem is the lack of an effective diagnostic to overcome misdiagnosis and treat asymptomatic carriers (about 45% of people living in endemic areas). The objective of this study was to identify new ***B. bacilliformis*** antigenic candidates that could lead to a new diagnostic tool able to be implemented in rural areas. Serum samples from 177 people were collected in 5 different localities of northern Peru (in 4 of them an outbreak occurred few months earlier and the another one is an endemic region). Clinical data were recorded and ELISA for IgM / IgG with whole cell as antigen was done. After sonication, total bacteria were separated via gel electrophoresis and electrotransferred onto a PVDF membrane. Seroreactive antigens were detected by Western blot analysis with each serum both for IgG and IgM. The candidate proteins detected were cut out and N-terminal amino acid sequencing was performed. The presence of at least one symptom compatible with Carrion disease was reported by 34.5%. After Western blot analysis and taking into account the ELISA levels obtained, four proteins were considered potential antigenic candidates, two detected by IgM and two by IgG. The amino acid sequencing identified Pap31 and GroEl, already described in the literature but with no optimal results, and two new antigenic candidates (both subunits of the same protein). One has 30.1 kDa and was detected with IgM while another has 42.75 kDa and was detected with IgG. These new antigenic candidates are involved in the tricarboxylic acid cycle and one was recently described as being able to play a role in the invasion process and in the pathogenesis of other Bartonella spp. infection. The fact that these new antigens were identified with these sera highlights their possible usefulness in the development of a rapid diagnostic tool.

402

PRECLINICAL VALIDATION OF ANTI-BURULI ULCER PLANTS USED IN TRADITIONAL MEDICINE

Patrick V. Tsouh[1], Abena A. Kissi-Twum[1], Dorothy Yeboah-Manu[1], Regina Appiah-Opong[1], Phyllis Addo[1], Fabrice F. Boyom[2], Alexander K. Nyarko[1]

[1]University of Ghana, Accra, Ghana, [2]University of Yaounde 1, Yaounde, Cameroon

Buruli ulcer (BU) is the third most prevalent mycobacteriosis, after tuberculosis and leprosy. West Africa bears more than 90% of the disease burden and mainly in remote rural areas. The recommended drug combination Rifampicin-Streptomycin is not affordable for the majority of affected populations who thereby rely mainly on herbal remedies. The systematic investigation of ethnobotanical facts is a reasonable first step to unveiling more efficacious remedies as affordable and more readily accessible treatment for BU locally. In the aim of validating the use of 15 traditional plant remedies used by the rural population for the treatment of BU, their biological activity and safety were assessed. The identification of the 15 plants used in traditional medicine to manage BU was achieved through a short survey based on ethnobotanical reports. Maceration of plants samples resulted in 18 hydroethanolic extracts. The activity of extracts against ***Mycobacterium ulcerans*** NM2O9 was tested using the Resazurin Microtiter Assay. The safety of promising extracts' fractions was assayed on WRL68 human hepatocyte cell line by Resazurin reduction assay. Generally, the selected plants are locally used as decoction, infusion and maceration and are taken orally or applied on the ulcerated lesions. Six extracts from 5 plants demonstrated activity with Minimum inhibitory concentrations (MIC) between 16.12-31.25µg/mL. ***Mangifera indica*** root and leaf, ***Azadirachta indica*** stembark, ***Vernonia amygdalina*** leaf, ***Alchornea cordifolia*** leaf and ***Spathodea campanulata*** root showed the lowest MIC value of 16.12µg/mL, while that from ***Zanthoxylum zanthoxyloides*** root showed the highest MIC value of 31.25µg/mL. Apart from ***V. amygdalina*** extract with CC_{50} value of 10.27µg/mL, promising extracts were not cytotoxic (CC_{50}≥40.9µg/mL) according to the American National Institute for Cancer criterion (CC_{50}<30µg/mL). These results support the traditional use of the 5 promising plants in the treatment of BU. However, detailed studies are required to unveil the active ingredients in the lead extracts and elucidate their mechanisms of action for further anti-BU drug development.

403

'A SOCIAL KILLER': LEPROSY, STIGMA, AND THE HISTORY OF THE CONTROL OF A NEGLECTED DISEASE IN CAMEROON, 1916-1974

Flavius M. Mokake

Ohio University, Athens, OH, United States

Just as disease eradication has social benefits, a highly stigmatized disease such as leprosy can lead to the social death of its sufferers as well as affect control measures. I assume that leprosy is both a 'social epidemic' and a 'social killer,' as the illness of an individual affects their immediate and whole community, and defines their personhood and social relations within their given social ecumenes. Studies have zoomed in on the degree of stigma that characterizes neglected tropical diseases (NTDs) such as leprosy. However, equal measure of attention has not been accorded the association of stigma and the control of NTDs from a historical perspective. This research aims to highlight the dynamic interrelationship between disease, medicine and society through history, building on the conjoined phenomena of tropical disease and tropical medicine. I argue that disease outbreaks and interventions can illuminate divisions within a society as they affect different groups of people differently. Using essentially primary data (archival and oral sources), it maps out the institutionalization and contours of stigma, marginality, and social change, and how those can be understood within the broader social, economic, and political forces that animated developments in Cameroon. The study also focuses on how the disease undermined the integrity of the body of leprosy patients, and how colonialism and political change transformed leprosy into a 'stigmatized phenomenon' in spite efforts to 'destigmatized' it in the various leprosy institutions in colonial and postcolonial Cameroon. Results from this study will inform us on the checkered history of global health and the control of NTDs, and how the problem of stigma has animated the cultural and social issues in the epicenters of leprosy in Cameroon violating racial, social, economic, and political boundaries.

404

ANTIBACTERIAL PROPERTIES OF EXTRACTS FROM *PSIDIUM GUAJAVA* (L) AGAINST MULTIDRUG RESISTANT *STAPHYLOCOCCUS AUREUS*

Daniel Boamah[1], Godfred F. Danso[1], Beverly Egyir[2], Slyvester Kaminta[1], Salomey Acheampong[1], Mark Addo Apenteng[1], Alfred A. Appiah[1], Dominic A. Edoh[1]

[1]Center for Plants Medicine Research, Mampong, Ghana, [2]Noguchi Memorial Institute for Medical Research. University of Ghana, Legon, Accra, Ghana

Pathogenic ***Staphylococcus aureus*** causes infections such as septicemia, pneumonia and renal abscess. It produces extracellular enzymes and heat stable enterotoxins that can cause food poisoning. Multi-drug resistance (MDR) in ***S. aureus*** is a major public health concern and methicillin resistant ***S. aureus*** (MRSA) remains a global health threat. It is difficult to successfully treat infections caused by such resistant strains since treatment options are limited. Medicinal plants have played important roles in drug discovery resulting in successful treatment of many diseases. ***Psidium guajava*** (apple guava) has been traditionally used to treat various diseases including malaria, gastroenteritis, diarrhea, coughs and sore throat. The study investigated the antibacterial activities of ***P. guajava*** leaves extracts against MDR-SA isolates identified and characterized from 5 major health facilities in Ghana. To ensure the viability of the 30 MDR-SA isolates, Mueller Hinton agar plates were spread with 50 µl of each isolate suspended in biological peptone followed by incubation at 37°C for 24 h. The antibacterial activities of the aqueous, 70% and absolute ethanolic crude extracts against the MDR-SA were investigated by the agar-well diffusion in duplicates and mean zones of inhibition recorded. The extracts showed effective antibacterial activities and in some cases inhibitions zone of 16, 14.5, 13.5, 11.5 and 10.5 mm were recorded for 200, 100, 50, 25, 12.5 mg/ml of the extract respectively. The 70% ethanolic extract appeared much more effective against the MDR-SA screened. The MIC value for each isolate was found to be considerably strong ranging from 1.56 to 6.25 mg/ml while the ATCC-25923 isolate had 3.13 mg/ml for both the extract and ciprofloxacin. The ***P. guajava*** extracts obtained may have broader antibacterial activities than the isolates tested. It is expected that the active phytochemical will the identified to develop more effective anti-MDR-SA agent that could be helpful in better management of infections associated with multi-drug resistance ***S. aureus***.

405

MOLECULAR DETECTION OF GENES CONFERRING ANTIBIOTIC RESISTANCE IN UROPATHOGENIC *ESCHERICHIA COLI* STRAINS (UPECS) ISOLATED IN MEXICO

Gloria Luz Paniagua-Contreras, Eric Monroy-Pérez, Arely Bautista-Cerón, Miguel Angel Ramos-Puebla, **Sergio Vaca**

Universidad Nacional Autonoma de Mexico FES-Iztacala, Tlalnepantla, Mexico

The emergence of UPEC strains multiresistant to antibiotics is considered as a serious health concern. The aim of this work was to determine the frequency of genes conferring resistance to antibiotics commonly used in Mexico, and to other genes coding for extended spectrum betalactamases (ESBLs) in a total of 194 UPEC strains isolated from community-acquired urinary tract infection patients from Unidad Médica Familiar No. 64 (Mexican Institute for Social Security of Tlalnepantla, Edo. de México, México). The ***Escherichia coli*** strains were identified by biochemical tests and by PCR amplification of 16S rRNA gene. Genes coding antibiotic resistance and betalactamases were identified by single and multiplex PCR. Percentages of antibiotic-resistance-conferring genes among UPEC strains were as follows: 30.9% (n=60) carried the ***sul1*** gene (sulfonamide resistance); 33.5% (n=65) ***tetA*** (tetracycline resistance); 17% (n=33) ***tetB*** (tetracycline resistance); 12.3% (n=24) ***dfrA1***(trimethoprim resistance); 11.8% (n=23) ***cat1*** (chloramphenicol); 4.1% (n=8) ***cmlA*** (chloramphenicol); 2% (n=4) ***aadA1*** (streptomycin) and 0% carried ***aac(3)-IV*** (gentamycin) or ***qnr*** (quinolone). Frequencies ESBLs genes among UPEC strains were: bla_{TEM} 26.3% (n=51); 13.9% (n=27) bla_{SHV}; 23.1% (n=45) $bla_{OXA\text{-}1\ Like}$, 22.6% (n=44) $bla_{CTX\text{-}M}$ phylogenetic group 1; 0% $bla_{CTX\text{-}M}$ phylogenetic group 2; and 3% (n=6) $bla_{CTX\text{-}M}$ phylogenetic group 9. Finally, 8.7% (n=17) of the strains carried the $bla_{OXA\text{-}48}$ gene coding for carbapenem-resistant betalactamase. These results shows that antibiotic resistance is common among UPEC strains, and notably high to sulfonamide, tetracycline and to cephalosporins. These data may be useful to document that patterns of antibiotic resistance in UPECs vary with patient population and geographic region.

406

RODENT RESERVOIRS AND ENVIRONMENTAL SOURCES OF *LEPTOSPIRA* ALONG THE TRANS-OCEANIC HIGHWAY IN THE SOUTHERN AMAZON BASIN OF PERU

Valerie Cortez, Enrique Canal, J. Catherine Dupont-Turkowsky, Tatiana Quevedo, Gabriela Salmon-Mulanovich, M. Claudia Guezala Villavicencio, Mark Simons, Daniel G. Bausch

U.S. Naval Medical Research Unit - 6, Lima, Peru

Rodents are the reservoir for numerous zoonotic pathogens, including ***Leptospira***, which are shed in the urine of infected animals. Transmission occurs by direct animal contact or through exposure to contaminated environmental sources such as stagnant water, exacerbated by flooding during rainy seasons. Deforestation, agricultural expansion, and human settlements can perturb rodent habitats, potentially increasing contact with humans and transmission of ***Leptospira***. Such perturbations have resulted from the construction of the trans-oceanic highway though the Madre de Dios Region in the southern Peruvian Amazon, increasing the potential for zoonotic infections among residents in newly established communities along the highway. We set out to determine the prevalence of ***Leptospira*** in rodent populations and in the environment along the highway in Madre de Dios. Urine and tissue samples from captured wild rodents, surface water samples, and soil were collected from 6 different locations in 4 communities along the highway, each with varying levels of habitat perturbation, during both dry and rainy seasons. Pathogenic ***Leptospira*** were detected by amplification of the ***lipL32*** gene by PCR. During the dry season, 21 environmental samples were collected from non-disturbed areas (3), border areas (7), disturbed areas (4), and from locations within the communities (7). Thirty-eight samples were collected during the rainy season, including non-disturbed areas (8), border areas (12), disturbed areas (6), and from locations within the communities (12). To date, 2/21 (9.5%) environmental samples from the dry season and 8/38 (21%) samples from the rainy season were PCR positive. Testing is underway on 136 rodent kidney and urine samples, as well as phylogenetic analysis of the 16S rRNA gene sequence to characterize the ***Leptospira*** species diversity in both rodent and environment samples. Our data are consistent with a higher prevalence of ***Leptospira*** in the environment during the rainy season and provides valuable data on the species circulating in the southern Amazon Basin.

407

INJECTIONAL ANTHRAX: AN EMERGING GLOBAL PUBLIC HEALTH THREAT

Joseph R. Miller, Shawn V. Patrick

Armstrong State University, Savannah, GA, United States

Anthrax (caused by ***Bacillus anthracis***) traditionally has been identified through three routes of exposure: cutaneous, gastrointestinal or inhalation. With the numbers of individuals using illicit drugs steadily rising since the turn of the 21st century, particularly in Europe where intravenous drug use is 4.6 times the global average, a new form of infection has cropped up. Coined injectional anthrax, contaminated heroin is administered into the individual whom proceeds to suffer from severe soft tissue infection, symptoms similar to cutaneous exposure, septic shock,

and death. The goal of this presentation is to examine existing data on injectional anthrax and to provide a detailed synopsis over the last fifteen years for physicians and government officials. Clearly, injectional anthrax represents an emerging infectious disease of public health importance.

408

RECOMBINANT TETANUS TOXIN FRAGMENT C DIPSTICK: A RAPID, COST-EFFECTIVE ASSAY FOR MEASURING VACCINE EFFICACY

Marcia Wright[1], Girija Ramakrishnan[2], Joyce Sink[1], Masud Alam[3], Mamun Kabir[3], Karl Pedersen[1], Carol A. Gilchrist[2], Rashidul Haque[3], William A. Petri, Jr.[2], Joel Herbein[1]

[1]TechLab, Inc., Blacksburg, VA, United States, [2]University of Virginia, Charlottesville, VA, United States, [3]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Tetanus vaccination efforts in developing countries require population-level monitoring to assess post-vaccination protective immunity. Tetanus toxin-based ELISAs are commonly used, but require venous whole blood, time, laboratory equipment, and training. Expression and purification of native tetanus toxin is a complex, inconsistent process, leading to added cost and variable performance with clinical specimens. We describe development of a single-use immunochromatographic test ("dipstick") for the rapid evaluation of protective immunity to tetanus toxin. The assay uses purified recombinant tetanus toxin Fragment C (rFragC) as a surrogate marker for native tetanus toxin. rFragC production yields >50mg/L of culture with >99% purity by Coomassie staining of SDS-PAGE gel fraction. The dipstick was compared to a commercial ELISA ("TBS," The Binding Site) using human 1) plasma from a vaccine-defined cohort in Dhaka, Bangladesh (ICDDR,B), 2) plasma from freshly collected US panels of random volunteers (Bioreclamation IVT), and 3) whole blood from freshly collected US panels of random volunteers (Bioreclamation IVT). Dipsticks were read visually using a scoring card and quantitatively using the ESE Quant lateral flow reader (Qiagen). TBS ELISA values ≥0.1 IU/mL were considered positive for a protective anti-tetanus toxin titer, while TBS ELISA values <0.1 IU/mL were considered negative. Plasma dipsticks from the Bengali panel (n=40, 38 positive, 2 negative on TBS ELISA) had a clinical correlation of 100%, and quantitative comparison yielded a bivariate fit line with R^2=0.51, p<0.001. Plasma dipsticks from the US panel (n=158, all positive on TBS ELISA) had a clinical correlation of 99%; bivariate fit line with R^2=0.64, p<0.001. Whole blood dipsticks from the US panel (n=18, all positive on TBS ELISA) had a clinical correlation of 100%; bivariate fit line with R^2=0.23, p=0.04. A future goal is to include more tetanus antibody-negative samples. The rFragC dipstick offers a simple, sensitive, inexpensive alternative to ELISAs for detecting tetanus antibody in plasma and whole blood at the point-of-care during vaccination programs.

409

USEFULNESS OF MODIFIED SIMPLIFIED CHINESE INK TECHNIQUE FOR DETECTION (VISUALIZATION) OF THE CAPSULE OF BACTERIA, FUNGI AND PARASITES

Rito Zerpa[1], Vilma Bejar[1], Jorge O. Alarcon[1], Roberto Rojas[2]

[1]Instituto de Medicina Tropical "DA Carrion", UNMSM, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru

There are few reports on a technique to visualize the capsule of bacteria, fungi and parasites. Here we present a technique to visualize the capsule of bacteria: ***Bacillus anthracis***, pneumococcus; fungi: ***Cryptococcus***; and parasites: ***Blastocystis*** in clinical specimens and cultures. We worked with clinical specimens and cultures of the collection of the microbiology department of the National Institute of Child Health, strains of ***Bacillus anthracis*** collection as well as ***Cryptococcus neoformans***; fecal culture and ***Blastocystis spp.*** samples. To display the capsule, we used the Modified simplified Chinese ink technique, and recorded images in photomicrographs. Direct examination with this technique shows the capsule of those microorganisms, some with intracellular colors and details ***Cryptococcvus neoformans*** and ***Bacillus anthracis***, also in ***Blastocystis spp.*** Consequently, the modified simplified Chinese ink technique allows visualizing the capsule of bacteria, fungi and parasites, which is useful for laboratory diagnosis, teaching and research.

410

PREVALENCE OF NEONATAL TETANUS IN NORTHEASTERN NIGERIA

Jalal-Eddeen A. Saleh

Walden University, Minneapolis, MN, United States

Although efforts have been made towards improving the health of children across the globe with notable results, neonatal tetanus (NNT) remains a major contributor to the neonatal death rates in Nigeria. This problem calls for a concerted effort by the government to achieve the revised global NNT elimination deadline of 2015. The purpose of this cross-sectional quantitative study using secondary data was to establish the prevalence of NNT in Nigeria's northeast region and to ascertain if there was any significant difference in frequency of antenatal care (ANC), trained traditional birth attendants (TBAs), and umbilical cord treatments, using single sample proportions test and chi-squared tests of independence. The framework for this research was the theory of planned behavior. The participants (N = 312) were mothers of NNT babies. In spite a continual decline in the NNT cases between 2010 (26%) and 2013 (9%), the prevalence rate of NNT was unacceptably high at 28.815%. Also, significant differences existed as mothers who gave birth to NNT babies received significantly fewer or no ANC ($p < 0.001$), received significantly fewer or no attention from TBAs ($p < 0.001$), and reported significantly fewer incidences of proper umbilical cord treatments ($p < 0.001$). The chi-squared tests of independence resulted in significant differences in the frequencies of mothers who received ANC between Nigerian provinces ($p < 0.001$) and mothers who had their baby's umbilical cord treated ($p = 0.005$). This study will contribute to social change by guiding health care policy makers and immunization program managers on maternal and newborn health care services and indicate ways to build capacity of the TBAs for safe home delivery/hygienic handling of umbilical cord of newborns.

411

GROUP B STREPTOCOCCUS IN THE GAMBIA - TWENTY YEARS ON

Kirsty Le Doare[1], Sheikh Jarju[1], Martin Antonio[1], Paul Heath[2], Beate Kampmann[1]

[1]MRC Unit, The Gambia, Fajara, Gambia, [2]St. George's University of London, London, United Kingdom

A report from 20 years ago indicated that GBS genital colonization in Gambian mothers was reportedly predominantly due to serotype-V. However, tThe trivalent capsular polysaccharide conjugate vaccine currently in phase III trials includes only serotypes Ia, Ib and III. Here We therefore aimed towe define the current epidemiology of GBS in Gambian mothers and babies. Rectovaginal swabs from Gambian mothers and nasopharyngeal and rectal swabs from their infants were collected in a prospective cohort study. Swabs were pre-cultured in Todd Hewitt Broth (THB), followed by culture on selective agar. Culture nNegative samples were analysed for the presence of DNA via real-time PCR. Positive isolates were serotyped using Conventional multiplex PCR and gel-agarose electrophoresis. 750 women/infant pairs were recruited to the study. 270 women (36%) were found to be GBS-colonized (260 by culture alone, 10 by culture and PCR). 134 infants were colonized (25%) at birth and all but one remained colonized at six days. By three months, 44 infants remained colonized (6%) and 12 infants were newly colonized (2%). The predominant serotypes were: serotypes V (40%), II (28%), Ib (20%), Ia (10%) and III (2%). 12 colonized infants were treated for presumed neonatal sepsis and 4 for presumed meningitis. Blood cultures were positive for GBS (serotype-V) in one case, equivalent to 1.4/1000 live-

births. In conclusion, the serotype distribution among colonizing GBS strains in the Gambia remains unchanged over the last twenty years with serotype V predominating. Knowledge of the current serotype prevalence in regions such as the Gambia is vital to ensure vaccine development matches regional requirements to maximize its impact in these settings.

412

PHYLOGENETIC VARIANTS OF *RICKETTSIA AFRICAE*, AND INCIDENTAL IDENTIFICATION OF "*CANDIDATUS RICKETTSIA MOYALENSIS*"

Gathii Kimita[1], Beth M. Kinya[1], Steven G. Nyanjom[2], Fred A. Wamunyokoli[2], John N. Waitumbi[1]

[1]KEMRI/Walter Reed Project, Kisumu, Kisumu, Kenya, [2]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Rickettsia africae, the etiological agent of African tick bite fever is widely distributed in sub-Saharan Africa. Contrary to reports of its homogeneity, a localized study in Kenya reported high genetic diversity. In the present study, gene concatenation phylogeny of gltA, ompA, ompB, 17kDa and sca4 genes was used to re-analyse ***R. africae*** samples from diverse regions of Kenya that had been collected in a previously reported study. The bona fide ***R. africae*** isolates formed two distinct clades. Clade I isolates (98%) branched with the validated ***R. africae*** str ESF-5, while clade II (two isolates) formed a distinct sublineage of clade 1. Some isolates were determined to be ***R. aeschlimanii*** and not ***R. africae***. One isolate turned out to be a novel rickettsiae and an interim name of "Candidatus Rickettsia Moyalensis" is proposed. In conclusion, this data supports the use of multilocus gene concatenation as opposed to individual gene trees for phylogenetic inferences. It is determined that, though only recently emerged, ***R. africae*** lineage is diverse.

413

ANALYSIS OF NEONATAL SEPSIS IN KUMASI, GHANA THROUGH PAPER-BASED MEDICAL RECORDS

Jessica Sexton, Evans Afriyie-Gyawu, Isaac Chun-Hai Fung, Zachary McGalliard, Daniel Linder

Georgia Southern University, Statesboro, GA, United States

Reducing infant mortality is Millennium Development Goal 4 in Ghana, though it has remained high and unchanged. Improving care and reducing health complications related to infections and respiratory distress has shown to decrease the prevalence of neonatal deaths and preterm births. The objective of this study is to present data originating from an electronic medical records (EMR) pilot project and communicate the results of an analysis of neonatal sepsis using health information from paper-based medical records to identify characteristics of the neonatal patients at the Komfo Anokye Teaching Hospital in Kumasi, Ghana. Medical records from the Mother Baby Ward (n=198) from 2009-2014 were processed using scanners connected to laptop computers. Health information was manually extracted and verified by two researchers for quality assurance purposes and included sepsis, respiratory distress, cough, difficulty feeding, lethargy, seizures, jaundice, birth history, birth maturity and birth location. Regression analysis revealed a significant association between sepsis and birth location (p=0.0180, 95% CI) as well as sepsis and jaundice (p=0.0446, 95% CI). A descriptive profile of the population revealed that 63.6% of infants comprised of 97 males and 101 females were differentially diagnosed as having sepsis. There were 21 (10%) twins observed. Of the 198 cases included in the analysis, there were 127 (64%) full-term births, 105 (53%) cases reporting respiratory distress and 93 (46%) reporting jaundice. The process of manually scanning and converting paper-based medical records to later use for manual data extraction provides a safe and secure way to evaluate health information related to infant and neonate health.

414

GROUP B STREPTOCOCCUS COLONIZATION AMONG PREGNANT WOMEN IN LUBUMBASHI, DRC, 2015

Karen D. Cowgill[1], Abel M. Ntambue[2], Eric Kasamba[2], Henri Mundongo[2], Malonga Kaj[2]

[1]Seattle University, Seattle, WA, United States, [2]Universite de Lubumbashi, Lubumbashi, Democratic Republic of the Congo

Globally, invasive bacterial infections account for nearly a quarter of neonatal mortality. In the US, group B streptococcus (GBS) is the leading cause of early-onset neonatal sepsis, even after the introduction of routine prenatal screening and intrapartum antibiotic prophylaxis to prevent transmission from colonized women to their infants. GBS colonization is also associated with risk of preterm or stillbirth, and the risk and severity of invasive GBS disease are higher in infants born before term. In sub-Saharan Africa, there are few estimates of perinatal GBS colonization or disease, and none at all from the Democratic Republic of the Congo (DRC). As a first step to assessing the contribution of GBS to DRC's high neonatal mortality rate, we will conduct a cross-sectional study of GBS colonization in pregnant women attending antenatal care in Lubumbashi, Upper Katanga Province, DRC. We will report the prevalence of GBS colonization in these women, the antimicrobial susceptibility of isolates, and the feasibility of intrapartum antibiotic prophylaxis administration in the setting of a referral hospital. We believe these results will be important to estimate the role of GBS in perinatal mortality in the DRC, the potential impact of a maternal vaccine, and the feasibility of studies to evaluate non-antibiotic prophylaxis measures that might be introduced while awaiting vaccine development, approval, and introduction.

THE EMERGENCE OF ESBL *SALMONELLA TYPHIMURIUM* EXPRESSING BLA CTX-M-15 IN MOZAMBIQUE

Michael Preziosi[1], Inacio Mandomando[2], Tomas Zimba[3], Wei-Wei Chiu[1], David Looney[1], Donald G. Guiney[1], Joel O. Wertheim[1]

[1]University of California, San Diego, La Jolla, CA, United States, [2]Manhica Health Research Center, Manhica, Mozambique, [3]Ministry of Health, Maputo, Mozambique

We observed several cases of bacteremia due to Extended Spectrum Beta-Lactamase producing (ESBL) ***Salmonella typhimurium*** at an Urban Mozambican hospital. We sought to identify antibiotic resistance genes in these strains, and phylogenetically characterize them in the context of other African and non-African strains, including ST313 ***S. typhimurium***, the dominant lineage causing epidemic invasive disease in sub-Saharan Africa. ***S. typhimurium*** strains were isolated from the blood of adults on the wards of Maputo Central Hospital in Maputo, Mozambique between 2011 and 2013. Older isolates were obtained from the blood of subjects in a cohort of HIV+ adults in Entebbe, Uganda from 1995-97. All subjects were HIV+ with a mean CD4 count of 150 cells/ml. Isolates typed as ***S. typhimurium*** using the Kaufman-White scheme, and confirmed with PCR. Antibiotic susceptibility was tested with the Kirby-Bauer disc diffusion method and confirmed with the automated Vitek 2 system. ESBL phenotype was confirmed with the double-disc diffusion method. Whole genome sequencing was done with the Ion Torrent PGM system. Genomes were assembled using D23580 ***S. typhimurium*** and virulence plasmid pSLT-BT as references, both of which are representative of epidemic invasive ST313 strains from sub-Saharan Africa. Chromosome and plasmid phylogenies were created based on variable sites. ESBL genes were identified with PCR and then sequenced. The phylogeny indicates that the Mozambique strains collected in 2011-2013 are descendants of Ugandan strains from 1995-1997. Non ESBL Mozambican strains are genetically similar to invasive epidemic strain D23580 (all separated by <0.02 substitutions/variable site; 100% bootstrap support), whereas the Mozambican ESBL isolates represent a distinct and a comparatively long branch of the tree (0.8 substitutions/variable site, 100% bootstrap support). All strains contain highly similar virulence plasmids with identical

Tn21- like elements containing antibiotic resistance genes, characteristic of epidemic lineage ST313. All ESBL strains contained identical ***bla***CTX-M-15 genes found on nearly identical 300 kb plasmids.

416

EPIDEMIOLOGY AND ANTIMICROBIAL RESISTANCE OF INVASIVE SALMONELLOSIS, RURAL THAILAND, 2006-2014

David W. McCormick[1], Anchalee Jatapai[2], Possawat Jokrate[2], Ornuma Sangwichian[2], Sirirat Makprasert[2], Saithip Bhengsri[2], Sathapana Naorat[2], Thantapat Akarachotpong[2], Christopher Gregory[2], Toni Whistler[2], Julia Rhodes[2]

[1]Centers for Disease Control and Prevention-Hubert Global Health Fellowship, Atlanta, GA, United States, [2]Global Disease Detection Regional Center, Thailand Ministry of Public Health-US Centers for Disease Control and Prevention Collaboration, Nonthaburi, Thailand

Invasive salmonellosis commonly causes bloodstream infection in Southeast Asia. Limited epidemiologic and antimicrobial resistance data are available. We captured blood cultures performed in all 20 hospitals in Nakhon Phanom (NP) and Sa Kaeo (SK) provinces in a surveillance system. Cultures were performed as clinically indicated in hospitalized patients; patients with multiple cultures had only the first included. Salmonella isolates were identified at the serogroup level using serological testing. Antimicrobial resistance was assessed by disk diffusion and interpreted using 2015 CLSI guidelines. 522 invasive salmonellosis cases were identified (214 in NP and 308 in SK); 12% were ≤5 years old and 18% were ≥65 years old. Salmonella was the 5th most common pathogen (522/144,271 cultures). Overall incidence increased from 3.9/100,000 person-years in 2006 to 7.7 in 2008; from 2009-2014 the annual incidence ranged from 3.5-6.4. From 2006-2010, mean incidence was higher in SK than NP (4.3/100,000 vs. 7.7 p = 0.01). Overall, the most common serogroups were Group C (42%), Group D (35%), and Group B (9.8%). Group D was the most common serogroup in NP (44%), followed by C (18%). In SK, Group C was the most common (59%), followed by D (28%) and B (7%). Groups E and A were uncommon in both provinces. Serogroups were not identified for 21% of isolates in NP and 5% in SK. Antibiotic resistance was 67% (326/490) for ampicillin, 18% (89/499) for trimethoprim-sulfamethoxazole (TMP-SMX), 16% (79/504) for cefotaxime, and 2% (9/468) for ciprofloxacin. 56% had intermediate ciprofloxacin resistance. Group C had the highest proportion of isolates resistant to ampicillin (92%, n = 194), cefotaxime (37%, n = 79), and TMP-SMX (37%, n = 78). Group D had the highest proportion of isolates with intermediate resistance to ciprofloxacin (65%, n = 109). There were no temporal trends in antibiotic resistance. Bloodstream Salmonella infection in rural Thailand is commonly resistant to ampicillin, cefotaxime, and TMP-SMX. Intermediate resistance to ciprofloxacin is common. Serogroup distribution and antibiotic resistance may differ throughout Thailand and the region.

417

SEROLOGIC EVIDENCE FOR THE GEOGRAPHIC DISTRIBUTION OF BACTERIAL ZOONOTIC AGENTS IN KENYA

Victor O. Omballa[1], Raymond N. Musyoka[1], Kabura B. Wamburu[1], Cyrus M. Wachira[1], Lilian W. Waiboci[2], Mamo U. Abudo[3], Bonventure W. Juma[1], Andrea A. Kim[1], Joel M. Montgomery[1], Robert F. Breiman[4], Barry S. Fields[1]

[1]Centers for Disease Control and Prevention-Kenya, Nairobi, Kenya, [2]University of Nairobi-Kenya, Nairobi, Kenya, [3]Kenya Ministry of Health-Kenya, Nairobi, Kenya, [4]Emory University, Atlanta, GA, United States

Diseases of zoonotic origin substantially contribute to the high burden of febrile illnesses in developing countries. We evaluated serologic evidence of previous exposure to Bacillus anthracis, Brucella spp., spotted fever group rickettsioses (SFGR) and typhus group rickettsioses (TGR) from HIV-negative samples of persons aged 15-64 years collected during a nationwide HIV serosurvey conducted in 2007 in Kenya. The national adjusted seroprevalence by pathogen was: Bacillus anthracis, 11.3% (141/1091); Brucella spp, 3.0% (27/968); SFGR, 23.3% (191/770); and TGR, 0.6 % (12/770). On bivariate analysis, positive titers to B. anthracis were only significantly associated with province of residence while sex, education level and wealth were significantly associated with positive titers to Brucella spp. Significant associations for SFGR seroprevalence included age, education level, wealth and province of residence while TGR was only significantly associated with province of residence. Wealth and province remained significantly associated with positive titers to B. anthracis on multivariate analysis while sex and age remained significant for Brucella spp. Significant associations for SFGR seroprevalence were sex, education level and province of residence on multivariate analysis while TGR had no significance. High IgG sero-prevalence to some of these zoonotic pathogens suggests that a large proportion of individuals have previous exposure, symptomatic or inapparent. Given that a substantial proportion of exposures to these pathogens result in illness, these pathogens should be considered in the differential diagnosis of febrile illness in Kenya.

418

ASSESSING THE RISING CASES OF METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS*: HOSPITAL AND COMMUNITY-ASSOCIATED CASES

Chinedu Onyedikachukwu Oraka

Build Africa Research Capacity, Nnamdi Azikiwe University Teaching Hospital, Nnewi, Anambra, Nigeria

Methicillin-resistant ***Staphylococcus aureus*** (MRSA) has since become a major cause of illness and death in our healthcare setting. Risk factors for HA-MRSA include hospitalization, older age, invasive devices, and residence in long-term care facility, including exposure to antimicrobial agents. HA-MRSA isolates are often resistant to several antimicrobial drug classes in addition to beta-lactams. The CA-MRSA infections usually affects young, healthy persons and associated with sharing towels or athletic equipment, participating in contact sports, living in unsanitary and crowded areas, using illegal intravenous drugs. Directions were given out for clinical microbiology laboratories to submit invasive isolates of MRSA to our unit, where we perform antimicrobial drug susceptibility tests on all isolates and characterize all isolates that were resistant to <3 non-beta-lactam antimicrobial drug classes. Most isolates were obtained from blood cultures. The full model for predicting invasive infection with CA-MRSA compared with HA-MRSA included age, seasonality, and hospital exposure, plus specimen type. The only significant predictors of CA-MRSA infection compared with HA-MRSA were age <69 years, which was associated with increased risk ([OR] 5.1, 95% [CI] 2.06-12.64), and hospital exposure (OR 0.07, 95% CI 0.01-0.51), which was associated with decreased risk. Most patients were hospitalized for their infections and the proportion of patients admitted to intensive care units did not vary by strain. Patients infected by MRSA were younger than those infected by other strains. The number of invasive MRSA infections reported and the number of invasive infections caused by CA-MRSA is on the increase. The increase of CA-MRSA poses a unique public health threat. It is now clear that CA-MRSA no longer causes only SSTIs but now causes an increased proportion of invasive infections in a rural state.

419

MAPPING BACTERIAL BLOODSTREAM INFECTIONS: A METAGENOMICS APPROACH

Saskia Decuypere[1], Conor Meehan[2], Jan Jacobs[2], Jessica Maltha[2], Jonathan Carapetis[1], Lompo Palpouguini[3], Halidou Tinto[3], **Stijn Deborggraeve**[2]

[1]Telethon Kids Institute, Perth, Australia, [2]Institute of Tropical Medicine, Antwerp, Belgium, [3]Clinical Research Unit of Nanoro, Nanoro, Burkina Faso

Deep sequencing of the 16S rRNA gene has been widely used to profile environmental bacterial communities. Albeit extremely powerful, the

applicability of this technology has not been demonstrated yet for the characterization and diagnosis of bacterial sepsis. In this study we have developed and evaluated a 16S metagenomics approach to profile the bacterial diversity in the blood of febrile patients. Seventy-five children (median age 15 months) with severe febrile illness were recruited at St. Camille District Hospital in Nanoro, Burkina Faso, between January and April 2013. A laboratory diagnosis could be obtained on site for 12 bacterial sepsis cases with positive blood culture, and 41 malaria cases with positive thick blood films or positive malaria rapid diagnostic tests. A variable volume of whole blood was available for all patients (200 - 1000 µl) and was used for DNA extraction and subsequent amplification of the V3-V4 regions of the bacterial 16S rRNA genes. The resulting PCR products were deep sequenced on the Illumina MiSeq platform. Reads were curated using the mothur pipeline and taxonomy assigned using both homology and phylogenetic placement approaches. Bio-informatic pipeline validation and data analysis is currently ongoing. We will present the design of the metagenomics assay and the bacterial diversity identified in the bloodstream of the study participants.

420

BLOODSTREAM BACTERIAL INFECTION AMONG OUTPATIENT CHILDREN WITH ACUTE FEBRILE ILLNESS IN NORTHEASTERN TANZANIA

Coline Mahende[1], Billy Ngasala[1], John Lusingu[2], Zul Premji[1]

[1]Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania, [2]National Institute for Medical Research, Tanga, United Republic of Tanzania

Fever is a common clinical symptom in children attending hospital outpatient clinics in rural Tanzania, yet there is still a paucity of data on the burden of bloodstream bacterial infection among these patients. The present study was conducted at Korogwe District Hospital in north-eastern Tanzania. Patients aged between 2 and 59 months with a history of fever or measured axillary temperature ≥ 37.5°C attending the outpatient clinic were screened for enrolment into the study. Blood culturing was performed using the BACTEC 9050® system. A biochemical analytical profile index and serological tests were used for identification and confirmation of bacterial isolates. In-vitro antimicrobial susceptibility testing was performed using the Kirby-Bauer disc diffusion method. The identification of ***Plasmodium falciparum*** malaria was performed by microscopy with Giemsa stained blood films. A total of 808 blood cultures were collected between January and October 2013. Bacterial growth was observed in 62/808 (7.7%) of the cultured samples. Pathogenic bacteria were identified in 26/808 (3.2%) cultures and the remaining 36/62 (58.1%) were classified as contaminants. Salmonella typhi was the predominant bacterial isolate detected in 17/26 (65.4%) patients of which 16/17 (94.1%) were from patients above 12 months of age. Streptococcus pneumoniae was the second leading bacterial isolate detected in 4/26 (15.4%) patients. A high proportion of Salmonella typhi 11/17 (64.7%) was isolated during the rainy season. Salmonella typhi isolates were susceptible to ciprofloxacin (n = 17/17, 100%) and ceftriaxone (n = 13/17, 76.5%) but resistant to chloramphenicol (n = 15/17, 88.2%). ***Plasmodium falciparum*** malaria was identified in 69/808 (8.5%) patients, none of whom had bacterial infection. Bloodstream bacterial infection was not found to be a common cause of fever in outpatient children; and Salmonella typhi was the predominant isolate. This study highlights the need for rational use of antimicrobial prescription in febrile paediatric outpatients presenting at healthcare facilities in rural Tanzania.

421

COXIELLA BURNETII ANTIBODIES ARE PREDOMINANT AMONG PATIENTS WITH UNDIFFERENTIATED FEVER IN AFGHANISTAN

Salwa F. Ahmed[1], Momtaz O. Wasfy[1], B. Abdel-Rahman[1], M. S. Motawea[1], Nasir Stanikzai[2], R. Alami[2], Bashir Noormal[2]

[1]Naval Medical Research Unit - 3, Cairo, Egypt, [2]Afghan Public Health Institute, Ministry of Public Health, Kabul, Afghanistan

Diagnosis of infectious diseases in Afghanistan remains a challenge with limited ability for pathogen isolation and identification. Baseline data on the prevalence of etiologies causing undifferentiated fever is lacking in Afghanistan. Herein we screened serum of Afghan patients suffering from undifferentiated fever for antibodies against number of pathogens, including ***Coxiella burnetii***, ***Leptospira*** spp.and typhoid fever. Patients > 5 years old with undifferentiated fever who meet the WHO case definition and presented at Kandahar provincial hospital (KDH), Helmand provincial hospital (LG) and a tertiary hospital in Kabul (KID) were enrolled and consented into a surveillance study between 2007 and 2012. A single serum sample was collected and tested by ELISA for the detection of IgM and IgG against Q fever ***(C.burnetii***, Panbio®), ***Leptospia*** spp. IgM (Panbio) and total immunoglobulins of ***Salmonella enterica*** serovar Typhi. A total of 566 patients were screened. Cases from KDH showed the highest frequency of ***C. burnetii*** antibodies (n=178, 36% IgG and 7.9 % IgM), followed by those from LG (n= 82, 23.2% IgG and 4.9% IgM) and KID (n= 303, 16.5% IgG and 1.3% IgM). ***Leptospia*** IgM was evident in 11.2% of patients, 12.9% in KID, 10.7 in KDH and 6.1 in LG. Typhoid fever titers >320 were found in11.2% of all patients, being higher in LG (15.9%) and KDH (12.9%) than KID (8.9%). Almost half of the ***C.burnetii*** IgM-positive cases (12/22) did not mount immune responses to other pathogens. The data suggest that both acute and past Q fever infections were evident within patients tested. The increased seropositivity rates in cases from KDH and LG provincial hospitals compared to those of KID in Kabul city may be attributed to limited sanitary measures in these areas. While typhoid fever is transmitted by ingestion of sewer polluted food and water, both Q fever and ***Leptospira*** are spread by contact with animals and their contaminated products or excreta. The obtained results provide initial disease burden information for Afghanistan and will be useful to health authorities in guiding hygiene improvement plans and disease prevention strategies.

422

REVERSE-TRANSCRIPTASE PCR DETECTION OF *LEPTOSPIRA* IN RIO DE JANEIRO: POOR AGREEMENT WITH SINGLE-SPECIMEN MICROSCOPIC AGGLUTINATION TESTING

Jesse J. Waggoner[1], Ilana Balassiano[2], Alisha Mohamed-Hadley[1], Malaya K. Sahoo[1], Juliana Magalhães Vital-Brazil[2], Benjamin A. Pinsky[1]

[1]Stanford University, Palo Alto, CA, United States, [2]Instituto Oswaldo Cruz, Fiocruz, Rio de Janeiro, Brazil

Leptospirosis is a potentially fatal zoonotic disease caused by bacteria of the genus ***Leptospira***. In the Americas, Brazil reports the majority of cases, though incidence remains underestimated due to limitations in available diagnostics. The reference standard for the diagnosis of leptospirosis remains microscopic agglutination testing (MAT) on acute and convalescent serum. However, paired specimens are rarely sent for testing, and positive MAT results from a single specimen (titer ≥1:800) are often used to provide a presumptive diagnosis. The purpose of this study was to test serum samples from patients in Rio de Janeiro with a real-time reverse-transcriptase PCR (rRT-PCR) targeting the Leptospira 16S rrs gene and compare these results to detection with MAT. Improved analytical sensitivity of ***Leptospira*** detection was shown using rRT-PCR compared to optimized real-time PCRs with the same primers and probe. We then tested up to 55 archived serum samples per month from 2008, for a total

of 478 samples. Thirty-five (7.3%) samples tested positive by rRT-PCR with no clear seasonality in the percent of cases detected. Clinician-reported day of disease information was available for 282 samples (18 rRT-PCR positive). ***Leptospira*** RNA was detected in samples collected as late as day 30, and cycle thresholds did not vary based on the day of disease of sample collection. The percentage of positive samples also did not differ when samples were categorized as acute [≤ 7 days; 8/127 (6.3%)]; late acute [8 to ≤14 days; 6/69 (8.7%)]; or convalescent [>14 days; 4/86 (4.7%)]. Thirty-three (6.9%) samples tested positive by MAT using a regional panel of 19 Leptospira strains. Only three samples tested positive by both rRT-PCR and MAT. Of the 282 samples with day of disease information, 19 (6.7%) were positive by MAT, and one sample tested positive by both methods. In conclusion, rRT-PCR and single-specimen MAT demonstrate poor agreement for the diagnosis of leptospirosis and identify distinct patient populations. The accuracy of using a single MAT result, even at a titer of ≥1:800, for the diagnosis of acute leptospirosis should be re-evaluated.

423

PATHOGEN-SPECIFIC FEATURES OF THE HUMAN PERIPHERAL BLOOD TRANSCRIPTIONAL PROFILE IN PATIENTS WITH SCRUB TYPHUS AND MURINE TYPHUS

Stephen J. Popper[1], Viegmon Davong[2], Josee Castonguay-Vanier[2], Anisone Chanthongthip[2], Koukeo Phommasone[2], Manivanh Vongsouvath[2], Peter M. Dull[3], Buddha Basnyat[4], David M. Murdoch[5], Christopher W. Woods[6], Catrin M. Moore[2], Paul N. Newton[2], David A. Relman[1]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Vientiane, Lao People's Democratic Republic, [3]Division of Infectious Diseases, Emory University, Atlanta, GA, United States, [4]Patan Hospital, Kathmandu, Nepal, [5]Christchurch School of Medicine and Healthy Sciences, University of Otago, Christchurch, New Zealand, [6]Duke University Medical Center, Durham, NC, United States

Scrub and murine typhus are important causes of fevers in Southeast Asia. The nonspecific clinical presentation and lack of sensitive acute-phase diagnostic tests hinder their early recognition. To identify pathogen-specific features of the host response to infection, we used oligonucleotide arrays to examine genome-wide patterns of whole blood gene expression in patients with scrub typhus (n=8) and murine typhus (n=6) admitted to Mahosot Hospital, Vientiane, Laos. We compared these patterns with those of healthy controls (n=12), as well as patients with dengue (n=13) and ***E. coli*** bacteremia (n=6). The average change in abundance of 15,643 transcripts following infection with ***Orientia tsutsugamushi*** and ***R. typhi***, causative agents of scrub and murine typhus, respectively, was similar to those seen in patients with dengue (Pearson's r=0.81 and 0.66, respectively). All three groups had elevated abundance levels of transcripts associated with the mitotic cell cycle and mitochondrial activity; these levels were highest with dengue and lowest with murine typhus infection. The transcriptional profile of patients with ***E. coli*** was distinct (r=0.23 and r=0.49 compared to scrub and murine typhus, respectively), and characterized by elevated abundance levels of transcripts associated with myeloid gene expression. Principal components analysis indicated that there were differences in gene expression that distinguished scrub and murine typhus patients from those with dengue and ***E. coli*** infection, and we found that gene sets associated with T and NK cells were expressed at higher levels in scrub and murine typhus. We also identified a set of 10 transcripts that correctly predicted 13 of 14 ***O. tsutsugamushi*** and ***R. typhi*** infections and 18 of 19 dengue and ***E. coli*** infections (10-fold cross-validation). Eight of 9 scrub typhus and murine typhus patient samples from Kathmandu, Nepal were also correctly predicted as rickettsial infections using the same gene set. Further validation will establish the potential of these gene expression patterns to improve diagnostic capabilities and our understanding of the early host responses to rickettsial infections.

424

MICROGEOGRAPHIC DIFFERENCES IN TRANSMISSION OF LEPTOSPIROSIS IN THE PERUVIAN AMAZON

Karen Ocampo[1], Kalina Campos[1], Julian Torres[2], Silvia Torres[2], Joseph Vinetz[3], Michael Matthias[3], **Jessica N. Ricaldi**[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Peruana Cayetano Heredia, Iquitos, Peru, [3]University of California San Diego, San Diego, CA, United States

Leptospirosis is hyperendemic in the Peruvian Amazon, and different transmission contexts seem to coexist within a small region. In this study we looked at the prevalence of leptospirosis in three areas around the city of Iquitos: the Belen neighborhood (part of which gets flooded seasonally), the riverine semi-rural community of Mazan, and the roadside community of Los Delfines. We enrolled adults and children over 5 years old in a household survey of the three communities. GIS and demographic data were collected and participants provided a blood samples, a urine sample, or both. Serology using the microagglutination test (MAT) was performed on all serum samples. Seroprevalence in Belen was 9.3 % (46/493), and it was significantly different between the flooded area (16%) and the non-flooded area (5.2%) ($p<0.01$). Seroprevalence was 5.5 % (12/238) in Mazan and 7.4% (17/229) in Los Delfines. We did not find any specific risk factors associated to seropositivity, besides living in a flooded area. Seroprevalence to the intermediate ***Leptospira licerasiae*** was 92.5% and 91.5% in the flooded and dry areas of Belen, and 88.2% and 85.6% in Mazan and Los Delfines respectively. A qPCR assay directed at ***Leptospira*** 16S rDNA , was done on 27 urine samples from MAT positives from Belen and 55% were positive. A sub group of urine samples from MAT negative was also assayed, 18% (11/61) were positive. The most prevalent serovar in Belen and Los Delfines was serovar Bratislava, which has been described to be mostly associated with pigs. We find that the seroprevalence to pathogenic ***Leptospira*** varies in different contexts, and that even within the area on Belen, exposure seems to be higher in the flooded area. The prevalence in the non-flooded area is similar to that in semi-rural areas not considered hot spots. Although MAT does not definitely define infective serovar, because of cross-reactivity within strains, our findings suggest an important role for pigs in the transmission of leptospirosis in this area.

425

THE EFFECT OF CIVIL WAR ON CUTANEOUS LEISHMANIASIS "ALEPPO BUTTON" IN ALEPPO CITY

Abdulnasser Kaadan

University of Aleppo, Aleppo, Syrian Arab Republic

In the ancient northern Syrian city of Aleppo, CL has been present for hundreds of years (if not longer), where it is known as the "Aleppo evil", "Aleppo ulcer", "Aleppo boil", or "Aleppo button" which is Cutaneous Leishmaniasis. Aleppo ulcer is a disfiguring condition that disproportionately occurs on the face, especially of young people. It typically lasts one or 2 years before the lesion heals spontaneously, and is often known locally as "one-year sore". However, in many cases specific anti-parasitic chemotherapy can hasten the healing process and improve clinical and cosmetic outcomes. A major problem with one-year sore is that the scar can produce permanent disfigurement of the face. It is well known about the rise and fall and then a rise again in the incidence of the disease in the city of Aleppo. During the 1950s the number of cases of CL fell after an insecticide campaign aimed at controlling malaria, but it then rose again during the 1960s. However, CL was mostly controlled during the 1980s.There is no doubt that the areas of Syria affected by the civil war are experiencing an increase in cutaneous leishmaniasis, and this will also be seen in the refugee camps in Jordan and Turkey. This is due to garbage collection, open sewage, and poverty which promote the habitats of ***Phlebotomus*** sandflies that transmit CL. Interestingly, a clinical trial conducted prior to the current civil conflict found that use of insecticide-treated bednets (ITNs) could prevent CL in Aleppo. Recently, WHO reports out of Syria indicate the emergence of epidemic cutaneous leishmaniasis

in the besieged city of Aleppo, adding further to the misery there, perhaps the international community needs to focus on refugees and refugee encampments to ensure local control and patient access to treatments.

426

DISTRIBUTION OF ESCHAR IN CHILDREN WITH SCRUB TYPHUS

Winsley Rose Selwin, Roshni Rajan, Urmi Ghosh, Anu Punnen

Christian Medical College, Vellore, India

Scrub typhus, caused by ***Orientia tsutsugamushi***, and transmitted by the bite of a trombiculid mite chigger is widely prevalent in the 'tsutsugamushi triangle' of the world. Prompt and appropriate antibiotic therapy is important in decreasing morbidity and mortality. Presence of eschar at the site of chigger bite is an important finding in the early diagnosis of scrub typhus. The chigger is microscopic and the eschar is painless. A careful examination is required to identify an eschar. Describing the distribution of these eschars is beneficial to clinicians. In our study, we describe the distribution of eschars in all children < 15 years of age admitted with a confirmed diagnosis of scrub typhus based on a positive scrub typhus IgM serology or a Weil Felix test OX K > 80 over a 3 year period. There were 286 children admitted with confirmed scrub typhus during this period. An eschar was present in 155(54.5%) children with 94(60.6%) males and 61(39.4%) females. The eschars were distributed in the following areas: scalp 2(1.3%), ears 5(3.2%), eyelids 4(2.6%), neck 15(9.7%), axillae 35(22.6%), chest and abdomen 21(13.5%), buttocks 2(1.3%), genitalia 25(16.1%)(scrotum 24 and labia 1), leg 3(1.9%), arm 3(1.9%), groin 24(15.5%), shoulder 9(5.8%) and back 7(4.5%). The commonest sites of eschars were scrotum 24/94(25.5%) and axillae 14/94(14.9%) in males and axillae 21/61(34.4%) and groin 14/61(23%) in females. Eschars were seen within skin folds in 84/155(54.2%) children. The distribution is children is predominantly in the axillae and genitalia whereas in adults, as described in literature, the distribution is predominantly over the chest, abdomen and the groin. Recognizing an eschar is the most useful clue to diagnose scrub typhus in children presenting with acute febrile illness. In endemic regions, children should be carefully examined for the presence of eschar especially in the skin folds of the genitalia, axillae and groin to make an early diagnosis of scrub typhus.

427

SPECTRUM OF WINTER DERMATOSES IN RURAL YEMEN

Mohamed A. Al-Kamel

Regional Leishmaniasis Control Center, Sana'a, Yemen

Surveys have been carried out to determine the prevalence of skin diseases in rural Yemen are scarce or even not available. This study was undertaken to investigate spectrum of winter dermatoses in a rural Yemeni community. At the dermatology outpatient clinic of Al-Helal Specialized Hospital at Radaa' district of Al Bayda' governorate, this retrospective study was conducted, by data analysis of 700 selected records of patients managed during 4 months of 2013-14 winter season. Results 700 patients with 730 diseases were reported in this study, the major bulk of patients (46.57%) were in >18-40 years age group, and females outnumbered males. By far, Dermatitis, eczematous and allergic disorders (38.49%) topped the list of the most frequent skin disorders groups, followed by skin infections and infestations (20%) and pigmentary disorders group (13.70%). Contact dermatitis (10.68%) was the most prevalent skin disorder, followed by hyperpigmentations (8.77%), acne (8.08%), viral infections (5.75%), atopic dermatitis (5.62%), and parasitic infestations (5.34%). In conclusion, this survey has documented spectrum of winter dermatoses in a rural Yemeni community, but also reflects pattern of common dermatoses in the whole country. Dermatitis, eczematous and allergic disorders, skin infections and pigmentary disorders are the commonest groups. Contact dermatitis is the most prevalent disorder, and leishmaniasis is the most prevalent skin infectious disease. Climate, occupational, social, and environmental factors are of main contributors. Such statistics can form an important basis for community-based health policies.

IRON DEFICIENCY DURING PREGNANCY AND NEURODEVELOPMENT OF ONE-YEAR-OLD CHILDREN

Michael O. Mireku[1], Michael J. Boivin[2], Achille Massougbodji[3], Michel Cot[4], Florence Bodeau-Livinec[5]

[1]French School of Public Health (EHESP), Rennes, France, [2]Michigan State University, East Lansing, MI, United States, [3]University of Abomey-Calavi, Cotonou, Benin, [4]Institute of Research For Development, Paris, France, [5]Sorbonne Paris Cite-Inserm, Paris, France

Iron deficiency (ID) in infancy is a known risk factor of short and long term neurocognitive deficits. Although evidence exists on the impossibility of completely reversing impaired cognition caused by early iron deficiency, little is known about the impact of prenatal ID on the neurocognitive function of children. The objectives of this study were to assess the impact of prenatal ID on the cognitive and motor functions of one-year-old children in Benin, and to determine the epidemiologic pathway underlying this relationship. Our prospective cohort study included one-year-old children born to women recruited at their first antenatal care (ANC) visit, before 29 weeks of pregnancy, within the MiPPAD trial comparing sulfadoxine-pyrimethamine and mefloquine. Pregnant women were enrolled if they had not taken any anthelminthics, iron or folic acid and were HIV negative prior to first ANC visit. Serum ferritin and C-reactive protein concentrations of pregnant women were determined from venous blood samples collected at first and second ANC visits of at least, one-month interval and at delivery. Women were given oral iron, folic acid and anthelminthics as part of the ANC package in Benin. A total of 636 children (76.8% of eligible children) were assessed for cognitive and motor functions, using the Mullen Scales of Early Learning (MSEL), at twelve months of age by trained research nurses. Prevalence of ID was 33.3%, 35.2% and 30.4% at first ANC visit, second ANC visit and delivery, respectively. There was no significant difference in the cognitive and motor functions between children whose mothers were iron deficient and those whose mothers were not iron deficient during pregnancy. Although we observed an increased risk of ID, RR = 2.3 (95% CI 1.9-2.8) and RR = 1.7 (95% CI 1.4-2.1) at second ANC and delivery, respectively, if pregnant women had ID at first ANC visit, persistent ID throughout pregnancy was not related to infant neurocognitive function. Preliminary analyses show no association between prenatal ID and early neurocognitive development of children.

429

INFLAMMATORY AND ANGIOGENIC FACTORS AT MID-PREGNANCY ARE ASSOCIATED WITH SPONTANEOUS PRETERM BIRTH IN A COHORT OF TANZANIAN WOMEN

Chloe R. McDonald[1], Anne M. Darling[2], **Valerie M. Crowley**[1], Andrea L. Conroy[1], Vanessa Tran[1], Ana Cabrera[1], W. Conrad Liles[3], Molin Wang[2], Said Aboud[4], Willy Urassa[4], Wafaie W. Fawzi[2], Kevin C. Kain[1]

[1]SAR Laboratories, Sandra Rotman Centre for Global Health, Toronto, ON, Canada, [2]Harvard School of Public Health, Boston, MA, United States, [3]University of Washington, Seattle, WA, United States, [4]Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania

Preterm birth (PTB) is the leading cause of perinatal mortality worldwide, with the greatest burden occurring in resource-constrained settings. Based on the hypothesis that altered placental angiogenesis and inflammation early in pregnancy lead to PTB, we examined whether levels of inflammatory and angiogenic mediators, measured early in pregnancy, were predictive of spontaneous PTB (sPTB). Plasma samples were collected from a prospective cohort of primigravid Tanzanian women between 12-

27 weeks gestation. A panel of 18 markers was screened on a training cohort of 426 women. Markers associated with sPTB in the training cohort were repeated in a test cohort of 628 women. All markers were measured by ELISA. In both the training and test cohorts plasma levels of IL-18BP, sICAM-1, sEndoglin and CHI3L1 were elevated and Leptin was lower at enrollment in women who subsequently experienced sPTB. In multivariate analysis women with plasma levels of CHI3L1, C5a, sICAM-1, AngptL3, sEndgolin, sFlt-1 and IL-18BP in the highest quartile had an increased risk of sPTB compared with those in the lowest quartile. Women with Leptin and Ang2 in the highest quartile had a reduced risk of sPTB compared with women in the lowest quartile. Levels of angiogenic and inflammatory mediators measured at mid pregnancy were associated with subsequent sPTB. These findings provide insight into mechanisms underlying sPTB and suggest biomarkers that may have clinical utility in risk-stratifying pregnancies.

430

THE IMPACT OF THE AMAZON HOPE MEDICAL PROGRAM ON THE PREVALENCE OF ANAEMIA IN CHILDREN FROM THE PERUVIAN AMAZON

Ronald Ramirez[1], Oscar M. Linárez[1], Tom Wingfield[2]

[1]Union Biblica Peru and Amazon Hope Medical Project, Iquitos, Peru, [2]Imperial College London, UK and Universidad Peruana Cayetano Heredia, London, United Kingdom

The Amazon Hope medical boat health program offers care to 167 impoverished communities of the Peruvian Amazon. In 2010, we performed a study into childhood anaemia in these communities, which identified a high prevalence (89%) of anaemia in children under 5 years old attending the boat clinics. Subsequently, we started an iron supplementation and anti-parasite program and studied its impact on anaemia prevalence post-intervention. Eligibility criteria included being a child from 6 to 59 months attending the boat clinic, diagnosed with anaemia in the initial study and whose guardian gave informed consent to participate. Participants with a haematocrit of <33% were offered operationally-defined "anaemia treatment" with 2-3mg/kg/day of oral iron for three months. Participants with a haematocrit of 33-35% received operationally-defined "iron supplementation treatment" with 0.5-1mg/kg/day of oral iron for two months repeated every three months for a total of one year. In addition, 400mg albendazole was given every three months to all children aged over 2 years and 200mg to children between 1 and 2 years. In 2011, haematocrit levels were repeated on visits to the study site communities. Data from 869 of the children originally tested for anaemia were available for analysis. Mean anaemia prevalence in participants decreased from 89% in 2010 to 20% in 2011. Older children had the greatest reduction in anaemia prevalence following the intervention: 68% (97-29%) in those aged 6-12 months, 62% (91-29%) in those aged 12-23 months, 65% (86-21%) in those aged 24-35 month, 73% (87-14%) in those aged 36-47 months, and 77% (84-7%) in those aged 48-59 months. Iron supplementation and anti-parasite therapy were associated with a marked reduction in anaemia prevalence in attending children. The largest reduction was seen in children over two years old, which perhaps relates to increased intake and adherence to iron supplementation. Further research is required to inform regional policy makers to consider the scope for potential implementation and scale-up of similar interventions to correct or prevent anaemia in these communities.

431

CONGENITAL TOXOPLASMOSIS AND PREGNANCY MALARIA DETECTION POST-PARTUM; EFFECTIVE DIAGNOSIS AND EFFECTIVENESS OF APPROVED CHEMOTHERAPEUTIC REGIMENS IN GHANA

Emmanuel A. Blay[1], Anita Ghansah[1], Joseph Otchere[1], Roberta Koku[1], Kofi D. Kwofie[1], Takashi Suzuki[2], Nobou Ohta[2], Irene Ayi[1]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Tokyo Medical and Dental University, Tokyo, Japan

Congenital toxoplasmosis (CT) and Pregnancy malaria (PM) have been individually reported to cause severe negative outcomes in pregnancies but the diagnostic method is still debatable. This study sought to estimate the prevalence of PM and CT single and co-infections in pregnant women by using various specimens including serum and placental tissues. Genomic DNA extracted from the placenta, cord blood or blood of mothers was tested by PCR. Conventional method of immunodiagnosis was done for CT. We tested 79 pregnant women and the mean age was 28±1.06. There was a big difference in the prevalence of ***Plasmodium falciparum*** infection determined by PCR between two specimens tested: PCR positive for mother's peripheral blood was 6.3% while 57.3% for placental tissues ($p < 0.001$). PCR testing for placental tissues showed 29.2% positive for ***Toxoplasma gondii***, while 76.0% of mothers had serum IgG against T. gondii. It should be noted that 6.32% of the placental tissues showed positive for SAG 3 in PCR, a marker of active infection in T. gondii. Although there were no enhanced fetal disorders at birth in our study, there is a possibility of active transmission of ***T. gondii*** from mothers to foetus even in immune mothers. Our study suggests that foetus were exposed to ***P. falciparum*** and ***T. gondii in utero***, and placenta PCR is a sensitive method for detecting such episodes. In cases of PCR-positive, clinical follow-up after birth may be important.

432

CHANGES IN THE PROFILE OF CIRCULATING B CELLS AND IGG AND COMPLEMENT RECEPTORS CAN BE ASSOCIATED WITH THE DEVELOPMENT OF *ERYTHEMA NODOSUM LEPROSUM*

Francianne M. Amorim[1], Larissa S. Nascimento[1], Alesson M. Miranda[1], Francisco P. Freire-Neto[1], Glória R. Monteiro[1], Maurício L. Nobre[1], Kathryn M. Dupnik[2], Selma M. Jeronimo[1]

[1]Laboratório de Imunogenética de Doenças Complexas, Centro de Biociências, Instituto de Medicina Tropical do Rio Grande do Norte, Universidade Federal do Rio Grande do Norte, Natal, Brazil, [2]Division of Infectious Diseases and Center for Global Health, Weill Cornell Medical College, New York, NY, United States

Reversal reaction (RR) and erythema nodosum leprosum (ENL) are severe complications of leprosy. We previously observed differences in the profile of circulating B cells and in the frequency of CD32 and CD21 between paucibacillary and multibacillary. We hypothesized that those differences may be associated with the pathogenesis of reactions. Peripheral blood mononuclear cells were obtained from 14 household contacts (HC), 43 patients without reaction, 7 tuberculoid, 20 borderline and 7 lepromatous, and 12 patients with reactions (9 RR and 3 ENL). Total lymphocytes and subpopulations of B cells, frequency of CD32 and CD21 were evaluated ***ex vivo*** by flow cytometry. A decrease in the frequency of lymphocytes was seen in borderline (61.0%; p= 0.0165) and lepromatous (61.2%; p= 0.0428) when compared to HC (71.2%). The frequency of B cells were higher in lepromatous (13.1%) when compared to HC (7.1%, p= 0.0300), tuberculoid (8.6%, p= 0.0021) and ENL (5.3%, p= 0.0121). There were no differences in the frequency of transitory, naïve or memory B cells between leprosy clinical forms. However, ENL had a higher frequency of memory B cells when compared to borderline (35.9% vs. 24.1%, p= 0.0344), lepromatous (22.3%, p= 0.0485) or RR (23.49%, p= 0.0182). Plasmoblasts were more frequent in lepromatous (8.9%) when

compared to tuberculoid (5.5%, p= 0.0108). Interestingly, there was a higher frequency of CD21+ B cells in lepromatous (92.2%) compared to tuberculoid (88.1%, p= 0.0090), borderline (89.1%, p= 0.0500), RR (81.84%, p= 0.0111) or ENL (82.3%, p= 0.0242). Furthermore, lepromatous (84%) presented a lower frequency of CD32+ B cells when compared to HC (93.5%, p= 0.0021), tuberculoid (91.5%, p= 0.0106) or ENL (95.6%, p= 0.0121). Lepromatous (70.3%) also presented a lower frequency of CD32+ plasmoblasts when compared to ENL (90.1%, p= 0.0303). Despite the differences in the profile of circulating B cells in clinical forms of leprosy, the increased frequency of CD21+ B cells and decreased frequency CD32+ B cells in lepromatous patients could contribute to exacerbation of the humoral immune response and increase the risk of developing ENL.

433

THROMBOCYTOPATHY CONTRIBUTES TO THE DEVELOPMENT OF BLEEDING COMPLICATIONS IN HUMAN LEPTOSPIROSIS

Rahajeng N. Tunjungputri[1], Quirijn de Mast[2], Willemijn van der Does[2], Pandu Herpri Sasongko[1], Andre van der Ven[2], M. Hussein Gasem[1]

[1]Center for Tropical and Infectious Disease, Faculty of Medicine, Diponegoro University - Dr. Kariadi Hospital, Semarang, Indonesia, [2]Department of Internal Medicine, Radboud University Medical Center, Nijmegen, Netherlands

Leptospirosis is a widespread zoonotic disease in the tropics caused by the pathogen Leptospira interrogans. Bleeding is one of the most important complications of which the pathogenesis is poorly understood. We hypothesized that impaired platelet function (thrombocytopathy) contributes to the bleeding complications of leptospirosis. We conducted a prospective study on 23 hospitalized patients with leptospirosis in Semarang, Indonesia, of whom 9 developed clinical bleeding. Platelet function and the binding of von Willebrand factor (vWF) to platelets was investigated using flow cytometry. The latter was included as vWF-platelet binding was recently suggested to cause thrombocytopathy. Leptospirosis was associated with ***in vivo*** platelet activation with increased expression of the platelet granule marker P-selectin and increased fibrinogen binding to αIIbβ3. However, upon ***ex vivo*** stimulation with the platelet agonists adenosine-diphosphate (ADP) and thrombin-receptor activating peptide (TRAP), P-selectin expression and fibrinogen binding were significantly lower compared to controls, suggesting thrombocytopathy. Patients with clinical bleeding had the most pronounced thrombocytopathy and these patients also had increased vWF binding to platelets. In conclusion, our study identifies thrombocytopathy as a contributing factor to bleeding in leptospirosis. Excessive platelet activation and platelet-vWF binding may be an underlying mechanism behind this thrombocytopathy.

434

ASSESSMENT OF THE EFFECTIVENESS AND UTILITY OF THE NEW WHO GUIDELINES FOR THE MANAGEMENT OF HEPATITIS B IN NORTHERN UGANDA

Nicholas Easom[1], Nicolas Laing[2], Henry Tufton[3], Emmanuel Ochola[2], Alison Elliot[4], Mala Maini[1]

[1]University College London, London, United Kingdom, [2]St. Mary's Hospital Lacor, Gulu, Uganda, [3]Kisubi Mission Hospital, Kisubi, Uganda, [4]Uganda Virus Research Institute, Entebbe, Uganda

Hepatitis B virus (HBV) kills 750,000 people a year, overwhelmingly in low and middle income countries (LMICs), despite the widespread use of HBV vaccine. However there is little research conducted into hepatitis B in sub-Saharan Africa. WHO published its first guideline for the investigation and management of hepatitis B in 2015. It highlights the lack of evidence to guide management in LMICs, particularly where HBV DNA testing is unaffordable. The emergence of tenofovir as a safe, effective and increasingly inexpensive treatment for hepatitis B has only served to emphasise the need for evidence-based criteria applicable to this setting. Previous guidelines for the management of hepatitis B (eg. from the American Association for the Study of Liver Diseases) have placed HBV DNA testing at the centre of patient assessment. The new WHO guidelines include guidance for management without this where it is not feasible. However little data is available to validate this approach. We aim to demonstrate that assessment of patients with hepatitis B without the use of HBV DNA testing is feasible and results in acceptable allocation to treatment. St Mary's Hospital Lacor is a regional referral hospital just outside Gulu in Northern Uganda. The local prevalence of hepatitis B is 17%, making this a significant cause of morbidity and mortality. HBV DNA tests in this setting must travel 335 miles to Kampala and cost $120, putting them far beyond the means of most patients. We performed a pragmatic prospective study to compare the therapeutic allocation of hepatitis B patients by the WHO guidelines without HBV DNA testing, taking a parallel assessment with HBV DNA as our gold standard. 100 patients with hepatitis B diagnosed at St Mary's Hospital were recruited. Liver ultrasound, liver and renal function tests, full blood count and HIV serology were performed. Investigators made a treatment decision while blinded to the HBV DNA result. HBV DNA results were then unblinded and patients were re-allocated to treatment or observation and the appropriate management commenced. We present the sensitivity and specificity of the without-HBV DNA WHO guideline in this setting.

435

USE OF ANTIBIOTICS AND ANTIMALARIALS IN THE MANAGEMENT OF FEBRILE ILLNESSES IN CHILDREN IN PUBLIC HEALTH FACILITIES IN WESTERN KENYA

Winnie C. Rono[1], Wendy P. O'Meara[2], Samson K. Ndege[1]

[1]Moi University, School of Public Health, Kenya, [2]Duke Global Health Institute, Durham, NC, United States

Malaria is a global tropical disease associated with high morbidity and mortality, especially among the children. Many diseases present clinically with fever and Integrated Management of Childhood Illnesses (IMCI) advocates for the use of antibiotics for other infections and antimalarials for malaria. With the signs and symptoms of malaria resembling those of other diseases, many febrile conditions are treated clinically as malaria. Without laboratory confirmation of malaria, continued use of artemisinin-based combination therapy on non-malaria cases may soon lead to resistance due to their unnecessary use. A randomized control study was put in place with the primary objective of testing whether financial incentives offered (to intervention group) at the facility level improve targeting of antimalarials to patients with parasitologically diagnosed malaria. This is a sub-study of the above describing the role of antibiotics and antimalarials in the management of febrile illnesses among children. The main objective was to describe the prescription habits of both antimalarials and antibiotics. This was a comparative, records-based cross-sectional study carried out in 17 public health facilities of high and low malaria endemicity in the western region of Kenya. Health facility records were reviewed by use of a checklist and data was analysed using STATA analysis package. 6086 children under the age of 5 years were included in the study with a mean age of 2 years and 51.2% being female. Among the 2124 study subjects who received antibiotics and other treatment regimens, (37.5% of intervention and 31.8% of control) most of them received cotrimoxazole dispensed at 46%. Positive blood smear results for Western and Rift Valley Provinces were 26.5% and 11.6% respectively. Among those who received medication, 70% of those with a negative blood smear result were given antibiotics and 68% of those with a positive blood smear result got AL.

436

SIMPLE, ECONOMICAL RABIES VACCINATION: WHY INTRADERMAL ADMINISTRATION SHOULD BECOME ROUTINE WORLDWIDE

Mary Warrell

University of Oxford, Oxford, United Kingdom

Rabies prophylaxis is expensive and unsatisfactory globally. Thousands of people die an agonising death unnecessarily because rabies vaccine is either unavailable or unaffordable. Shortages may occur anywhere. Dog rabies virus encephalitis is always fatal in unvaccinated patients, and post-exposure prophylaxis (PEP) may fail if it is incomplete. Doctors are understandably afraid of trying the low dose intradermal (ID) regimens. Confusingly, the WHO currently recommends 9 different vaccine regimens. It is now urgent to agree and then strongly recommend highly immunogenic, economical, safe and simplified methods suitable for all. This is now possible using the ID route for all three essential types of rabies vaccine regimens: Pre-exposure, Post-Exposure Booster for those previously immunised and Primary Post-exposure. The WHO already approves ID Pre-exposure: (0.1 ml, Days 0, 7, 28) and the PEP Booster: (Single Day ID 0.1 ml at 4-sites). For Primary PEP, the mandatory rapid immune response can be achieved by inoculating small doses of vaccine at multiple ID sites. Two 4-site ID candidate regimens have been proposed: a 'One Week' version suffers several disadvantages compared with the '4-site ID One Month' regimen, which uses the same total dose of vaccine and timing as the original 8-site ID regimen that was regarded as highly immunogenic by WHO. The new 4-site method involves 3 clinic visits, minimises vaccine wastage, accommodates inexperienced ID technique, is economical compared with all other regimens, and gives the same dose of vaccine antigen dispensed in either 1ml or 0.5 ml vials. The '4-site ID One Month' schedule is: Day 0, a whole vial ÷ ID 4-sites; Day 7, half a vial ÷ ID 2-sites; Day 28, 0.1/0.2 ml (one fifth of a vial) ID at 1-site. The result is three essential ID regimens: a Pre-exposure 3 dose (0,7,28); a Booster PEP Single Day 4-site; and a Primary PEP 4-site 3 dose (0,7,28). Should these ID regimens become routine globally? This strategy could pave the way to a new ID pre-exposure regimen and a Primary PEP regimen of only 2 visits.

437

UPDATING THE CDC YELLOW BOOK DENGUE MAP FOR CLINICIANS TO IMPROVE UNDERSTANDING OF DENGUE RISK AREAS

Emily S. Jentes[1], R. Ryan Lash[1], Michael Johansson[2], Tyler Sharp[2], Ronald Henry[1], Oliver J. Brady[3], Mark J. Sotir[1], Simon I. Hay[3], Harold S. Margolis[2], Gary W. Brunette[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Centers for Disease Control and Prevention, San Juan, PR, United States, [3]Oxford University, Oxford, United Kingdom

The *CDC Health Information for International Travel* (Yellow Book) publication is used by clinicians both during a pre-travel consultation to prepare travelers for international travel and when evaluating ill patients after travel. For the 2016 Yellow Book, CDC Dengue and Travelers' Health Branches sought to provide clinicians clearer, more rigorous guidance regarding dengue risk by improving the map that shows where travelers should employ mosquito bite prevention measures and where dengue should be considered in the differential diagnoses of ill travelers. Instead of one "dengue risk" category which included only areas with known dengue cases and potentially omitted areas with sporadic risk, CDC moved to describe two categories of risk: "frequent or continuous (FC)" or "sporadic or uncertain (SU)." FC areas are those with strong evidence of recent dengue cases over multiple years or reports of more than 10 cases in at least 3 of the previous 10 years. SU areas are those with weak evidence of transmission or locations with at least one locally acquired dengue case reported in the last 10 years that do not fit the FC definition. Evidence used to categorize geographic areas included dengue outbreak and surveillance data from official reports, ProMED reports, and published scientific research compiled by Oxford University and CDC. Because not all dengue outbreaks are reported worldwide, expert opinion was used when evidence for a given locale was missing, since the absence of cases does not indicate an absence of risk. The inclusion of the SU category, which augmented the geographic expanse of potential dengue risk areas, helps provide clinicians with a more risk-based map to inform both recommendations for avoiding dengue and differential diagnoses for returning ill travelers. An international traveler's risk for dengue virus infection depends on the local prevalence of dengue and exposure to vector mosquitoes. Although risk areas change over time, the revised dengue map incorporates a larger body of direct evidence and a more detailed assessment of risk to improve the information available to clinicians consulting the 2016 Yellow Book.

438

FACTORS CONTRIBUTING TO ADHERENCE TO THE BURULI ULCER ANTIBIOTIC TREATMENT REGIME: A CASE-CONTROL STUDY AT THE AMASAMAN SUB-DISTRICT IN GHANA

Bisi Adewale

Ministry of Health, Accra, Ghana

Buruli Ulcer is a debilitating disease caused by the mycobacterium ulcerans. In 2005 antibiotic regime was introduced in the treatment of the disease in addition to surgical treatment for advanced stages. The study aimed at finding the factors that contributed to adherence to the antibiotic treatment for Buruli ulcer, in Amasaman sub-district. A structured questionnaire which focused on patients access to treatment both geographically and financially, counseling patients prior to start of treatment and outcomes of the having the disease such as stigmatization and cumbersomeness of daily wound care was used to answer the identified study objectives. A case-control study was carried out with 100 each of cases and controls. The study found that patients knowledge about the disease, support from family, and effect of patient seeking treatment on daily activity were associated with patients adherence to treatment. Showing an OR 0.38(CI 95% 0.18-0.74) for patients knowledge about the disease, an OR 2.27(CI 95% 1.17-4.45)) for support from family and OR 0.30(CI 95% 1.54-7.34)) for effect of patient seeking treatment on daily activity. Other factors such as patients access to health with OR 11.29(CI 95% 5.56-23.11), experience with medication side effect with OR 2.53(CI 95% 1.03-6.65), patient being counseled before treatment having an OR 4.51(CI 95% 2.31-8.93) and quality of care given to patients by health care providers with OR 0.15(CI 95% 0.02-0.71) were also found to be associated with adherence to treatment. It is recommended that, staffs providing care for Buruli Ulcer patients should be well trained to deliver good counselling to patients prior to the start of treatment so as to enhance patients understanding the treatment regimen and the benefits of completing appropriately.

439

DENGUE AND COMORBIDITIES IN THE PERUVIAN AMAZON: 2010-2014

Stalin Vilcarromero[1], Crystyan Siles[1], Sandra Olkowski[2], Isabel Bazan[1], Cesar Ramal-Asayag[3], Carlos E. Vidal[4], Carlos Alvarez-Antonio[5], Robert D. Hontz[6], Eric S. Halsey[6], Amy C. Morrison[7], Julia S. Ampuero[6]

[1]U.S Naval Medical Research Unit-6, Iquitos, Peru, [2]Department of Entomology, University of California Davis, Davis, CA, United States, [3]Hospital Regional de Loreto, Iquitos, Peru, [4]Hospital de Apoyo Iquitos, Iquitos, Peru, [5]Direccion Regional de Salud Loreto, Iquitos, Peru, [6]U.S Naval Medical Research Unit-6, Lima, Peru, [7]U.S Naval Medical Research Unit-6 and Department of Entomology, University of California, Davis, Iquitos, Peru

Dengue illness is endemic throughout urban centers in the Peruvian Amazon, especially in Iquitos city, causing high morbidity and mortality

every year. Arterial hypertension, diabetes, rheumatoid arthritis, and other chronic diseases have been shown to be risk factors for severe dengue elsewhere, but little is known about the impact of these comorbidities on hospitalization and mortality rates in this region. To assess this impact, we analyzed the epidemiology and clinical data from patients, with acute undifferentiated febrile illness (AUFI), who were enrolled through clinic-based passive surveillance in Health facilities (3 hospitals, 9 health centers) located in Iquitos, from December 2010 to December 2014. We obtained acute and convalescent blood samples as well as clinical history of any comorbidity (hypertension, diabetes, asthma, rheumatoid arthritis and others). Dengue virus infection (DENV) was confirmed by real time PCR or virus isolation in the acute sample or by seroconversion (4-fold increase in IgM antibodies) between acute and convalescent samples. All probable cases (presence of IgM without a rise in titer) were excluded. We confirmed DENV in 1,941 of 4,435 AUFI cases screened. Of these, 1,493 were treated as outpatients compared to 448 who were hospitalized. Of the 60 DENV+ patients with comorbidity, 18 required hospitalization and 42 did not, a similar ratio to those without comorbidity (OR=1.42, CI95%: 0.81 to 2.5). Hypertension was the most common comorbidity. Shock and death occurred in four patients who did not have any comorbidity. Although the 2009 World Health Organization Dengue Guidelines list certain co-morbidities in their criteria for hospital admission, none of the comorbidities we evaluated were associated with hospitalization. Longitudinal research is necessary to assess the true impact of comorbidities on DENV outcomes in this region.

440

CORRECTING IRON DEFICIENCY PREVALENCE FOR PLASMA INFLAMMATION IN BOLIVIAN INFANTS

Rachel M. Burke[1], Rita Revollo[2], Volga Iñiguez[3], Juan Leon[1], Parminder Suchdev[1]

[1]Rollins School of Public Health, Emory University, Atlanta, GA, United States, [2]Servicio Departamental de Salud, La Paz, Plurinational State of Bolivia, [3]Instituto de Biología Molecular y Biotecnología, Universidad Mayor de San Andés, La Paz, Plurinational State of Bolivia

Iron deficiency (ID) in infancy can cause cognitive and developmental deficits that may be irreversible after the age of 2. Plasma ferritin (Fer), reflective of iron stores, is often used as a sensitive measure of ID, yet levels of Fer are affected by inflammation. The goals of this study were to quantify the prevalence of ID among 6 - 8 month-old infants in a high-altitude population of Bolivia and compare different methods of correcting ID for the effect of inflammation. Healthy infants were recruited from 2 hospitals in El Alto, Bolivia, and followed from 1 to 8 months of age. Blood taken at 2 and 6 - 8 months was analyzed for ferritin (Fer), C-Reactive Protein (CRP), and alpha(1)-acid-glycoprotein (AGP). ID was defined as Fer < 12 µg/L. Inflammation was defined as CRP ≥ 5 µg/L or AGP ≥ 1 mg/L. Six methods were tested for correcting Fer for inflammation: exclusion, internal correction factors, meta-analysis-derived correction factors, and 3 linear regression models of Fer on CRP and AGP (each used different CRP and AGP reference values). The ID prevalence values generated from these 6 methods were compared to the crude (uncorrected) prevalence. At 2 months of age, only 1 of 160 infants (< 1%) demonstrated evidence of ID, and 6 (4%) were inflamed. At 6 - 8 months of age, the prevalence of inflammation in this cohort was 20.2% (33/163). Uncorrected ID prevalence was 41.1% (67/163 infants measured). Exclusion yielded a prevalence of 44.6% (58/130), while different correction methods showed ID prevalence between 41.7% and 49.7% at 6 - 8 months of age. This analysis suggests that adjusting Fer for inflammation may lead to a more sensitive and valid measure of ID, depending on the correction method chosen. While infants in this population were born with adequate iron stores, by 6 - 8 months these stores were depleted to the point of ID in nearly half of the infants, a strikingly high figure. This analysis confirms that inflammation can significantly affect ferritin, and even in a low-inflammation setting can cause ID prevalence using Fer to be underestimated by nearly 10 percentage points. Interventions to prevent ID and inflammation in early infancy should be further explored.

441

TRENDS IN CARE SEEKING FOR CHILDREN'S RECENT FEVER IN LIBERIA: EVIDENCE OF IMPACT OF THE MALARIA COMMUNITIES PROGRAM (MCP)

Rebecca A. Winter[1], Lia Florey[1], Wenjuan Wang[1], Tom Pullum[1], Roland T. Suomie[2], Debra Prosnitz[3]

[1]The Demographic and Health Surveys Program, Rockville, MD, United States, [2]EQUIP Liberia, Monrovia, Liberia, [3]ICF International, Rockville, MD, United States

Through the Malaria Communities Program (MCP), the President's Malaria Initiative (PMI) awarded small grants to local organizations in 12 countries to implement projects around malaria prevention and treatment. One such organization, EQUIP Liberia, was awarded an MCP grant to work in two counties in Liberia: Nimba and Sinoe. In these counties, the EQUIP project piloted integrated community case management (iCCM), trained general Community Health Volunteers (gCHVs) and used behavior change communication to generate demand and increase care seeking. This study analyzed the 2007 Liberia Demographic and Health Survey (LDHS) and 2011 Liberia Malaria Indicator Survey (LMIS) data to evaluate how trends in care seeking for children's fever in counties covered by the EQUIP project compared with care seeking trends in non-project counties. Two logit regression models were developed to assess the odds that care was sought from any public facility and from any private facility. Results show that the increase in care seeking from public facilities was significantly greater in EQUIP project areas compared with the rate of increase in areas with no EQUIP presence, after adjusting for socio-demographic characteristics (adjusted OR for the additional increase associated with project counties: OR=3.6, p<0.05). Similarly, the rate of decline in care seeking from private facilities in EQUIP project areas was significantly more rapid than the rate of decline in areas with no EQUIP presence (adjusted OR for additional decline associated with project counties: OR=0.14, p<0.001). While the observed patterns could be explained by external factors such as urbanization, health system expansion, or other programs implemented during the same period, results provide some observational evidence of impact of EQUIP's malaria community-based malaria control program on care seeking in two counties in Liberia.

ANEMIA AND MICRONUTRIENT DEFICIENCIES IN ECUADOR: RESULTS FROM THE ECUADORIAN NATIONAL HEALTH AND NUTRITION SURVEY (ENSANUT-ECU)

Winnie Chu[1], Wilma B. Freire[2], Saurabh Mehta[1], Jere D. Haas[1], Julia L. Finkelstein[1]

[1]Cornell University, Ithaca, NY, United States, [2]Ministry of Health of Ecuador and the Universidad San Francisco de Quito, Ecuador, Quito, Ecuador

The burden of malnutrition in Latin America is high, although there is limited data from Ecuador. The recent Ecuadorian National Health and Nutrition Survey is the first national level nutrition survey since 1987, and provides a unique opportunity to examine the burden of anemia and micronutrient deficiencies in Ecuador. A total of 21,479 individuals were surveyed, including 11,325 adults (>19y), 3,646 adolescents (12-18y), 4,459 school-aged children (5-11y), and 2,049 children under five. Socio-demographic data and venous blood samples were collected and hemoglobin and micronutrient concentrations were analyzed. The prevalence of anemia and micronutrient deficiencies (zinc, vitamin A, iron, vitamin B12, folate) were calculated and mapped using ArcGIS. Binomial and linear regression models were used to examine the associations of micronutrient status and socio-demographic characteristics. Micronutrient deficiencies were common, including zinc deficiency (Zn<65.0 µg/dL; 41%), anemia (Hb<11.0 g/dL; 8%), and vitamin B12 insufficiency (vitamin B12<221.0 pmol/L; 30%). Coastal Ecuador had the highest prevalence of anemia (13%; RR: 2.46, 95% CI: 2.22-2.72, p<0.01) and zinc deficiency

(46%; RR: 1.32, 95% CI: 1.24-1.42, p<0.01), compared to other regions. Anemia was more prevalent in urban areas compared to rural settings (RR: 1.15, CI: 1.05-1.26, p<0.01). Anemia (16%; RR: 2.32, 95% CI: 2.08-2.59, p<0.01), vitamin A deficiency (serum retinol<20.0 µg/dL; 25%; RR: 3.50, 95% CI: 3.06-4.00, p<0.01) and iron deficiency (serum ferritin<12.0 µg/L; 9%; RR: 1.75, 95% CI: 1.51-2.03, p<0.01) were more prevalent among children, compared to other age groups. The highest prevalence of anemia (16%; RR: 2.08, 95% CI: 1.76-2.46, p<0.01), vitamin A deficiency (15%; RR: 2.39, 95% CI: 1.89-3.00, p<0.01), and zinc deficiency (50%; RR: 1.24, 95% CI: 1.14-1.34, p<0.01) was reported among Afro-Ecuadorians; the indigenous population had the highest prevalence of vitamin B12 insufficiency (35%; RR: 1.35, 95% CI: 1.13-1.61, p<0.01). Findings suggest the burden of micronutrient deficiencies is high in Ecuador, particularly in urban and coastal settings.

443

SECRETED FILARIAL SMALL RNAS - LOCALIZATION IN BIOFLUIDS AND BIOMARKER POTENTIAL FOR ONCHOCERCIASIS

Juan F. Quintana[1], Simon A. Babayan[2], Benjamin L. Makepeace[3], Alasdair Ivens[1], Kenneth Pfarr[4], Alexander Debrah[5], Samuel Wanji[6], David W. Taylor[7], Achim Hoerauf[4], Amy H. Buck[1]

[1]Centre for Immunity, Infection and Evolution, University of Edinburgh, Edinburgh, United Kingdom, [2]Institute of Biodiversity, Animal Health and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom, [3]Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom, [4]Institute of Medical Microbiology, Immunology and Parasitology, University Hospital of Bonn, Bonn, Germany, [5]Kumasi Centre for Collaborative Research and Kwame Nkrumah, University of Science and Technology, Kumasi, Ghana, [6]Research Foundation in Tropical Diseases and Environment, Department of Life Sciences, Faculty of Science, University of Buea, Buea, Cameroon, [7]Centre for Immunity, Infection and Evolution, Division of Pathway Medicine, School of Biomedical Studies, University of Edinburgh, Edinburgh, United Kingdom

Extracellular small RNAs, in particular miRNAs, are found in a wide variety of bodily fluids and have been proposed as biomarkers for diseases. More recently, reports have suggested that parasitic nematodes secrete specific miRNAs in exosomes and these can be found in serum of infected patients, with major implications for diagnosis and evaluation for treatment efficacy. We have identified microRNAs derived from three different filarial nematodes (Clade III): ***Litomosoides sigmodontis*** (murine filariasis), ***Onchocerca volvulus*** (human filariasis) and ***O. ochengi*** (bovine filariasis), in serum or nodule fluids obtained from their definitive hosts. Specifically, miRDeep revealed a total of 62 mature miRNAs from 52 distinct pre-miRNA candidates in nodule fluids from cattle infected with ***O. ochengi*** of which 59 are identical in the genome of the human parasite ***O. volvulus***. Six of the extracellular miRNAs were also identified in sequencing analyses of serum and plasma from humans infected with ***O. volvulus*** from endemic regions in Cameroon and Ghana. Also, fourteen parasite-derived miRNAs were found in mouse serum during the patent stage of the infection, all of which were detected in either human serum or bovine nodule fluid samples from endemic geographical regions in Cameroon. These results suggest that common miRNAs are secreted by filarial parasites and we have carried out an initial assessment of the ability of these miRNAs to detect infection in the serum of mice infected with ***L. sigmodontis***, suggesting high sensitivity and specificity (80/100). Interestingly, among all of the secreted miRNAs described to date, whether in secretory-excretory products or detected in host body fluids, there are common secreted miRNA such as miR-71 and miRNA families including miR-100 and bantam, as well as specific differences across the clades. These results confirm the conserved nature of RNA secretion by nematodes and also suggest that there might be specific secreted signatures depending on each parasite, their life cycle, developmental stage and the niche that they occupy within the final host.

IN VIVO EFFECTS OF DRUGS USED IN LYMPHATIC FILARIASIS MDA PROGRAMS ON *BRUGIA MALAYI* IN GERBILS

Mary J. Maclean[1], Ashley M. Rogers[1], Eman Mostafa[2], Michael T. Dzimianski[1], Bob E. Storey[1], Adrian J. Wolstenholme[1]

[1]University of Georgia, Athens, GA, United States, [2]University of Zagazig, Zagazig, Egypt

Lymphatic filariasis threatens nearly 20% of the world's population and has already handicapped one-third of the 120 million people currently infected, making continued control and research efforts a global health priority. Control is managed through mass drug administration (MDA) programs with three drugs: ivermectin (IVM), albendazole (ALB), and diethylcarbamazine (DEC), of which only ALB is well-understood. The lack of clarity regarding the mechanism of action of IVM and DEC is compounded by the disparity in results obtained ***in vitro*** versus ***in vivo***. The alteration of motility is the most simple and rapid way to gauge drug response ***in vitro***, making it the current standard for anthelmintic efficacy. In order to impair parasite motility, IVM requires drug concentrations orders of magnitude higher ***in vitro*** to even approach ***in vivo*** effects. In ***Brugia malayi***, the IC50 for microfilariae (Mf) was 43 µM, 10,000 times the amount of drug that clears Mf in human patients. DEC and ALB yielded less profound differences, with IC50 values 5.8 and 1.8 times the peak plasma concentration. These findings, and others suggest that the rapid clearance of Mf observed after MDAs with IVM or DEC is aided by the host's immune system. Given that ***in vitro*** experiments have proven to be inauthentic substitutes for studying antifilarial drug action, we have used an ***in vivo*** model with ***B. malayi*** in gerbils. Gerbils were intraperitoneally administered the infectious L3 and the worms allowed to develop to adulthood and begin producing Mf. They were then treated with 6 mg/kg DEC, 1 mg/kg ALB, or 0.15 mg/kg IVM mirroring human MDA dosages. Adults and Mf were collected 1 and 7 days post-treatment and RNA was isolated for transcriptomic analysis. Preliminary data analyzing the effects of IVM on adult females and Mf revealed changes in transcripts related to muscle regulation and locomotion as well as those encoding muscle protein and collagen expression, suggesting that IVM alters filarial neuromusculature and protein secretion. Further analysis of the effects of IVM, ALB, and DEC ***in vivo*** will provide a better understanding of how these drugs clear filarial parasites.

445

MOLECULAR STUDIES OF THE PHYSIOLOGICAL ROLE OF THE ECDYSONE RECEPTOR IN FILARIAL PARASITES

Amruta Mhashilkar, Rays Jiang, Thomas R. Unnasch

University of South Florida, Tampa, FL, United States

A homologue of the ecdysone receptor (EcR), a master regulator of development in insects has previously been identified and shown to be responsive to 20- hydroxyecdysone (20HE) in transfected ***Brugia malayi***. As the EcR is not found in vertebrate animals, it and the regulatory pathways it controls represent a attractive potential chemotherapeutic targets. In order to deduce the role the EcR plays in filarial parasites, adult female ***B. malayi*** were treated with 20HE in culture and microfilarial output and embryograms were monitored in treated and control parasites. RNAseq of the transcripts of adult females treated with 20HE was conducted to observe changes in gene expression. Proteomic analysis of the total protein extract of adult female worms treated with 20HE was also conducted to observe changes in gene expression at a biochemical level. Females treated with 20HE ecdysone produced significantly more microfilaria than control worms, implicating the EcR in regulation of microfilarial development. RNAseq identified 30 genes whose expression was genes significantly upregulated in the treated parasites compared to untreated controls. Of these, 18% were involved in regulating transcription. The proteomic analysis revealed 932 proteins to be significantly upregulated. Of these, 384 exhibited a greater than 2 fold difference in between the induced and uninduced parasites. A total of

15% of the upregulated proteins were involved in transcription regulation. Structural Activity Relationship (SAR) modeling was used to predict molecules capable of actively binding to the BmEcR. This has identified the diacylhydrazine family of molecules as potential agonists or antagonists of the receptor. These studies should assist in the development of inhibitors for the BmEcR that may be evaluated as potential lead compounds for development of a new class of drugs against the filaria.

WORMBASE-PARASITE: A COMPREHENSIVE, OPEN-ACCESS RESOURCE FOR HELMINTH GENOMIC DATA

Jane Lomax[1], WormBase Consortium[2]

[1]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [2]California Institute of Technology, Pasadena, CA, United States

WormBase-Parasite (parasite.wormbase.org) is a major new resource for storing, analyzing and exploring the genomes of helminth parasites. The public database, developed jointly by EMBL-EBI and the Wellcome Trust Sanger Institute, contains 97 annotated genomes from a total of 89 helminth species. A large number of the genomes were sequenced as part of the International Helminth Genomes Initiative - the largest collection of helminth genomic data ever assembled. The majority of the genome assemblies in WormBase-ParaSite are as yet unpublished so this resource provides unprecedented access to this high quality genomic data. WormBase-ParaSite is based on the well-established Ensembl infrastructure and provides several tools for exploring and analyzing the helminth data: a BLAST tool for aligning sequence to multiple genomes; a BioMart data-mining tool and Compara gene trees for comparative genomics analysis. We plan to add tools for the exploration of transcriptomic data for the next release of WormBase-ParaSite. This resource will allow researchers to perform critical investigations for example to identify of orthologs for existing drug targets, to discover new 'druggable' candidate genes, or to study the evolution of parasitic traits such as the ability to infect through skin. WormBase-ParaSite is closely integrated with WormBase, the genomic database for C. elegans and related species. Key reference parasitic genomes are incorporated in WormBase, as they become established and stable, where they are more richly curated. We welcome submissions from the helminth research community to gradually improve the phylogenetic coverage and build a robust resource for future research.

447

LOCALIZATION OF ACETYLCHOLINE RECEPTOR (ACHR) SUBUNIT PROTEINS IN *BRUGIA MALAYI* GAMETES AND EARLY EMBRYOS

Benwen Li, Amy H. Rush, Gary J. Weil

Washington Universtiy School of Medicine, St. Louis, MO, United States

AChRs are required for body movement in nematodes, and they are targets of several "classical" drugs that have been used to treat nematode parasite infections. We have recently reported that AChR subunit genes are highly expressed in reproductive tissues and muscle in ***Brugia malayi*** male and female adult worms and suggested that this may partially explain effects of drugs such as levamisole on worm reproduction. We now report results of parallel protein localization studies for AChRs. Anti-peptide antibodies to AChR subunit proteins Bm-unc-29 and Bm-acr-26 were used to localize the proteins in histological sections of ***B. malayi*** adult worms. Both of these proteins were detected in oocytes in the ovary and in early embryos (morulae through early pretzel stages) in females. The proteins were also present in spermatogonia and spermatocytes in the male testis. The uterus wall adjacent to stretched microfilariae (Mf) and the vas deferens adjacent to mature sperm were also strongly labelled by the anti-peptide antibodies. However, the uterus wall adjacent to developing embryos was not labeled. These results support the hypothesis that AChRs are involved in gameteogenesis and early embryo development and that they are also involved in the release of Mf and mature sperm. While the latter findings are consistent with neuromuscular signaling for Mf and sperm release, there are no nerves in oocytes or spermatogonia, and early embryos are not motile. Since acetylcholine has been shown to be a paracrine signaling molecule in several systems, the presence of AChR subunit proteins in germ line cells and in early embryos suggests that ACh may have an autocrine or paracrine function in filarial worms that promotes gametogenesis and growth of early embryos.

448

BIOINFORMATIC IDENTIFICATION OF NEW DNA BIOMARKERS FOR *LOA LOA* INFECTION SUITABLE FOR LOOP-MEDIATED ISOTHERMAL AMPLIFICATION

Catherine B. Poole[1], Laurence Ettwiller[1], Nathan A. Tanner[1], Yinhua Zhang[1], Thomas C. Evans Jr.[1], Samuel Wanji[2], Clotilde K. S. Carlow[1]

[1]New England Biolabs, Ipswich, MA, United States, [2]Research Foundation in Tropical Diseases and Environment, Buea, Cameroon

Loa loa infections have emerged as a serious public health problem because of severe adverse neurological reactions in patients after treatment with ivermectin for onchocericasis or lymphatic filariasis. This necessitates the need for careful mapping of ***L. loa***, ***O. volvulus*** and ***Wuchereria bancrofti*** infections in regions were these parasites are co-endemic. Loop-mediated isothermal amplification (LAMP) has become a widely adopted screening method because of its operational simplicity, rapidity and versatility of visual detection readout options. Previous publications have described LAMP assays for ***L. loa*** using targets developed for PCR. In this study, we present a LAMP and the development of a species-specific LAMP assay for ***L. loa***. This pipeline identified ~140 new ***L. loa*** specific DNA repeat families as putative biomarkers of infection. The consensus sequence of one of these, repeat family 4 (RF4), was compiled from ~ 350 sequences dispersed throughout the ***L. loa*** genome. PCR and LAMP primers sets targeting RF4 only amplified ***L. loa*** and not ***W. bancrofti***, ***O. volvulus***, ***B. malayi***, human or mosquito DNA. Using turbidity as the readout, RF4 LAMP detects as little as 0.060 pg of ***L. loa*** DNA (~1/1600th of mf) purified from spiked blood samples in ~ 50 minutes, well within the 60 minute cut off time for the assay. The equivalent of one mf worth of DNA (100 pg) was consistently detected by RF4 LAMP in 25-30 minutes. In summary, we have successfully employed a bioinformatics approach to mine the ***L. loa*** genome for species-specific repeat families that could serve as biomarkers for LAMP. The species-specificity and sensitivity of the RF4 LAMP assay suggests that it shows promise as a field tool for the implementation and management of MDA programs and warrants further testing on clinical samples as the next stage in development towards this goal.

449

POPULATION GENOMICS ESTIMATES HISTORICAL PREVALENCE OF *WUCHERERIA BANCROFTI* POPULATIONS

Scott T. Small[1], David Serre[2], Peter A. Zimmerman[1]

[1]Case Western Reserve University, Cleveland, OH, United States, [2]Cleveland Clinic Foundation, Cleveland, OH, United States

To assess the progress of elimination we must first have a reference point for comparison. For ***Wuchereria bancrofti*** (Wb), elimination programs are recent. Therefore, there is an absence of past prevalence data for many newly mapped endemic areas. Without a reference measure it is difficult to evaluate elimination progress in light of stochastic fluctuations. We present a solution whereas we utilize population genomic models to infer the past demography of Wb populations in regions currently undergoing elimination. We apply the Pairwise Sequential Markovian Coalescent (PSMC) model to reconstruct infection history from a single Wb genome. We then use a more recent, multi-genome, version of PSMC to resolve more recent demography, closer to the start of elimination programs. Our methods demonstrate that information critical to Wb elimination can be obtained from a very small investment. Our results determine that Wb populations in Papua New Guinea were in decline before human

intervention, possibly as early as 500 AD. With population genomics we now have a metric for which to compare the progress of any future elimination program.

450

IMPACT OF COMMUNITY DIRECTED TREATMENT WITH IVERMECTIN ON FOREST TYPE OF ONCHOCERCIASIS IN TANZANIA, EAST AFRICA: FROM CONTROL TO ELIMINATION

Afework H. Tekle

World Health Organization/APOC, Ouagadougou, Burkina Faso

Onchocerciasis is a public health problem in Tanzania and ivermectin mass drug administration has been used to control the disease since 1994. After evidence from Mali and Senegal showed that onchocerciasis elimination can be achieved in Africa by ivermectin mass treatment, Tanzania shifted its target from control to elimination by 2020. However, more empirical evidence is required to understand where and when onchocerciasis elimination can be achieved by ivermectin mass treatment and how that depends on the pre-control endemicity level, achieved coverage in mass drug administration programmes and the duration of mass treatment. Here, we present empirical data from epidemiological evaluation carried out in seven onchocerciasis ***foci*** in Tanzania, located four regions. These ***foci*** had received 9 to 12 years of ivermectin treatment with more than an average of 75% reported coverage. Per focus we selected 10-20 communities, based on their high pre-control endemicity level and proximity to vector breeding sites of the rivers. Mf prevalence and intensity were measured in through skin snips in all individuals aged 5 years and older who consented to the procedure. In total 23,638 individuals from 132 communities were examined. Based on the extensive epidemiological evaluation conducted and the statistical significance testing made during analysis, focal onchocerciasis infection elimination might already have been achieved in three of the seven ***foci*** evaluated namely Tanga, Tukuyu and Tunduru, although interruption of transmission remains to be confirmed by additional epidemiological surveys and/or entomological evaluations. Infection levels were still high in Mahenge and Kilosa ***foci***. However, due to poor implementation of mass drug administration in some the evaluated ***foci*** onchocerciasis is still highly prevalent which might need an alternative strategy to accelerate elimination in Tanzania. This will guide the policy decision and next steps to achieve elimination of onchocerciasis by 2020 in Tanzania.

451

ONCHOCERCIASIS: SHIFT FROM CONTROL TO ELIMINATION-VECTOR CONTROL SHALL NOT REMAIN UNDER A BUSHEL!

Moses N. Katabarwa, Frank Richards

The Carter Center, Atlanta, GA, United States

A little more than two decades ago, the approach to human onchocerciasis control was to attack the Simulium sp. vector through large scale and expensive aerial spraying, executed in the well-known Onchocerciasis Control Program (OCP) of West Africa. Larviciding was aimed at reducing vector densities to levels where transmission of the disease was eliminated and in some East Africa ***foci*** where it achieved local vector elimination. With the discovery of the drug ivermectin (Mectizan®) in 1987, there began a shift from vector control to annual mass treatment with ivermectin for onchocerciasis control that began with the launching of APOC in 1996, and culminated in the closure of OCP in 2002. APOC, with some small exceptions in Equatorial Guinea, Tanzania and Uganda, was focused on the Community Directed Treatment with Ivermectin (CDTI), where community volunteers are trained and utilized to treat their respective community members. It seems that since the establishment of APOC "vector control" become a "forbidden" term among polite onchocerciasis circles. Recently however vector control has been resurrected with the stated goal of attaining elimination in most of Africa by 2025. Vector control directed against Simulium larval stages through ground larviciding using WHO approved and environmentally safe insecticides was successful in eliminating S. yahense in Bioko Island, Guinea Bissau, S.neavei in 2003 and 2008 in Itwara and Mt. Elgon ***foci*** of Uganda respectively. It is also an important way forward in areas of onchocerciasis transmission that have concomitant ***Loa loa*** hyper-endemicity. Vector control encourages best practices in mapping breeding sites and defining clearly transmission zones and transmission seasons while focusing on elimination efforts in geographic areas where the resources are needed. Ground larviciding can be done at an affordable level by endemic countries and their partners in many instances, thus accelerating transmission interruption. The era of vector control taboo is gratefully over; it must be considered as a complementary tool for accelerating onchocerciasis elimination.

452

EVALUATION OF ONCHOCERCIASIS STATUS IN SIXTEEN SELECTED CDTI ENDEMIC VILLAGES IN EDO, ENUGU AND DELTA STATES NIGERIA 2014

Emmanuel C. Emukah[1], Nimzing F. Jip[2], Precious Inyanga[3], MaryFlora Ezeabikwa[4], Chinyere Ukaga[5], Bertram E. Nwoke[5], Josephine I. Obiezu[1], Njideka T. OKpala[1], Ukamaka T. Eze[5], Emmanuel S. Miri[2], Moses N. Katabarwa[6], Donald Hopkins[6], Mark Eberhard[7], Frank O. Richards[6]

[1]The Carter Center, Owerri, Nigeria, [2]The Carter Center, Jos, Nigeria, [3]Ministry of Health Imo State, Owerri, Nigeria, [4]University of Nigeria, Nsukka, Nigeria, [5]Imo State University, Owerri, Nigeria, [6]The Carter Center, Atlanta, GA, United States, [7]Centers For Disease Control, Atlanta, GA, United States

We conducted an evaluation of the status of Onchocerciasis control in 16 villages (10 random and 6 Sentinel)April 2012 and April, 2014 after 19 years of annual mass drug administration - MDA, During the survey,1,203 persons aged 2 - 82 years were interviewed and examined for clinical Onchocerciasis, microfilaria - mf and 741 persons for ocular disease. We interviewed 16 village heads, 170 heads of households, 32 community directed distributors - CDDs and 10 health workers on CDTI. Entomological study in 6 sentinel villages, 6,695, S. damnosum s.l were examined by Polymerase chain reaction (PCR). We found mean skin mf (40.2% mf) in 10 random villages($p<0.001$) and 12.9% in 6 sentinel villages, all age groups affected, increasing with age and highest for age 50+ (49.3%) $p<0.05$. Community microfilaria load was above 0 mf/mg skin and highest in Utesse (1.8mf/mg skin). Notably, 60% of random villages were excluded from CDTI as hypo-endemic but showed evidence of onchocerciasis transmission of skin mf (33%), (29%)nodules with viable embryonic mf ***in utero*** and live male worms (9.5%). PCR showed infective O. volvulus mf L3 in the head in two villages (Oke, 5.8/10,000 and Idumogo, 30.7/10,000). Children <10 were found to have mf in skin (1.4%) $p<0.01$. Low therapeutic (49.5%) and low geographic (74%) coverage rates were observed indicative of failed CDTI. Few CDDs per village in random villages(1: 5,207), community involvement (54%) and willingness (60%) in contrast to the 6 sentinel villages (100%). Government funding was zero resulting in poor supervision. However, ocular and clinical skin lesions significantly reduced or not found. We concluded that Onchocerciasis prevalence following ivermectin has significantly reduced but the disease transmission is still ongoing. Villages considered hypo-endemic were found to be transmitting onchocerciasis. This is indicative of failed CDTI based on ONCHOSIM model. There is need to urgently modify current APOC/CDTI implementation strategy, conduct entomological assessments and adopt twice annual MDA in high transmission zones

456

CHALLENGES IN THE DETECTION OF *WUCHERERIA BANCROFTI* MICROFILARIA IN AREAS WITH MULTIPLE FILARIAL INFECTIONS IN THE DEMOCRATIC REPUBLIC OF CONGO

Manko Kennedy Munganga[1], Joseph Linguba[1], Naomi Awaca[1], Jean Jacques Tougoue[2], Martin Ndombe[3], Sammy Njenga[4], Daniel Cohn[2], Molly Brady[2], Achille Kabore[2]

[1]Ministère de la Santé Publique, Democratic Republic of Congo, Kinshasa, Democratic Republic of the Congo, [2]RTI International, Washington, DC, United States, [3]RTI International, Kinshasa, Democratic Republic of the Congo, [4]Kenya Medical Research Institute, Nairobi, Kenya

The Democratic Republic of Congo (DRC) is endemic for a variety of filarial infections. In 2014, surveys were undertaken in 13 sites (villages) to provide baseline data for the national lymphatic filariasis (LF) program. During the daytime 300 to 500 people in each site were tested using immuno-chromatographic tests (ICT) and filarial test strips (FTS). Nighttime capillary blood samples were then drawn only from participants who tested positive for LF antigenemia (by ICT and/or FTS). The smears were stained, fixed and examined microscopically. Antigenemia was detected in 319 individuals from 8 sites, with microfilarial (mf) parasites being visualized in 129 of the 319 (40.4%) - 86 with ***Wuchereria bancrofti*** (Wb), 72 with ***Mansonella perstans***, 7 with ***M. sterptocerca*** and 3 with ***Loa loa***. The only co-infections identified microscopically were between Wb and ***M. perstans*** (30 individuals or 34.9% of those with Wb mf), but since the 43 other individuals with non-Wb mf were also ICT and/or FTS-positive, it is likely that they too were co-infected since many individuals with Wb infection are amicrofilaremic. The median intensity of infection for Wb was 2004 mf/µl (range 33.4- 12558.4), 517.7 mf/µl (range 33.4-25818.2) for M. perstans, 116.9 mf/µl (range 50.1-183.7) for M. streptocerca and 2054 mf/µl (range 492 - 4108.2) for ***L. loa***. In the context of these multiple filarial infections, the identification of Wb infections is programmatically challenging. Heavy M. perstans infections can obscure Wb mf in night-blood exams; and even the generally diurnally periodicic ***L. loa*** and the 'subcutaneous' mf of M. streptocerca could be found in nighttime blood smears. While diagnosis of Wb is most effectively made by ICT or FTS antigen detection, determining exactly how mass drug administration for LF should be implemented in the complex environments of DRC may require not only antigen detection but also the assistance of specific antifilarial antibodies as well.

457

MAPPING THE DISTRIBUTION AND ENVIRONMENTAL DRIVERS OF *LOA LOA* IN NIGERIA: PREPARING FOR THE SCALE UP OF INTERVENTIONS AND ELIMINATION OF LYMPHATIC FILARIASIS AND ONCHOCERCIASIS

Patricia N. Okorie[1], Michelle C. Stanton[2], Louise A. Kelly-Hope[2]

[1]Institute for Advanced Medical Research and Training, College of Medicine, University of Ibadan, Ibadan, Nigeria, [2]Department of Parasitology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The distribution of ***Loa loa*** filariasis (also loiasis or tropical eye worm) in Nigeria is potentially a major obstacle to the elimination of lymphatic filariasis (elephantiasis) and onchocerciasis (river blindness) due to the risk of severe adverse events associated with the standard drug regime including ivermectin. Understanding the distribution and environmental drivers of the ***L. loa*** parasitic disease transmitted by the forest Chrysops spp. may help to predict high risk co-endemic areas, and where alternative treatment strategies are required to interrupt transmission of lymphatic filariasis (caused by ***Wuchereria bancrofti***, transmitted by Anopheles spp. mosquitoes), and onchocerciasis (caused by ***Onchocerca volvulus***, transmitted by riverine Simulium spp). This study aimed to develop a historical ***L. loa*** database for Nigeria from all available public scientific sources, including information on the location, time period, vector, diagnostic methods and prevalence of infection of microfilaria or history of eyeworm. All data were geo-referenced and mapped to identify high risk areas, and data on climate, vegetation, land cover and river systems examined. The results to date include more than 40 publications since the year 1910, and encompass more than 200 data points, in over 130 study sites across 19 states and five zones of the country. The majority of data were found in the southern region of the country, with ***Chrysops silacea*** and ***C. dimidiata*** as main vectors. Parasitological examination of blood films for microfilaria were the main diagnostic method until the last decade where the new Rapid Assessment Procedure for loiasis (RAPLOA) has been used. Prevalence varied across geographical areas, and was more predominant in the tropical forested areas. Detailed environmental analysis is currently underway and will be presented and discussed. This extensive ***L. loa*** database will be a critical resource to the lymphatic filariasis and onchocerciasis elimination programmes. It will help to predict problems areas and where alternative strategies such as different drug regimes and vector control can be implemented safely and effectively.

BEYOND MASS DRUG ADMINISTRATION: IDENTIFYING OPTIMAL DIAGNOSTIC TOOLS FOR LYMPHATIC FILARIASIS POST-TREATMENT SURVEILLANCE

Kimberly Won[1], Amanda Barry[1], Leda Hernandez[2], Maria Cecilia Oreta Graza-Pan[3], Nana-Kwadwo Biritwum[4], Irene Offei Owusu[5], Brian Chu[6], Katherine Gass[6], Patrick Lammie[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Philippines Department of Health, Manila, Philippines, [3]Philippines Department of Health, Region V, Legazpi City, Philippines, [4]Ghana Health Service, Accra, Ghana, [5]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [6]Task Force for Global Health, Decatur, GA, United States

Significant progress has been made toward the global goal to eliminate lymphatic filariasis (LF). Many LF endemic countries have implemented successful mass drug administration (MDA) programs and have stopped MDA in some areas based on reduced infection in children, including Ghana and the Philippines. Post-treatment surveillance (PTS) guidelines include a recommendation to detect new ***foci*** of transmission using available diagnostic tools, including antigen and antibody tests. While antigen tests (ICT) are widely used, the utility of antibody tests for monitoring LF transmission has not been well-defined. In order to define optimal strategies for the use of antibody tests for PTS, it is necessary to have a better understanding community-wide clearance of antibody responses following MDA. To characterize antigen and antibody responses post-MDA, samples from Ghanaian adults (15-45 years) and individuals from the Philippines (4-85 years) were tested by ICT and two LF ELISAs (Wb123, Bm14). For both countries, ICT prevalence was below 2%, the threshold that warrants MDA (Ghana – 10/988 (1.0%); Philippines – 10/1153 (0.9%)). Overall Wb123 antibody prevalence was low (Ghana – 5/749 (0.7%); Philippines – 34/1131 (3.0%)) but increased with age in the Philippines where > 90% of positive individuals were ≥20 years of age. Of the samples that were also tested for Bm14 antibodies, the prevalence of Bm14 was higher than Wb123 (Ghana – 39/96 (40.6%); Philippines – 38/118 (32.2%)). There was no correlation between ICT and antibody positivity to either Wb123 or Bm14. Additional samples from both countries are currently being analyzed by Bm14 ELISA. The observed difference between Wb123 and Bm14 results suggests a lower sensitivity for Wb123 compared to Bm14 antibodies post-MDA, perhaps indicative of a more rapid clearance of Wb123 antibodies. These results may have implications for selecting the optimal tool to monitor incident infections in young children, but strategies to monitor the decline in antibody prevalence in adult populations may be appropriate for PTS.

459

FAMILIAL AGGREGATION AND HERITABILITY OF *WUCHERERIA BANCROFTI* LYMPHATIC FILARIASIS

Cédric B. Chesnais[1], Audrey Sabbagh[2], Sébastien D. Pion[1], François Missamou[3], André Garcia[2], Michel Boussinesq[1]

[1]Institut de Recherche pour le Développement, UMI 233 TransVIHMI, Montpellier, France, [2]Institut de Recherche pour le Développement, UMR 216, Paris, France, [3]Ministère de la Santé Publique, Brazzaville, Republic of the Congo

Lymphatic filariasis (LF) is responsible for severe disabilities across the world, especially because of lymphedema. Although immune factors were identified to explain the development of lymphedema in infected individuals, few studies have investigated the genetic susceptibility to infection. To assess familial aggregation and heritability of ***Wuchereria bancrofti*** infection, we conducted a study in a village of the Republic of Congo. Pedigree was built for 829 individuals (broken down in 267 households and 36 families) from which 143 were positive at the immunochromatographic card test (prevalence: 17.3%) and 44 (5.3%) had ***W. bancrofti*** microfilariae (mf). Analyses were adjusted on individual risk factors for LF (age, sex, outdoor activities, usage of bednet) and for environmental factors (eg: distance between house and nearest river), and accounted for possible household effect. Patterns of familial aggregation, assessed using S.A.G.E. software, showed that the presence of antigenemia was very slightly but significantly correlated within families ($0.06 < r < 0.10$; with $0.001 <$ P-value < 0.013). Regarding microfilaremia, correlation values were much higher: $r = 0.45$ between fathers and sons (P-value = 0.013), $r = 0.78$ between mothers and sons (P-value = 0.034), and $r = 0.94$ between fathers and daughters (P-value < 0.001). Heritability was estimated using SOLAR software. Genetic factors explained 13% (P-value = 0.226), 61% (P-value = 0.166) and 51% (P-value = 0.048) of variation in the presence of antigenemia, presence of mf, and in mf density, respectively. Household effect was never found significant. Our results show that the acquisition of ***W. bancrofti*** infection (as assessed by antigenemia) barely depends on genetic factors and is thus mainly due to exposure factors. However, both the presence of mf and variation in ***W. bancrofti*** mf density seem significantly influenced by genetic factors. Additional genetic studies are needed to confirm this finding.

460

HUMAN ONCHOCERCIASIS: MODELLING THE POTENTIAL LONG-TERM CONSEQUENCES OF A VACCINATION PROGRAM

Hugo C. Turner[1], Martin Walker[2], Sara Lustigman[3], David W. Taylor[4], **Maria-Gloria Basáñez**[2]

[1]London Centre for Neglected Tropical Disease Research, Imperial College London, London, United Kingdom, [2]Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [3]Laboratory of Molecular Parasitology, Lindsley F. Kimball Research Institute, New York Blood Center, New York, NY, United States, [4]Division of Infection and Pathway Medicine, University of Edinburgh Medical School, Edinburgh, United Kingdom

Currently, the predominant onchocerciasis control strategy in Africa is annual mass drug administration (MDA) with ivermectin. However, there is a consensus among the global health community, supported by mathematical modelling, that onchocerciasis in Africa will not be eliminated within proposed time frameworks in all endemic ***foci*** with only annual MDA, and that novel and alternative strategies are urgently needed. Furthermore, use of MDA with ivermectin is already compromised in large areas of central Africa co-endemic with loiasis and there are areas where suboptimal or atypical responses to ivermectin have been documented. An onchocerciasis vaccine would be highly advantageous in these areas. We used a previously developed onchocerciasis transmission model (EPIONCHO) to investigate the impact of vaccination in areas where loiasis and onchocerciasis are co-endemic and ivermectin is contraindicated. We also explore the potential influence of a vaccination programme on infection resurgence in areas where local elimination has been successfully achieved. Based on the age range included in the Expanded Programme on Immunization (EPI), the vaccine was assumed to target 1 to 5 year olds. Our modelling results indicate that the deployment of an onchocerciasis vaccine would have a beneficial impact in onchocerciasis-loiasis co-endemic areas, markedly reducing microfilarial load in the young (under 20 yr) age groups. An onchocerciasis vaccine would reduce the onchocerciasis disease burden in populations where ivermectin cannot be administered safely. Moreover, a vaccine could substantially decrease the chance of re-emergence of ***Onchocerca volvulus*** infection in areas where it is deemed that MDA with ivermectin can be stopped. Therefore, a vaccine would protect the substantial investments made by present and past onchocerciasis control programmes, decreasing the chance of disease recrudescence and offering an important additional tool to mitigate the potentially devastating impact of emerging ivermectin resistance.

461

IMMUNO-EPIDEMIOLOGY OF SOIL-TRANSMITTED HELMINTH INFECTIONS AFTER REPEATED SCHOOL-BASED DEWORMING: A COMMUNITY-WIDE CROSS SECTIONAL STUDY IN WESTERN KENYA

Rita G. Oliveira[1], Alice Easton[1], Stella Kepha[2], Sammy M. Njenga[3], Charles S. Mwandawiro[3], Poppy H. Lamberton[1], Johnny Vlaminck[4], Coreen M. Beaumier[5], Peter J. Hotez[5], Peter Geldhof[6], Chris Drakeley[7], Simon J. Brooker[7], Roy M. Anderson[1]

[1]Imperial College London, London, United Kingdom, [2]Makerere University, Kampala, Uganda, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]Washington University, St Louis, MO, United States, [5]Baylor College of Medicine, Houston, TX, United States, [6]Ghent University, Merelbeke, Belgium, [7]London School of Hygiene & Tropical Medicine, London, United Kingdom

The development of human immunity to soil-transmitted helminths remains poorly understood despite their widespread endemicity in tropical and subtropical countries. Infected individuals in endemic areas do not appear to develop fully protective immune responses, and the factors driving possible partial immunity acquired are unclear. With the increasing number of endemic countries introducing school-based deworming programs, there is a need to understand the effect of anthelminthic treatment on immune responses to helminths, not only in school-age children but also in younger and older members of the treated community. This study investigates both the development of humoral immunity against ***Ascaris lumbricoides*** and hookworm in an endemic community, and the effect of school-based and community-based anthelminthic treatment on antibody responses. The study took place in 2014 in four villages of Bungoma County, Western Kenya, where annual school-based deworming has been taking place since 2012. Stool and finger-prick blood samples were collected from over 1300 individuals aged 2 to 88 years, before and three months following community-wide treatment with 400mg albendazole. Parasite egg counts were obtained using Kato-Katz thick smears and antibody seroprevalence was measured by enzyme-linked immunosorbent assay (ELISA). Prevalence of ***A. lumbricoides*** and hookworm infections was 7.3% and 6.2%, respectively, at study baseline, and 2.6% and 2.0% at follow-up. Individual antibody profiles against ***A. suum*** haemoglobin (AsHb) and ***Necator americanus*** larval (Na-ASP2) and adult (Na-SSA-2) antigens were obtained and analysed by age-group, village and population level. Correlations between antibody seroprevalence and intensity of soil-transmitted helminth infection were investigated at both sampling time-points, taking into consideration a series of confounding factors including malaria co-infection and socio-economic and hygiene and sanitation ranks. Changes in antibody seroprevalence levels post community treatment with albendazole were also investigated, with particular emphasis on differences between age-groups.

462

COMPARISON OF KATO KATZ AND MINI-FLOTAC FOR ESTIMATION OF PREVALENCE AND INTENSITY OF INFECTION WITH SOIL-TRANSMITTED HELMINTHS IN THE PERUVIAN AMAZON

Layla S. Mofid[1], Martin Casapia[2], Theresa W. Gyorkos[1]

[1]McGill University, Montreal, QC, Canada, [2]Asociación Civil Selva Amazónica, Iquitos, Peru

Women of reproductive age are considered a high-risk group for soil-transmitted helminth (STH) infections. A randomized placebo-controlled trial on maternal postpartum deworming with single-dose 400 mg albendazole is currently underway in Iquitos, Peru. In order to evaluate re-infection rates, stool specimens were collected six months after treatment allocation. In a substudy of participants, stool specimens were analyzed by both the Kato Katz (KK) and mini-FLOTAC (MF) methods. The aim of this substudy was to compare the diagnostic accuracy of the World Health Organization recommended quantitative diagnostic method, KK, to the MF method. All laboratory personnel were blinded to the results of the other test, using a code switching technique. Eggs per gram of stool were calculated for each species using a multiplication factor of 24 for KK and 10 for MF. The total number of positive specimens detected by either method was taken as the diagnostic reference standard for each parasite species. Of the 306 women screened for STH infections, 41% were found to be positive for at least one of the helminth species, using either diagnostic method (17% ***Ascaris***, 34% ***Trichuris***, and 7% hookworm). The KK method had a higher sensitivity compared to MF for ***Ascaris*** (98% vs. 81%), and hookworm (90% vs. 60%), but not ***Trichuris*** (84% vs. 91%), though these differences were not statistically significant. The strength of the agreement (k Cohen coefficient) between the two methods was high, ranging from 0.86 for ***Ascaris***, 0.80 for ***Trichuris***, and 0.65 for hookworm. The KK method diagnosed a statistically significant higher number of eggs for all three helminth species compared with MF. These results contribute to the on-going discussion of which diagnostic method is optimal for assessment of STH prevalence and intensity in field conditions.

463

IMMUNOLOGICAL CHARACTERIZATION OF HUMAN HOSTS TO *ASCARIS LUMBRICOIDES* AND *TRICHURIS TRICHIURA* INFECTION IN A POPULATION LIVING IN THE RURAL MUNICIPALITY OF COLOMONCAGUA, HONDURAS

Neima Briggs[1], Rojelio Mejia[2], Coreen Beaumier[2], Graeme Segal[1], Stephanie Mena[1], Harihan Athreya[1], Paul Musgrave[1], Patricia Lenihan[1], Travis Vowels[1], Patricia Bryan[2], Philip C. Johnson[1], Carol Gomez[3], Jagannadha Sastry[4], Peter Hotez[2], Maria Elena Bottazzi[2]

[1]The University of Texas Health Science Center at Houston, Houston, TX, United States, [2]Baylor College of Medicine, Houston, TX, United States, [3]Hombro a Hombro, Santa Ana, Honduras, [4]The University of Texas M.D. Anderson Cancer Center, Houston, TX, United States

Soil-transmitted helminth (STH) infections, specifically ***Ascaris***, ***Trichuris***, and Hookworm, compose three of the most prevalent Neglected Tropical Diseases, infecting over a billion people worldwide. Recurrent childhood STH infections have been shown to cause stunted physical growth, reduced physical fitness, and decreased school performance. ***Ascaris*** and ***Trichuris*** are of notable interest, given their abrupt decline from a peak prevalence and intensity in pre-adolescence to adulthood, with little published works evaluating the possible underlying immunological mechanism in human. We used modern molecular techniques to (a) determine the burden of disease and (b) evaluate the immune profile of 30 adolescents and 51 adults between the ages 13-45, in rural Honduras, endemic for ***Ascaris*** and ***Trichuris***. Using quantitative PCR of DNA extracted from stool we quantified the burden of disease of both ***Ascaris*** and ***Trichuris***. Positive samples were stratified into groups based on the degree of infection, and controlled for with samples positive for 6 other common gastrointestinal parasites: ***Necator americanus, Ancylostoma duodenale, Entamoeba histolytica, Strongyloides stercoralis, Giardia lamblia***, and ***Cryptosporidium parvum***. Each group was immunologically characterized for serum Th1, Th2, and Th17 cytokines using LUMINEX analysis. Further immunological work-up was done using ELISA analysis to identify ***Trichuris*** and ***Ascaris*** specific IgG, IgM, and IgE antibodies. Select putative serum to ***Trichuris*** and ***Ascaris*** may be used to screen vaccine antigen candidates. Results from this pilot study identify the basic serum immune profile associated with protection against ***Ascaris*** and ***Trichuris*** and serve as the foundation for a second, more comprehensive study.

464

A CONTEXTUAL FRAMEWORK TO ASSESS HETEROGENEITY IN IMPACT OF NATIONAL NEGLECTED TROPICAL DISEASE CONTROL PROGRAMS: EVIDENCE FROM SCHOOL-BASED DEWORMING IN KENYA

Birgit Nikolay[1], Charles S. Mwandawiro[2], Jimmy H. Kihara[2], Okoyo Collins[2], Jorge Cano[1], Mariam T. Mwanje[3], Hadley Sultani[3], Dorcas Alusala[3], Hugo C. Turner[4], Caroline Teti[5], Josh Garn[6], Matthew C. Freeman[6], Elizabeth Allen[1], Roy M. Anderson[4], Rachel L. Pullan[1], Sammy M. Njenga[2], Simon J. Brooker[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Kenya Medical Research Institute, Nairobi, Kenya, [3]Ministry of Health, Nairobi, Kenya, [4]Imperial College, London, United Kingdom, [5]Evidence Action, Nairobi, Kenya, [6]Emory University, Atlanta, GA, United States

The majority of countries endemic for soil-transmitted helminths are now implementing mass drug administration programmes, either as part of school-based deworming (SBD) efforts or lymphatic filariasis control programmes. MDA implementation happens however in a heterogeneous social and economic environment, so that the success of STH treatment programmes will vary according to the context. The impact of STH treatment programmes on reducing infection and reinfection is theoretically influenced by a variety of factors, including: drug efficacy, treatment coverage, and intensity of transmission, which itself is influenced by climate and levels of water, sanitation and hygiene (WASH). Based on data from the national SBD programme in Kenya, we describe the heterogeneity in programme impact and investigate the influence of contextual factors. Indicators of the domains STH epidemiology, capacity to deliver treatment, operational feasibility and financial capacity were developed based on open access data and basic school WASH questionnaires. Associations of these variables with relative prevalence and intensity reductions were investigated using mixed effects linear regression analysis at the school-level. Our findings demonstrate that relative prevalence and intensity reductions for ***Ascaris lumbricoides*** and hookworms varied significantly by county (equivalent to district) and within counties by school. Multivariable analysis of factors associated with programme impact showed evidence for a higher reduction of ***A. lumbricoides*** among schools with ventilation improved pit (VIP) latrines compared to pit latrines and among schools located in areas with a higher land surface temperature. Whereas, higher hookworm reductions were found among schools in locations with higher community-level access to improved sanitation. In conclusion, this study demonstrated the influence of contextual factors on the implementation of deworming programmes and highlights the importance of improved sanitation in support of deworming efforts.

465

THE USE OF *ASCARIS SUUM* HAEMOGLOBIN AS DIAGNOSTIC ANTIGEN FOR HUMAN ASCARIASIS

Johnny Vlaminck[1], Peter Geldhof[2], Cornelius H. Hokke[3], Taniawati Supali[4], Peter U. Fischer[1], Gary J. Weil[1]

[1]Washington University, St. Louis, St. Louis, MO, United States, [2]Ghent University, Ghent, Belgium, [3]University Medical Center, Leiden, Netherlands, [4]University of Indonesia, Jakarta, Indonesia

The human roundworm ***Ascaris lumbricoides*** infects some 800 million people in the developing world. Standard diagnostic tests for ascariasis depend on detection of parasite eggs in stool samples. This technique has some important limitations in terms of both application and interpretation. A new antibody test has recently been developed for detecting ***Ascaris*** infections in domestic pigs using ***A. suum*** hemoglobin antigen (AsHb). Since ***Ascaris*** worms in humans and pigs are very similar, the objective of this study was to evaluate the diagnostic value of native and recombinant AsHb for community diagnosis of human ascariasis. Initial results showed that humans living in an endemic area in Indonesia had high rates of IgG4 antibodies to AsHb. Antibody rates and titers significantly decreased in the community following two annual rounds of mass treatment with albendazole. Unfortunately, further studies showed that sera from patients with hookworm infections contain cross-reactive antibodies to AsHb. Interestingly, antibodies in ***Ascaris*** and hookworm infection sera do not bind to recombinant AsHb produced in ***E. coli*** or to AsHb after treatment with PNGaseB. This suggests that the antibodies bind to carbohydrate epitopes. This study has provided a proof of principle that antibody testing may be useful for monitoring the effects of deworming programs in communities. While antibodies to shared carbohydrate antigens may have some value, we are now searching for antigens that can provide species-specific diagnoses.

466

PERSISTENCE OF HIGH PREVALENCE OF SOIL TRANSMITTED HELMINTHS IN CHILDREN IN SUBURBAN AREA OF DAKAR SENEGAL, DESPITE MASS DE-WORMING STRATEGIES

Doudou Sow

Parasitology-Mycology/UCAD, Dakar, Senegal

Soil-transmitted helminths are the most widespread Neglected Tropical Diseases (NTDs). Senegalese ministry of health has implemented mass drug administration with mebendazole and albendazole since 2006 as per recommended by WHO. This study aimed to describe the burden of these diseases among children several years after the scale up of these strategies. A retrospective study was conducted in a pediatric clinic in a hospital located in suburban area of Dakar, Senegal between March and December 2013. Stool samples from children under 15 years old attending hospital, were collected and examined by microscope using the modified Ritchie concentration techniques. For each child, hematologic parameters and nutritional status were also assessed. Out of 402 children surveyed, 207 (53.9%) were infected with one or more species of intestinal parasites. The prevalence rate was 120 (55.3%) for male and 97 (44.7%) for female. The prevalence was high (43.7%) in age group of 1-5 years compared to other age group. Infections with soil-transmitted helminths were more important (65.9%) compared to protozoan (18.4%). ***Ascaris lumbricoides*** was the predominant isolate (34.1%), followed by Trichirus trichiura (22.5%) and Giardia intestinalis (9.6%). Among the 140 (64.5%) infected children with anemia, 23 (16.4%) presented severe anemia with hemoglobin level below 8g/l. Severe stunting was also noted in 35 (15.6%) infected patients. Prevalence of soil-transmitted helminths remains high among children in suburban area despite the mass de-worming strategies. So, it's urgent to conduct more epidemiological survey in these areas to assess the impact of the mass drug administration.

467

PERFORMANCE OF REAL-TIME PCRS FOR THE DETECTION AND THE QUANTIFICATION OF GASTROINTESTINAL PARASITES IN CLINICAL SAMPLES FROM SENEGAL

Doudou Sow[1], Fadi Bittar[2], Khadime Sylla[1], Maguette Ndiaye[1], Thérèse Dieng[1], Roger CK Tine[1], Babacar Faye[1], Jean Louis Ndiaye[1], Yémou Dieng[1], Oumar Gaye[1], Didier Raoult[2], Philippe Parola[2]

[1]Parasitology- Mycology/UCAD, Dakar, Senegal, [2]Urmite, Aix Marseille Universite, Marseille, France

Gastrointestinal parasites infections represent one of the major public health problems in the world. Therefore, appropriate innovative tools for clinical diagnosis and epidemiological investigations are needed for assessing interventions to control these infections. This study aimed to compare the performance of real time PCR (qPCR) systems to microscopic examination in the detection of intestinal parasites.One hundred fecal samples were collected from patients and control groups attending Senegalese hospitals. Microscopic examination was made on fresh stool samples, after modified Ritchie and modified Ziehl Neelsen concentration techniques. Species-specific primers/probes were used for 21 common gastrointestinal protozoans and helminths. Positive frequency, sensitivity and specificity of each qPCR system were compared to conventional microscopic examination. Real-time PCR was positive in 37 of 103 samples (35.9%) for 18 parasite species tested while microscopic examination was positive in 19 (18.4%) samples ($p < 0.05$). QPCR enabled to identify 30 single infections and 7 multiples infections. Among the most detected protozoa, comparative results between qPCR and microscopy showed respectively 12 positive cases (11.6%) vs 7 (6.8%) for ***Giardia intestinalis***, 3 (2.9%) vs 1 (0.9%) for ***Entamoeba histolytica*** and 4 (3.8%) vs 0 (0.0%) for ***Dientamoeba fragilis***. In helminths group, the number of positive cases by qPCR vs microscopy for the most detected parasites was respectively at 8 (7.7%) vs 5 (4.8%) for ***Trichuris trichiura***, 4 (3.8%) vs 1 (0.9%) for ***Taenia saginata*** and 3 (2.9%) vs 0 (0.0%) for ***Strongyloides stercoralis***. Considering results obtained by both methods as gold standard, overall sensitivity and specificity of qPCR were at 90.2% and 100% respectively.QPCR seems to be superior to microscopic examination for the detection of protozoan and helminths in stool samples. However, these are preliminary results which should be confirmed during next steps.

468

IMPROVEMENT OF REAL-TIME PCR DIAGNOSIS OF *TRICHURIS TRICHIURA* USING ETHANOL PRESERVED STOOL SAMPLES AND A BEAD-BEATING PROCEDURE

Lisette van Lieshout[1], Maria M. Kaisar[1], Eric A. Brienen[1], Yenny Djuardi[2], Maria Yazdanbakhsh[1], Jaco J. Verweij[3], Taniawati Supali[2]

[1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Indonesia, Jakarta, Indonesia, [3]St. Elisabeth Hospital, Tilburg, Netherlands

Real-time PCR has proven to be a highly specific and comparatively sensitive tool in the detection of virtually all clinically relevant stool parasites, with the exception of ***Trichuris trichiura***. The robustness of the eggs seems the most likely cause of diminished DNA yields for this helminth. Here we evaluated different sample preparation procedures in order to optimize PCR-based detection of ***T. trichiura***. Stool samples (n=60) from a ***T. trichiura*** endemic community were used to compare four different sample preparation procedures. All samples were microscopically examined for intestinal helminths, while two aliquots were taken for DNA detection. One aliquot was frozen directly without preservation; the other was mixed with 96% ethanol. After transportation to a centralized laboratory, the present ethanol was washed away. Thereafter a bead-beating procedure was performed and compared to non-beating controls. DNA isolation was done using a spin column-based method followed by multiplex real-time PCRs for the detection of six helminth species and four protozoa. ***T. trichiura*** DNA could be detected in 40% of the directly frozen samples using the standard procedure. Higher detection levels

were found by microscopy (45%), ethanol preservation (45%), bead-beating (52%) and the combination of the latter two (55%). A significant correlation was seen in all used procedures between microscopy egg counts and the PCR cycle threshold (Ct) value, representing the detected parasite DNA load. At the same time Ct-values decreased significantly with the combination of ethanol preservation and bead-beating, reflecting increased efficiency of the DNA isolation. The various procedures hardly influenced the detection rate of the other parasites present, being ***Ascaris lumbricoides*** (≈60%), ***Necator americanus*** (≈60%), ***Dientamoeba fragilis*** (≈50%) and ***Giardia lamblia*** (≈12%). In this study we showed that preservation of stool samples using 96% ethanol in combination with a bead-beating step before DNA extraction is performed, improves the DNA yield of ***T. trichiura*** without hampering the real-time PCR detection levels of other intestinal parasites.

469

FACTORS ASSOCIATED WITH NATIONAL DEWORMING COVERAGE OF SCHOOL-AGE CHILDREN FOR SOIL-TRANSMITTED HELMINTHIASIS

Eric Strunz, Alex Jones, David Addiss

Children Without Worms, Decatur, GA, United States

The World Health Organization (WHO) has established a target of providing preventive chemotherapy (PC) for soil-transmitted helminthiasis (STH) to at least 75% of at-risk school-age children (SAC) in each endemic country by 2020. According to World Health Organization, 29 of 106 endemic countries reached or surpassed this threshold in 2013. To identify factors associated with higher PC coverage in SAC, we compared national treatment data from the WHO Preventive Chemotherapy Databank with indicators for economic development, health systems, infrastructure, school enrollment, and related programmatic metrics (e.g., coverage of preschool children). We categorized countries into two groups by reported coverage, with 28 countries reaching at least 75% of at-risk SAC and 27 reaching fewer than 75%. Coverage data were not available for 51 endemic countries. Considering endemic countries by WHO region, 26% (11/42) of Africa, 25% (6/24) of the Americas, 50% (4/8) of South-East Asia, 13% (1/8) of the Eastern Mediterranean, 25% (2/8) of Europe, and 27% (4/15) of the Western Pacific achieved at least 75% coverage. Compared to countries reporting <75% coverage, countries with ≥75% coverage had a 11% higher average per capita gross domestic product ($4848 vs. $4384) and 53% higher physician density (0.65 doctors per thousand people vs. 0.42). Countries with higher coverage for SAC also reported much higher coverage for preschool-age children as well (57% vs. 8%), suggesting underlying factors may be linking performance for both metrics. Other metrics, such as net school enrollment and access to improved sanitation, differed by <10% for both groups. While only limited causal insights can be drawn from this descriptive exploration, our findings highlight the need for a more rigorous longitudinal analysis that considers a wide range of indicators and programmatic variables, some of which may not be readily available. These results also underscore the potential value of improving the detail of treatment data, which could help identify predictors of success as the global community strives to cover 75% of children by 2020.

470

DELINEATING THE REGULATION AND FUNCTION OF HUMAN RESISTIN USING TRANSGENIC MICE AND CLINICAL SAMPLES FROM SOIL-TRANSMITTED HELMINTH INFECTIONS

Meera G. Nair

University of California Riverside, Riverside, CA, United States

Resistin-like molecules (RELM) belong to a family of secreted proteins that are expressed in multiple helminth infections with important effects on the host immune response. However the importance of human RELM proteins in helminth infections is less well understood. To investigate this, we utilize transgenic mice in which the human resistin gene along with its transcriptional regulatory elements was inserted. We recently showed that infection with the hookworm ***Nippostrongylus brasiliensis*** caused significantly increased human resistin expression in the infected lung and intestine. Human resistin expression was detrimental to the host and provoked a monocyte-rich inflammatory response in the lung, increased expression of inflammatory cytokines such as TNFα and impaired parasite expulsion. Additionally, ***Ascaris***-infected children from Ecuador had elevated serum resistin levels, which were positively correlated with parasite egg counts in the stool and with serum inflammatory cytokines. Together, these studies identify a detrimental role for human resistin in instigating a non-protective inflammatory response following helminth infection. In ongoing studies, we are investigating the genetic determinants that regulate resistin expression including single nucleotide polymorphisms in the gene and putative transcription binding sites in the promoter. Preliminary analysis has identified two STAT6 binding sites in the human resistin promoter implicating the Th2 cytokine pathway in promoting human resistin expression, and we have validated STAT6 induced resistin expression ***in vitro*** and ***in vivo***. Identifying the cellular and molecular signals that regulate resistin expression may have important diagnostic and therapeutic implications for helminth infection.

471

DEVELOPMENT OF A CONTROLLED HUMAN INFECTION MODEL FOR TESTING THE EFFICACY OF EXPERIMENTAL HOOKWORM VACCINES

David Diemert[1], Maria Zumer[1], Doreen Campbell[1], Shannon Grahek[1], Melissa Keany[1], Jill Brelsford[1], Anna Yakovleva[1], Marie Borum[1], David Pritchard[2], John Hawdon[1], Jeffrey Bethony[1]

[1]George Washington University, Washington, DC, United States, [2]University of Nottingham, Nottingham, United Kingdom

A controlled human hookworm infection model is being developed to provide early proof-of-concept that experimental hookworm vaccine candidates are feasible and efficacious. The proposed model consists of vaccinating healthy, hookworm-naïve adults with a candidate hookworm vaccine, followed by challenging them with infectious ***Necator americanus*** larvae (L3) to assess the effect of vaccination on infection. Currently, a feasibility study is underway in Washington, DC, in which different doses of L3 are administered to healthy adult volunteers to determine the optimal dose that is safe, well-tolerated and results in consistent levels of infection. 3 cohorts of 10 healthy, hookworm-naive adult volunteers are receiving 25, 50, or 75 L3 in a dose-escalating design. L3 are obtained from the feces of an infected donor who is regularly screened for blood borne pathogens. Batches of L3 are tested for identity, motility/viability, and bacterial/fungal growth prior to release for use. Individual doses are prepared by counting motile L3 by microscopy; these are then applied to a gauze pad that is placed on the subject's forearm for 1 hour. Subjects are seen weekly until 12 weeks post-infection, when they are treated with albendazole. Fecal and blood samples are collected at regular time points. Preliminary results from the 25 L3 dose cohort indicate that it is well tolerated by volunteers (n=10). Early manifestations of infection included pruritus, erythema, pain, and papulovesicular rash (duration: 4-48 days) at the application site. Gastrointestinal complaints (abdominal bloating, flatulence, nausea and abdominal pain) are frequent starting between weeks 4-5 post-infection. Eosinophilia developed in 8 of 10 (range: 0.5-4.9 x 10^3/mm^3). As of 9 weeks post-infection, 3/10 subjects have eggs detectable by microscopy in their feces. Additional investigations being performed include video capsule endoscopy to visualize adult worms in the intestine, serology for crude and defined hookworm antigens, fecal PCR for hookworm egg antigen, and fecal worm counts post-treatment. Full results, including those from the remaining cohorts, will be presented.

KATO KATZ VERSUS LUMBRERAS RAPID SEDIMENTATION TEST TO EVALUATE HELMINTH PREVALENCE IN THE SETTING OF A SCHOOL BASED DEWORMING PROGRAM

Martha Lopez[1], Maria L. Morales[1], A. Clinton White[2], H. Hugo Garcia[3], Andres G. Lescano[4], Eduardo Gotuzzo[3], **Miguel M. Cabada**[5]

[1]Universidad Peruana Cayetano Heredia, Cusco, Peru, [2]University of Texas Medical Branch, Galveston, TX, United States, [3]Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Naval Medical Research Unit - 6, Lima, Peru, [5]University of Texas Medical Branch, Cusco, Peru

The sensitivity of the Kato Katz (KK) test is suboptimal for the evaluation of intestinal helminths prevalence. Moreover, during mass deworming with albendazole, when helminths egg burden decreases, the KK sensitivity is likely to be even lower. The Lumbreras rapid sedimentation is a low cost non quantitative test, but may provide useful information in low burden areas. A descriptive study comparing the prevalence of intestinal helminth infections assessed by the KK and the Lumbreras rapid sedimentation test was performed. A database of an ongoing study in the Anta province of Cusco where school based mass albendazole treatment is provided twice a year was used. Lumbreras rapid sedimentation tests were read in a Petri dish at 100x (dish) and in a slide at 100x and 400x (slide). Kato Katz, slide, and dish tests were performed following standard procedures, in different days, by 3 different observes blinded to other test results. The sensitivities were compared using the McNemar test with a significant $p<0.05$. A total of 774 children were included in the study and each provided 3 stool specimens for testing. The prevalence of Ascaris infection was 6.6% by KK, 6.6% by slide, and 7.4% by dish. Similarly, the prevalence of Trichuris was 0.5% by KK, 1.2% by slide, and 1.3% by dish and the prevalence of hookworm was 0% by KK, 0.5% by slide, and 0.8% by dish. The prevalence of other helminths like Strongyloides (0% KK, 0.6% slide, 1.8% dish) and Hymenolepis nana (15.4% KK, 16% slide, 19.6% dish) also varied with the diagnostic method used. Using the combined outcome of the 3 different stool tests as the standard, the sensitivities of the KK and dish sedimentation tests were 83.6% and 93.4% ($p=0.070$) for Ascaris, 77.3% and 98.7% ($p<0.001$) for H. nana, 36.4% and 90.9% ($p=0.031$) for Trichuris, 0% and 100% ($p=0.031$) for hookworm, and 0% and 77.8% ($p<0.001$) for Strongyloides respectively. The rapid-sedimentation and Petri dish reading was able to detect more infections with intestinal helminthes than the other methods. When compared with this method, Kato Katz demonstrated significantly lower sensitivity, missing most Trichuris, hookworm, and Strongyloides infections

473

AURANOFIN REPURPOSING: A NEW CURE FOR SOIL-TRANSMITTED HELMINTHES INFECTION

Yan Hu, Thanh-Thanh Nguyen, David Koch, Raffi V. Aroian

University of Massachusetts Medical School, Worcester, MA, United States

Soil-transmitted helminth (STH) are nematode parasites (hookworms, ***Ascaris*** and ***Trichuris***) and are key contributors to morbidity and poverty worldwide. Few anthelmintics are available for treatment, and only one anthelmintic, albendazole, are considered adequate for mass drug administrations, even though there are more than 1 billion people are infected. New anthelmintics and treatment strategies are greatly needed, in particular as albendazole resistance is inevitable given its current method of usage and given the widespread resistance to benzimidazoles (like albendazole) in veterinary use. Due to the cost and time of developing new drugs, researchers have been working on "repurposing" the FDA approved drugs for the new usages. A gold complex named as auranofin received more attention for its great potential to be repurposed for multiple therapeutic applications. Auranofin is approved for the treatment of rheumatoid arthritis by WHO in 1985. More recently, it was found auranofin has great potential as a treatment for a number of parasitic infections including lymphatic filariasis, onchocerciasis, African trypanosomiasis, malaria, and schistosomiasis. We hypothesize that auranofin has efficacy against STHs and other nematodes as well. We exposed Auranofin to four different nematodes, including a free-living nematode ***Caenorhabditis elegans*** and the various intestinal parasitic nematodes such as ***Ancylostoma ceylanicum, Trichrus muris***, and ***Heligomasmidoes polygyrus in vitro.*** The ***in vivo*** efficacy of auranofin against all these three parasitic worms also was evaluated in rodents. Here we present the results of these studies and the potential efficacy of auranofin against STH infections.

474

IMMUNODIAGNOSIS OF *STRONGYLOIDES STERCORALIS* INFECTION IN CANDIDATE PATIENTS FOR TRANSPLANTATION

Maiara Gottardi[1], Fabiana M. Paula[1], Marcelo A. Corral[2], Dirce M. Meisel[1], Silvia F. Costa[3], Edson Abdala[3], Ligia Pierrotti[3], Pedro Paulo Chieffi[4], **Ronaldo C. Gryschek**[4]

[1]Laboratorio de Investigacao Medica (LIM/06), Hospital das Clinicas da Faculdade de Medicina, USP, Sao Paulo, Brazil, [2]University of Sao Paulo Medical School, Sao Paulo, Brazil, [3]Hospital das Clinicas, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil, [4]Faculdade de Ciencias Medicas, Santa Casa, Sao Paulo, Brazil

Strongyloidiasis is an intestinal infection caused by the nematode ***Strongyloides stercoralis***. Most cases progress to a benign chronic condition, however hyperinfection and dissemination may occur, especially in immunocompromised patients. The aim of this study was to evaluate RIFI, ELISA and WB techniques for the diagnosis of ***S. stercoralis*** in candidate patients for transplantation. In order to validate the tests were used serum samples from immunocompetent patients. Feces and serum samples from candidate patients for transplantation were used as follows: 50 for renal transplant (RT), 50 for liver transplant (LT), 50 for bone marrow transplant (BMT). Fecal samples from all patients were analyzed by spontaneous sedimentation, Rugai and Agar plate culture techniques. Filariform larvae of S. venezuelensis were used as source of antigen. For RIFI, sera at 1:40 and human anti-IgG conjugate fluorescein at 1:500 were diluted in PBS. For ELISA, 10µg of antigen (saline and alkaline soluble fractions), sera diluted at 1:200 and conjugate (human anti-IgG peroxidase) at 30.000 in PBS 0.05% Tween 3% of milk were used. For WB, sera at 1:100 and conjugate (human anti-IgG peroxidase) at 1:1000 in were diluted in Tris-HCl 5% of milk. Among the patients candidates for transplantation, 9.3% (14/150) were positive by parasitological techniques; agar plate culture detected 6.6% (10/150). With RIFI positivity was 16.6% (25/150), among which 22% RT, 18% LT and 10% for BMT. By ELISA technique positivity was 11.3% (17/150), among which 14% in patients candidates for RT, 14% LT and 3% BMT, using alkaline antigen, and 24.6% (37/150), among which 18% in patients candidates for RT, 50% LT and 6% BMT, using saline antigen. By WB technique positivity was 20.6% (31/150), among which 18% in patients candidates for RT, 32% LT and 12% BMT, using alkaline antigen, and 18.6% (28/150) among which 10% in patients candidates for RT, 14% LT and 32% BMT, using saline antigen. Application of immunodiagnostic techniques may be indicated in screening of candidate patients in transplant, however limitations of serological reactions in immunosuppressed patients should be considered.

475

PEDIATRIC STRONGYLOIDIASIS AND POVERTY IN TUMBES, PERU

Gabriela Goyoneche[1], Ricardo Gamboa[2], Viterbo Ayvar[2], Luz M. Moyano[2], Andres G. Lescano[3], Héctor H. García[4]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Center for Global Health - Tumbes Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Department of Parasitology and Public Health Training Program, U.S. Naval Medical Research Unit - 6, Lima, Peru, [4]Cysticercosis Unit, Institute of Neurological Sciences, Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

Strongyloides stercoralis is a helminth that causes chronic infections in humans worldwide. Although zoonotic transmission has been described for many helminthes, studies about the zoonotic potential of ***S. stercoralis*** and possible role of domestic animals are scarce, especially in resource-limited areas. This precludes the identification of risk factors and the development of potentially effective interventions. We conducted a population-based cross-sectional study in 14,833 children aged 2-15 years old who resided in 115 rural villages of Tumbes, a low-resource, low-endemicity setting in Peru. We used a generalized linear model to estimate the prevalence ratio (PR) of strongyloidiasis according to socioeconomic factors and zoonotic potential such as dog ownership, after controlling for potential confounders. The overall prevalence of ***S. stercoralis*** was 0.7% and the 50% of the positive children had dogs at home. We didn´t find a significant association between strongyloidiasis and dog ownership (adjusted PR [aPR] = 0.97; 95% CI = 0.66-1.44; p = 0.883). Compared with houses built with brick and cement, the prevalence of strongyloidiasis was higher in adobe and thatch houses (aPR = 1.79; 95% CI = 1.05-3.05; p = 0.032), and houses built with mats and other local material (aPR = 3.03; 95% CI = 1.31- 6.99; p = 0.009). Also, households that disposed stools in the open field had a higher prevalence of strongyloidiasis than those with sewage facilities (aPR = 1.89; 95% CI = 1.04 - 3.44; p = 0.037). Children four years or older had higher prevalence than children of three years or less. Infections by ***S. stercoralis*** in low-resource, low-endemicity setting in Peru, are strongly associated to poor living conditions without evidence of canine-human transmission. The results highlight the role of poverty-alleviation and sanitary interventions for controlling strongyloidiasis.

476

RECOMBINASE POLYMERASE AMPLIFICATION-BASED ASSAY TO DIAGNOSE SOIL-TRANSMITTED HELMINTHS IN STOOLS

Jason Cantera, Heather White, Helen Storey, Tala de los Santos

PATH, Seattle, WA, United States

Soil-transmitted helminths (STH) are parasitic nematodes that populate the human intestine and affect more than 1 billion people worldwide, causing impairment to physical, nutritional, and cognitive development in children. The global strategy to control STH infection involves periodic mass drug administration (MDA) with mebendazole and albendazole. The standard microscopy method used to measure disease prevalence has diminished sensitivity as intensity of infection decreases. As the prevalence and intensity of infections are reduced due to continued MDA, improved diagnostic tools to support control program decisions are needed. To identify available diagnostic technologies and potential biomarkers, a landscape analysis was conducted. Based on the landscape analysis, a nucleic acid amplification test based on recombinant polymerase amplification (RPA) technology is being developed to detect STH in stool. Primers and probes specific to ***Ascaris lumbricoides, Trichuris trichiura, Ancylostoma duodenale*** and ***Necator americanus*** were designed and the assay was optimized. Comparison with an established polymerase chain reaction (PCR) assay showed that each species-specific RPA assay is as sensitive as real-time PCR, detecting 5 to 20 copies of the cloned target sequences after incubation at 39°C for < 20 minutes. Also, the assay was able to amplify the target region in DNA extracted from human stool samples that were positive for STH based on Kato-Katz, with no cross-reactivity of the non-target genomic DNA. This suggests that RPA is highly specific for rapidly detecting A***. lumbricoides, T. trichiura, A. duodenale*** and ***N. americanus***. Studies using stool from patients with light, moderate, and heavy intensity STH infections will be performed to further evaluate its performance.

477

PRELIMINARY STUDY ON THE PREVALENCE OF INTESTINAL PARASITES IN AN AREA FROM THE ECOLOGICAL REGION OF THE GRAN CHACO, ARGENTINA

Maria V. Periago[1], Rosa G. Cejas[2], Rocio Garcia[3], Osvaldo G. Astudillo[3], Marta Cabrera[3], Marcelo Abril[1]

[1]Fundación Mundo Sano, Buenos Aires, Argentina, [2]Fundación Mundo Sano, Añatuya, Argentina, [3]Instituto Nacional de Enfermedades Infecciosas, Administración Nacional de Laboratorios e Institutos de Salud "Dr. Carlos G. Malbrán", Buenos Aires, Argentina

A previously published systematic review of the literature has shown that there is an incomplete prevalence map of soil-transmitted helminths (STHs) in Argentina. Until now, the highest prevalences were observed in the northeast and northwest regions of the country. In this study we centered on the Argentinian area of an ecological region denominated Gran Chaco that is located between both regions and comprises the provinces of Chaco, Santiago del Estero, Formosa and parts of Santa Fe, Cordoba, San Luis, Salta, Tucumán, La Rioja Catamarca and Corrientes. The Argentinian Gran Chaco is divided into a sub-humid, arid and serrano region each with its own climate and characteristic vegetation. This study was conducted in the surrounding areas of the city of Añatuya, Department of General Taboada, Province of Santiago del Estero located within the arid region of the Gran Chaco. Since there is no record of prevalence for either STHs or other intestinal parasites in this area, the aim of this study was to determine the prevalence of intestinal parasites in different rural settlements surrounding the city of Añatuya. Even though the communities included had similar characteristics with respect to water, sanitation and hygiene (WASH), the prevalences found varied and were unexpectedly low with regards to STHs.

478

IN VIVO EVALUATION OF PLANT NATURAL PRODUCTS FOR ACTIVITY AGAINST THE HOOKWORM *ANCYLOSTOMA CEYLANICUM*

Blaise Dondji[1], Kaitlin L. Koppinger[1], Jocelyn McCornack[1], Brianda Cardenas-Garcia[1], Kiah Jones[1], Gil Belofsky[2], Eric Winterstein[2]

[1]Laboratory of Cellular Immunology and Parasitology, Department of Biological Sciences, Central Washington University, Ellensburg, WA, United States, [2]Department of Chemistry, Central Washington University, Ellensburg, WA, United States

Hookworms are blood feeding intestinal parasites causing iron-deficiency anemia, weight loss, stunted growth and malnutrition to more than 700 million people worldwide. Major control strategies rely on mass treatment with albendazole or mebendazole. However, there is increasing evidence that hookworms and other soil-transmitted nematodes are developing resistance to these drugs. In an attempt to find alternative control tools and considering that in several endemic areas, local populations use plant products to treat several ailments including parasitic diseases, compounds from plants were tested ***in vitro*** for their anthelminthic activity against the adult stage of the hookworm, ***Ancylostoma ceylanicum***. Extracts from five plant species and chromatographically-enriched fractions of the most active one were screened. These plants were collected from the western United States. Extracts from two of the plants namely Dalea ornata and Oemlaria cerasiformis showed anthelminthic activity (mortality and/or reduced motility) of their crude extracts and enriched fractions against A. ceylanicum. Associated worm mortality rates ranged from 25% at

24 hours to 100% at 120 hours, after incubating worms with the test compounds. Three concentrations of the compounds were tested (100, 50, 10 mg/mL). Our ***in vitro*** data showed a dose-dependent activity where the lowest concentration (10 mg/mL) achieved 100% mortality 120 hours post exposure while the same activity level was obtained at 48 hours with 100 mg/mL. We are currently assessing the anthelminthic potentials of these candidates using our hamster model of hookworm infection. Their toxicity to mammalian cells is also being evaluated. Studies aiming at purifying and testing active components of the extracts ***in vitro*** and ***in vivo*** are underway. The anthelminthic activity of these compounds in the animal model of the disease is being evaluated using clinical, parasitological and immunological criteria such as weight gain, anemia, egg output, worm burden, immune cell proliferation potentials, and immune cell population types and sizes by flow cytometry.

479

STRONGYLOIDES STERCORALIS INFECTION AND HYPERINFECTION SYNDROME DURING MEDICAL INTERNISHIP (2014): EXPERIENCE FROM A MEDICAL STUDENT PERSPECTIVE IN PERU

George Vasquez- Rios[1], Angelica Terashima[2], Marco Canales[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto de Medicina Tropical "Alexander von Humboldt", Lima, Peru

Strongyloides stercoralis is an intestinal parasite with a worldwide distribution and potential life threatening capacity. However, it is still a neglected disease by the health care in endemic areas. The aim of this study was to describe ***S. stercoralis*** cases during the Internal Medicine internship in a public hospital in Peru. A total of 5 cases were identified during the period June- December 2014. Medical information was collected from chart review. 60% (N= 3/5) of the patients were male and 60% (N= 3/5) were ≥ 50 years. 60% (N= 3/5) resided at Lima city at the moment of admission and 60% (N= 3/5) had a travel history to an endemic area for ***S. stercoralis*** infection. All the patients were farmers either from the coast, rainforest or the highlands. Previous history of diarrhea was present in 20% (N= 1/5) of the patients, whereas 80% (N= 4/5) reported constipation and abdominal pain as chronic disturbances. Eosinophilia was present in 60% (N= 3/5) of the patients. 60% (N= 3/5) of the cases developed Hyperinfection syndrome (HS) with progressive recovery in 66.66% (N= 2/3) of them. HS risk factors identified in this subgroup consisted of: (1) High dose corticosteroid use and (2) Cancer along with HTLV-1 infection. Interestingly, 33.33% (N= 1/3) did not present a known risk factor for HS. Diagnosis of HS was made by means of microscopic examination of the sputum sample collected from Bronchoalveolar Lavage (BAL) in 66.66% (N= 2/3) of the patient whereas in 33.33% (N=1/3), positive fecal samples along to a compatible clinical picture led to the diagnosis. Overall, survival rate was 80% (N= 4/5) and HTLV-1 infection was present only in the patient who died. All the patients received ivermectin and were followed 1, 6 and 12 months after discharge with 100% (N= 4/4) clearance of the larvae (except for the one who died). Conclusion: Awareness of ***S. stercoralis*** as an important parasitic infection in endemic areas should be encouraged in health care professionals and medical students in training in an attempt to achieve an early diagnosis and appropriate treatment.

480

HIV/MALARIA CO-INFECTION AMONG PREGNANT WOMEN IN ADAMA AND 'AWASH SEBAT KILO' ETHIOPIA: A CROSS-SECTIONAL STUDY

Heven Sime Firew[1], Beyene Petros[2], Afework Tekle[3]

[1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]Addis Ababa University, Addis Ababa, Ethiopia, [3]World Health Organization, Ouagadougou, Burkina Faso

Due to the high prevalence of HIV and malaria in Sub-Saharan Africa, co-infections are very common. This study was undertaken to determine the prevalence and severity of malaria in HIV positive pregnant and non-pregnant women who receive ART. Demographic information was collected through questionnaire. Blood samples were taken from the study participants and thick and thin blood smears prepared. Malaria parasite detection and parasite density was done microscopically. CD4+ T cell count was determined by BD FACS Count (Becton, Dickinson and Company (BD), USA machine and Hb value determined by the CELL DYN 1800 machine (Abbott Company, USA). 500 HIV positive women from Adama hospital and 'Awash Sebat Kilo' health center participated in the study. Out of these, 22.2% were malaria infected. Among the pregnant HIV positive women, 44.6% were malaria infected. Pregnant HIV/malaria co-infected women, on the average, had a significantly higher (P<0.001) malaria parasite density (26,595 15,309 versus 15,400 12,278), a significantly lower (P=0.05) Hb values (7.49 3.34 versus 8.37 3.13) and lower mean CD4+ T cell count (195 123 versus 220 140) compared to non- pregnant HIV positive women. Compared to pregnant women infected with only HIV, malaria/HIV co-infected pregnant women had significantly lower (P=0.005) CD4+ T cell count (195 123 versus 279 151) and significantly lower (P<0.001) mean Hb level (7.49 3.34 versus 10.53 2.96). Lower CD4+ T cell count and Hb level and higher parasite density were recorded in primigravid HIV/malaria co-infected pregnant women than in the multigravid ones. The study revealed high malaria parasite density, reduced Hb level and CD4+ T cell count in HIV positive pregnant women, indicating that pregnancy has an adverse effect leading to severe malaria in HIV positive women.

481

PREVALENCE AND COMPARATIVE DIAGNOSIS OF CRYPTOSPORIDIOSIS IN HIV INDIVIDUALS IN OSOGBO, NIGERIA

Victor O. Mabayoje

Ladoke Akintola University of Technology, Department of Haematology/ HIV and AIDS Prevention and Treatment, Osogbo, Nigeria

Cryptosporidiosis is an important opportunistic infection responsible for significant morbidity and mortality in HIV/AIDS patients. The conventional diagnosis of ***Cryptosporidium*** with conventional modified Ziehl-Neelsen (ZN) staining techniques requires observation of the infective oocysts that fail to detect cases of cryptosporidiosis in many immunocompromised patients. This study compare the diagnostic efficacy of modified ZN and Enzyme Linked Immounosorbent Assay (ELISA) for detection of ***Cryptosporidium*** in HIV and AIDS individuals attend HIV clinic in LAUTECH Stool samples from 172 (67(39.0%) males; 105(61.0%) females) HIV-seropositive cases were examined for ***Cryptosporidium*** spp using the modified ZN technique and ELISA. Cyflow machine was used to measure their CD4+ count. The overall prevalence of ***Cryptosporidium*** spp. detected with ZN technique and ELISA was 59 (34.3%) and 98 (57%) respectively (p<0.05). Using a composite reference method generated from the two diagnostic methods, 49 (28.5%) patients were found to be truly infected and 61 (35.5%) truly uninfected. ELISA had a sensitivity of 79.0%, specificity of 56.5%, positive predictive value (PPV) of 51.0%, and negative predictive value (NPV) of 82.4% while ZN had sensitivity of 51.0%, specificity of 82.4%, PPV of 79.0%, and NPV of 56.5%. There was a significant association between ***Cryptosporidium*** infection and

CD4+ count (P=0.0001), with the highest parasite prevalence observed among patients who had the lowest CD4+ count (<200 cells/mm3). There was no statistical significant difference (P=0.979) among the age groups, with the age group 30-39 having the highest prevalence 70(40.7%) of infection. The ZN staining technique was less sensitive for the detection of ***Cryptosporidium*** in comparison to ELISA in this study. ELISA method can therefore have considerable advantages in the treatment of immunosuppressed individuals allowing early diagnosis thereby decreasing morbidity and the mortality.

PROCYANIDIN TRIMER C1 DERIVED FROM *THEOBROMA CACAO* REACTIVATES LATENT HUMAN IMMUNODEFICIENCY VIRUS TYPE 1 PROVIRUS

Angela Frimpong[1], Takanori Hori[2], Jacob S. Barnor[1], Tung N. Huu[3], Osamu Morinaga[3], Akiko Hamano[2], Jerry Ndzinu[1], Keren Minta-Asare[1], Mildred Amoa-Bosompem[1], James Brandful[1], John K. Odoom[1], Joseph H. Bonney[1], William Ampofo[1], Kwadwo Koram[1], Takuhiro Uto[3], Yoshiyuki Yoshinaka[2], Shin Uota[2], Yukihiro Shoyama[3], Shoji Yamaoka[2]

[1]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Tokyo Medical and Dental University, Tokyo, Japan, [3]Nagasaki International University, Nagasaki, Japan

Despite remarkable advances in combination antiretroviral therapy (cART), human immunodeficiency virus type 1 (HIV-1) infection remains incurable due to the incomplete elimination of the replication-competent virus, which persists in latent reservoirs. HIV-1 latency can be defined as a reversibly nonproductive infection of a cell which is usually interpreted to refer to an integrated provirus that is replication-competent but transcriptionally silent. In light of recent evidence, this definition might be expanded to include proviruses that express some but not all gene products in the absence of virion production.Multiple approaches to reactivation and depletion of the latent reservoir have been attempted clinically. These efforts aim to reactivate latently infected cells so as to render them susceptible to viral cytopathic effects, an antiviral immune response, or other means of targeted cell killing while protecting uninfected cells by cART. However, complete depletion of the latent reservoir remains a long-term goal. We screened medicinal plant extracts for compounds that could reactivate the latent HIV-1 provirus and identified a procyanidin trimer C1 derived from Theobroma cacao as a potent activator of the provirus in human T cells latently infected with HIV-1 . This reactivation largely depends on the NF-κB and MAPK signaling pathways because either overexpression of a super-repressor form of IκBα or pretreatment with a MEK inhibitor U0126 diminished provirus reactivation by C1. A pan-PKC inhibitor significantly blocked the phorbol ester-induced but not the C1-induced HIV-1 reactivation. Although C1-induced viral gene expression persisted for as long as 48 h post-stimulation, NF-κB-dependent transcription peaked at 12 h post-stimulation and then quickly declined, suggesting Tat-mediated self-sustainment of HIV-1 expression. These results suggest that procyanidin C1 trimer is a potential compound for reactivation of latent HIV-1 reservoirs.

INVESTIGATING CLIENT PERCEPTION AND ATTITUDE TO DECENTRALIZATION OF HIV/AIDS TREATMENT SERVICES TO PRIMARY HEALTH CENTERS IN THREE NIGERIAN STATES

Obinna Onwujekwe[1], Ifeanyi Chikezie[1], Chinyere Mbachu[1], Robert Chiegil[2], Kwasi Torpey[2], Benjamin Uzochukwu[1]

[1]University of Nigeria, Enugu, Nigeria, [2]FHI 360, Abuja, Nigeria

The views and opinions of end-users in decentralization provide insights into level of uptake of services and improvement in access. We examined clients' perception and attitude towards decentralization of antiretroviral treatment services to primary health centers (PHCs). A cross-sectional survey was undertaken in three Nigerian states. Study sites were purposively selected and respondents were equally sampled from each site. A total of 1265 interviews were conducted with HIV/AIDS clients exiting health facilities. High level of perception of decentralization of antiretroviral services to PHCs as beneficial to HIV/AIDS control (70%) of the respondents, as well as high stated community support for decentralization to PHCs were found. The difference in willingness to accept decentralization between the three states was found to be statistically significant (<0.05). However, over 90% of respondents in all three states felt decentralization of ART services to PHCs would be beneficial in controlling HIV/AIDS in Nigeria; the difference in respondents' perception across the three state was found to be statistically significant (p<0.001). These imply that scaling up of treatment services to PHCs would be widely accepted; and probably result in increased uptake. However, this must be accompanied by targeted behavior change interventions for clients who for the fear of disclosure and stigma would still not access care from proximate facilities.

484

GEOGRAPHIC INFORMATION SYSTEM-BASED MODELING OF THE HIV/AIDS EPIDEMIC IN ECUADOR USING NATIONALLY COLLECTED DATA

Miguel Reina Ortiz, Vinita Sharma, Ricardo Izurieta

University of South Florida, Tampa, FL, United States

Ecuador holds a disproportionate burden of HIV in Latin America and reports an increase in HIV/AIDS cases after 2008. It is extremely important to understand HIV/AIDS spatiotemporal dynamics. This study uses Geographic Information System (GIS)-based disease modeling to describe, predict and identify areas of higher HIV activity in Ecuador. Nationally collected data on HIV screening, number of HIV cases and AIDS incidence rates during 2009 and 2010 were used for GIS-based disease modeling. Descriptive cartographic representation of the geospatial distribution of each of these variables was conducted. Different interpolation algorithms were tested on their performance to predict the values of HIV cases and AIDS incidence rates for unsampled geographical locations. Finally, spatial autocorrelation using Moran's I statistics indexes was conducted as part of a Hot Spot analysis to identify areas of significantly higher clustering of HIV cases (i.e. HIV activity). Overall, AIDS incidence rates were highest in the Coast, mid-level in the Andes and lowest in the Amazon basin. HIV testing and screening rates were highest in different provinces located across the different regions (i.e. Coast, Andes and Amazon basin). Ordinary Kriging was the interpolation algorithm that best fit the data being analyzed. Autocorrelation models suggested that the province of Santa Elena (near the port of Guayaquil) represents a Hot Spot for AIDS incidence rate in Ecuador. It has been suggested that increased screening efforts have led to higher reported number of AIDS cases in Ecuador. However, nationally collected data evidences a mismatch between screening and AIDS incidence rates. Further analysis showed one Hot Spot in the Province of Santa Elena, near the main port and largest city of Ecuador, Guayaquil. This study helps in the understanding of the geospatial distribution and statistically significant association, aggregation and autocorrelation of HIV/AIDS cases in Ecuador. Further research is needed to identify geospatial locations where HIV socio-structural determinants collude to increase HIV/AIDS transmission in the local population.

485

TUBERCULOSIS DISEASE AMONG HIV POSITIVE ADULTS ON ANTIRETROVIRAL THERAPY IN MALAWI

Osward M. Nyirenda[1], Jaya Goswami[2], Randy G. Mungwira[1], Titus H. Divala[1], Maxwell Kanjala[1], Francis Muwalo[1], Felix Mkandawire[1], Terrie E. Taylor[1], Jane Mallewa[3], Joep van Oosterhout[4], Miriam K. Laufer[2], Matthew B. Laurens[2]

[1]Blantyre Malaria Project, Blantyre, Malawi, [2]Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States, [3]University of Malawi College of Medicine, Blantyre, Malawi, [4]Dignitas International, Zomba, Malawi

Tuberculosis (TB) and HIV co-infection is common and associated with a high mortality rate. The incidence of TB among people who are stable on antiretroviral therapy (ART) is not well described. We used data from the screened and the enrolled participants in a clinical trial of adults on ART to determine the prevalence and incidence of TB infection in patients who have symptoms that are consistent with TB and assessed the impact of TB infection in this population. We screened all participants in our clinical trial for typical symptoms of TB. Participants with TB symptoms submitted samples for GeneXpert testing. We only enrolled adults with CD4 count>250 and undetectable viral load into our prospective study. Pulmonary TB (PTB) was diagnosed if in patients with typical TB symptoms, there was a positive TB test (GeneXpert) or positive chest x-ray finding. Extrapulmonary TB (XTB) was diagnosed based on clinical and radiological findings. We screened 1416 participants for enrollment in our clinical trial and 41 participants had symptoms suggestive of TB. One participant with a positive test and one with a negative test but with a typical chest X-ray finding were diagnosed with PTB. The prevalence of PTB in the adult ART population was 0.1% and among those with symptoms of PTB, prevalence was 4.9%. We enrolled 900 participants and accumulated 1,117 years of follow up. The incidence rates were 8.4, 0.8, 0.6 and 0.9 per 100 person years for PTB symptoms, PTB diagnosis, PTB laboratory confirmed diagnosis and XTB, respectively. There were no deaths among the 9 cases of PTB but 5/11 participants with XTB died (case fatality rate 45%). PTB was not associated with changes in CD4 cell count or viral load. Further analysis of the effect of PTB and XTB on clinical, immunological and virological outcomes is being conducted. PTB and XTB are rare in adults who are stable on ART. When PTB is actively diagnosed and treated, it was not associated with adverse outcomes in our small sample of cases. Extrapulmonary TB has a poor prognosis even when patients are on appropriate ART.

HIV-1 EXPOSED UNINFECTED AND UNEXPOSED INFANTS HAVE SIMILAR ANTIBODY RESPONSES TO CHILDHOOD VACCINES, BUT THE RESPONSES AGAINST HEPATITIS B VACCINE DECAY BY TWENTY ONE MONTHS OF AGE

Maxwel M. Omenda

Kenya Medical Research Institute, Kisumu, Kenya

HIV-1 exposed uninfected infants (HEU) residing in regions with high burden of infectious diseases, have high mortality and morbidity. The underlying mechanisms causing the increased vulnerability of HEU compared to unexposed infants (HUU) are not clear. While childhood vaccination against most infections protects majority of the vaccinees, it is not known whether it provides equal protection in all children including those with prenatal exposure to infectious diseases that may alter infants' immune responses. Vaccine-specific IgG responses were compared among three groups of children: HEU N=13, HIV-1 unexposed/malaria exposed (HUME) N=25 and HIV-1/malaria unexposed (HMU) N=18 infants to address the hypothesis that in-utero exposure to HIV-1 alters infants capacity to develop long lasting protective humoral immune responses to childhood vaccines. Antibody levels against hepatitis B virus (HBV), measles, tetanus toxoid (TT) and diphtheria toxoid (DT) were measured by ELISA at multiple time-points beginning from birth up to 21months of age in a longitudinal cohort study conducted in malaria holoendemic region of western Kenya. Pre-vaccine antibody levels were lower for HBV and DT compared to measles and TT, but were similar between infant and mother. These antibodies tended to be lower in HEU compared to HMU or HUME. Peak IgG responses were also lower for HBsAg and DT compared to measles or TT in all the groups. Overall, the three groups responded similarly to vaccination (Kruskal Willis test: p=0.85 for measles, p=0.845 for TT, p=0.434 for DT and p= 0.365 for HBV) with varying peak responses across the vaccines. Measles, TT and DT antibody responses were maintained at high levels even by 21 months of age. However, responses against HBV decayed to pre-vaccine levels by 21 months of age, suggesting that even though HBV vaccine elicits robust antibody responses in all infants, these responses are not long lasting. These data suggest that HEU respond equally well as HUU to vaccines test here, but long-term efficacy of HBV vaccine needs to be evaluated particularly in infants residing in malaria holoendemic regions.

487

BASELINE CHARACTERISTICS OF PATIENTS RECEIVING CARE FOR HIV/AIDS AT THE ANTI-RETROVIRAL CLINIC OF PANTANG HOSPITAL: A LONGITUDINAL COHORT STUDY

Bismark Sarfo[1], Jane Kelly[2], Chirag G. Patel[3], Andrew A. Adjei[4], Richard Adanu[1], Peter Nyasulu[5]

[1]School of Public Health, University of Ghana, Legon-Accra, Ghana, [2]HIV/AIDS Epidemiology Program, Georgia Department of Public Health, Atlanta, GA, United States, [3]Oak Ridge Institute of Technology, Oak Ridge, TN, United States, [4]School of Biomedical and Allied Health Sciences, University of Ghana, Legon-Accra, Ghana, [5]School of Health Sciences, Monash University, Johannesburg, South Africa

The recommended medical care for HIV/AIDS patients consist of providing antiretroviral therapy (ART) for viral suppression, management of comorbidities, and interventions to reduce HIV transmission. In Ghana, 123,245 HIV/AIDS patients are on ART. Characterization of the infected population under treatment creates a baseline for monitoring the HIV care continuum, identification of those most likely to fall out of care, and possible interventions to improve retention in care and ongoing viral suppression. In this study we describe socio-demographic characteristics, self-reported adherence to medication, behavioral risk factors, and access to prevention services among patients receiving care at Pantang hospital as part of a longitudinal cohort study. A cross-sectional study design was used to recruit participants 18 years or older, HIV positive, receiving care with the ability to provide informed consent for interview using a structured in-person closed-ended questionnaire. 211 HIV/AIDS patients (mean=44) participated in the study. There were 44(20.85%), and 167 (79.15%) heterosexual males and females respectively. 17(8.06%) were not yet on ART, whereas 173 (81.99%) are on ART medication. 122 (62.24%) have never experienced any side effect of their medication while 11(5.61%) rarely did. 143 (67.77%) reported they followed the specific instruction for taking their medication, while 17(9.0%) don't follow those instructions. 151 (71.56%) strongly disagreed while 22 (10.43%) strongly agreed that they will have unprotected sex if their partners are also HIV positive. 152(72.04%) reported they never took alcohol before sex, while 10(4.74%) had ever had alcohol before sex. Majority (186, 88.15%) have never used drugs in their lifetime. 164 (83.67%) never received any free condoms during the past 12 months while only 18 (9.18%) said they had. 155 (79.08%) have never been diagnosed with active TB, whereas only 5(2.55%) have ever had TB. Only 2 (1.02%) of the participants have ever had pneumocystic pneumonia infection. Targeted HIV/AIDS prevention programs at this cohort will be beneficial in reducing HIV transmission.

LEVERAGING ON COMMUNITY-BASED PEPFAR PROGRAMS ACHIEVEMENTS IN STRENGTHENING SURVEILLANCE, PREVENTION AND CONTROL TOWARD HIV/AIDS EPIDEMIC FREE GENERATION IN SUB-SAHARA AFRICA

Ernest Tambo[1], Clarence S. Yah[2], Chidiebere E. Ugwu[3], Oluwasogo A. Olalubi[4], Isatta Wurie[5], Jeannetta K. Jonhson[6], Jeane Y. Ngogang[7]

[1]Sydney Brenner Instiute for Molecular Bioscience, Johannesburg, South Africa, [2]Department of Biochemistry and Microbiology, Nelson Mandela Metropolitan University, Petermaryberg, South Africa, [3]Faculty of Basic Medical Sciences, Department of Human Biochemistry, Nnamdi Azikiwe University Awka, Nnewi, Nigeria, [4]School of Allied and Environmental Health, Kwara State University, Malete, Kwara, Nigeria, [5]Health and Education Quality Systems Strengthening, Freetown, Sierra Leone, [6]Public Health Development Initiative, Monrovia, Liberia, [7]Faculté des Sciences Biomédicales et Pharmaceutiques, Université des Montagnes, Bagangté, Cameroon

About 3.2 million children under the age of 15 are living with HIV/AIDS globally and 91 percent burden of whom is in Africa. The US President's Emergency Plan For AIDS Relief (PEPFAR) partnership scaling up for impact and efficiency on HIV/AIDS programs has be laudable in alleviating morbidity and mortality and sustainably accelerate core prevention and care interventions quality services estimated at $19.1 to $22-24 billion made available in LMIC including in reshaping health policy reforms and programs across African resources limited countries in 2013-2015. Strategic and geographical allocations in Community evidence-based programs promote accessible and cost-effective service delivery to populations at greatest risk communities across Sub-Saharan Africa. A strategic systematic search on Medline and acknowledged PEPFAR programs partners was used to assess publications from 2005- 2015 in Sub-Saharan Africa, scrutinized and categorised upon type and nature in improving strategic planning, quality of care and outcomes. Our findings showed that PEPFAR programs support community-based capacity building and social service systems delivery through sensitization and participatory activities on HIV risk factors, voluntary screening and care seeking for PLWHIV and caregivers, treatment adherence, ABCs practice attitudes, and empowering health systems paramount in strengthening HIV/AIDS free generation. Community's partnership impact highlights the differential benefits and issues related to transparency and accountability as useful indicators of communities' programs performance impacts and outcomes. The urgent need to maximize on PEPFAR and related programs in fostering sustainable country-driven and ownership of integrated community-based HIV/AIDS surveillance, prevention and control must be prioritized. Implementing effective core capabilities and better coordination in proven PEPFAR and national Ebola immunization programs (NEIP) has potential asset to inform Africa's policy decisions and health systems investments toward deadly viral disease free generation.

REDUCED PLACENTAL TRANSFER OF IGG TO *PLASMODIUM FALCIPARUM* MALARIA IN HIV-EXPOSED UNINFECTED CAMEROONIAN INFANTS

Anna Babakhanyan[1], John Tamo[2], Emile Yuosembom[2], Barriere Yetgang Airy[2], Livo Esemu[2], Claude Djontu[2], Rose G. Leke[2], Diane W. Taylor[1]

[1]University of Hawaii, Honolulu, HI, United States, [2]University of Yaounde I, Yaounde, Cameroon

Although mother-to-child transmission of HIV has dramatically declined, the number of ***in utero*** HIV-exposed uninfected (HIV-EU) infants is on the rise. HIV-EU infants are at a greater risk of mortality and morbidity compared to their non-HIV exposed counterparts. Poor health outcomes in this pediatric population are, in part, explained by increased susceptibility to and severity of infections, including pneumonia and malaria. Passively acquired immunity through placental transfer of IgG from the mother is fundamental for protection of infants against infectious agents during the first year of life. Transplacental transfer of IgG to tetanus, measles, pneumococcus, VZV and haemophilus influenza type b is reduced in HIV-EU newborns. However, conflicting results are reported for the influence of maternal HIV on placental transfer of IgG to malarial antigens. We conducted a case-controlled study, in which HIV-positive (cases) and HIV-negative (controls) pregnant Cameroonian women were recruited. Maternal peripheral and cord plasma was used to measure IgG to malarial pre-erythrocytic (CSP, LSA-1) and erythrocytic (AMA-1, MSP-1, MSP-2, MSP-3, EBA-175, RESA, PfEMP1) antigens, that are important for protection and tetanus toxoid. Cord IgG levels to malarial sporozoite and merozoite proteins, as well as tetanus toxoid, were reduced in full-term HIV-EU newborns compared to non-HIV exposed newborns (all p values <0.05). Since significant differences in IgG levels to the above antigens were not found between HIV-positive and HIV-negative women, reduced IgG levels in HIV-EU infants were not due to reduced levels in their mothers. The results suggest that an alternative mechanism is responsible for low IgG levels in HIV-EU cord blood. Additional studies are in progress to determine possible mechanisms responsible for HIV-induced decrease in transplacental transfer of IgG.

PERINATAL HIV-INFECTION AND LONG-TERM DEFICITS IN COGNITIVE EXECUTIVE FUNCTION AMONG SCHOOL-AGED UGANDAN CHILDREN

Amara E. Ezeamama[1], Florence N. Kizza[2], Sarah K. Zalwango[3], Allan K. Nkwata[2], Juliet N. Sekandi[2], Robert Kakaire[2], Noah Kiwanuka[3], Christopher C. Whalen[1]

[1]The University of Georgia, Athens, GA, United States, [2]The University of Georgia, Athens, GA, United States, [3]Makerere University School of Public Health, Kampala, Uganda

The study was undertaken to evaluate the hypothesis that perinatal HIV infection predicts long-term deficits in cognitive executive function (CEF) among Ugandan children 6 -18 years old. Perinatal HIV-infection was diagnosed by end of breast-feeding via DNA polymerase chain reaction test. Current HIV status was confirmed with HIV-rapid diagnostic test. Proxy report of Child CEF was measured with behavior rating inventory of executive function (BRIEF). Descriptive analyses estimated means, standard deviations (SD), numbers and percentages by perinatal HIV status. Multivariable linear regression estimated HIV-related differences (β) in CEF scores and 95% confidence intervals (CI). HIV-infected (n=56), exposed negative (n=56) and unexposed children (n=54) were enrolled. Dysregulation (i.e. higher scores) in CEF domains - including significant elevations for emotional control, inhibition, initiation and working memory sub-scales, were noted for perinatally HIV-infected compared to HIV-unexposed children. CEF scores was highest (mean=54.2,SD=12.8), for HIV-infected intermediate (mean=48.4,SD=11.2) for HIV-exposed negative and lowest (mean=46.8, SD=8.8) for HIV-unexposed children. Overall, clinically relevant CEF elevations (BRIEF t-score ≥65 vs. <65) were noted in 12(20.7%), 5(9.1%) and 2(3.8%) HIV-infected, HIV-exposed and HIV-unexposed children respectively (p-value=0.016). Normal t-scores across all BRIEF sub-scales was least prevalent in HIV-infected (34.5%) vs. 50.9% in HIV-exposed negative and 60.4% HIV-unexposed children. Conversely, dysregulation in ≥2 subscales was more prevalent in HIV+(44.8%), vs. 30.9% in HIV-exposed negative, and 20.7% in HIV-unexposed children (P =0.0598). CEF scores were significantly elevated for HIV+ (β=5.4, 95%CI:1.4,9.4) but not HIV-exposed negative (β=-0.81,95% CI: -5.0,3.4) relative to HIV-unexposed. In conclusion, perinatal HIV-infection is a significant predictor of low CEF. Specific interventions to improve executive function may improve long-term functional status in HIV-infected children.

491

HEPATITIS E VIRUS IMMUNOLOGICAL MARKERS IN HIV-INFECTED INDIVIDUALS, DOMINICAN REPUBLIC

Robert Paulino, Eduardo Fernandez, Monica Orizondo

Universidad Iberoamericana, Santo Domingo, Dominican Republic

Hepatitis E virus (HEV) is an RNA (+) virus, primarily transmitted through foecal-contaminated water. HEV is endemic to various countries and currently considered the most common cause of viral hepatitis worldwide. In immunocompetent hosts causes a mild viral acute hepatitis, although in pregnant women it causes acute fulminant hepatitis. Recent studies have shown persistent infection by HEV in immunocompromised hosts, especially those infected by the HIV. The purpose of this investigation was to determine the presence of HEV specific antibodies in the Dominican Republic. Two cohorts were obtained from an outpatient clinic located in Santo Domingo, Dominican Republic; one consisted of 36 HIV (+) patients while the other was composed of 54 HIV (-) patients, both with persistent elevated liver enzymes and negative laboratory tests for hepatitis B or C. Informed consent was obtained from each participant. An epidemiological form was completed with relevant data of each participant; and their HIV status was confirmed by either rapid testing or record files. Blood samples where drawn from each participant to whom a rapid IgG test for HEV was performed, posteriorly a rapid IgM test for HEV was done to those who were positive to confirm chronic markers of HEV infection. Ten of the fourty-three (n=43) patients were positive for IgG against HEV. Of those 10, two were positive for HEV-IgM, both of which were on antiretroviral therapy and had a CD4 count over 200 cells/ml. Sixty percent of the patients who had a positive IgG against HEV had an ALT over 80 U/L, and an AST over 70 U/L. HEV should be considered as a differential diagnosis in HIV + patients with elevated liver enzymes in the Dominican Republic. Chronic infection with HEV should also be considered as an opportunistic infection in these patients in warm countries with poor water and sanitation quality.

492

VIROLOGICAL RESPONSE OF FIRST LINE COMBINATION ANTIRETROVIRAL THERAPY (CART) AMONG PEDIATRIC PATIENTS IN LONGITUDINAL CAMBODIAN COHORT

Zuzana Dudova[1], **Andrea Shahum**[2], Maria Holesova[3], Vladimir Krcmery[4]

[1]Humanitarian Program for HIV Positive Children, Phnom Penh, Cambodia, [2]University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, [3]Humanitarian Program for HIV Positive Children, Sihanoukville, Cambodia, [4]St. Elizabeth University College of Health and Social Sciences, Bratislava, Slovakia

Increase access to cART for HIV+ children in resource-limited settings is expanding, although documented experiences remain limited. In most pediatric studies virological response rates are highly variable and inferior to adults, with reasons being not well understood. We describe experiences with virological responses to cART among perinatally infected children in Cambodia, followed since 2003 with a mean age at enrollment of 6.9 (SD±3.1). HIV viral load measurements became available from 2008, but remain not fully integrated in the routine monitoring due to prohibitive cost. NNRTI-based triple regimen (WHO-prequalified generic fixed-dose combinations) and boosted protease inhibitor (PI) with 2 NRTIs are standard first and second line therapies. Virological failure was defined as sustained HIV RNA ≥1000 copies/mL while on cART or persistent virological rebound above ≥1000 copies/mL after initial virological response. Of 113 children, 107 (95%) started cART based on WHO criteria and 29 (27%) had virological failure to the first line cART, although all initially restored immunologically. Time to switch to the second line therapy from the first documented viremia was an average of 16 months (95% CI: 11-21) with median HIV RNA 14734 copies/mL (474-294451). 10 (34%) children with virological failure had a period when adherence was not observed and 5 (17%) had cART interruption due to side effects. Despite excellent medication adherence the remaining 14 (48%) developed virological failure. Clinico-immunological monitoring and documented medication adherence were not sensitive enough to predict poor virological response resulting in late diagnosis of treatment failure. Prolonged treatment failure was associated with accumulated NRTI and NNRTI cross-resistance with the most common mutations M184V (21), K103N (16), V75M (4), and Q151M (3). Our experience showed that children tend to be maintained longer on failing regimens, mainly because of challenges associated with high cost of viral load, genotype testing, and limited treatment options. Access to virological monitoring should be expanded to enable early failure detection.

493

LARGE PROPORTION OF HIV POSITIVE CHILDREN WITHOUT RECEIPT OF ANTIRETROVIRAL TREATMENT (SLOW PROGRESSOR, SPG) FOR 10 AND MORE YEARS IN PHNOM PENH, CAMBODIA

Andrea Kalavska[1], Maria Chabadova[1], Erich Kalavsky[1], Juraj Benca[1], Andrea Shahum[1], Jozef Suvada[1], Gertruda Mikolasova[1], **Lenka Michalikova**[2], Zuzana Dudová[1], Vladimir Krcmery[3]

[1]St. Elizabeth University, Bratislava, Slovakia, [2]Trnava University, Faculty of Health Sciences and Social Work, Trnava, Slovakia, [3]Institution of Microbiology, Medical school, Commenius University, Bratislava, Slovakia

More than 90% of children infected with HIV live in Africa and Asia. 2,5 million children live with HIV infection worldwide, and 370 000 children are newly infected every year. The aim of this study is to present a cohort of children who were not received highly active antiretroviral therapy (HAART) (slow progressor, SPG) for 10-16 years because of not decreased CD4 or increased viral load neither presented with opportunistic infections and AIDS-related comorbidities. HIV positive children on active antiretroviral therapy (HAART) were observed within 2002 - 2015 (12 years) in Phnom Penh. Subgroup of SPG children (n=32) did not need therapy at least 10 years from the year they have been diagnosed to be HIV positive. Because they were fully asymptomatic, and because of the guidelines valid in that time, they did not received HAART. Therapy has been started (due to the change of the guidelines) in all children of them in 2013. Group slow progressor was compared with non-slow progressor (NPG). 32 children of 140 (23%) did not present any sign of AIDS (clinical, immunological and virological) for 10 years after diagnosis of HIV. Average age, when they received 1st line HAART was 12 years in Group SPG and 9,2 years in the NPG Group. Average number of opportunistic infections was significantly higher in NPG (1,3% vs. 0,7%; P= 0,04), as well as the incidence of tuberculosis (52,3% vs. 29%; P=0,04). First line therapy was not significantly more common among SPG, as well as mortality (SPG vs. non- SPS) which was similar in both groups (2,9% vs. 0% P=NS). In conclusion, children infected with HIV have more opportunistic infections and therefore receive more prophylactic or therapeutic antibiotics and may be more colonized or infected with resistant organisms.

494

TUBERCULOSIS DIAGNOSIS AND TREATMENT MONITORING AT PEDIATRIC HIV CLINICS IN SUB-SAHARAN AFRICA

Raghuveer Puttagunta, Katherine Ngo, Anna M. Mandalakas

Baylor College of Medicine; Texas Children's Hospital, Houston, TX, United States

Among people living with HIV, Tuberculosis (TB) accounts for almost a quarter of all deaths. Given the overlapping burden of disease between HIV and TB worldwide, integration of TB and HIV care and preventive services is essential , especially among children, where is there is a paucity of data related to TB-HIV co-infection. Given the complexity of diagnosing childhood TB coupled with the poor sensitivity of confirmatory tests in this population, it is important to evaluate the feasibility of implementing WHO guidelines and recommendations related to TB care in the context of resource poor settings. The Global TB Program of Texas Children's Hospital

and Baylor College of Medicine has developed a comprehensive approach to integrating, monitoring and evaluating TB best practices within the Baylor International Pediatric AIDS Initiative (BIPAI) network of pediatric HIV clinics that spans six sub-Saharan African countries. We describe the process of monitoring and evaluation of TB programming that has been implemented throughout the BIPAI clinical network. Fourteen TB indicators were identified and incorporated into the standardized medical record. The indicators cover a broad range of aspects dealing with TB care including preventive services, quantification of TB disease, diagnostic services, drug resistance, and treatment in relation to HIV. Indicators are stratified by age and past treatment history when available. On a quarterly bases each clinical site is able to generate summary statistics with accompanying visual aids so that each site is able to independently evaluate their performance and make appropriate quality improvement decisions. Providing practical interpretations of WHO TB guidelines for program monitoring and evaluations to clinics in resource poor environments is possible after addressing clinic sustainability, training, and standardization of metrics.

495

QUALITATIVE PROCESS ASSESSMENT OF GENE-ENVIRONMENT HEALTH EDUCATION INTERVENTION IN SOUTHERN ETHIOPIA: ADDRESSING GENOMIC LITERACY GAPS IN THE CONTEXT OF PODOCONIOSIS DISEASE

Abebayehu Tora[1], Desta Ayode[1], David Farrel[2], Getnet Tadele[1], Gail Davey[3], Colleen McBride[4]

[1]Addis Ababa University, Addis Ababa, Ethiopia, [2]People Designs Inc., Durham, NC, United States, [3]Brighton and Sussex Medical School, Falmer, Brighton, United Kingdom, [4]Emory University, Atlanta, GA, United States

Though scientific knowledge on the etiology and prevention of podoconiosis rapidly advanced the last few decades, little effort has been made so far to curb the lay people's misconceptions and enhance their motivations for preventive behavior. In this study, we qualitatively assessed the impact of skills training trial on lay peoples' understanding of gene-environment-contributions to podoconiosis etiology and their motivations for behavioral change. Sixty-five affected and unaffected adult participants in the trial were purposively selected and involved in semi-structured individual interviews (IDIs) or Focus Group Discussions (FGDs). Most of the participants indicated great enthusiasm for the household training and had retained messages related to environmental and behavioral risk factors and pinpointed barefoot exposure to mineral particles in the soil as an important cause. Using various metaphors, participants also discussed the joint role of heredity and environment: distinguishing 'inherited susceptibility' from that of 'inherited disease', specifying the pathways barefoot exposure to irritant mineral particles operate with inherited susceptibility, stating the contribution of heredity in population-risk variation, identifying strategies for behavioral control of genetic expression, and indicating favorable attitude towards interpersonal interactions. However, some still faced difficulties in understanding the mode of inheritance of podoconiosis. These participants either persisted with beliefs in either genetic or environmental essentialism in podoconiosis etiology. Younger participants seemed to have better understanding of hereditary risk than older participants. Economic hardship was the major barrier perceived to impede translation of the skills training into action. Community-wide dissemination of linguistically and culturally adapted gene-environment messages through younger populations may encourage accuracy of understanding, while integrating this with development packages may contribute to sustained preventive behavior.

496

MULTISECTORAL APPROACHES TO HELMINTH CONTROL WITH DEWORMING AND WASH IN AN HIV-INFECTED POPULATION

Arianna Means[1], Lisette van Lieshout[2], Krista Yuhas[1], Jaqueline Naulikha[3], Paul Ndungu[3], Benson Singa[3], Heidi Hillesland[1], Judd Walson[1]

[1]University of Washington, Seattle, WA, United States, [2]Leiden University Medical Center, Leiden, Netherlands, [3]KEMRI, Nairobi, Kenya

The London Declaration calls for a reduction in helminth-associated morbidity by 2020 and as a result it is important to understand how infection can be prevented through mass treatment as well as how transmission may be disrupted by removing reservoirs of infection from the environment with water, sanitation, and hygiene (WASH) strategies. We aimed to estimate the association of different chemotherapeutic and WASH "packages" with helminth infection status and infection intensity. This study is a retrospective cohort study nested within the Helminth Eradication to delay ART Trial (HEAT). Participants are HIV-infected patients recruited from clinics at three sites in Kenya (Kisii Provincial Hospital, Kisumu District Hospital, and Kilifi District Hospital). The exposures of interest are four WASH and helminth protection categories, including (1) access to deworming and WASH, (2) access to deworming only, (3) access to WASH only, and (4) access to neither. Because WASH access is actually comprised of a multitude of protective factors, the analysis is performed considering combinations of four definitions of WASH access, including: individuals who purchase purified water or treat water independently (filtration, chlorination, etc), individuals who have access to a flush toilet or pit latrine in their house or on their compound, individuals who always report hand washing post-toilet, and individuals who live in houses in which the floors of the house are made of cement, iron, stone, or timber (non-earthen). Although microscopy was previously performed, the 740 stool specimens were also analyzed for helminth infections using multiplex real time PCR analysis. We performed logistic and multiple linear regression to estimate the association between different helminth protection categories and presence of infection and infection intensity, by helminth species. Thus this study uniquely identifies the WASH factors that alone and in combination with deworming can reduce helminth infections in this immunocompromised patient group.

497

INTEGRATED HEALTHCARE DELIVERY: IDENTIFYING AND HARMONIZING MULTILEVEL STAKEHOLDER PERSPECTIVES REGARDING INTEGRATED NEGLECTED TROPICAL DISEASE PROGRAMS

Arianna Means[1], Julie Jacobson[2], Aryc Mosher[2], Judd Walson[1]

[1]University of Washington, Seattle, WA, United States, [2]Bill & Melinda Gates Foundation, Seattle, WA, United States

One of the major challenges facing Ministries of Health in less developed countries is the ad-hoc manner in which health systems have been built to vertically address single diseases at a time. To strengthen health systems sustainably, many global health leaders promote integration of vertical programs into shared delivery infrastructures. Due to their significant degree of co-endemicity, the neglected tropical diseases (NTDs) are an example of a group of diseases in which synergistic integration is possible. The goal of this research is to harmonize different stakeholder approaches to integrated program delivery and, as a result, identify strategies for increasing the effectiveness of integrated programs and reducing NTD prevalence. Thus this study's primary research question is: how do perceptions regarding the role, effectiveness, and implementation of integrated NTD programs differ among NTD stakeholders? We conducted key informant interviews with stakeholders at each level of the integrated delivery implementation spectrum including: the World Health Organization, Ministry of Health workers in endemic countries,

implementation partner organizations, donor partners, local health providers, and community members. The study design is mixed methods; baseline quantitative surveys informed development of the qualitative study and guided the purposeful sampling of stakeholders. Based in an inductive grounded theory approach, this research utilizes a mix of respondent and informant questions during semi-structured interviews to identify how stakeholders define, prioritize, and execute integrated NTD programming. We present key findings from 43 interviews and propose a framework for integrated NTD delivery to harmonize stakeholder perspectives. Thus this study offers important insights for health systems more broadly by serving as an opportunity for understanding how to promote inclusive frameworks for cross-program coordination.

498

HOW CAN INTEGRATING SANITATION AND HYGIENE INTO NTD CONTROL PROGRAM ACCELERATE REDUCTION IN NTDS? BURKINA FASO CASE STUDY

Renuka Bery[1], Edouard Tianhoun[2], Lonna Shafritz[1]

[1]FHI 360, Washington, DC, United States, [2]FHI 360, Ouagadougou, Burkina Faso

Burkina Faso, one of the poorest countries in the world, has low sanitation coverage, inadequate hygiene practices, and high levels of morbidity associated with poor water, sanitation and hygiene (WASH), all factors that contribute to high rates of neglected tropical diseases. For example, WHO recommends the use of the Surgery, Antibiotics, Face Cleanliness and Environmental Improvement (SAFE) strategy for trachoma, and without proper WASH, zones of high trachoma prevalence will continue to exist and jeopardize any progress achieved as a result of addressing other SAFE strategy elements. United States Agency for International Development's WASHplus project identified WASH interventions to assist in eliminating and/or controlling trachoma, soil transmitted helminths, and schistosomiasis. The project conducted a desk review and chose to develop an integrated pilot program to integrate sanitation and hygiene into NTD programming in Burkina Faso, which has had a national NTD control program since 2007. Integration is gaining traction in the public health community but the means to monitor progress and identify the most effective indicators is still under discussion by the NTD and WASH communities. This activity aims to develop a model for an integrated WASH-NTD program, working with multiple stakeholders (predominantly Government and UNICEF), that can be scaled up in Burkina Faso by other implementers and be adapted and replicated in other countries. To achieve this objective, the intervention will be a comprehensive, community-focused WASH-NTD program implemented using multiple behavior change approaches and channels to support the adoption of crucial practices for disease prevention, including programming for caregivers, through schools and through local health workers, and radio. The comparison area in this area will use only one channel: local radio. Currently implementing the baseline study in Gnagna province, WASHplus will describe the intervention, present the combined WASH/NTD indicators developed to measure this integrated WASH-NTD program and highlight the preliminary findings gleaned through the baseline survey.

499

PATENT EXTENSION VOUCHER: A POTENTIAL INCENTIVE FOR NEGLECTED TROPICAL DISEASES RESEARCH

Laureano Mestra

Ipsum Clinical, Medellin, Colombia

A Neglected Tropical Disease (NTD) is a condition that, despite its frequency is not necessarily low, has been for different reasons, especially for affecting the poorest people of the world, submitted to the ostracism of low investment to find better therapeutic options. The burden of disease coming from the NTDs is really high and is very close to other very prevalent conditions in terms of disability-adjusted life years (DALYs). But, none less important is the burden of annual losses on productivity within the low-income countries affected by NTDs. NTDs are not only a health problem, they are also an economic and social problem that is delaying the economies of these countries and why not, the whole world. Therefore, it is important to find the best way to stimulate the funding in the NTDs research arena. Unfortunately, it seems to be that not only good intentions are enough in order to obtain the funds to shorten the pipeline to find new compounds for these diseases. In 2006 a group of academics proposed what today we know as the FDA's NTDs Voucher. The idea is quite simple; if a pharmaceutical company succeeds getting the approval from FDA of a compound for one of the NTDs, this company will obtain a Priority Review Voucher (PRV). This means that the time it takes FDA, within the Fast Track Program (FTP), to review a new drug application is reduced. The goal for completing a Priority Review is six months. This is supposed to be a tool that can be very useful to put new compounds for NTDs into the market but the outcomes so far are not like they were expected at the beginning. An improved version of the voucher to stimulate the development of drugs for NTDs is proposed. The idea is based on granting a Patent Extension Voucher (PEV) for the companies that achieve in marketing an NTD compound, but taking into account the possibility of second use compounds for NTDs, a demonstrated effectiveness, impact on the targeted NTD and the current advantages of the FDA's PRV. Finally, a way to calculate the value of the proposed PEV is explained.

BURDEN OF NEGLECTED TROPICAL DISEASES IN MACHALA, ECUADOR

Abigail G. Fessler[1], Saurabh Mehta[1], Efraín Beltrán-Ayala[2], Anita L. Arichábala Wilches[2], Timothy P. Endy[3], Mark Polhemus[3], Anna M. Stewart-Ibarra[3], Sadie J. Ryan[4], Julia L. Finkelstein[1]

[1]Cornell University, Ithaca, NY, United States, [2]Ministry of Health, Machala, Ecuador, [3]Center for Global Health and Translational Science, SUNY Upstate Medical University, Syracuse, NY, United States, [4]Department of Geography and Emerging Pathogens Institute, University of Florida, Gainesville, FL, United States

Neglected tropical diseases (NTDs) are a major threat to public health, particularly in Latin America where the disease burden remains high. We examined the burden of neglected tropical diseases in Machala, Ecuador, a coastal city in southern Ecuador near the Peruvian border. A total of 398,919 records were analyzed from a citywide database of clinic visits in Machala, Ecuador in 2014, to report the prevalence of NTDs, including helminthic, viral, bacterial, and protozoan infections. Binomial regression was used to examine the associations of NTD occurrence with socio-demographic factors. There were 1,919 NTD-related clinic visits in Machala in 2014; viral infections were the most commonly reported (85.0%), followed by helminthic (13.9%), bacterial (<1.0%), and protozoan (<1.0%) infections. Dengue fever was the most common NTD, with 1,631 cases throughout the year, accounting for over 95% of viral NTD cases. Ascariasis was the most common helminthic infection (73.8%), followed by schistosomiasis (9.7%). Children under five had a 2-fold greater risk of presenting with ascariasis (RR: 1.95, 95% CI: 1.44-2.64, $p<0.0001$), and school-age children (5-11y) had a 7-fold higher risk of presenting with strongyloidiasis (RR: 6.84, 95% CI: 1.53-30.55, $p<0.05$), compared to all other age groups. The burden of dengue fever was the highest in adolescents (12-18y), with a 3-fold higher risk (RR: 3.05, 95% CI: 2.73-3.40, $p<0.0001$), compared to all other age groups. Bacterial infections were most common in the elderly (≥65y), with a 16-fold higher risk of bacterial NTDs (RR: 16.19, 95% CI: 5.44-48.18, $p<0.0001$), and a seven times greater risk of yaws (Treponema pertenue) (RR: 6.94, 95% CI: 1.74-27.75, $p<0.01$), compared to other age groups. Men had a nine times greater risk of cysticercosis (OR: 8.79, 95% CI: 1.90-40.68, $p<0.01$), compared to women. The burden of NTDs, including dengue fever and helminthic infections, is high in coastal Ecuador, and varies by age and sex. Findings highlight the need for continuous active surveillance to identify risk groups and target preventive interventions to reduce the burden of neglected tropical diseases in Ecuador.

IMPACT OF ONCE AND TWICE YEARLY MASS DRUG ADMINISTRATION ON BANCROFTIAN FILARIASIS AND SOIL TRANSMITTED HELMINTH INFECTION IN CENTRAL JAVA, INDONESIA

Taniawati Supali[1], Yenny Djuardi[1], Maria Kaisar[1], Difa Stefanie[1], Gary J. Weil[2], Peter Fischer[2]

[1]University of Indonesia, Faculty of Medicine, Jakarta, Indonesia, [2]Infectious Diseases Division, Department of Internal Medicine, Washington University School of Medicine, St. Louis, MO, United States

Lymphatic filariasis is still prevalent in many areas of Indonesia. The Global Program to Eliminate Lymphatic Filariasis is based on annual mass drug administration (MDA) of the at-risk population. Although previous studies have shown a significant decrease of microfilaremia (Mf) after MDA in some areas, elimination from all endemic areas may need many years. Therefore, intensified MDA would be more useful in terms of duration, cost and compliance. The aim of the study was to compare the impact of annual and semi-annual MDA on W. bancrofti infections and on co-endemic soil transmitted helminth (STH). Two sub-urban villages Pekalongan District, Central Java with Mf prevalence rates ranging from 2%-7% received either once or twice yearly MDA with single dose of DEC/albendazole. Blood and stool samples were collected for detection of filarial antigen in blood by the ICT card test, Mf by three-line blood smear, and STH eggs in stool by duplicate Kato Katz smear. There was no significant difference in Mf prevalence before and after treatment in both groups; however, the decrease of antigen rates was significant on both regimens: once-yearly treatment (p0.1). Trichuris prevalence decreased significantly either with once a year treatment (p=0.004) or twice yearly MDA (p<0.0001). In conclusion, short-term evaluation showed that in our study area an additional round of DEC/albendazole did not lead to stronger reduction of Mf rates, but the beneficial effect on STH was larger after twice yearly MDA.

502

DEVELOPMENT OF A SIMPLE DIPSTICK ASSAY FOR OPERATIONAL MONITORING OF DDT FOR VISCERAL LEISHMANIASIS AND OTHER VECTOR CONTROL PROGRAMS

Mark J. Paine[1], Hanafy M. Ismail[1], Marlize Coleman[1], Rudra P. Singh[2], Rudraprakash K. Das Gupta[3], Akshay C. Dhariwal[3], Vijay Kumar[2], Pradeep Das[2]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Rajendra Memorial Reserach Institute of Medical Sciences, Patna, India, [3]National Vector Borne Disease Control Programe, New Delhi, India

Indoor residual spraying (IRS) of insecticides can be extremely effective but only if correct quantities are applied. Unfortunately, disease control programmes are being hampered by a lack of affordable, user-friendly tools to monitor insecticide concentrations as part of quality assurance activities. The application of DDT insecticide continues to be a frontline option for the control and ultimately elimination of visceral leishmaniasis in India. We have developed a simple dipstick assay for DDT quantification. The assay is specific for active DDT (p,p`-DDT). It has been tested against ~2000 field samples from residential houses in Bihar state in India and validated against high performance liquid chromatography (HPLC). The dipstick assay matched HPLC results very closely and appeared to indicate a large variation in the actual levels of DDT being sprayed. Further field trials to confirm performance are planned. With the continuing use of DDT spraying as a strategic intervention for VL control, the simple dipstick assay provides a much needed quality assurance tool for monitoring DDT levels to promote the effective use of the insecticide.

CO-IMPLEMENTATION OF NTD MASS DRUG ADMINISTRATION AND IMMUNIZATION: THE TANZANIA EXPERIENCE

Upendo Mwingira[1], Bernard Kilembe[1], Alex Mphuru[1], Neema Rusibamayila[1], Kathryn Crowley[2], Lisa Rotondo[2], Dafrossa Lyimo[1]

[1]Ministry of Health and Social Welfare, Tanzania, Dar es Salaam, United Republic of Tanzania, [2]RTI International, Washington, DC, United States

The Tanzania NTD control program aims to eliminate LF by 2020 through five years of annual MDA treatment. Immunization services are provided free of charge as part of Primary Health Care (PHC) in all public and private Reproductive and Child Health (RCH) clinics. IVD's recent expansion of activities has resulted in coverage of >85% of health facilities in the country and is projected to reach 95% in 2015. At the same time, Tanzania had 166,743 children unvaccinated for measles from 2011 to 2013. This huge number of unvaccinated children puts the country at risk of measles outbreaks and thus a need to catch up in 2 -3 years interval. In 2014, the Ministry of Health (MOH) planned to conduct two separate campaigns in roughly the same time period: annual mass drug administration (MDA) for children and adults aged 5 and older with ivermectin and albendazole to treat LF, STH, and onchocerciasis where endemic in 101 districts, and a national immunization campaign to vaccinate children 5-15 for measles and rubella and distribute mebendazole and vitamin A to children < 5 in 166 districts. Given the short interval between the two campaigns and overlap in target populations, the MOH decided to coordinate the campaigns to increase coverage and decrease cost and effort. A total of 20,529,629 (97%) children targeted were vaccinated with Measles With respect to Vitamin A, a total 8,136,451 (109%) children targeted were supplemented. Moreover, Mebendazole coverage was also 109%. And a total of 20,864,594 (76%) people were reached with Ivermectin and Albendazole. Furthermore, the NTD program conducted mop-up visits to districts with low program coverage. The joint campaign demonstrated the importance of adequate micro planning and mapping of service areas to ensure all communities, including the hard-to-reach, receive interventions. This experience demonstrated that integrated vaccination campaigns can be used as a vehicle to increase the uptake other important health interventions including NTD medicines with relatively low implementation costs and time when compared if the two interventions were implemented vertically.

504

ARE WE ACHIEVING TREATMENT COVERAGE TARGETS FOR NTD ELIMINATION AND CONTROL PROGRAMS?

Katie Zoerhoff[1], Kalpana Bhandari[1], Hannah Frawley[1], Russell Owen[1], Margaret Baker[1], Zunera Gilani[2]

[1]RTI International, Washington, DC, United States, [2]United States Agency for International Development, Washington, DC, United States

Treatment coverage is a key performance indicator to measure whether NTD programs are on track to achieve their control and elimination goals. Identifying persistent pockets of disease transmission due to low coverage is important in order to prevent derailing a country's progress towards achieving elimination. The question explored here is whether countries supported by United States Agency for International Development are meeting the minimum coverage targets set for mass drug administration (MDA) for NTDs. NTD MDA treatment datasets created by national programs in 19 countries supported by United States Agency for International Development between 2007 and 2015 were analyzed. Program coverage was calculated as the number treated as a percentage of the number persons targeted and eligible for treatment. Results were measured against the global program coverage target of 80%. In 2013, mean program coverage was 80% or higher for all of the diseases in 12 out of the 17 countries supported, and between 2007-2015 districts achieved sufficient coverage 79% of the time. This means that about one

fifth of MDAs have fallen short of the targets set, with 15% of all districts found to be "repeat offenders" - achieving <80% coverage in at least two consecutive years. The percentage of MDAs meeting coverage targets varied across diseases, ranging from an average of 86% for districts treated for onchocerciasis to 39% for districts treated for schistosomiasis. Reasons for low reported coverage include data quality concerns such as accurately estimating the target population, and program implementation issues including MDA timing, staff and volunteer retention, and social mobilization. These results highlight the need for national programs to analyze their data after every MDA in order to identify districts with persistently low coverage, diagnose the cause, and take action. Actions may include checking coverage estimates by implementing post-MDA coverage surveys or conducting formal data quality assessments, collecting information on reasons for not participating in the MDAs, and adjusting program implementation strategies such as tailoring social mobilization approaches among populations with poor compliance.

505

ASSESSING DATA QUALITY OF NEGLECTED TROPICAL DISEASE INTEGRATED CONTROL PROGRAMS: THE TANZANIA EXPERIENCE

Andreas Nshala[1], Bernard Kilembe[2], Honorati Zoure[3], Alexander Tiendrebeogo[4], Deogratias Damas[1], Sarah Craciunoiu[5], Maria Chikawe[2], Upendo Mwingira[2]

[1]IMA World Health, Dar es Salaam, United Republic of Tanzania, [2]Tanzania Neglected Tropical Disease Program, NTD Secretariat, Dar es Salaam, United Republic of Tanzania, [3]World Health Organization, AFRO, Brazzavile, Republic of the Congo, [4]World Health Organization, AFRO, Ouagadougou, Burkina Faso, [5]IMA World Health, Washington, DC, United States

Neglected tropical diseases (NTDs) are endemic in all parts of Tanzania. This puts 47 million Tanzanians at risk of infection of two or more NTDs. In 2014 alone, over 57 million treatments were distributed reaching 21 million people countrywide. The program is expanding its activities and the geographical coverage is expected to rise from 64% in 2014 to 100% by 2016. As the program expands, maintaining good quality data becomes even more important. A data quality assessment (DQA) was implemented in May 2014 using pilot tools developed by the World Health Organization (WHO) and partners to assess the quality of the reported data from lower levels and the ability of the program to collect and report quality data. A brief desk review of programmatic reporting challenges was completed and four indicators for DQA were identified. Three regions that reported good to moderate coverage were purposefully selected to take part in the assessment. One district per region was randomly selected. Two health facilities per district and four communities (service delivery points (SDPs)) per health facility were selected using population proportionate to size. A recount of data was carried out on paper at all levels and a systems assessment was completed using a Microsoft excel-based system. DQA results indicate that the Tanzania program has a sound data management and reporting system (scores of 2.1-3) and produces quality data (verification factor of 0.8 to 1). However, there was sub-optimal performance across all service delivery points and health facilities, calling for more support and training to be provided at these lower levels of data collection to ensure quality data is generated and reported properly. Despite the strong reporting system, quality data across all intermediate levels and the SDPs needs greater attention. It was concluded that these types of assessments should be done routinely and frequently at district level to help provide more immediate feedback, which can facilitate timely corrective actions.

506

A NATIONWIDE INTEGRATED EVALUATION OF PROGRESS WITH ONCHOCERCIASIS, SCHISTOSOMIASIS, SOIL-TRANSMITTED HELMINTH AND LYMPHATIC FILARIASIS CONTROL IN TOGO

Rachel N. Bronzan[1], Yao M. Agbo[2], Yao Layibo[2], Gbati M. Datagni[3], Wemboo Halatoko[2], Kossi G. Yakpa[2], Koffi S. Sognikin[2], Potchoziou Karabou[2], Anders Seim[4], Améyo M. Dorkenoo[2]

[1]HDI, Seattle, WA, United States, [2]Ministry of Health, Lomé, Togo, [3]HDI, Lomé, Togo, [4]HDI, Oslo, Norway

Togo has numerous national programs aimed at the control of neglected tropical diseases. Togo's Onchocerciasis Control Program has implemented mass drug administration (MDA) for onchocerciasis for over 15 years and has drafted a national plan for onchocerciasis elimination, the Lymphatic Filariasis (LF) Elimination Program just successfully completed its second post-MDA Transmission Assessment Survey (TAS), and the Integrated NTD Control Program has implemented integrated MDA for schistosomiasis (SCH) and soil-transmitted helminths (STH) for six years. In February 2015, the Togo Ministry of Health launched a nationwide, integrated evaluation for these three programs to 1) measure the impact of multiple years of MDA for SCH and STH, 2) gather preliminary data on Ov16 seroprevalence, 3) validate the results of the final post-MDA LF TAS using the Wb123 ELISA, and 4) examine the feasibility, challenges and cost of this complicated integrated activity. The survey used the same sampling scheme as that used for the 2009 baseline mapping of SCH and STH prevalence. At the same two schools in each of the 560 peripheral health units sampled in 2009, a convenience sample of 15 school-going children aged 6 to 9 years submitted stool and urine samples. Stool was examined for SCH and STH using the Kato-Katz method. Urine reagent strips were used to detect hematuria as an indirect measure of ***S. haematobium***. Eight of the 15 children in each school were tested for onchocerciasis using the Ov16 rapid test. In 8 districts previously endemic for LF and 1 district containing villages with a persistence of onchocerciasis, all children tested by Ov16 rapid test provided blood spots on filter paper for later testing by Ov16 ELISA and Wb123 ELISA for LF. More than 16,000 children at 1,128 schools were tested for SCH, STH and onchocerciasis and more than 2,700 children were tested by ELISA for onchocerciasis and LF. Preliminary results show low prevalence of onchocerciasis and LF, and significantly reduced prevalence of SCH and STH. Though the survey posed logistical challenges, it proved to be an effective and cost-saving means of assessing multiple programs simultaneously.

507

THE GEOGRAPHIC DISTRIBUTION OF LEPROSY, SCHISTOSOMIASIS AND LEISHMANIASIS IN FOUR MUNICIPALITIES IN MINAS GERAIS, BRAZIL: IMPLICATIONS FOR CONTROL OF NTDS IN AN ENDEMIC AREA

Deidra Ansah[1], José A. Ferreira[2], Marcelo H. de Alcântara[3], Soraya Herica[2], Uriel Kitron[4], **Jessica K. Fairley**[1]

[1]Emory University School of Medicine, Atlanta, GA, United States, [2]Faculdade de Saude e Ecologia Humana, Vespasiano, Brazil, [3]Vespasiano Department of Health, Vespasiano, Brazil, [4]Emory University, Atlanta, GA, United States

While it is known that leprosy is associated with poverty, the exact mechanisms remain to be elucidated. Limited data suggest that helminth infections could shift its presentation towards the lepromatous end of the spectrum; however, there is little published on the geographic overlap of leprosy and parasitic infections in Brazil. This study aims to investigate the geospatial distribution of leprosy, ***Schistosoma mansoni*** infection, and visceral leishmaniasis reported in 4 municipalities of Minas Gerais, Brazil over the last 8-10 years. Using the Brazilian national notifiable disease surveillance system (SINAN), data were collected on cases of leprosy, S. mansoni infection and visceral leishmaniasis between January 1, 2007

(January 1, 2005 for leprosy only) and February 28, 2015 reported in the following municipalities: Vespasiano, Pedro Leopoldo, Confins, and Santano do Riacho. Demographic characteristics such as age, gender, occupation, neighborhood and municipality of residence were tabulated. Analyses including those using geospatial information system (GIS) are underway. During the study period, there were 183 cases of leprosy, 200 cases of ***S. mansoni*** infection, and 318 cases of visceral leishmaniasis. For leprosy, the median age at notification of disease was 48 years (range 6-97) and 46% were female. Multibacillary disease predominated at 76% of cases. For ***Schistosoma mansoni*** infection, the median age was 30.5 years (range <1 to 84) and 33% were female. The median age for leishmaniasis was 32.5 years (range <1 to 89) and 38.7% were female. The highest proportions of cases of leprosy (42.1%) and of schistosomiasis (34.0%) were in the same municipality, which also had the second highest number of leishmaniasis cases (33.5%). Geospatial mapping will inform the epidemiology of these infections to lay the foundation for more in-depth studies of potential interactions between them. With the immunologic consequences of chronic parasitic diseases, investigating co-infections and their role in the presentation of leprosy has the potential for significant impact on the control of leprosy and other neglected tropical diseases.

508

IMPACT OF FOUR TO FIVE YEARS OF INTEGRATED MASS DRUG ADMINISTRATION ON SCHISTOSOMIASIS AND SOIL-TRANSMITTED HELMINTHS IN TOGO

Améyo M. Dorkenoo[1], Wemboo Halatoko[1], Yao M. Agbo[1], Yao Layibo[1], Efoé Sossou[1], Kossi G. Yakpa[1], Koffi S. Sognikin[1], Komi I. Amegbo[1], Rachel N. Bronzan[2]

[1]Ministry of Health, Lomé, Togo, [2]HDI, Seattle, WA, United States

Schistosomiasis and soil-transmitted helminths (STH) are prevalent throughout Togo. In 2009, the Ministry of Health of Togo (MOH) mapped the prevalence of schistosomiasis and STH throughout Togo in preparation for treatment through mass drug administration (MDA). All 560 peripheral health units (PHU) outside the capital of Lomé were mapped, except for 11 PHU mapped in 2006 during a pilot phase. Since 2010, the MOH has implemented integrated MDA for the control of schistosomiasis, STH and onchocerciasis based on the prevalence of disease and according to WHO guidelines. Reported coverage for the MDAs has been high, averaging 97.0% for schistosomiasis and 99.2% for STH during the past three years. In February 2015, Togo's MOH conducted a nationwide assessment (integrated with onchocerciasis and lymphatic filariasis surveillance) to measure the impact of MDA and amend MDA targets based on the new prevalence data. The sampling scheme was identical to that used during the baseline mapping. The two schools sampled at baseline in each of the 560 PHU were revisited and a convenience sample of 15 school-going children aged 6 to 9 years submitted stool and urine samples. Stool was examined for schistosoma and STH eggs using the Kato-Katz method. Urine reagent strips were used to detect hematuria as an indirect measure of ***S. haematobium***. A subset of urine samples were filtered and examined for eggs. More than 16,000 children at 1,128 schools were tested for schistosomiasis and STH. Preliminary results show a significant reduction in the prevalence of schistosomiasis and STH compared to 2009. Implementation of future MDAs will be based on the new prevalence data for schistosomiasis and STH, however, new population targets must be developed with consideration of the risk of disease recrudescence if MDA ceases. The findings from this study provide cause for optimism in the long-term control of schistosomiasis and soil-transmitted helminths. Efforts will be made to engage partners to support additional interventions (snail control, improvements in water, sanitation and hygiene) to achieve greater and sustained reductions in these diseases.

509

HEALTHY HOUSING FOR HEALTHY LIVING: HOME IMPROVEMENT TO CONTROL VECTORIAL TRANSMISSION OF CHAGAS DISEASE IN LOJA PROVINCE, ECUADOR

Claudia Nieto-Sanchez[1], Sylvia Jimenez[2], Juan G. Gomez[1], Darwin Guerrero[3], Esteban G. Baus[3], Mario J. Grijalva[1]

[1]Tropical Disease Institute, Heritage College of Osteopathic Medicine, Ohio University, Athens, OH, United States, [2]Facultad de Arquitectura, Pontifical Catholic University of Ecuador, Quito, Ecuador, [3]Center for Infectious Disease Research, School of Biological Sciences, Pontifical Catholic University of Ecuador, Quito, Ecuador

Healthy Homes for Healthy Living (HHHL) is a health promotion strategy aimed at interrupting Chagas disease transmission by creating living environments designed to prevent the presence of triatomines in homes of three rural communities of southern Ecuador. These living environments consider the conditions of domestic and peridomestic areas, as well as practices associated with hygiene and organization of the space according to social, cultural and economic practices of this region. Based on a participatory decision-making processes that stimulated knowledge sharing between local communities and researchers, HHHL built the first prototype of an entirely reconstructed anti-triatomine house in 2013. Subsequently, HHHL partnered with two new families in 2014 to determine infrastructural and health promotion processes required to improve homes that do not require full reconstruction but minimal improvement. Anti-triatomine measures in this case included screen in doors and windows, installation of false ceilings to improve internal temperature, roof marquee to facilitate entrance of natural light, and walls plastering and painting that facilitate localization of triatomines. Local materials were used to create fences, storage units, and animal shelters in the peridomestic areas. Particular attention was given to health promotion activities emphasizing the relationship between health, living environments, and Chagas disease. Health promotion efforts included regular reinforcement of practices previously identified as protective against triatomines presence such as sweeping with natural insecticides, prevention of cohabitation with domestic animals, and reduction of materials piled around the home. A Healthy Home Guardian was selected amongst the children of the family. Most Significant Change evaluative framework was used to assess appropriation of the space after a year of use of the anti-triatomine measures.

510

COMMUNITY HEALTH WORKERS SPECIALIZED IN CHAGAS DISEASE: A NEW APPROACH TO OVERCOME UNDERDIAGNOSIS

Miriam Navarro[1], Bárbara Navaza[1], Teresa Blasco[2], Lucía García San Miguel[2], Paloma Merino[3], Isabel Clavería[4]

[1]Fundación Mundo Sano, Madrid, Spain, [2]Centro Nacional de Medicina Tropical, Instituto de Salud Carlos III, Madrid, Spain, [3]Hospital Universitario Clínico San Carlos, Madrid, Spain, [4]Centro de Medicina Tropical Drassanes-Vall d'Hebron, PROSICS, Barcelona, Spain

Chagas disease has overcome borders and become global. Spain is the most affected country of Chagas disease in Europe, and the second globally in terms of infection among migrants (after US). More than 60% of the estimated people with Chagas disease (more than 45,000 adults) are women of child-bearing age. Mother to child transmission of ***Trypanosoma cruzi*** is feasible in non-endemic countries. Europe still faces an underdiagnosis of 90%. Among population from endemic areas, lack of knowledge, stigma and fear are still linked to the disease. From February to September 2013, we recruited and trained in Madrid four mothers ***T. cruzi*** as community health workers (CHW) specialized in Chagas disease ("Mothers Committed To Chagas' Disease: Taking Action Here And There"® program). They came from Bolivia (Cochabamba and Santa Cruz), and average age was 34.7 (28-47y). Qualitative research

was performed concurrently in order to evaluate the program and the evolution of their experiences related to Chagas disease. After the training, all mothers shown improved knowledge about Chagas disease and maternal and child health, and their evaluations of the program were excellent. Their way to face the disease also changed. They started to perform activities among their communities, showing their commitment to the program. Since then (14 months), in Spain, population at-risk (par) have been informed: 424 through 30 chats given to groups, 460 par individually (in person/by telephone), around 300 have been tested thanks to the program (35 people were accompanied to the consultation by the CHW), and more than 7,000 par have received informative material). Last July (2014) in Cochabamba (Bolivia): 185 par were informed through 25 chats performed in hospitals, open spaces and churches. These CHW specialized in Chagas disease represent a global, pioneer and very useful tool in our settings (here, non-endemic countries) and in their countries of origin (there). The program is going to be replicated in Madrid and Barcelona in 2015.

511

THE CRITICAL ROLE OF SCIENTIFIC RESEARCH IN THE FIGHT AGAINST THE NEGLECTED TROPICAL DISEASES: EXPERIENCE FROM THE AFRICAN PROGRAM FOR ONCHOCERCIASIS CONTROL

Daniel A. Boakye[1], Wilma Stolk[2], Afework Tekle[1], Honorat Zoure[1], Grace Fobi[1], Francois Sobela[1], Adrian Hopkins[3], Chris Mwikisa[1], Jean-Baptiste Roungou[1]

[1]African Programme for Onchocerciasis Control, Ouagadougou, Burkina Faso, [2]Erasmus MC, University Medical Center Roterdam, Roterdam, Netherlands, [3]Taskforce for Global Health, Mectizan Donation Program, Decatur, GA, United States

The African Programme for Onchocerciasis Control (APOC, 1995-2015) is one of the most successful Public-Private health partnerships in Africa. The programme was set up following the donation of ivermectin by Merck and Co. Inc, to implement a sustainable distribution treatment system with ivermectin in all onchocerciasis-endemic countries in Africa. Currently onchocerciasis is controlled in most of the 31 endemic African countries with Malawi, Niger, Senegal, Mali and Chad performing surveys to see whether transmission is interrupted and interventions can be stopped. A key factor underlying this phenomenal public health achievement has been the quick uptake of research results for interventions and strategy adjustments. We review the interplay between science and policy, that has shaped APOC operations from mapping the extent of the disease endemicity, adoption of the CDTI strategy for implementation, resolving implementation challenges such as ***Loa loa*** endemicity, change in objective from control to elimination and development of new tools and methodologies including modelling in the assessment of the impact of interventions and progress towards elimination. For example, recent research findings from studies on vector species distribution have led to the development of maps delineating transmission zones which has been used to modify operational procedures to assess interruption of transmission. Another example is a quick research uptake of the Esperanza window trap and its introduction in the operations of APOC for transmission assessment. The most recent finding of some critical research such as modelling the spread of possible non-response to ivermectin and its impact on elimination will also be presented. APOC will cease by the end of 2015 paving the way for the establishment of a new entity for the control and elimination of neglected tropical diseases amenable to preventive chemotherapy (PC-NTDs). As illustrated by the APOC experience, for the fight against the PC-NTDs to be successful, it is critical that strong structures remain in place to steer critical research and ensure the rapid uptake of results.

INVESTIGATING CHANGES IN MONOCYTE PHENOTYPES AND FUNCTIONS IN ACTIVE VISCERAL LEISHMANIASIS PATIENTS

Neetu Singh[1], Rajiv Kumar[2], Lynette Beattie[3], Susanne Nylen[4], David Sacks[5], Christian Engwerda[3], Shyam Sundar[1]

[1]Institute of Medical Sciences, BHU, Varanasi, U.P., India, [2]National Institute of Technology, Raurkela, Orissa, India, [3]QIMR Berghofer Medical Research Institute, Herston, Brisbane, Australia, [4]Karolinska Institutet, Department of Microbiology Tumor and Cell Biology, Stockholm, Sweden, [5]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Immune mechanisms underlying Visceral Leishmaniasis (VL) pathology are not well characterised. We hypothesised that M2 macrophages play an important role in disease pathogenesis during VL, and aimed to establish whether macrophages became polarised towards an M2 phenotype. We examined the dynamics of M1 and M2 macrophage frequencies and phenotypes in the whole blood of active VL patients, at intervals of 7 days for four weeks until their drug treatment was complete.We found only minor changes in the frequency of M1 and M2 macrophages, but observed significant changes in the expression of cell surface markers. In particular, we found that M2 macrophages increased in frequency 14 days after drug treatment commenced.We also observed significantly reduced expression of CD14 on monocytes from active VL patients, but exacerbated TNF-α production in response to LPS, compared with the same cells from drug cured and endemic control samples. Although we found a strong correlation between CD14 expression and TNF-α production in response to LPS in cells from endemic controls, no such correlation was found in VL patients, suggesting a hyperactive phenotype in VL patient monocytes. Together, our findings indicate dynamic changes to macrophage and monocytes populations in VL patients over the course of drug treatment, and suggest that the functions of these cells may change at different stages of disease.

TRYPANOSOMA CRUZI CAUSES POLYARTERITIS NODOSA-LIKE LESIONS IN MICE DRIVEN BY PATHOGEN-SPECIFIC TYPE I IMMUNITY

Ester Roffe[1], Ana Paula M. Marino[2], Joseph Weaver[1], Wuzhou Wan[1], Fernanda F. Araujo[3], Victoria Hoffman[4], Helton C. Santiago[5], Philip M. Murphy[1]

[1]National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States, [2]Lab. Imunopatologia, CPqRR/Fiocruz, Belo Horizonte, Brazil, [3]CPqRR/Fiocruz, Belo Horizonte, Brazil, [4]ORS/OD/National Institutes of Health, Bethesda, MD, United States, [5]UFMG, Belo Horizonte, Brazil

Infectious agents are often considered potential triggers for chronic inflammatory disease, including autoimmunity; however, direct evidence is usually lacking. Recently we have established an experimental murine model for studying chronic chagasic heart disease, the most important clinical manifestation of Chagas' disease. In mice experimentally infected with the myotropic Colombiana strain of ***Trypanosoma cruzi***, parasitemia was controlled following acute infection. However, low levels of parasites persisted in tissue associated with development of a severe chronic systemic vasculopathy having the pathologic hallmarks of the human disease polyarteritis nodosa (PAN). Lesions occurred in many but not all organs and tissues, with hind limb skeletal muscle arteries most severely affected, resulting in associated myositis, atrophy, paresis/paralysis and death. Histopathology showed fibrinoid necrosis, rare perilesional amastigote nests within skeletal myocytes, and massive leukocyte infiltrates composed mainly of inflammatory monocytes, F4/80+ macrophages and ***T. cruzi*** tetramer-specific CD8+ T lymphocytes capable of producing IFNγ and TNFα, but not IL-17. ***T. cruzi***-specific IgG was detected in serum from infected mice, but antibody deposits were

absent from the lesions. Thus, ***T. cruzi*** infection in mice may be a specific infectious trigger of severe PAN-like chronic systemic vasculopathy driven by pathogen-specific Type I immune responses.

514

MODULATION OF MACROPHAGE FUNCTION VIA METABOLISM BY *TRYPANOSOMA CRUZI*

Sue-Jie Koo

University of Texas Medical Branch, Galveston, TX, United States

Chagas cardiomyopathy is a neglected disease that develops in approximately 30% of those infected with the blood-borne parasite, ***Trypanosoma cruzi***. Over 8 million people are infected with ***Trypamosoma cruzi;*** however, no vaccine or safe therapeutics are available. Macrophages constitute the early host defense; however, are unable to clear ***T. cruzi*** resulting in parasite dissemination and disease progression. Differential metabolic states, i.e., anaerobic glycolysis and mitochondria-dependent oxidative phosphorylation, respectively, are suggested to be associated with pro-inflammatory (M1) and anti-inflammatory (M2) functional activation of macrophages. Reactive oxygen species (ROS) have been shown to be an intracellular signal for glycolysis while peroxisome proliferator-activated receptors (PPARs) that enhance fatty acid oxidation provide transcription control of macrophage functional state. In our studies using diverse ***T. cruzi*** isolates, we showed that SylvioX10 (virulent), but not TCC (non-virulent), isolate of ***T. cruzi*** was able to control extracellular and intracellular ROS levels in macrophages. We found in macrophages infected with SylvioX10, the nuclear expression of PPAR-α was increased by 18 h post-infection, and mitochondrial metabolic activity was similar to that noted in normal controls; these events are indicative of anti-inflammatory function of macrophages therefore prohibiting ***T. cruzi*** clearance. In ongoing studies, we are examining the impact of PPAR-α inhibitors in modulating the metabolic gene expression profile, functional phenotype and parasite survival in macrophages. Our data will provide the first indication that host macrophages have deficient pro-inflammatory capacity due to sub-optimal glucose oxidation and enhancing the metabolism that supports ***T. cruzi*** clearance will provide a valuable basis for a strategy to arrest Chagas disease progression.

515

CASPASE-1/ASC INFLAMMASOME-MEDIATED ACTIVATION OF IL-1B-ROS-NF-KB PATHWAY FOR CONTROL OF *TRYPANOSOMA CRUZI* REPLICATION AND SURVIVAL IS DISPENSABLE IN NLRP3-/- MACROPHAGES

Nilay Dey, Nisha Jain Garg

University of Texas Medical Branch, Galveston, TX, United States

Chagas disease, caused by ***Trypanosoma cruzi***, is endemic in Latin America and an emerging disease in US and other developed countries, globally affecting 11-18 million people. Studies in experimental models have shown that macrophages (mφ) among other immune cells play an important role in control of ***T. cruzi*** infection. The interaction of ***T. cruzi*** with mφs and other cell types involved in the innate immune response are mediated by pattern recognition receptors (PRRs) such as toll-like receptors (TLRs) and Nucleotide binding oligomerization domain (NOD) like receptors (NLRs).Multi-meric protein macromolecules formed by NLRs, named inflammasomes activate caspase-1 leading to secretion of IL-1β and IL-18. In this study, we utilized wild-type (WT), ASC-/- and NLRP3-/- macrophages and inhibition approaches to investigate the mechanisms of inflammasome activation and their role in ***T. cruzi*** infection. ***T. cruzi*** infection elicited a subdued and delayed activation of inflammasome-related gene expression and IL-1β production in macrophages in comparison to LPS-treated controls. When WT and ASC-/- mφ were treated with inhibitors of caspase-1, IL-1β, or NADPH oxidase, we found that IL-1β production by inflammasomes required reactive oxygen species (ROS) as a secondary signal. Moreover, IL-1β regulated NF-κB signaling of inflammatory cytokine gene expression and, subsequently, intracellular parasite replication in macrophages. NLRP3-/- mφ, despite an inability to secrete IL-1β and elicit inflammatory cytokine gene expression, exhibited a 4-fold decline in intracellular parasites w.r.t. WT controls. NLRP3-/- mφ were not refractory to ***T. cruzi*** and exhibited a high basal ROS level, maintained in an IL-1β-independent manner that contributed to efficient parasite killing. We conclude that caspase-1/ASC inflammasomes play a significant role in the activation of IL-1β/ROS and NF-κB signaling of cytokine gene expression for ***T. cruzi*** control in human and mouse macrophages. However, NLRP3-mediated IL-1β/NF-κB activation is dispensable and compensated for by ROS-mediated control of ***T. cruzi*** replication and survival in macrophages.

516

MODULATIONS IN HLA-DR EXPRESSION IN VISCERAL LEISHMANIASIS INFECTION

Bhawana Singh

Department of Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

HLA class II is a highly polymorphic cell surface glycoprotein, crucial for regulating host immune responses and thereby determining the disease outcome in visceral leishmaniasis by their ability to present the foreign antigens to CD4+ T lymphocytes and activating the T-cells. The highly complex regulation of HLA class II in different cellular compartments determines the triggering and maintenance of immune responses and has vital role in determining the parasite clearance. This study determines the differences in the expression of HLA-DR at the gene as well as the functional level in visceral leishmaniasis cases. The study was performed on whole blood and splenic aspirates from VL patients pre-/post-treatment and endemic control groups at the gene level real time-PCR and the functional expression by flow cytometry. There was significantly lower expression of DRB1 (p=0.047) in active cases compared to endemic healthy controls but there were no significant differences in DRB1 expression in active cases compared to paired cured cases in either PBMC (p=0.848) or splenic aspirates (p=0.628). At the cellular level, HLA-DR was significantly increased on CD14, CD16 and CD19 positive populations while CD4+ cells were having lowered kinetics of expression upon drug cure in splenic as well as the whole blood. We found that the HLA-DR expression by cell types was similar in splenic aspirates as well as the whole blood assays but there were functional differences in the levels of HLA-DR expression at the gene as well as the protein level. The variable levels of expression of HLA-DR on macrophages and B-cells indicates for targeting these cell populations for modulating the immune responses by altering the antigen processing and presentation abilities hence designing the therapeutic/prophylactic options for VL.

517

CONTRIBUTION OF NK CELLS TO THE IMMUNOPATHOLOGY OBSERVED IN CUTANEOUS LEISHMANIASIS PATIENTS

Sara Passos[1], Tais Campos[1], Fernanda Novais[2], David Mosser[3], Lucas P. Carvalho[1], Phillip Scott[2], Edgar M. Carvalho[1]

[1]Federal University of Bahia, Salvador, Brazil, [2]University of Pennsylvania, Philadelphia, PA, United States, [3]University of Maryland, College Park, MD, United States

Cutaneous leishmaniasis (CL) due to ***Leishmania braziliensis*** infection is characterized by the development of ulcerative skin lesions. A cross-sectional study with CL patients from Corte de Pedra and healthy subjects was performed. Peripheral blood and lesion biopsies were collected to characterize, determine the frequency of cytotoxic sub-populations, determine the expression of granzyme and perforin in the cytotoxic sub-populations and to determine the percentage of degranulating cells. We identified four sub-populations of cytotoxic cells in the peripheral blood based on the expression of CD56, CD8 and CD3. Then, we determined the frequency of these sub-populations in peripheral blood from healthy subjects and CL patients. We found that the frequency of NK cells were increased in CL patients when compared with healthy subjects while the

frequency of CD8 T cells were decreased in CL patients when compared with healthy subjects. We evaluated the expression of granzime and perforin in cytotoxic sub-populations and we found that NK cells CD8- and CD8+ express more granzyme than CD8+ T cells in peripheral blood from CL patients and the same way, the two sub-populatios of NK cells CD8- and CD8+ express more perforin than CD8+ T cells in peripheral blood from CL patients. Cytotoxic lymphocytes presented granzyme and perforin proteins. The center is covered by a lysosomal membrane glycoprotein, CD107a. During degranulation, CD107a is exposed on the cell surface. Thus, CD107a can be a marker of degranulation on cytotoxic lymphocytes. We found that NK cells expressed more CD107a than CD8+ T cells. NKG2D is an activating receptor found on NK cells and CD8 T cells. The ligands for NKG2D are induced during infections making the cell susceptible for the lysis by NK cells and CD8 T cells. In experiments performed by microarray we found that MICB is expressed in the lesions of CL patients. Flow cytometry experiment showed that MICA/B is expressed in CD11b cells from the CL lesions and immunostaining for MICB showed this ligand in CL lesion. In conclusion, our data suggest a role of NK cells in the pathogenesis of cutaneous leishmaniasis.

518

TYPE I INTERFERON SIGNALLING SUPPRESSES ANTI-PARASITIC CD4+ T CELL RESPONSES DURING VISCERAL LEISHMANIASIS

Rajiv Kumar[1], Patrick Bunn[2], Neetu Singh[3], Shyam Sundar[3], Christian Engwerda[2]

[1]National Institute of Technology Rourkela, Sundargarh Odisha, India, [2]QIMR Berghofer Medical Research Institute, Herston Brisbane, Australia, [3]Institute of Medical Sciences Banaras Hindu University, Varanasi UP, India

Many pathogens, including viruses, bacteria, and protozoan parasites, suppress cell mediated immune responses through activation of type I IFN signalling. However the role of type 1 IFN's during ***Leishmania donovani*** infection causing visceral leishmaniasis (VL) is not well known. Here we report that type-1 IFN's play an important role in the pathogenesis of VL by impairing parasite clearance and suppressing pro-inflammatory cytokine production. Mice lacking type-1 IFN signalling (B6.IFNαR1-/- mice) had better control of parasite growth and an enhanced Th1 cell response. Studies in VL patients supported these findings and showed enhanced accumulation of mRNA encoding type I IFN signature genes in peripheral blood mononuclear cells (PBMCs) that were reduced following successful drug therapy. Critically, we also showed, using a whole blood assay, that blockade of type-1 IFN signalling enhanced antigen specific IFN-γ production, and that this response was HLA-II restricted. Together, these results identify the type-1 IFN signalling pathways as a potential therapeutic target to treat VL by stimulating anti-parasitic CD4+ T cell responses.

519

CYTOTOXICITY INDUCED BY CD8+ T CELL IN *LEISHMANIA BRAZILIENSIS* LESIONS RESULTS IN INFLAMMASOME ACTIVATION, IL-1B RELEASE AND SEVERE DISEASE

Fernanda Novais[1], Lucas Carvalho[2], Edgar Marcelino Carvalho[2], Phillip Scott[1]

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]Federal University of Bahia, Salvador, Brazil

The host immune response plays a critical role not only in protection from human leishmaniasis, but also in promoting disease severity. We have recently described a pathological role for CD8+ T cells in cutaneous leishmaniasis caused by ***Leishmania braziliensis***. Using experimental models of infection and skin samples from infected patients, we found that cytotoxicity induced by CD8+ T cells is a major mediator of immunopathology in cutaneous leishmaniasis. However, the downstream mechanisms of cytolytic activity that cause disease severity remain unclear. We hypothesized that CD8+ T cells release damage associated molecular patterns that activate the inflammasome with the consequent release of the pro-inflammatory cytokine IL-1β, amplifying the inflammatory response. Using experimental models of cutaneous leishmaniasis, we observed that cytotoxic CD8+ T cells induce inflammasome activation as measured by IL-1β protein production and active caspase-1 expression. We also found increased production of IL-1β by cells from the lesions of ***L. braziliensis*** patients. Importantly, blocking IL-1β signaling prevented pathology induced by CD8+ T cells mice. In summary, we show that IL-1β is detrimental in ***L. braziliensis*** infection and therefore targeting this pathway should be considered for immunotherapy in patients infected with ***L. braziliensis***.

520

ROLE OF IL-17 IN THE PROTECTION INDUCED IMMUNITY BY LIVE ATTENUATED *LEISHMANIA DONOVANI* CENTRIN DELETED PARASITES AGAINST EXPERIMENTAL VISCERAL LEISHMANIASIS

Antara Banerjee, Ranadhir Dey, Hira Nakhasi

US Food and Drug Administration, Silver Spring, MD, United States

Visceral leishmaniasis (VL), a neglected Tropical Disease, is the fatal form of the leishmaniasis-disease complex. The estimated disease burden of VL varies from 1,969,000 to 2,357,000 Disability Adjusted Life Years. Existing drugs are toxic, and the emergence of drug-resistant parasites makes ***Leishmania*** treatment challenging; till date there is no licensed vaccine available. Previously our laboratory reported on the protective role of live attenuated centrin gene-deleted ***L. donovani*** (LdCen1-/-) parasites through induction of Th1 type immune response in mice, hamsters and dogs. Previous and recent studies showed that along with Th1 cytokines, IL-17 plays a complementary role in human protection against ***L. donovani*** infection, and acts synergistically with IFN-γ to promote protection against L. infantum Infection in C57BL/6 mice, respectively. In the present study we explored role of IL-17 in protection induced by LdCen1-/- in C57BL/6 mice. We measured, mRNA level of IL-6, Il-1β and TGF-β (inducers of IL-17) from Bone Marrow Derived DCs infected with LdCen1-/- and wild type parasites (LdWT) ***in vitro***. LdCen1-/- infection induced IL-6, Il-β and TGF-β at 96 h suggesting LdCen1-/- parasites induce DC to produce IL-17 promoting cytokines. Next we evaluated levels of Th17 cytokines ***in vivo*** at 2 and 5 wk after infection with LdCen-/- and wild type parasite. RT-PCR was performed with RNA extracted from splenocytes and ELISA was performed with leishmanial-antigen stimulated spleen cell culture supernatants, respectively. Both mRNA and protein levels of IL-17A were significantly increased in LdCen1-/- immunized C57BL/6 mice in comparison to LdWT. There was also concomitant increase in IL-17 inducers such as IL-6 mRNA at 2wk post immunization and IL-23 mRNA at 5wk post immunization. Role of IL-17 induced protective immunity by LdCen-/- will be further investigated using IL-17-/- C57BL/6 mice. In addition, we will investigate the role of IL-17 in protection against wild type ***L. donovani*** challenge. To our knowledge this is the first attempt addressing the role of IL-17 in vaccine induced protection in VL.

521

MONOCYTE SUBSETS CONTRIBUTING TO DELETERIOUS INFLAMMATORY RESPONSE IN CUTANEOUS LEISHMANIASIS PATIENTS

Lucas P. Carvalho[1], Daniela Celestino[1], Rubia Costa[1], Sara Passos[1], Paulo Machado[1], Fernanda Novais[2], Daniel Beiting[2], David Mosser[3], Phillip Scott[2], Edgar M. Carvalho[1]

[1]Federal University of Bahia, Salvador, Brazil, [2]University of Pennsylvania, Philadelphia, PA, United States, [3]University of Maryland, Bethesda, MD, United States

Skin ulcer development in cutaneous leishmaniasis (CL) patients is associated with exaggerated inflammatory response with high levels of

TNF. ***Leishmania braziliensis*** is the most prevalent species causing CL in Brazil and also the one responsible for the most severe skin forms of the disease. Lesion infiltrate is mainly composed by lymphocytes and mononuclear phagocytes, and few parasites are observed. To investigate the presence of inflammatory mediators in ulcer from CL patients we first conducted an unbiased microarray analysis of lesion biopsies and compared with healthy skin transcripts. Among the upregulated genes in CL lesions we found the inflammatory genes Metalloproteinase-9, CXCL9, CXCL10, TNF and IL-1β. We than confirmed these findings by looking at protein of these mediators in supernatants of peripheral blood mononuclear cells culture and also in supernatants of lesion biopsies, in response to soluble Leishmania antigen. Interestingly, these chemokines and cytokines were present in groups of patients with ulcerated lesions and those with pre-ulcerative lesions. Peripheral monocytes in human are known to be heterogeneous and based on CD14 and CD16 expression they are subdivided in classical, intermediate and non-classical monocytes. We found that while all monocyte subsets produce Metalloproteinase-9 and CXCL9, the intermediate monocyte population is the main source of CXCL10, TNF and IL-1β. The production of IL-1β can happen upon activation of inflammasomes. To test the pathway by which ***L. braziliensis*** triggers IL-1β production we infected C57BL/6 mouse macrophages lacking NLRP3, AIM2, Caspase1, ASC and IL-1R. We found that ***L. braziliensis***-induced IL-1β production is dependent on NLRP3, Caspase1 and ASC. Altogether our data show that intermediate monocytes are the main population producing inflammatory cytokines and hence may be a potential therapeutic target candidate.

522

ALTERED NUMBER AND MIGRATION OF DENDRITIC CELLS IN MALNUTRITION CONTRIBUTES TO VISCERALIZATION OF *LEISHMANIA DONOVANI*

Elvia Y. Osorio, Gracie Thaxton, Bruno L. Travi, Peter C. Melby

University of Texas Medical Branch, Galveston, TX, United States

Malnutrition affects about 800 million people worldwide and is a risk factor for visceral leishmaniasis (VL) caused by ***Leishmania donovani***. Most people infected with ***L. donovani*** have a subclinical infection, but malnourished children are more likely to develop fatal VL. The underlying mechanisms of immune deficiencies driven by MN are not clearly defined. We found that the increased risk of VL was recapitulated in a mouse model of malnutrition. Dissemination of ***L. donovani*** was associated with a deficit of dendritic cells (DCs) in the skin-draining lymph node in the malnourished host. Following infection in the skin, ***L. donovani*** infects phagocytes, including DCs, which then traffic parasites to the draining lymph node. We examined possible causes of the reduced DCs in malnutrition and the effect on parasite dissemination. In the bone marrow of malnourished mice we found a slight reduction in common myeloid progenitors but higher proportions of CCR2+ inflammatory monocytes. A lower frequency of CCR2+ DCs and inflammatory monocyte precursors was also found in the lymph node of malnourished mice. These results suggested malnutrition leads to impaired egress and/or subsequent death of inflammatory monocytes, which are potential precursors of DCs. We also found that the expression of CCR2 and CCL2, which are required for emigration of inflammatory monocytes from the bone marrow, were increased in the skin but reduced in the draining lymph node. Furthermore, transwell assays showed DCs from malnourished mice had impaired migration toward the CCL2 chemokine. Fluorescent labeling of DCs in the infected skin revealed more rapid migration and increased accumulation of infected DCs in the spleen of malnourished mice. This was associated with increased expression of CCR7 and its ligands in the lymph node and spleen. Collectively, these data indicate that (1) impaired DC development from inflammatory monocytes contributes to the deficit of DCs in the lymph node in malnutrition, and (2) increased migration and/or reduced retention of dermal DCs in the lymph node promotes visceralization of ***L. donovani*** in the malnourished host.

523

IMMUNE RESPONSE IN PATIENTS WITH ACUTE CHAGAS DISEASE: POSSIBLE IMPLICATIONS FOR DISEASE SEVERITY DURING THE CHRONIC PHASE

Walderez O. Dutra[1], Daniela V. Andrade[1], Adriana de Jesus[2], Leonardo Damasceno[1], Germano Costa[3], Kenneth J. Gollob[4]

[1]UFMG, Belo Horizonte, MG, Brazil, [2]Secretaria de Saude Pública do Estado do Pará, Para, Brazil, [3]UFV, Viçoza, MG, Brazil, [4]Hospital Santa Casa-BH, Belo Horizonte, MG, Brazil

Chagas disease is caused by the intracellular protozoan ***Trypanosoma cruzi*** that affects16 to 18 million people, with 80 million considered at risk. Infection with ***T. cruzi*** via oral route has recently been an important focus of attention, currently being amongst the most frequent modes of transmission in Brazil, even in localities where vector transmission has been eradicated. Identification of the acute phase is critical for treatment administration; however, due to the difficulty to detect this phase, especially in endemic areas where the symptoms can be mild or inexistent, patients may progress to the chronic phase. During the chronic phase, while most patients remain asymptomatic, about 30% of the infected individuals develop a deadly cardiac disease. It is well accepted that the host's immune response is critical in determining disease evolution. Our hypothesis is that early immunological events that take place in the acute phase of Chagas disease will be critical to determine clinical outcome during the chronic phase. We compared the immunological profiles of patients in the acute phase and after they entered the chronic phase, at an early stage. We evaluated the frequency of CD4+, CD8+ and TCD4-CD8- (double negative - DN) cells in acute Chagasic patients (ACT) and non-infected individuals (NI). Similar frequencies of these cell populations between ACT and NI groups were observed. However, we observed that ACT displayed higher levels CD4+HLA-DR+ compared to NI. Moreover, we observed that expression of the inflammatory cytokines TNF-α and IL1-β by CD8+Granzyme A+ cells was higher in ACT as compared to NI. In our follow-up study, we compared the immunological profile of chagasic patients in the acute (ACT) and chronic (CHR) phase. As disease progresses to chronic phase, we observed a lower frequency of CD8+IFN-γ and an increase in IL-10 expression. Our data show an activated immune profile of patients in acute phase and, as disease progresses, cell populations with distinct functional profiles could be controlling an exacerbated inflammatory response.

524

DENDRIMERIC ACID-LABILE LINKED OLIGOSACCHARIDES OF *LEISHMANIA* SPP. LIPOPHOSPHOGLYCAN ALTER INNATE AND ADAPTIVE IMMUNE RESPONSES

Tara Grinnage-Pulley[1], Rajarshi Roychoudhury[2], Pedro A. Martinez[1], Robert G. Schaut[1], Nicola L. Pohl[2], Christine A. Petersen[1]

[1]University of Iowa, Iowa City, IA, United States, [2]Indiana University, Bloomington, IN, United States

Lipophosoglycans (LPG) of ***Leishmania spp***. are known to alter innate immune responses and be critical for parasite binding to the vector gut wall. However, the ability of the oligosaccharide sugars capping the apex and terminal branches of LPG to specifically alter adaptive T cell responses is unclear. To study cap sugar-T cell interactions, pathogen mimics—namely tri-sugar dendrimer-coated latex beads with acid labile linkers were synthesized. Upon lysosomal acidification, linker breakdown releases the sugar dendrimers for possible loading on antigen presenting molecules to induce T cell growth. To determine the role of ***Leishmania*** oligosaccharides in altering adaptive immune responses, we measured T cell subset proliferation via FACS and cytokine production via ELISA. T cell proliferation was significantly increased after co-culture with macrophages exposed to covalently and acid-labile-linked di- and tri-mannose beads as compared to T cell proliferation from cells co-cultured with macrophages

exposed to non-functionalized beads. Inhibition of phagolysosomal acidification only reduced T cell proliferation within T cells co-cultured with macrophages exposed to acid-labile-linked beads and not to covalently-linked beads. These sugar-modified reagents show that oligosaccharides alone can drive T cell proliferation by acidification-requiring presentation, most significantly in NKT receptor (CD160)-restricted T cells.

525

URINARY BLADDER BILHARZIASIS IN A SOMALI REFUGEE: AN IMPORTED CASE FROM THE JUBBA RIVER VALLEY IN SOMALIA

Ambika Eranki, Oleg Shapiro, Rohin Mehta, Timothy Endy

Upstate Medical University, Syracuse, NY, United States

Schistosomiasis (Bilharziasis) is a neglected tropical disease which is associated with significant morbidity which infects an estimated 200 million people globally. The burden is highest in Sub-Saharan Africa: the disease is closely linked with poverty, and lack of access to basic resources such as clean water and sanitation. Transmission to human occurs through freshwater contaminated with feces or urine, via infected snails, which are the intermediate hosts. Schistosoma is endemic in Southern Somalia, of note in the Shabeelie and Jubba river valleys which are the farming regions. Herein we present a case of chronic granulomatous urinary bladder Schistosomiasis in a male refugee from Somalia, who lived in the Juba River valley, which is one of the endemic areas in Somalia. A few months after he came to the U.S, he presented with diffuse abdominal and rectal pain: colonoscopy and endoscopy were non-revealing. A CT scan of the abdomen showed a small, circumferentially thickened urinary bladder with calcifications, and subtle calcification of the distal right ureter. A cystoscopy with bladder biopsy showed focal granulomas, chronic inflammation and numerous calcified Schistosoma eggs: some of the eggs had terminal spines consistent with ***Schistosoma hematobium***. Even though the patient had presented with chronic urinary bladder disease, he was treated with the standard WHO dosing regimen of oral Praziquantel at a dose of 40 mg/kg/day in two doses for one day. He continued to be symptomatic, and was retreated 4 weeks later, with mild improvement in symptoms. Chronic infection with ***S. hematobium*** is known to lead to granulomas, fibrosis, and eventually cause obstructive uropathy and renal failure. This case illustrates the importance of being aware of the high prevalence of this infection and its sequelae in immigrants from endemic areas.

526

FIRST REPORT OF *BIOMPHALARIA PFEIFFERI* SHEDDING *SCHISTOSOMA* CERCARIAE IN NKALAGU, SOUTHEASTERN NIGERIA

Ogochukwu C. Okeke[1], Patience O. Ubachukwu[2]

[1]Federal University Ndufu-Alike, Ikwo, Ebonyi State, Nigeria, [2]University of Nigeria, Nsukka, Enugu State, Nigeria

Published studies have shown that ***Biomphalaria*** species found in south-eastern Nigeria did not shed ***Schistosoma*** cercariae, which has led to the total absence of ***Schistosoma mansoni*** infection in the area. This study was birthed from a research aimed at studying the distribution of snails of medical and veterinary importance in Nkalagu, a rural community endemic for ***S. haematobium***. ***Biomphalaria pfeifferi*** were collected from water contact site from October 2011-September 2012 and made to shed cercariae by exposure to light. ***Schistosoma*** shedding snails were collected between April and May, with overall infection rate of 4.35. Other morphological types of cercariae found in ***B. pfeifferi*** were armatae xiphidocercariae, echinostome cercariae, cercariaum cercaririae and cystophorous cercariae. Mice were infected with ***Schistosoma*** cercariae and at 12 weeks post infection, they were perfused to recover adult worms while sections of liver and spleen were examined for histopathologic changes. Worms recovered had characteristic adult ***Schistosoma*** morphologic features while histopathologic changes were ***S. mansoni***-like. A purposive sampling technique was employed to select primary school children living close to the infected water contact site. From 286 children sampled, no ***S. mansoni*** egg was seen in stool samples. Consequently, rats were caught along the water contact site and examined for ***S. rhodaini*** eggs but none was seen. In conclusion, this is the first report of ***Schistosoma*** cercariae in ***B. pfeifferi*** in south-eastern Nigeria. However, the results obtained highlight the need for further studies on the Schistosoma cercariae encountered in ***B. pfeifferi*** in the study area to confirm the species. If confirmed to be ***S. mansoni***, control measures will be recommended to prevent human infection.

527

ESTABLISHING THE EVIDENCE OF SCHISTOSOMIASIS AND SOIL-TRANSMITTED HELMINTHIASIS INFECTIONS IN BENIN

Moudachirou Ibikounlé[1], Jean Jacques Tougoué[2], Pélagie Boko[3], Wilfrid Batcho[3], Yolande Sissinto-Savi de Tovè[1], Aboudou Daré[3], Dorothée Kindé-Gazard[1], Achille Kaboré[2]

[1]University of Abomey-Calavi, Cotonou, Benin, [2]RTI International, Washington, DC, United States, [3]Ministère de la Santé, Cotonou, Benin

There is a scarcity of data about the prevalence of Schistosomiasis (SCH) and Soil-Transmitted helminths (STH) in Benin. Initial surveys conducted decades ago showed highly focal and intense SCH infections around the mountainous regions of Atacora and Borgou. In 2013 the national NTD control program started an ambitious exercise of mapping all the communes for SCH and STH. The results of the new surveys will allow to launch mass drug campaigns for the control and or the elimination of SCH and STH in Benin. The mapping was carried out from March to April 2014 in 30 communes. In each commune, 5 villages/schools were selected purposely based on proximity with water bodies and anecdotal reports and clinical records from health facilities. In total, 7500 school children were surveyed in 150 primary schools throughout the 30 communes. In each school, 25 girls and 25 boys aged 8 to 14 years were randomly selected and both urine and stool samples collected from each child were analyzed using urine filtration and Kato Katz. Results were compared with historical data from WHO Atlas of SCH issued in 1987. ***S. haematobium*** was found in all 30 communes with a prevalence ranging from 0.80% (95% CI: 0 - 1.9) to 56.40% (95% CI: 50.3-62.6) while ***S. mansoni*** was found in only 16 communes with a prevalence from 0.40% (95% CI: 0-1.2) to 46.0% (95% CI: 39.8-52.2). At least 10 communes were co endemic for both urinary and intestinal SCH. The commune of Cobli showed the highest co-infection rate of 14% (95% CI: 7.2-20.8). All four common STH were found in stool samples with a predominance of hookworms followed by roundworm, whipworm. The overall prevalence of STH varied from 9.2% (95% CI: 5.6-12.8) to 60.0% (95% CI: 53.9-66.1). In comparison with historical data the results demonstrated a persistence and almost stagnant level of SCH endemicity located in the Atacora region where urinary SCH prevalence up to 60% were recorded 28 years ago. In all communes surveyed, children are suffering more for diseases related to the lack of sanitation and hygiene than water related disease. The prevalence remains stable for many years if no major environmental change occurs and if no mass treatment is undertaken.

528

LAMP: POINT-OF-CARE DIAGNOSIS FOR *SCHISTOSOMA MANSONI* AND *S. HAEMATOBIUM*

Nilanjan Lodh[1], Kei Mikita[2], Clive Shiff[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]National Defense Medical College, Tokorozawa City, Japan

Schistosomes are easily transmitted and multiply considerably so if control strategies based on targeted mass drug administration (MDA) are to succeed it is essential to have a simple to operate sensitive and accurate test. As the control programs operating become more and more effective in reducing the parasite burden in the individual, the issue of diagnostic sensitivity will become more critical in the assessment of program

effectiveness. We have demonstrated that species-specific DNA can be detected in human urine by PCR when some specimens are apparently egg negative. This method is effective in detecting and amplifying DNA from urine residue on Whatman No. 3 filter paper that is dried after filtration and can be stored for several months without freezing and easy to transport. In the current study done in a low to moderate transmission area in Ghana, we assessed the efficacy of detection of either or both ***Schistosoma mansoni*** and ***S. haematobium*** specific DNA from 86 urine residues both by PCR and loop mediated isothermal amplification (LAMP). We also compared the DNA extraction techniques by standard extraction kit and field usable LAMP PURE kit and have evaluated these procedures on species-specific DNA detection. With ***S. haematobium*** all three methods showed similar sensitivity and specificity when compared with PCR amplification (100%). For ***S. mansoni*** sensitivity was highest for LAMP amplification (100%) than PCR and LAMP PURE (99% and 94%). The LAMP PURE extraction produced false negatives, which require further investigation for this field usable extraction kit. Overall high positive and negative predictive values (90% - 100%) for both species were indicative of a highly robust approach. The same pattern was observed when stratified for sex specific analysis. LAMP approach is close to point of care use and more sensitive than detection of parasite eggs in urine or stool. Our approach with LAMP can be an effective means to detect low intensity infection and would enhance the effectiveness of surveillance and MDA control programs of schistosomiasis.

SCHISTOSOMIASIS SEROPREVALENCE IN THE GAMBIA

Muna Affara[1], Ine Van Loon[2], Serign Jawo Ceesay[1], Julia Mwesigwa[1], Alfred Amambua Ngwa[1], Umberto D'Alessandro[1], Davis Nwakanma[1]

[1]MRC, Banjul, Gambia, [2]Institute of Tropical Medicine, Antwerp, Belgium

Schistosomiasis or bilharzia remains a chronically debilitating and potentially lethal parasitic disease, affecting an estimated 200 million people globally, mostly in Sub Saharan Africa. The disease is caused by the blood fluke (trematoda) of the genus ***Schistosoma***, with both S***. haematobium*** and ***S. mansoni*** endemic in the Gambia. Country prevalence estimates for both species are based on historical data and stand at 0.5% for ***S. mansoni*** and 17.6% for S. ***haematobium*** respectively. With no comprehensive survey conducted on schistosomiasis in the Gambia in the past 30 years, there is little understanding of how the prevalence of this neglected tropical disease might have changed. We conducted a preliminary survey of 3277 school-aged children in the eastern part of the Gambia in 2011 which revealed S. ***haematobium*** prevalence of 7.5% (range 0.9 - 44.8%) based on urine egg counts from a single time point. Although likely to be an underestimation, it nevertheless, showed that the disease is localized to a number of ***foci*** in the region and remains a public health problem in the Gambia. A better understanding of the epidemiology of Schistomiasis across the entire country and in all age groups is required to inform effective control interventions. We therefore carried out a nationwide seroprevalence survey of Schistosomiasis in the Gambia using ELISA screening of 4000 dried blood spot (DBS) samples collected from all 6 regions (32 villages) across the length of the Gambia in 2012. This is the first comprehensive survey in recent years to analyse the distribution of infection within the country and provides a rapid and cost effective screening tool for surveillance of infection capable of supporting focused intervention in the Gambia.

530

ELEVATED P-GLYCOPROTEIN AND MDR1 LEVELS CORRELATE WITH REDUCED PRAZIQUANTEL SUSCEPTIBILITY IN *SCHISTOSOMA JAPONICUM*

Wei Wang, Zhengyang Zhao, Yousheng Liang

Jiangsu Institute of Parasitic Diseases, Wuxi, China

Schistosomiasis ***japonica*** remains a major public health concern in China. Currently, praziquantel is virtually the only drug of choice for the treatment of human ***Schistosoma japonicum*** infections. Following long-term extensive use, there is a worry about the emergence of praziquantel-resistant parasites. It has been proved that ***S. japonicum*** may develop resistance to praziquantel under drug pressure. P-glycoprotein and MDR1 have been shown to be involved in the resistance to praziquantel in ***S. mansoni***. We investigated and compared the expression of P-glycoprotein and MDR1 at various developmental stages of praziquantel-susceptible and -resistant isolates of ***S. japonicum*** using quantitative real time PCR (qRT-PCR) and Western blotting assay. Significantly elevated P-glycoprotein and MDR1 levels were detected in praziquantel-resistant isolate than in susceptible isolate at the developmental stages of miracidia, cercariae, and adults at both protein and mRNA levels ($P < 0.01$). It is concluded that elevated P-glycoprotein and MDR1 levels may correlate with reduced praziquantel susceptibility in ***Schistosoma japonicum***

EPIDEMIOLOGICAL STUDY OF ZOONOTIC SCHISTOSOMIASIS AMONG WATER BUFFALOES IN DIFFERENT ENDEMIC AREAS IN THE PHILIPPINES

Jose Ma. M. Angeles[1], Lydia R. Leonardo[2], Yasuyuki Goto[3], Masashi Kirinoki[4], Kharleezelle Moendeg[1], Elena A. Villacorte[2], Noboru Inoue[1], Yuichi Chigusa[4], Shin-ichiro Kawazu[1]

[1]Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan, [2]Department of Parasitology, College of Public Health, University of the Philippines, Manila, Philippines, [3]Laboratory of Molecular Immunology, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Tokyo, Japan, [4]Department of Tropical Medicine and Parasitology, Dokkyo Medical University, Tochigi, Japan

The contribution of animals in the transmission of the zoonotic schistosomiasis caused by ***Schistosoma japonicum*** has been already established in several studies. However despite this significant role, animals were not given much importance in the control of this parasitic disease. Among these animals, water buffaloes are perceived to be the most important as they are continuously and constantly exposed to the parasites in the transmission sites. In this study, a cross-sectional study was done among water buffaloes in endemic areas in the Philippines. Study sites include municipalities with varying degrees of endemicities for schistosomiasis ranging from near elimination areas (Talibon and Trinidad) to moderate (New Corella and Gonzaga,) to highly endemic area (Calatrava and Catarman). Samples were tested using microscopy, stool PCR, SEA-ELISA, SjTPx-1 ELISA and Sj1TR ELISA. Results showed significant positivities for schistosome infection in all the municipalities with the highest prevalence at 45.7% seen in Catarman and 40.5% in Gonzaga. Water buffaloes also tested positive in near elimination areas of Talibon (15.7%) and Trinidad (20.6%). This proved that high prevalence in water buffaloes does not really reflects the human prevalence but represents the threat of human transmission. Water buffaloes are good indices for human transmission of ***S. japonicum*** parasite and should therefore be included formulating elimination guidelines to prevent emergence and re-emergence of zoonotic schistosomiasis.

532

UTILIZATION OF COCKTAIL-ANTIGEN ELISA FOR THE DETECTION OF ZOONOTIC SCHISTOSOMIASIS IN MULTIPLE HOST SPECIES

Kharleezelle J. Moendeg[1], Jose Ma. M. Angeles[1], Yasuyuki Goto[2], Lydia R. Leonardo[3], Masashi Kirinoki[4], Elena A. Villacorte[3], Pilarita T. Rivera[3], Noboru Inoue[1], Yuichi Chigusa[4], Shin-ichiro Kawazu[1]

[1]Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Japan, [2]Laboratory of Molecular Immunology, Department of Animal Resource Sciences, Graduate School of Agricultural and Life Sciences, University of Tokyo, Tokyo, Japan, [3]Department of Parasitology, College of Public Health, University of the Philippines, Manila, Philippines, [4]Laboratory of Tropical Medicine and Parasitology, Dokkyo Medical University, Tochigi, Japan

Due to the zoonotic nature of the ***Schistosoma japonicum*** parasite, the development of a unified surveillance in multiple host species is necessary to strengthen the current schistosomiasis control. Among these animals, dogs and water buffaloes were identified as the most important reservoirs contributing to ***S. japonicum*** human transmission. Previous studies showed that thioredoxin peroxidase-1 (SjTPx-1) and tandem repeat proteins (Sj1TR, Sj7TR) were good diagnostic antigens individually in humans, water buffaloes and dogs. This study aimed to test the diagnostic potentials of mixing these recombinant antigens in different combinations in a cocktail-ELISA against the samples from the three host species obtained from endemic areas in the Philippines. As compared with the diagnostic potential calculated for each of the three recombinant antigens used, their combination has presented improved specificities, positive predictive values and kappa values. Results showed that the cocktail-ELISA having the combination of SjTPx-1/Sj7TR/Sj1TR has the highest sensitivity (84.1% in humans, 80% in water buffaloes and dogs) and specificity (100% in all host species). The results of this study indicate the potential of the optimized cocktail-ELISA used in the development of a common diagnostic tool that will improve the surveillance for zoonotic schistosomiasis in multiple host species.

533

DEFINITIVE DIAGNOSTICS ARE CRITICAL FOR ELIMINATION OF SCHISTOSOMES INFECTIONS

Clive J. Shiff

Johns Hopkins University, Baltimore, MD, United States

As our understanding of parasite epidemiology expands and to meet the needs of large scale and repeated mass drug administration to control or even eliminate the problem, there is a critical need for accurate definitive diagnostics. While point-of-care tests are useful in planning interventions, their lack of sensitivity overlooks a large proportion of cases either miss-diagnosed or inadequately treated but yet sufficiently productive with parasite eggs to repopulate the intermediate host snails with parasites. This is particularly important with schistosomes that are transmitted by massive intramolluscan reproduction. Irrefutable evidence from numerous sources indicates that relying on detection of eggs in urine or fecal specimens will miss a large proportion of infected persons. This has been shown in two recent studies of ***S. japonicum***, in China, that mentioned a six fold increase of prevalence using DNA detection in serum and more recently in the Philippines which showed an increase in prevalence from 22.9% to 90.2% in a cohort examined by Kato-Katz method and rtPCR of stool. Studies in Zambia showed that PCR detection of ***S. mansoni*** specific DNA in urine residue on filter paper yielded a prevalence of 89% in a heterogeneous group of people, whereas Kato Katz detected 51% and CCA detected 60% of infections. In her original work with urine based DNA detection found in Nigeria that of a cohort of 89 adults, 64.0% were found to carry parasite specific DNA in urine, while eggs were found in only 48.3%. Diagnostic tests with poor sensitivity will be misleading and will miss partial cures and low intensity infection which may not be a serious problem for the patient, but it will certainly not eliminate the infection from communities or from regions. Available point of care schistosomiasis tests are insufficient to assess the epidemiology of schistosomiasis associated with mass drug administration programs currently under way.

534

DIAGNOSTIC PERFORMANCE OF SCREENING METHODS FOR URINARY SCHISTOSOMIASIS IN A SCHOOL-BASED ANTIHELMITHIC PROGRAM IN RURAL ENDEMIC DISTRICT, TANZANIA

Billy Ngasala

MUHAS, Dar es Salaam, United Republic of Tanzania

Diagnostic performance of screening methods varies in different endemic zones, age groups and sexes especially when there is low prevalence. This study aimed at evaluating the diagnostic performance of screening methods for urinary schistosomiasis after wide scale use of praziquantel in a school based antihelminthic control programme in Mbozi District. A cross-sectional study was conducted from March to June, 2013. A total of 429 participants from standard I - VII were chosen proportionally from twelve schools which were obtained through multistage cluster random sampling. The diagnostic performance of screening tests were compared with microscopic examination of urine for ***Schistosoma haematobium*** egg (filtration method, which was regarded as the gold standard) Chemical reagent strip for haematuria was the most sensitive of all screening methods assessed with sensitivity of (78.8%) also with high NPV (97.8%), followed by self-reported haematuria (51.9%), and visual examination of urine was least sensitive of all (42.4%). In terms of specificity, self-reported haematuria was the most specific (91.7%) with positive predictive value (34.9%). In conclusion, chemical reagent strip and history of haematuria are still useful diagnostic tools for targeting Praziquantel-MDA to school children in schistosomiasis endemic areas.

535

PRODUCT INNOVATION IN SCHISTOSOMIASIS AND ITS POTENTIAL ROLE IN PREVENTING CO-INFECTIONS

Jutta Reinhard-Rupp

Merck Serono, Coinsins, Switzerland

At Merck Serono, R&D Global Health aims at delivering innovative, integrated and affordable solutions to tackle unmet medical needs of poverty-related diseases, focusing on pediatric health solutions for schistosomiasis and malaria. In this context, a recently formed public-private partnership has been established with the goal to develop, register, manufacture and launch a pediatric formulation of praziquantel (PZQ). Younger children (< 6 yr) suffering from schistosomiasis are currently left untreated due to a missing pediatric formulation of PZQ, resulting in a manifestation of the disease during early childhood. An international consortium has been formed which consists of Merck KGaA, Astellas, the Swiss TPH Institute, TI Pharma, Farmanguinhos and Simcyp. This consortium showcases the importance of working in partnership to leverage and synergize expertise, know-how and resources and is currently completing Phase I of clinical development. Amongst all different consequences, schistosomiasis may cause significant damage to the human genitalia: in particular, Female Genital Schistosomiasis (FGS) represents a common complication mainly caused by ***Schistosoma haematobium.*** The consequences of FGS are not widely acknowledged and could be more significant than suspected until now: recent studies have substantiated the plausibility that FGS may elevate general transmission of HIV and that control of schistosomiasis might have an impact on HIV/AIDS. Access to anti-schistosomal treatment in the battle against HIV, sexually transmitted infections (STIs) and other reproductive tract morbidities is therefore of high interest, and partnerships are being built to define a research platform for further clinical testing. In this context, a new pediatric formulation of PZQ plays a very active role, not

only in the effort towards elimination of schistosomiasis, but also with respect to regular treatment of young girls which may potentially prevent HIV, STIs and/or other diseases affecting the reproductive tract.

MEASURING THE PERFORMANCE AND IMPACT OF THREE ANNUAL NATIONAL TREATMENTS FOR SCHISTOSOMIASIS AND SOIL TRANSMITTED HELMINTHES IN MALAWI

Jane M. Whitton[1], Samuel Jemu[2], Michelle Clements[1], Fiona Fleming[1]

[1]Schistosomiasis Control Initiative, London, United Kingdom, [2]Malawi Ministry of Health, Lilongwe, Malawi

Since 2012, the Malawi Ministry of Health with the technical support of the Schistosomiasis Control Initiative has successfully carried out three national treatment campaigns totalling 8,400,000 treatments with praziquantel to treat schistosomiasis and albendazole for soil transmitted helminth infections (STH). We present results from two different surveys assessing the programmatic performance – impact monitoring and coverage surveys. Twenty-two schools were randomly selected from districts with moderate and high prevalence, as sentinel sites for impact evaluation. Cross-sectional parasitological data was collected to evaluate the reduction in prevalence and high-intensity infection of ***S. mansoni*** and STH, and ***S. haematobium*** using Kato Katz technique and urine filtration, respectively. At baseline in 2012, 2642 children were surveyed, 2304 in 2014, and an additional 2,640 children in the same schools were surveyed during the second follow up in 2015. Reductions in prevalence and high-intensity infection were observed for both ***Schistosoma*** species and STH in all but one school with varying impact. To validate the performance in terms of treatment coverage, two multi-stage cluster surveys were used. The first survey was conducted in 2 districts after the 2012 treatment campaign and a second was done in 6 districts after the 2014 campaign. Findings highlighted the need to increase treatment coverage of non-enrolled school-age children and adults particularly in areas known for high transmission. Alternative information channels, as well as the quality and frequency of treatment messages to communities also needs to be reviewed to improve community participation. Results from the latest survey show that the national NTD control programme has improved its performance, shown an impact on prevalence and intensity, improved its process monitoring and sensitisation within the districts, all of which lead to a more effective program; however, many areas still need to be improved in order to maximise the performance of Malawi's treatment campaigns if they are to achieve elimination.

537

COMPARISON OF FULL AGE-INTENSITY PROFILES FOR SCHISTOSOMIASIS AND SOIL-TRANSMITTED HELMINTH INFECTION FROM A TWO-YEAR STUDY IN UGANDA

Arminder Kaur Deol[1], Maria-Gloria Basáñez[2], Martin Walker[2], Edridah Muheki Tukahebwa[3], Fiona Fleming[1], Judy Fernandez[1], Michael French[1]

[1]Schistosomiasis Control Initiative, London, United Kingdom, [2]Imperial College London, London, United Kingdom, [3]Ministry of Health, Kampala, Uganda

Many large-scale schistosomiasis and soil-transmitted helminth (STH) control programmes are now operational. Most of these also incorporate a monitoring and evaluation component which aims to estimate the impact of the control programme on levels of infection in a population, often using data collected from school-aged children (who are usually the target for treatment). The age-intensity (AI) profiles developed from this information could be used to help provide an accurate picture of the current infection patterns in endemic countries. In the present study data were collected from 7500 individuals across a wide age-range (1 - 103 years) from 10 different sites in Uganda which displayed a range of underlying endemicities and treatment histories. Data were collected from 3 different representative prevalence and treatment history groups: 1. "low prevalence and treated" - areas that have supressed transmission as a result of MDA; 2. "low prevalence and untreated" -areas that are at low-prevalence endemic equilibrium; 3. "high prevalence and treated" - areas still experiencing high levels of infection after multiple treatment rounds. The AI profiles of each of the major helminth species infecting humans in these regions were then developed. The analysis has been separated by parasite species, sex of host, and prevalence/treatment history group. Results showed that the age-infection profile for S. mansoni followed similar patterns as found in previous studies. However, group 1 and group 2 sites followed this pattern more closely. For the STHs, the overall prevalence was low and a trend could only be seen in the AI profile for hookworm infection, where infection intensities increased with age and reached a plateau. The same information in this study will be collected at one year following treatment which will allow a fuller evaluation of the impact of treatment in the different settings and parts of the community. The opportunity will be taken to estimate the age-specific force of infection and the basic reproductive number, R0, using these AI profiles. The findings from these will be discussed as well as the conclusions from the full AI analysis.

538

USING SURFACTANTS TO DISPERSE NICLOSAMIDE ON SCHISTOSOME INFESTED WATERS

Amsul Khanal, Michael Hsieh

Biomedical Research Institute, Rockville, MD, United States

Schistosomiasis, a parasitic disease with socioeconomic burden that rivals malaria, is prevalent in developing areas in Africa and Asia and affects upwards of 200 million people worldwide. Snails are the intermediate carriers for the Schistosoma (the infecting parasite), which emerge as cercariae, the larval form which infects humans. Niclosamide, an FDA approved molluscicide, is used to control snail growth and has shown cercariacidal effects as well. Niclosamide is usually hand sprayed onto infested water bodies using mechanical pumps. Suspensions of niclosamide have surface tensions of approximately 71 mN/m, which are close to that of water. This limits the surface transport of these suspensions once they land on water, and hence they have to be sprayed over the whole water body to cover all of the area. Niclosamide use has also resulted in fish and tadpole die-off, which has been attributed to non-uniform distribution of niclosamide when sprayed onto bodies of water. We are attempting to develop the use of surfactants for spreading of niclosamide and to maintain niclosamide concentrations that are lower than the LD50 for fishes and tadpoles so as to reduce die-off but still control snail and cercarial growth. Surfactants are surface active agents that can reduce the surface tension of formulations. Due to reductions in surface tension when sprayed onto water bodies, these suspensions can spread and disperse across the surface via surface tension gradients. This is beneficial as it can allow for the suspension to be sprayed onto a smaller area and still cover the whole affected area. With microliter scale droplets, we have observed that these suspensions can cover areas much larger than those covered by their surfactant-free counterparts at similar volume. We suspect that niclosamide travels along with the spreading drop, which will be confirmed with resonance light scattering (RLS). RLS has previously been used to measure very low niclosamide concentrations with precision. After establishing that surfactants allow for surface transport of niclosamide, it will be important to test and implement this novel technology using sprays and aerosols.

539

UNDIAGNOSED ACUTE SCHISTOSOMIASIS AND DEVELOPMENT OF NEUROSCHISTOSOMIASIS IN ONE OF FIVE TRAVELERS AFTER FIVE YEARS POST-EXPOSURE

Marta G. Cavalcanti[1], Aline Ferreira Cunha[1], Luiz Felipe Guimarães[1], Victor Gonçalves Lopes[2], José Mauro Peralta[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Hospital Federal dos Servidores do Estado, Rio de Janeiro, Brazil

Unsuspected Schistosoma infection after exposure to contaminated waters represents a challenge in travelers returning from endemic areas. Acute manifestations may be inconspicuous in addition to risk of disability-related outcomes. Neuroschistosomiasis (NS) is one of the most severe clinical forms of ***Schistosoma mansoni*** infection, presenting with no or low parasite load. Also, NS may occur without concomitant intestinal and/or hepatic disease. Herein, we report five cases of S.mansoni infection undiagnosed during acute phase and progression to NS in one of the cases after five years post-exposure. Five adult males (ages: 29 to 36 y) became infected with S.mansoni during a trip to Simonésia (Minas Gerais, Brazil) in 2009. One week post exposure, four out of five reported symptoms like malaise, local transient itching in two, epigastric discomfort in one and a three week duration fever in another. In 2014, the later individual complained of acute back pain, weakness and pain on lower limbs. Also, progressive paraparesis and paraplegia with loss of urinary and bowel sphincter control and erectile dysfunction were reported. MRI showed a thickening of cauda equina roots and specific anti-Schistosoma antibodies were detected in cerebrospinal fluid. Ultrasound excluded hepatic disease. Albeit coproscopy was negative, IgG and IgE anti-***Schistosoma*** were detectable and real-time PCR demonstrated DNA amplification in serum and fecal samples, respectively. Corticoid pulse therapy and praziquantel were initiated. In another traveler of the group, epigastric discomfort was the solely symptom persisting for the past 2-3 years while no manifestations were reported by the others. Among the four cases, active Schistosoma infection was confirmed by coproscopy and/or DNA amplification and high levels of specific IgG and IgE in three travelers and only by serology in one. Single dose of praziquantel was prescribed. Diagnosis and treatment of returning travelers from schistosomiasis endemic areas may require not only clinical and epidemiological suspicion but also the use of accurate diagnostic tools such as immunodiagnosis and DNA - based assays.

540

IMPACT OF THE DESIGN OF PREVENTIVE CHEMOTHERAPY STRATEGY ON CONTROL AND ELIMINATION OF SCHISTOSOMIASIS

James Truscott, Roy Anderson

Imperial College London, London, United Kingdom

The World Health Organisation's (WHO) 2020 Roadmap on NTDs has targeted schistosomiasis for control and elimination in the Americas and selected countries in Africa by 2020. WHO's guidelines recommend control through the repeated administration of praziquantel to school-aged children (SAC) in affected communities, at levels defined by baseline infection prevalence. We assess the expected impact of these guidelines using a deterministic model of parasite dynamics within the host community in combination with a description of the demography of the host population and its contact with reservoirs of infection. The model is fitted to baseline datasets for host infection intensity with age from high, moderate and low risk areas. We examine the impact of the current treatment guidelines on schistosome infection prevalence and intensity with age in 2020 and beyond. Additionally, we investigate under what conditions elimination might be achieved and whether additional drug supplies are better spent extending treatment to adults compared to increasing the treatment frequency among SAC.

541

MASS DRUG ADMINISTRATION STRATEGIES TO CONTROL SCABIES IN A HIGHLY ENDEMIC POPULATION

Lucia Romani[1], Margot J. Whitfeld[2], Josefa Koroivueta[3], Mike Kama[4], Lisi Tikoduadua[5], Meciusela Tuicakau[4], Aminiasi Koroi[4], Ross Andrews[6], John Kaldor[1], Andrew C. Steer[7]

[1]The Kirby Institute, Sydney, Australia, [2]St. Vincent's Hospital, Sydney, Australia, [3]Ministry for Women, Children and Poverty Alleviation, Suva, Fiji, [4]Ministry of Health, Suva, Fiji, [5]Colonial War Memorial Hospital, Suva, Fiji, [6]Menzies School of Health Research, Darwin, Australia, [7]Murdoch Children's Research Institute, Melbourne, Australia

Recently added to the World Health Organization list of neglected tropical diseases, scabies is an under-recognised case of morbidity in many developing countries, due to secondary bacterial infection of the skin leading to septicaemia, kidney disease and potentially rheumatic heart disease. Countries of the Pacific region have a particularly high burden of scabies and its complications. Control of scabies based on treatment of individual cases is difficult due to frequent re-infestation. We implemented a large-scale intervention trial of Mass Drug Administration (MDA) for endemic scabies to ascertain the efficacy and safety of two alternative regimens (topical permethrin and oral ivermectin MDA) compared with current standard care. We identified 3 isolated island communities to which we randomly assigned one of the 3 treatment regimens. The study enrolled 2051 people: 803 participants in the standard care arm, 716 in the ivermectin arm and 532 in the permethrin arm. In each site, the proportion of the total island population enrolled was >85%. At baseline, scabies prevalence was found to be high in all arms, with the highest prevalence in the permethrin arm (41.7%) followed by 36.6% in the standard care arm and 32.1% in the ivermectin arm. A year after the intervention we observed a considerably greater reduction in scabies prevalence in the ivermectin arm with a prevalence of 1.9% corresponding to a relative risk reduction (RRR) of 94% (95% CI 83-100). The prevalence of scabies was reduced in the 2 other arms, however with lower effect size: permethrin RRR 62% (95% CI 49-75) and standard care RRR 49% (95% CI 37-60). The prevalence of impetigo was also high at baseline, ranging from 20% to 24%. The effect of the intervention followed a similar trend to that of scabies, with greatest reduction in the ivermectin arm (RRR 67%, 95% CI 52-83) compared to the permethrin arm (RRR 54%, 95% CI 35-73) and the standard care arm (RRR 32%, 95% CI 14-50). These results show that ivermectin MDA is a highly effective strategy for reducing community scabies prevalence and demonstrate the potential role of MDA in addressing a serious cause of illness in many developing countries.

542

HOW TO OPTIMALLY DIAGNOSE *ORIENTIA TSUTSUGAMUSHI* OR *RICKETTSIA TYPHI* INFECTIONS IN PATIENTS WITH CENTRAL NERVOUS SYSTEM DISEASE?

Sabine Dittrich[1], Phonepasith Panyanivong[2], Soulignasak Thongpaseuth[2], Daniel H. Paris[3], Stuart D. Blacksell[3], Rattanaphone Phetsouvanh[2], Paul N. Newton[1]

[1]Lao-Oxford-Mahosot Hospital Wellcome Trust Research Unit, Microbiology Laboratory, Mahosot Hospital, Lao PDR and Centre for Tropical Medicine and Global Health, Churchill Hospital, University of Oxford, Vientiane, Lao People's Democratic Republic, [2]Lao-Oxford-Mahosot Hospital Wellcome Trust Research Unit, Vientiane, Lao People's Democratic Republic, [3]Mahidol Oxford Tropical Medicine Research Unit and Center for Tropical Medicine and Global Health, Churchill Hospital, University of Oxford, Bangkok, Thailand

The importance of ***Orientia tsutsugamushi*** (scrub typhus, ST) and ***Rickettia typhi*** (murine typhus, MT) not only as causes of fever but also severe infections with central nervous system (CNS) involvement has recently been highlighted. In order to reduce morbidity and mortality, early diagnosis is important to guide anti-rickettsial therapy. The aim of this

study was to investigate the value of different diagnostic tests in diagnosis of rickettsial CNS disease. As part of a hospital-based study in Laos (n=1011), quantitative PCRs (qPCR) and antibody-based rapid diagnostic tests (RDTs; ST: IgM/IgG Standard Diagnostic, Korea; MT: IgM GeneBio, USA) were used with different sample types (CSF, buffy coat, plasma, serum) and compared to a combined reference group (Immunofluorescent assay (IFA), qPCR). Bacterial loads and positivity rates in relation to epidemiological characteristics and sample type were analyzed. Approximately half of the patients had paired CSF and blood available with 3.1% of blood and 1.2% of CSF samples positive for O. tsutsugamushi by qPCR. For Rickettsia spp. the same proportion of CSF and blood samples was positive by qPCR (0.8%; n=509). No significant correlations between bacterial loads and sample type, age, fever days and severity could be identified. The majority of ST was detected, by qPCR or IFA, between 4 and 8 days post-disease onset while MT was detected between day 1 and 4. In this pilot study the RDTs for ST exhibited a sensitivity of 71.4% (10/14) with plasma and 35.7% (5/14) with CSF compared to qPCR or IFA. For MT the sensitivity of RDTs using both sample types was low with 7.7% (1/13) and 0% (0/13) for plasma and CSF, respectively, in comparison to qPCR or IFA. Specificities for all sample types and test were between 85-100%. Planned latent class modeling will allow a more in-depth analysis of the test characteristics. These data illustrate the myriad difficulties of rickettsial diagnosis, even in severe disease. We will discuss new approaches to improve diagnosis based on epidemiological clues and combined molecular and serological methods to guide innovative developments in the future.

543

GEOGRAPHIC VARIATION IN THE MICROBIOTA OF *IXODES* TICKS FROM THE EASTERN UNITED STATES

Steven R. Meshnick[1], Will Van Treuren[2], Loganathan Ponnusamy[3], Antonio Gonzalez[4], Christian Parobek[1], Jonathan Juliano[1], Theodore Andreadis[5], Richard Falco[6], Jory Brinkerhoff[7], Lorenza Beati Ziegler[8], Nicholas Hathaway[9], Corina Keeler[1], Michael Emch[1], Jeffrey Bailey[9], Michael Roe[3], Charles Apperson[3], Rob Knight[10]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Stanford University, Palo Alto, CA, United States, [3]North Carolina State University, Raleigh, NC, United States, [4]University of Colorado, Boulder, CO, United States, [5]Connecticut Agriculture Station, New Haven, CT, United States, [6]Fordham University, Armonk, NY, United States, [7]University of Richmond, Richmond, VA, United States, [8]Georgia Southern University, Statesboro, GA, United States, [9]University of Massachussetts, Worcester, MA, United States, [10]University of California San Diego, San Diego, CA, United States

Ixodes scapularis is the principle vector of Lyme disease in the East coast and upper Midwest regions of the United States, yet the tick is also present in the Southeast, where Lyme disease is absent or rare. A closely related species, I. affinis also carries the pathogen in the South but does not seem to transmit to humans. In order to better understand the microbial community structure and its geographic differences, we analyzed the microbiomes of 89 adult ***I. scapularis*** and affinis ticks captured in 15 locations in South Carolina, North Carolina, Virginia, Connecticut and New York. Initially ticks from 4 sites were analyzed by 454-pyrosequencing. Subsequently, ticks from these sites plus 11 others were analyzed by Illumina MiSeq. Data were analyzed using the QIIME-based pipeline. By both analyses, female tick microbiomes were significantly less diverse than those of male ticks. The dissimilarity between tick microbiomes increased with distance between sites. The genus Rickettsia was prominent in all locations. ***Borrelia*** was also present in most locations, and was especially high in one site in Western Virginia. In contrast, Enterobacteriacea was very common in North Carolina ***I. scapularis*** but uncommon in North Carolina I. affinis and in ***I. scapularis*** from other sites. These data suggest substantial variations in the ***I. scapularis*** microbiome associated with geography.

DEER REDUCTION REDUCES THE FORCE OF ENZOOTIC TRANSMISSION OF *BABESIA MICROTI*

Heidi Goethert, Sam Telford III

Tufts University School of Veterinary Medicine, North Grafton, MA, United States

The public health burden of Lyme disease and the associated guild of deer tick-transmitted infections has increased in the northeastern U.S. in the last decade. The only intervention that may stably reduce vector density is deer reduction. However, evidence demonstrating a long term change in enzootic transmission due to deer reduction remains to be presented. We hypothesized that the agent of human babesiosis, ***Babesia microti***, may be less efficiently transmitted than those of Lyme disease or granulocytic ehrlichiosis and thus may be sufficiently sensitive to detect evidence of reduced transmission within a short ecological time frame after intervention. Accordingly, we compared the force of B. microti transmission on Great Island (GI), MA, where the seminal deer reduction experiment was initiated in 1984; deer tick densities were reduced by 80% as a result and have been maintained at the same low level ever since. Our comparison site was Nantucket Island, where no such intervention has occurred. A main reservoir host for B. microti, Peromyscus leucopus, was intensively sampled from 1984 to 1997 and on an ad hoc basis since. Archived blood samples were analyzed for the presence of B. microti and positive samples genotyped using a variable number tandem repeat (VNTR) assay. The prevalence of infection in mice on GI decreased significantly from 72% (95% confidence interval 62-81) in the late 1980s to 44% (35-53) in the 1990s. The prevalence of infection in mice from Nantucket did not differ between the two time periods, 64% (52-75) and 59% (47-70), respectively. The diversity of B.microti VNTR genotypes, as measured by Shannon indices, tended to diminish from the 1980s to the 1990s on Great Island (P=0.08), while the diversity increased on Nantucket. We conclude that deer reduction reduced the force of transmission of B. microti on Great Island as a result of reduced infestation of mice by subadult deer ticks.

545

PROBING THE GENOMIC DIVERSITY OF THE TICK-BORNE PATHOGEN, *BABESIA MICROTI*

Giovanna Carpi[1], Katharine S. Walter[1], Choukri Ben Mamoun[2], Peter Krause[1], Adalgisa Caccone[3], Maria Diuk-Wasser[4]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Yale School of Medicine, New Haven, CT, United States, [3]Yale University, New Haven, CT, United States, [4]Columbia University, New York, NY, United States

Babesia microti is an emerging pathogen causing human babesiosis, a malaria-like febrile illness whose geographic range and human incidence are on the rise in the United States. Despite the epidemiological relevance of ***B. microti***, little is known about its standing genetic variation, population dynamics, and the genetic basis of human virulence. A major bottleneck in our understanding of the ***B. microti*** genetic diversity stems from the difficulty to efficiently obtain sufficient number of whole genome sequences of this parasite from vector or clinical samples, without the need to propagate strains in rodents. To start probing ***B. microti*** genomic diversity we adopted hybrid capture techniques to enrich for and sequence ***B. microti*** strains directly from 22 tick and clinical samples originated form 12 geographic sites in US. Hybrid capture enabled efficient sequencing across these samples, yielding a minimum of 15X coverage across >92% of the target ***B. microti*** genome (6.4Mb) (mean coverage: 320X). We identified up to 2,574 single nucleotide polymorphisms across these samples, enabling a first assessment of patterns and levels of ***B. microti*** strain genomic variation in ticks and humans.

546

ELUCIDATING THE ROLE OF INFILTRATING IMMUNE CELLS AT THE TICK-HOST INTERFACE DURING POWASSAN VIRUS INFECTION

Meghan E. Hermance, Rodrigo I. Santos, Saravanan Thangamani

The University of Texas Medical Branch, Galveston, TX, United States

Tick-borne diseases continue to emerge in the United States, as demonstrated by the identification of three new tick-borne pathogens (***Heartland virus***, ***Ehrlicha muris***-like agent, ***Borrelia miyamotoi***) and the expanding geographic range of ***Powassan virus*** (POWV) in the past few years. POWV is a neuroinvasive virus transmitted to humans by infected tick bites. Skin is the interface between an attached, feeding tick and a host; consequently, it is the first line of defense against invading pathogens that are delivered to a vertebrate host together with tick saliva at the bite site. POWV can be transmitted to a host as early as one hour after attachment and initiation of tick feeding. To our knowledge, no research has systematically examined the host immune response during the earliest stages of tick-borne virus transmission at the tick-host interface (i.e. the skin). The objective of this study was to immunophenotype infiltrating immune cells and to identify POWV-infected cells at the tick bite site during early feeding time points. We expect that this data will provide us with a better understanding of the role of cutaneous and infiltrating immune cells during the early stages of POWV-infected tick feeding. In the present study we fed POWV-infected and uninfected ***Ixodes scapularis*** nymphs on naïve mice for 3, 6, 12, and 24 hours (1 tick per mouse). 4-µm sections were taken near the mouthparts of each feeding tick. Infiltrating immune cells and POWV-infected cells at the tick bite site were identified by immunohistochemistry. Our data clearly demonstrates that the hypostome of ***I. scapularis*** nymphs penetrate to the subcutaneous layer of the skin during the feeding process. After 12 and 24 hours of tick feeding we have identified macrophages and fibroblasts that stained positive for POWV at the tick bite site. Complete immunophenotyping of infiltrating immune cells for all time points of tick feeding (3, 6, 12, and 24 hours post-infestation) is underway. The location, timing, identity, and quantity of immune cells determined via histology will enable us to define the quality and kinetics of the host response to tick-borne POWV infection.

547

DISTRIBUTION AND SURVIVAL OF *BORRELIA MIYAMOTOI* IN HUMAN BLOOD COMPONENTS: RELATIONSHIP TO TRANSFUSION TRANSMISSION

Laura Tonnetti, Aaron Thorp

American Red Cross, Rockville, MD, United States

Borrelia miyamotoi (Bm), the agent of relapsing fever is a tick-borne spirochete, first isolated in Japan in 1994. Since then, the spirochete has been detected in ticks globally, generally in the same vectors as the Lyme disease agent. Human infection has been reported in Russia, Europe, Japan and the U.S., as influenza-like febrile illness. Two cases of meningoencephalitis caused by ***Bm*** have been reported in immunocompromised patients. We explore the distribution and infectivity of the spirochete in human blood components after separation and storage, using standard blood bank conditions. Freshly collected human whole blood was spiked with ***Bm***-infected mouse plasma and separated into red blood cells (RBCs), plasma and platelets. Bacterial counting in the components after separation determined that the majority of the bacteria were found in the RBCs fraction. Components were injected into immunocompromised (SCID) or wild type mice (***Peromyscus leucopus***), either after collection of after storage at 4°C for the RBCs and -20°C for plasma. Platelet samples were not stored. Infection was determined by increasing spirochetemia in the mouse blood collected at different time points. Spirochetemia was detectable in all the SCID animals (30 total) injected with RBCs, either before or after storage for 21 and 42 days. Similarly, all SCID mice (20 total) injected with plasma and platelets derived from ***Bm***-spiked whole blood before storage developed spirochetemia. In the wild-type mice, 9 out of 10 developed infection when challenged with RBCs before storage or after 21 days in both groups, while RBC samples stored for 42 days infected 5 of 10 wild-type mice. Plasma and platelet samples before storage infected 5 of 10 and 6 of 10 challenged ***P. leucopus,*** respectively. Also, SCID mice were unable to clear the infection by the last observation (day 30) while, in the wild- type mice, spirochetes were not detectable after day 20. None of the mice developed the infection when injected with frozen plasma. This study demonstrates that ***Bm*** survives standard storage condition of most human blood components, suggesting the possibility of transmission by blood transfusion.

548

MAPPING OF DENGUE VIRUS SEROTYPE 2 NEUTRALIZING ANTIBODIES HIGHLIGHTS A QUATERNARY STRUCTURE EPITOPE

Emily N. Gallichotte, Doug Widman, Boyd Yount, Ralph Baric, Aravinda de Silva

University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Dengue fever and dengue hemorrhagic fever are caused by the four serotypes of dengue virus (DENV), which circulate globally. Dengue serotype 2 (DENV2) is widespread and frequently responsible for severe epidemics. DENV2 infections stimulate durable, serotype-specific neutralizing and protective antibodies in people. The leading live tetravalent dengue vaccine was protective against DENV1, DENV3 and DENV4, but not DENV2. The epitope of protective antibodies that develop in people following DENV2 infections have not been defined. Here we show that DENV2 specific neutralizing antibodies target a quaternary epitope that is only displayed on intact virus particles. By mapping human DENV2 type-specific monoclonal antibodies and using recombinant viruses, we demonstrate that the majority of DENV2 specific neutralizing antibodies in immune sera use a complex epitope. The epitopes recognized by DENV2 neutralizing antibodies include envelope domain III (EDIII) of one E monomer and additional regions on adjacent E proteins. Thus, the display of this epitope requires the assembly of E protein into higher order structures. Our results reveal the identity of a major neutralizing epitope of DENV2 that is targeted by natural infection and a live virus vaccine induced antibodies. The identification of DENV2 type-specific neutralizing antibody epitopes could be harnessed to evaluate antibody response of vaccines under development and develop next generation vaccines.

AN ATOMIC-LEVEL FUNCTIONAL MODEL OF DENGUE VIRUS ENVELOPE PROTEIN INFECTIVITY

Elizabeth A. Christian, Kristen M. Kahle, Kimberly-Anne Mattia, Bridget A. Puffer, Jennifer M. Pfaff, Adam Miller, Cheryl Paes, Edgar Davidson, **Benjamin J. Doranz**

Integral Molecular, Inc., Philadelphia, PA, United States

A number of structures have been solved for the Envelope (E) protein from Dengue virus (DENV) and closely related flaviviruses, providing detailed pictures of the conformational states of the protein at different stages of infectivity. However, the key functional residues responsible for mediating the dynamic changes between these structures remain largely unknown. Using a comprehensive library of point mutations covering all 390 residues of the DENV-3 E protein ectodomain, we identified residues that are critical for virus infectivity, but that do not affect E protein expression, folding, virion assembly, or budding. The locations and atomic interactions of these critical residues within different structures representing distinct fusogenic conformations help to explain how E protein 1) regulates fusion loop exposure by shielding, tethering, and triggering its release, 2) enables hinge movements between E domain interfaces during triggered structural transformations, and 3) drives membrane fusion through late stage zipper contacts with stem. These results provide new targets for drug and vaccine

development and integrate the findings from structural studies into a cohesive functional model that explains how specific residues in this class II viral fusion protein enable virus infectivity.

DISSECTING THE SPECIFICITY OF THE NEUTRALIZING ANTIBODY RESPONSE *TO* A LIVE ATTENUATED TETRAVALENT DENGUE VACCINE (TDV) CANDIDATE

Sandra Henein[1], Jesica Swanstrom[1], Douglas G. Widman[1], Dan T. Stinchcomb[2], Hansi Dean[2], Jorge E Osorio[2], Charalambos D Partidos[2], Ralph S. Baric[1], Aravinda de Silva[1]

[1]Department of Microbiology and Immunology, University of North Carolina, Chapel Hill, Chapel Hill, NC, United States, [2]Takeda Vaccines, Inc., Deerfield, Chicago, IL, United States

Dengue is a major medical and public health problem worldwide. The four DENV serotypes (DENV-1 to -4) can cause a range of pathologies from mild fever to severe hemorrhagic fever and shock. Currently, there are no vaccines available for dengue. As dengue specific antibodies can enhance infection and disease under certain conditions, vaccine candidates must stimulate responses that simultaneously protect against all four serotypes. We have developed a live attenuated Tetravalent Dengue Vaccine candidate (TDV) that consists of an attenuated DENV-2 strain (TDV-2) and three chimeric viruses containing the prM and E protein genes of DENV-1, -3 and -4 expressed in the context of the attenuated TDV-2 genome backbone (TDV-1, TDV-3, and TDV-4, respectively). TDV has been shown to be immunogenic and efficacious in animal models, well tolerated in Phase I trials in humans, and is currently in Phase II clinical trials in dengue endemic regions. In the present study we sought to analyze the qualitative features of the neutralizing antibody response induced in naïve and DENV immune individuals who received TDV. Using a structural-based epitope exchange technology of transplanting conformational epitopes from one DENV serotype to another as well as human monoclonal antibody blockade assays, we demonstrate that TDV elicits type-specific DENV-1 and DENV-2 neutralizing antibody responses in many vaccinated individuals. In the case of TDV-1, the neutralizing antibody response was focused on a quaternary epitope surrounding the DENV-1 EDI/II hinge region. In the case of TDV-2 the specificity of the antibody response was directed towards a quaternary epitope centered on EDIII of DENV-2. Studies are currently in progress to determine the specificity for the neutralizing response induced by TDV-3 and TDV-4. These early findings highlight the potential of using novel technologies to determine relationships between antibody epitopes targeted by natural DENV infections and dengue vaccine candidates, and may also pave the path for defining correlates and specific mechanisms of TDV induced protection.

551

ENGINEERING OF A FULL SPECTRUM POTENT ANTIBODY FOR THE TREATMENT OF DENGUE

Luke Robinson, Kirk Rowley, Tyree Koch, Hamid Tissire, Karthik Viswanathan, James Myette, Zachary Shriver, **Gregory Babcock**

Visterra, Inc., Cambridge, MA, United States

Dengue is an illness caused by one of four dengue virus (DENV) serotypes. The disease is endemic to the tropics and subtropics and the global incidence of dengue has increased gradually over recent years due to increased air travel, population, and urbanization with reduced vector control. There are currently no approved anti-viral therapies to treat dengue. Utilizing our computational amino acid interaction network technology, we have engineered VIS513, a humanized antibody targeting domain III of the E protein that is able to efficiently bind to and neutralize all four serotypes of the virus. We demonstrate that the antibody is highly potent, neutralizing virus in the low nM (ng per mL) range across a wide range of isolates, encompassing diverse genotypes within the four serotypes, and including challenge strains that represent significant diversity within the VIS513 epitope. In comparative ***in vitro*** studies, we show that VIS513 is more highly neutralizing than other recently discovered antibodies, including fusion loop or E dimer epitope (EDE) antibodies. Furthermore, serial ***in vitro*** passaging of virus in the presence of VIS513 demonstrates that VIS513 escape variants arise less frequently than serotype-specific antibodies that engage quaternary epitopes. In various mouse models, we extend the above findings and show that a single administration of VIS513 up to 48 hours following DENV infection is able to rapidly decrease viral titers, prevent thrombocytopenia of human platelets and mitigate disease progression. Furthermore, we demonstrate that VIS513 is produced at high levels in a CHO cell line, appropriate for manufacturing, and thus is able to reduce costs associated with production of a biologic. Taken together, these data demonstrate that VIS513 is a potent, efficacious, and broad binding immunotherapy for dengue. Given the proven track record of safety associated with antibodies targeting foreign antigens, we anticipate that VIS513 has the potential to be an important agent for the treatment or prophylaxis of DENV infection and mitigation of disease complications. We anticipate clinical study of VIS513 to begin in 2016.

552

DENGUE VIRUS INFECTION ELICITS HIGHLY POLARIZED CX3CR1+ CYTOTOXIC CD4+ T CELLS

Daniela Weiskopf[1], Derek J. Bangs[1], John Sidney[1], Aruna D. de Silva[2], Aravinda M. de Silva[3], Shane Crotty[1], Bjoern Peters[1], Alessandro Sette[1]

[1]La Jolla Institute for Allegy and Immunology, La Jolla, CA, United States, [2]Genetech Research Institute, Colombo, Sri Lanka, [3]University of North Carolina School of Medicine, Chapel Hill, NC, United States

The frequency of infection with any of the four dengue viruses (DENV 1-4) has increased dramatically in the last few decades, and the lack of a vaccine has led to significant morbidity and mortality worldwide. Dengue virus is a pathogen with unusual pathogenesis and protective immunity is poorly understood. While DENV-specific CD8+ T cell responses have been extensively studied, the breadth and specificity of CD4+ T cell responses remains to be defined. In effort to define HLA-restricted CD4+ T cell responses resulting from natural infection with DENV, we endeavored to map T cell responses in individuals from Sri Lanka where DENV is hyper-epidemic. Characterization of the phenotype of the responding CD4+ T cells revealed a DENV specific T cell subset that is specifically expanded in donors carrying an allele associated with protection from severe DENV disease. Analysis of DENV-specific CD4+ T cells revealed that the virus specific cells were highly polarized, with a strong bias towards a CX3CR1+ Eomes+ Tbet+ perforin+ granzyme B+ CD45RA+ CD4 CTL phenotype. Importantly, frequency of these cells correlated with a protective HLA DR allele and we demonstrate these cells have direct DENV-specific cytolytic activity. We speculate that cytotoxic dengue-specific CD4+ T cells may play a role in control of dengue infection ***in vivo***, and this immune correlate may be a key target for dengue virus vaccine development.

553

IMMUNOLOGICAL INVESTIGATIONS TO UNDERSTAND THE OUTCOME OF THE PHASE III EFFICACY STUDIES OF THE SANOFI PASTEUR CANDIDATE DENGUE VACCINE

Bruno Guy[1], Janice Moser[2], Antony Byers[2], Anatoly Kachurin[2], Anke Harenberg[3], Florence Boudet[3], Corinne Dunod[1], Karen Fanouillere[1], Matthew Bonaparte[4], Nicholas Jackson[1]

[1]Sanofi Pasteur, Lyon, France, [2]Sanofi Pasteur, Orlando, FL, United States, [3]Sanofi Pasteur, Marcy l'Etoile, France, [4]Sanofi Pasteur, Swiftwater, PA, United States

Two pivotal large scale Phase III studies have been conducted in Asia and Latin America to assess the efficacy of the Sanofi Pasteur candidate dengue vaccine. These trials are now in the hospital phase, and long-term follow up data are being accrued, in addition to those obtained during the first two years of the active phase. Scientific investigations have

been launched to deepen our understanding of the impact of different host parameters, and address their potential link to the observed results. New immunological assays have been developed and applied, aiming at evaluating in vaccinees and controls the homotypic and heterotypic nature and affinity of the vaccine and/or dengue-induced immune responses. The immunological signature present in the acute samples of breakthrough dengue cases has also been characterized in both hospitalized vaccinees and controls. The results of these ongoing investigations will be presented, which combined analyses may help understand the observed short term and long term efficacy and safety profile of the vaccine.

554

DENGUE VIRUSES GROUP AS DIFFUSE CLUSTERS ON ANTIGENIC MAPS MADE WITH PRIMARY HUMAN VACCINATION AND NATURAL INFECTION ANTISERA

Leah Katzelnick[1], Angela Green[2], Louis Lau[2], Judith Fonville[1], Chunling Wang[2], Anna Durbin[3], Eva Harris[2], Stephen Whitehead[4], Derek Smith[1]

[1]Centre for Pathogen Evolution, Department of Zoology, University of Cambridge, Cambridge, United Kingdom, [2]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [3]Center for Immunization Research, Department of International Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [4]Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

The four dengue virus types, DENV1-4, are mosquito-borne flaviviruses that infect an estimated 390 million individuals each year. Isolates of DENV1-4 are thought to group into four discrete serotypes, in large part because the enduring, protective neutralizing antibody response following primary infection is observed to be serotype-specific. We previously found that primary African green monkey (AGM) antisera recognize DENVs as diffuse antigenic clusters. Here we use antigenic cartography to further test: 1) if primary human monovalent vaccine and natural infection antisera recognize a genetically diverse panel of DENV isolates as discrete serotypes, and 2) if the neutralizing responses of these antisera are type-specific. We generated two antigenic maps of the DENV panel: one using antisera from 40 individuals, each inoculated with a monovalent vaccine component of the NIH live vaccine, and a second using antisera from 21 Nicaraguan children drawn in the year following their first DENV infection. On maps made with monovalent vaccine and natural infection antisera, similar to what we observed with AGM antisera, the antigenic distance within a DENV type was the same as the antigenic distance between types. We then tested if the neutralizing antibody responses were type-specific. On both the monovalent vaccine and natural infection antigenic maps, some individuals had type-specific responses, but just as often, individuals had neutralizing antibody responses that fell between DENV types. Further, we found that the monovalent vaccine antigenic map changed very little if made with only the most central, cross-reactive antisera or only the most peripheral, type-specific antisera. We thus found that human monovalent vaccine and natural infection antisera reacted to the DENV panel as diffuse antigenic clusters, that both type-specific and cross-reactive neutralizing antibody responses were observed following primary DENV exposure, and that these neutralizing responses identified similar underlying antigenic relationships among genetically diverse DENV strains.

555

DELIVERY OF A MALARIA PRE-ERYTHROCYTIC PEPTIDE VACCINE FORMULATED IN TLR AGONIST ADJUVANTS TO SKIN ASSOCIATED LYMPHOID TISSUE (SALT)

Roshawn Johnson, Robert Mitchell, Elizabeth Nardin, Ute Frevert

New York University School of Medicine, New York, NY, United States

Long-lived protective immunity against malaria can be elicited in human volunteers by immunization with sporozoites, however, mass vaccination with cryopreserved parasites or by mosquito bite presents logistical challenges for delivery to the one third of the world's population currently at risk of ***Plasmodium*** infection. The "gold standard" for large scale vaccination remains the Smallpox Eradication campaign which demonstrated the utility and cost effectiveness of vaccine delivery by skin scarification (SS) using trained community health workers. SS delivery of malaria vaccines may more closely mimic the natural route of sporozoite injection by mosquito bite which is known to elicit neutralizing antibodies that immobilize sporozoites in the skin and protective cellular immunity in the skin draining lymph nodes. Our recent studies demonstrate that mice immunized SS with a ***P. falciparum*** circumsporozoite peptide formulated in adjuvants containing synthetic TLR agonists can elicit neutralizing antibody that protect mice against sporozoite challenge. Inclusion of TLR agonists was critical, as SS immunization with peptide administered in oil adjuvants without TLR agonists elicited a Th2-type antibody response that was not protective. Immune responses in the skin reflect a complex dermal network of innate and adaptive immune cells that potentially include keratinocytes, Langerhans cells, dendritic cells and NK cells, as well as resident memory T cells recently shown to be elicited by various viral vaccines. In an effort to elucidate the spacio-temporal response in SALT to an SS delivered malaria vaccine, we have utilized reporter mice and intravital imagining, confocal microscopy, and flow cytometry to define the TLR agonist- dependent mechanisms functioning in the induction of sporozoite neutralizing antibodies. These studies identify elements of the innate and adaptive immune response that can be used to guide the rational development of improved SS adjuvant formulations for vaccines against ***Plasmodium*** parasites as well as other skin invasive pathogens.

556

VACCINE MEDIATED PROTECTION WITH SINGLE AND DOUBLE SPECIES CHALLENGE AFTER WHOLE PARASITE CHEMICALLY ATTENUATED BLOOD STAGE VACCINES

Jennifer M. Reiman, Bibiana Rodriquez, Amber Raja, Virginia McPhun, Michael F. Good

Griffith University, Southport, QLD, Australia

Mixed species malaria infections are common in parts of the world and can result in more severe malarial disease than infection with a single species. Understanding the impact mixed infections have on vaccine mediated protection is important for developing an effective malaria vaccine. To model this we assessed protection against single and double species challenge in C57BL/6 mice immunized with a chemically attenuated blood stage vaccine containing ***Plasmodium chabaudi AS, Plasmodium yoelii 17X,*** or a combination vaccine containing both species. Mice received three doses of vaccine containing 10^6 centanamycin attenuated pRBCs of a single species or each species within a single inoculum or an equivalent number of centanamycin-treated normal red blood cells (control) from a naive mouse. Mice were challenged five weeks post vaccination with 10^5 pRBC of each species or 10^5 pRBC of both species in a single inoculum. Utilizing differences in the MSP1 gene sequence between ***Plasmodium chabaudi AS*** and ***Plasmodium yoelii 17X*** quantitative real-time PCR was used to measure species-specific parasite levels. Blood samples were collected prior to challenge and post challenge for PCR. Physiological data including internal temperature, body weight, glucose, and hemoglobin were collected on alternate days from day 1 and compared to baseline. Additionally, the severity of disease in mice was evaluated using our system of clinical scoring based on criteria such as pallor, urine color, fur texture, activity, and posture. All data were collected blinded post challenge. None of the vaccines (single or double) conferred complete protection against parasite burden (as measured by qPCR). However, single and combination vaccines provided clinical protection against severe disease following a single parasite challenge. Double (mixed) challenges resulted in increased disease severity (clinical score) in all groups of vaccinated and control mice relative to single challenge. Nonetheless, a combination vaccine provided enhanced survival against a double challenge compared to control or single vaccines. The full results of these new studies are presented here.

557

ENABLING THE VACCINE POTENTIAL OF DUFFY BINDING PROTEIN (DBP): BROADLY NEUTRALIZING EPITOPES, RECEPTOR BINDING, AND ANTIGEN ENGINEERING

Niraj H. Tolia[1], Edwin Chen[1], Nichole D. Salinas[1], Joseph D. Batchelor[1], Brian M. Malpede[1], Francis B. Ntumngia[2], John H. Adams[2]

[1]Washington University School of Medicine, St. Louis, MO, United States, [2]University of South Florida, Tampa, FL, United States

The Duffy Binding Protein (DBP) plays a critical role in ***Plasmodium vivax*** invasion of reticulocytes. Three features have hampered the progression of DBP as a vaccine candidate: 1) The polymorphic nature of DBP induces strain-specific immune responses; 2) the epitopes of broadly-neutralizing versus non-protective antibodies are not known; and 3) a limited understanding of the structure of DBP bound to its receptor DARC. We will present structural, computational and functional data on DEKnull, a synthetic DBP based antigen that has been engineered through mutation to enhance the induction of strain-transcending, blocking inhibitory antibodies. We will also present high-resolution epitope mapping data of multiple anti-DBP antibodies. The mapping data clearly identifies broadly neutralizing epitopes that, in conjunction with our structural determination of the DBP:DARC complex, lay a clear path forward for the rational design of the next generation of DBP-based antigens. This work highlights new approaches to target the molecular mechanism of invasion and increases the inhibitory epitope repertoire to be incorporated into future vaccine designs. Vaccine efficacy may be improved by targeting critical functional regions and broadly-neutralizing epitopes of parasite proteins, while avoiding decoy-epitopes identified by these studies.

558

MIDGUT FIBRINOGEN-RELATED PROTEIN 1 (FREP1) AS A NOVEL TARGET FOR MALARIA TRANSMISSION-BLOCKING VACCINES

Caio Martinelle França[1], Genwei Zhang[1], Guodong Niu[1], Noah S. Butler[2], Jun Li[1]

[1]University of Oklahoma, Norman, OK, United States, [2]Oklahoma Health Sciences Center, Oklahoma City, OK, United States

Plasmodium development in mosquito midguts is imperative for malaria transmission. Recently, fibrinogen-related protein 1 (FREP1) has been demonstrated to be critical for parasite infection in mosquitoes. FREP1 is expressed in the mosquito midgut where it mediates ***P. falciparum*** ookinete invasion assisting parasite through anchoring to the peritrophic matrix and penetration of the midgut epithelium. Here, we determined that FREP1 protein could also bind ***P. berghei***-infected mice red blood cells and ookinetes using indirect immunofluorescence assays. We propose that anti-FREP1 antibodies disrupting the interaction between FREP1 and ***Plasmodium*** will interfere with parasite infection in mosquitoes. To test this hypothesis, we expressed FREP1 in ***E. coli***, using the purified protein to generate polyclonal anti-FREP1 antibody in rabbits. We demonstrated that feeding mosquitoes with the purified anti-FREP1 rabbit polyclonal antibody (200μg/ml) mixed with ***P. berghei*** infected mouse blood significantly reduced the number of oocysts in ***A. gambiae*** compared with pre-immune rabbit IgG ($p<0.0001$). The number of oocysts per midgut decreased from 10 in the control group to 3 in experimental group. To further examine whether FREP1 can be a potential vaccine antigen against parasite transmission to mosquitoes, we immunized mice with purified recombinant protein and boosted twice with a 16-day interval to elicit a high titer antibody response in outbred mice. Two weeks after the third boost, we infected the immunized mice with ***P. berghei*** that were used to infect mosquitoes 10 days later. Results showed that 80% of mosquitoes in experimental groups were free from infection compared to 12.5% of mosquitoes from control group. We repeated the experiments >3 times, and obtained consistent results, suggesting that antibodies that recognize FREP1 is able to inhibit the ***Plasmodium*** invasion in midguts and then interfere with parasite infection in mosquitoes. Collectively, we confirmed FREP1's role in the ookinetes invasion of mosquito midgut and demonstrated that FREP1 can be used as a midgut antigen target for mosquito-based transmission blocking vaccine.

DISCOVERY OF NOVEL TRANSMISSION BLOCKING VACCINE CANDIDATES USING GAMETOCYTE PROTEIN MICROARRAY

Will Stone[1], Joseph Campo[2], Isabelle Morlais[3], Anna Cohuet[4], Chris Drakely[5], Colin Sutherland[5], Douglas Molina[2], Arlo Randall[2], Jozelyn Pablo[2], Chris Hung[2], Adam Shandling[2], Kevin Tettah[5], Chris Janse[6], Shahid Khan[6], Edwin Lasonder[7], Robert Sauerwein[1], Phil Felgner[8], Teun Bousema[1]

[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Antigen Discovery Inc., Irvine, CA, United States, [3]Laboratoire de Recherche sur le Paludisme, Institut de Recherche pour le Développement IRD-OCEAC, Yaoundé, Cameroon, [4]Institut de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]Leiden University Medical Centre, Leiden, Netherlands, [7]Plymouth University, Plymouth, United Kingdom, [8]University of California Irvine, Irvine, CA, United States

Natural and vaccine-induced immune responses can reduce the transmission of malaria from man to mosquitoes. The development of malaria transmission blocking vaccine (MTBV) candidates has so far been limited by difficulties achieving correctly folded immunogenic proteins for vaccination. Two leading candidates, pre-fertilization antigens Pfs48/45 and Pfs230, are expressed on the surface of mature gametocytes and elicit transmission blocking immunity (TBI) in a fraction of individuals naturally exposed to malaria infection. It has been shown repeatedly that full TBI may be present in absence of immune responses to these well characterised proteins, yet no attempts have been made to comprehensively identify the immune signatures of naturally acquired TBI. To this end we compiled a list of 319 ***P. falciparum*** proteins whose transcription is upregulated in mature gametocytes and which possess characteristics of surface-located proteins (e.g. transmembrane domains, GPI anchor). These proteins were expressed in an E. coli based ***in vitro*** transcription-translation system and printed onto a nitrocellulose microarray. To assess the relationship between functional TBI and reactivity to the array of gametocyte proteins, we collected a library of 587 sera from naturally malaria exposed expatriates and individuals from the Gambia, Cameroon, and Burkina Faso. Serum IgG was purified from all samples and provided to mosquitoes with cultured gametocytes in the standard membrane feeding assay (SMFA), revealing that 3.6% (21/587) of individuals possessed strong, reproducible TBI. Probing the sera on the array identified 10 proteins that individuals with TBI reacted to more intensely, and more commonly. One of the reactive proteins, PF3D7_1103800 ($p=0.014$), has not previously been associated with TBI but is highly expressed in stage V gametocytes and ookinetes and was associated with TBI in multiple endemic settings. Our analysis substantially increases the number of ***Plasmodium*** antigens implicated in the development of immune responses that inhibit parasite development in mosquitoes, and provides multiple novel targets for MTBV development.

INTERACTIONS BETWEEN TRANSMISSION BLOCKING VACCINES AND NATURAL IMMUNITY AGAINST *PLASMODIUM FALCIPARUM*

Dari F. Da[1], Anaïs Bompard[2], R. Serge Yerbanga[3], Thierry Lefèvre[1], Bienvenue K. Yaméogo[3], Sumi Biswas[4], Jean Bosco Ouédraogo[3], Thomas S. Churcher[2], Anna Cohuet[1]

[1]Institut de Recherche en Sciences de la Santé (IRSS/DRO), Institut de Recherche pour le Dévéloppemnt (IRD/MIVEGEC), Bobo-Dioulasso, Burkina Faso, [2]Imperial College, London, United Kingdom, [3]Institut de Recherche en Sciences de la Santé (IRSS/DRO), Bobo-Dioulasso, Burkina Faso, [4]Jenner Institute, Oxford University, Oxford, United Kingdom

Malaria transmission-blocking vaccines (TBV) are promising candidates for disrupting the ***Plasmodium*** life cycle within mosquitoes. Using membrane feeding assays, pre-clinical studies identified vaccine candidates able to impede ***Plasmodium*** development in the mosquitoes. This vaccine-induced immunity could complement observed natural human immunity, which also reduces ***Plasmodium*** human to mosquito transmission. In this study, we investigated the efficacy of two major TBV candidates and the interaction between natural and vaccine-induced immunity. Mosquito Membrane Feeding Assays were performed by exposing ***Anopheles coluzzii*** females to gametocyte-infected blood from naturally infected patients. Total IgG purified from mice immunized with viral-vectors expressing Pfs25 or Pfs230-C were mixed with gametocyte-infected blood, with and without serum replacement. Female mosquitoes were then fed on the mixture. Fully fed mosquitoes were dissected 7 days-post feeding and oocysts were counted. The effect of natural immunity on TBV efficacy was tested using blood from 6 different gametocyte carriers. We observed a reduced TBV efficacy when using whole blood compared to blood with serum replacement. In the context of the translational investigations for implementation of transmission blocking vaccines, this finding highlights the need to consider the natural immunity of the patients when evaluating TBV candidates.

IN VITRO PRODUCED *PLASMODIUM FALCIPARUM* SPOROZOITES ARE AS INFECTIOUS AS MOSQUITO PRODUCED SPOROZOITES IN HEPATOCYTE ASSAYS

Abraham G. Eappen, Meghan Marquette, Patricia De La Vega, Tao Li, Peter F. Billingsley, B. Kim Lee Sim, Stephen L. Hoffman

Sanaria Inc., Rockville, MD, United States

Development of an effective ***in vitro*** methodology for ***Plasmodium falciparum*** (Pf) sporogony and the production of infective sporozoites (SPZ) without the use of mosquitoes will radically alter Pf biology research paradigms and vaccine development program similar to the revolutionary discovery of Pf asexual ***in vitro*** culture methodology, as reported. This enabling technology will also dramatically reduce the cost of production of Sanaria® PfSPZ products; PfSPZ Vaccine (radiation attenuated PfSPZ), PfSPZ Challenge (infectious PfSPZ for controlled human malaria infection [CHMI]) and PfSPZ-CVac (PfSPZ Challenge given with antimalarial drugs as a vaccine) all of which have shown excellent results in clinical trials, as previously reported. Using the ***in vitro*** culture protocol developed at Sanaria, we consistently achieved 2.4 to 12.5% (mean 8.3%) transformation of stage V gametocyte to 8 day oocysts. This was 39-fold higher than that observed in mosquitoes. ***In vitro***-produced PfSPZ were harvested from culture supernatants and we produced between 180,000 and 350,000 mature PfSPZ in 7 independent experiments. Mature ***in vitro***-produced PfSPZ were motile, 10-13 µm long, and highly reactive to anti-PfCSP mAb, thus identical to salivary gland produced PfSPZ. ***In vitro*** produced PfSPZ were tested for their infectivity in 6 day hepatocyte potency assays. In 4 independent 6 day hepatocyte assays, ***in vitro*** produced PfSPZ seeded at 56,598 ± 7,294 PfSPZ/well produced 28.6 ± 7.0 PfMSP-1 expressing 6 day parasites greater than 10 µm in diameter. While mosquito-produced, fresh aseptically purified PfSPZ seeded at 50,000 per well, produced 25.7 ± 4.1 mature 6 day parasites expressing PfMSP-1. The size of the 6 day parasites developed in HC04 cells from ***in vitro*** and ***in vivo*** (mosquito) produced PfSPZ were similar. These data demonstrate that ***in vitro***-produced PfSPZ were as infectious in hepatocyte cultures as fresh mosquito-produced PfSPZ, and provide the foundation for ongoing efforts to optimize ***in vitro*** PfSPZ production.

562

DEPLOYMENT AND USE OF MOBILE PHONE TECHNOLOGY FOR REAL-TIME REPORTING OF FEVER CASES AND MALARIA TREATMENT FAILURE IN AREAS OF DECLINING MALARIA TRANSMISSION IN MUHEZA DISTRICT NORTHEASTERN TANZANIA

Filbert F. Temba[1], Deus S. Ishengoma[1], Brunno P. Mmbando[1], Acleus S. Rutta[1], Mwelecele N. Malecela[2], Martha M. Lemnge[1], Edwin Michael[3]

[1]National Institute for Medical Research Tanzania, Tanga, United Republic of Tanzania, [2]National Institute for Medical Research Tanzania, Dar es Salaam, United Republic of Tanzania, [3]University of Notre Dame, South Bend, IN, United States

Early detection of febrile illnesses at community level is essential for improved malaria case management and control. Currently, mobile phone based-technology is common used in developing world for collecting and transferring health information and services. This study assessed the applicability of mobile phone technology for real-time reporting of fever cases and management of malaria by village health workers (VHWs) in northeastern Tanzania. The Community mobile phone-based Disease Surveillance and Treatment for Malaria (ComDSTM) system combined mobile phones and web applications was developed and implemented in three villages and one dispensary in Muheza district from November 2013 to October 2014. A baseline census was conducted in May 2013; data were uploaded on a web-based database and updated during follow-up visits by VHWs. Active (ACD) and passive case detection (PCD) of febrile cases was done by VHWs. Cases found positive by malaria rapid diagnostic test (mRDT) were treated by artemether-lumefantrine (AL). The first dose was given by nurse while other doses were taken under supervision of VHW at home. Each patient was visited on day 7 to observe recovery process. Data from each stages of the surveillance life cycle were captured and transmitted to the database using mobile phones.The baseline population in the three villages was 2934 in 678 households. A total of 1907 febrile cases were recorded by VHWs. Out of these, 1828 (95.9%) were captured using mobile phone. At the dispensary, 1778(93.2%) febrile cases were registered where 84.2% captured through PCD. Positivity rates were 48.2% and 45.8% by mRDT and microscopy, respectively. Nine cases had treatment failure reported on day seven post-treatment and adherence to treatment was 98%. In conclusion, the study showed that mobile phone based-technology can be successfully used by VHWs for surveillance and timely reporting of fever episodes and monitoring of treatment failure in remote areas. Further optimization and scaling-up of tools will be required to improve malaria case management and drug resistance surveillance

563

SPATIAL CLUSTERING OF MALARIA INFECTIONS IN NORTHERN NAMIBIA: IMPLICATIONS FOR SURVEILLANCE AND RESPONSE STRATEGIES FOR ELIMINATION

Hugh J. Sturrock[1], Joyce Auala[2], Munyaradzi Tambo[2], Erastus Haindongo[2], Immo Kleinschmidt[3], Davis R. Mumbengegwi[2], Roly D. Gosling[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]University of Namibia, Windhoek, Namibia, [3]London School of Hygiene & Tropical Medicine, London, United Kingdom

Reactive case detection (RACD), whereby household members and neighbours of passively detected index cases are tested and treated when positive, is a widely used method to identify and target malaria hotspots. Typically RACD is carried out using rapid diagnostic tests (RDTs) or microscopy, both of which are likely to miss low density (sub-patent) infections. This represents a potential barrier to interrupting transmission as these sub-patent infections are still able to infect mosquitoes. Using data from a larger epidemiological study in Engela district in northern Namibia between January 2013 - June 2014, we explore the occurrence and spatial clustering of sub-patent infections around passively detected cases. Individuals testing RDT positive at any health facility in Engela district were followed up to their home. Household members and individuals of four neighbouring households were asked to provide a blood sample for RDT and dried blood spot (DBS) for later molecular analysis. Blood samples for RDT and DBS were also taken from randomly selected individuals within the district. If they tested negative by RDT, members of their household and individuals of the four nearest neighbouring households were also screened. Households of study participants were geolocated using GPS devices. Sub-patent infections were identified by subsequent analysis of DBS samples by Loop-mediated isothermal amplification (LAMP). In total, 1,759 individuals from 62 case neighbourhoods and 944 individuals from 56 control neighbourhoods provided DBS samples. Results show that sub-patent infections were more prevalent in the neighbourhoods of cases than controls (OR 7.0, p=0.002). Furthermore, there appeared to be a decay in risk around case households, with the odds of finding additional infections far higher within the index household than in neighbouring households (OR 3.8, p=0.005). These results suggest that RACD with RDTs is insufficient to target the infectious reservoir and more aggressive interventions, such as targeted presumptive treatment, may be required.

HETEROGENEITY IN MALARIA PROPAGATION POTENTIAL: QUANTIFYING REAL-LIFE EXPOSURE TO *ANOPHELES* VECTORS USING DNA FINGERPRINTING

Wamdaogo M. Guelbéogo[1], Bronner P. Gonçalves[2], Alfred Tiono[1], Lynn Grignard[2], Alphonse Ouédraogo[1], Amidou Diarra[1], Sagnon N'Falé[1], Sodiomon B. Sirima[1], Teun Bousema[3], Chris Drakeley[2]

[1]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Radboud University Medical Center, Nijmegen, Netherlands

The number of mosquito bites individuals infected with malaria receive is a major determinant for onward transmission of infection. In this study, we quantified individual-specific exposure to Anopheline mosquitoes throughout the transmission season. In a village in Burkina Faso, 189, 326 and 620 blood-fed mosquitoes were collected from 40 households at the end of the transmission season (November-December 2013), and from 20 households at the start (July 2014) and peak (September 2014) of the following wet season, respectively. Finger prick blood samples were collected from individuals living in these households to allow for the identification of blood meal source by DNA fingerprinting. 171/189 mosquitoes collected during the first survey (2013) had their blood meal genotyped. 82.9 % of Anopheles vectors with single blood meals were linked to individuals living in the household where they were caught. A non-negligible proportion of mosquitoes (22.1 %) took their blood meal from multiple human hosts. Most bites (69.6%) were on adults even though they represented only 38.1% of the population. The mean number of mosquito bites per study participant and its variance were 1.2 and 7.4. 11.1 % of the population living in households where fed mosquitoes were collected received 71.8 % of mosquito bites. Mosquitoes collected during the start and peak of the wet season are currently being analysed and data will be presented. Our preliminary results provide evidence that encounters between malaria vectors and human hosts are heterogeneously distributed and that a high proportion of mosquitoes feed on more than one human host. This heterogeneous effective exposure to mosquitoes has profound consequences for our interpretation of the human infectious reservoir for malaria.

565

MOLECULAR INVESTIGATION OF A MALARIA OUTBREAK IN CUSCO DEPARTMENT OF PERU LINKS IT TO A STRAIN OF *PLASMODIUM FALCIPARUM* GENETICALLY SIMILAR TO A RECENT TUMBES DEPARTMENT OUTBREAK STRAIN

Sheila Akinyi Okoth[1], Nancy Arrospide[2], **Stella M. Chenet**[1], Sonia Gutierrez[2], Cesar Cabezas[2], Jose Antonio Matta[3], Venkatachalam Udhayakumar[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Instituto Nacional de Salud, Lima, Peru, [3]Laboratorio de Referencia de La Convención, Cusco, Peru

In November 2013, a malaria outbreak occurred in Cusco department, southern Peru. Eleven cases were detected, four of which persisted after presumptive treatment for ***Plasmodium vivax*** infection. Eventually,microscopic examination confirmed ***P. falciparum***, which had been reportedly absent in Cusco since 1946. In order to define the genotypic characteristics of the ***P.falciparum*** isolates from this outbreak and their possible origin(s), we utilized a panel of seven neutral microsatellites (MS) that had been used previously to characterize parasite populations in Peru and other countries. We had employed the same MS markers to investigate a malaria outbreak that occurred in Tumbes department, northern Peru, from 2010-2012; ***P.falciparum*** transmission had been halted for five years prior to that outbreak.The Tumbes investigation identified the origin of the outbreak as being a B-variant falciparum strain (B_{V1}) from Loreto department. In the current investigation, we found that all four Cusco isolates were genetically identical to the B_{V1} strain linked to the Tumbes outbreak. These isolates had drug resistance marker alleles that matched those of the B_{V1} strain at ***Pfcrt, Pfmdr1***, ***Pfdhfr*** and ***Pfdhps*** genes. The isolates had also deleted ***Pfhrp2*** and ***Pfhrp3.*** Epidemiological data suggested that this outbreak was caused by road construction workers who migrated from Loreto department. Our molecular data was consistent with the epidemiological findings. Previous laboratory investigations revealed that the B_{V1} strain was circulating in Loreto department as early as 2009. Given that the B_{V1} strain is multi-drug resistant, can escape detection by PfHRP2-based RDTs and has contributed to two outbreaks in different geographical regions where ***P. falciparum*** transmission had been halted for several years prior, it is important for countries in the Amazon Basin to monitor for its potential expansion. Molecular epidemiological investigations are valuable for tracking the potential source of outbreak parasite strains and their drug and diagnostic resistance genetic characteristics.

ASSESSMENT OF COMMON GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY ALLELIC TYPES IN ETHIOPIA

Ashenafi Assefa[1], Wendimagegn Tsegaye[2], Getachew Abebe[2], Heven Sime[1], Amha Kebede[1], Daddi Jima[1], Moges Kassa[1], Adugna Woyessa[1], Tesfay Abreha[3], Hiwot Teka[4], Hiwot Solomon[5], Joseph Malone[6], Dissanayake Gunawardena[7], S.Patrick Kachur[8], Ya Ping Shi[8], Zhiyong Zhou[8], Richard Reithinger[9], Jimee Hwang[6]

[1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]Addis Ababa University, Addis Ababa, Ethiopia, [3]Columbia University ICAP, Addis Ababa, Ethiopia, [4]President's Malaria Initiative and United States Agency for International Development, Addis Ababa, Ethiopia, [5]Ethiopian Federal Ministry of Health, Addis Ababa, Ethiopia, [6]Malaria Branch, Centers for Disease Control and Prevention and President's Malaria Initiative, Atlanta, GA, United States, [7]President's Malaria Initiative, Addis Ababa, Ethiopia, [8]Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, [9]President's Malaria Initiative and RTI International, Washington, DC, United States

Ethiopia aims to eliminate malaria from selected low transmission settings by 2020. As ***Plasmodium falciparum*** and ***P. vivax*** are co-endemic in Ethiopia, the use of primaquine is indicated for both transmission interruption and radical cure, respectively. However, primaquine use has been limited in Ethiopia due to the limited data available on G6PD deficiency. Dried blood spot (DBS) samples were collected in 2011 as part of the national Malaria Indicator Survey-a multi-stage nationally representative survey of all malaria-endemic areas of Ethiopia. A randomly selected subset of DBS was genotyped by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). Considering the geographical position and ethnic mix of the country, three common G6PD variants, i.e. G6PD*A (A376G), G6PD*A- (G202A) and Mediterranean (C563T), were investigated in 2000 DBS samples. Of the 2000 samples selected, 1585 (76.8%) were available for genotyping, among which 54% were from females. G6PD*A (8.99%) was the only genotype detected, with no samples positive for A- or Mediterranean variants. Regional variation in G6PD*A prevalence was observed, with the highest prevalence reported in samples from the Southern Nation and Nationalities Peoples' Region (11.33%), followed by Tigray (10.94%), Oromia (9.48%),Gambella / Benishangul Gumuz (9.4%), Afar / Somali (7.03%), and Amhara (5.73%); no G6PD deficiency was detected in samples from Harari. Of the A mutation 31% were found in males; 62.1% and 6.8% of mutations found in females were heterozygous and homozygous, respectively. The results support the limited historical evidence of low prevalence of G6PD deficiency in Ethiopia. The A mutation observed is a mild deficiency causing around 85% of the normal enzymatic activity and is of little clinical significance. The more severe G6PD deficiency allelic types, A- and Mediterranean, common in other parts of Africa were not observed. Our results support the safe use of primaquine especially the single low-dose (0.25 mg/kg) as an elimination strategy for falciparum malaria in Ethiopia.

567

SPATIAL ANALYSIS USING SEROLOGICAL MARKERS FOR THE IDENTIFICATION OF AREAS OF HIGH MALARIA TRANSMISSION IN THE LOW ENDEMIC NORTHERN COAST OF PERU

Gabriel Carrasco-Escobar[1], Ángel Rosas-Aguirre[2], Mónica Melendez[3], Dionicia Gamboa[4], Juan Contreras-Mancilla[5], Anna Rosanas-Urgell[6], Niko Speybroeck[2], Annette Erhart[7], Sócrates Herrera[8], Alejandro Llanos-Cuentas[1]

[1]Institute of Tropical Medicine "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Research Institute of Health and Society, Université Catholique de Louvain, Brussels, Belgium, [3]Sub-Región de Salud Luciano Castillo Colonna, Sullana, Peru, [4]Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Institute of Tropical Medicine "Alexander von Humboldt", Universidad Peruana Cayetano Heredia., Lima, Peru, [6]Unit of Malariology, Institute of Tropical Medicine, Antwerp, Belgium, [7]Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp, Belgium, [8]Caucaseco Scientific Research Center, Cali, Colombia

As transmission becomes increasingly focal in low transmission settings, an accurate identification of malaria hotspots is crucial to better design targeted interventions. In this study, we evaluated the ability of a spatial analysis using serological markers for identifying cluster areas with high incidence rates of clinical ***P. vivax*** malaria in a low endemic district (Bellavista) of the Peruvian Northern Coast. After a full census and georeferencing of houses in the study setting in May 2010, a cross-sectional survey was conducted to collect blood samples on filter paper from 1925 individuals. Antibodies for specific IgG responses to ***P. vivax*** merozoite surface protein-1 —terminal region 19-kDa C— (PvMSP-119) and apical membrane antigen-1 (PvAMA-1) were detected by ELISA. A mixture model was used to determine the cut-off of antibody responses for each antigen. An individual with antibody responses exceeding the cut-off value for at least one of the two antigens was considered seropositive. QGIS was used to map all surveyed individuals and SaTScan (applying a Bernoulli model) to detect spatial clusters of individuals with ***P. vivax*** seropositivity. The most likely spatial cluster was a 0.22 km radius cluster including 694 individuals (19.7% of total censored individuals) in 163 households (21.9% of total censored houses) (RR=2.3, p<0.001). After the survey, an enhanced passive case detection (PCD) at local health facilities from June 2010 to May 2012 allowed the detection of 35 clinical ***P. vivax*** episodes in the study setting. A logistic regression analysis showed that individuals living inside the most likely seropositivity cluster (identified in May 2010) were four times more likely to present clinical ***P. vivax*** episodes detected by PCD in the following two years than those living outside the cluster (OR=3.92, 95%CI 2.01-7.64). Study findings confirmed that the spatial analysis using serological markers allowed identifying future areas with high risk of clinical ***P. vivax*** malaria. These tools may support the risk stratification and prioritization of targeted interventions to better reduce transmission and move towards malaria elimination.

568

MICRO-EPIDEMIOLOGY OF *PLASMODIUM VIVAX* AND *P. FALCIPARUM* INFECTIONS IN AN AREA OF LOW TRANSMISSION OF SOLOMON ISLANDS: STRIKING CONTRAST WITH IMPLICATIONS FOR FUTURE INTERVENTIONS

Andreea Waltmann[1], Cristian Koepfli[1], Natacha Tessier[1], Céline Barnadas[1], Harin Karunajeewa[1], Ivor Harris[2], G.L. Abby Harrison[1], Melanie Bahlo[1], Andrew W. Darcy[3], Maxine Whittaker[4], James Kazura[5], Alyssa E. Barry[1], Ivo Mueller[1]

[1]The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [2]The Army Malaria Institute, Brisbane, Australia, [3]The National Health Training and Research Institute, Ministry of Health, Honiara, Solomon Islands, [4]School of Population Health, University of Queensland, Brisbane, Australia, [5]Case Western Reserve University, Cleveland, OH, United States

Historically, Solomon Islands has endured considerable ***Plasmodium falciparum*** and ***P. vivax*** burden. In the last 20 years, it has achieved 90% reduction in malaria cases and is aiming for elimination. In 2012, we conducted a cross-sectional survey in Ngella (n=3501), an area of low transmission of Solomon Islands to investigate the natural reservoir and local epidemiology of ***P. vivax*** and ***P. falciparum***. The contrast was striking. Whilst only five clonal ***P. falciparum*** infections were identified from a single village, ***P. vivax*** prevalence remains moderately high (qPCR 13.4%), with predominantly afebrile, submicroscopic infections, which display genetic complexity and considerable spatial heterogeneity. We typed 360 ***P. vivax*** infections at nine microsatellite loci and subsequent analyses of diversity (F_{ST}, G_{ST}, Jost's D) and structure (Bayesian clustering, multidimensional scaling and phylogenetics) revealed a genetically diverse ***P. vivax*** population, but spatially fragmented, even among villages 10-30km apart. This indicates that whilst ***P. vivax*** may be more difficult to eliminate than ***P. falciparum***, local parasite populations have been affected by control interventions. Living in a household with at least one other ***P. vivax*** carrier increased the risk of ***P. vivax*** infection, indicating possible intra-household transmission. Genetic relatedness of ***P. vivax*** clones will be measured and compared at household, village and island levels to decipher fine scale spatial clustering of infection and thus presence of transmission hotspots. Association of ***P. vivax*** infection with human genetic factors known to confer protection against infection (α-thalassemia and Southeast Asian ovalocytosis) will also be integrated in this analysis. The implication of these findings will be discussed in the context of factors which may impact on the efficacy of follow-up elimination strategies: i) enhanced and targeted surveillance, ii) source of ***P. vivax*** importation, and iii) prevalence of glucose-6-phosphate dehydrogenase deficiency and the use of primaquine mass drug administration to eliminate malaria.

569

NATURAL HISTORY OF PERILESIONAL EDEMA IN CALCIFIC NEUROCYSTICERCOSIS

Theodore E. Nash, JeanAnne Ware, Siddhartha Mahanty

National Institutes of Health, Bethesda, MD, United States

Perilesional edema around calcified ***Taenia solium*** granulomas (calcifications) is commonly detected in patients with seizures in endemic regions, occurring in 50% of recurrent seizures in persons who have calcifications, a history of seizures and a positive cysticercosis serology. We characterized the long-term course and consequences for persons experiencing one or more documented episodes of perilesional edema (episodes) in 21 patients followed for a median of 8.5 years (range 0.4-28.8 yrs) at the National Institutes of Health (NIH). A perilesional event (event) was defined as a transient fluid-attenuated version recovery (FLAIR) magnetic resonance imaging (MRI) signal at least twice the diameter of the involved calcification, whose presence was confirmed by computerized tomography (CT) examination and/or on SWI MRI sequences on or before the first episode. A sizable minority of episodes (15.4%) encompassed multiple events involving separate calcifications. Repeat MRI examinations were done when new symptoms occurred, at intervals after documented episodes when possible, when evaluating other lesions or complications and semiannually or annually. The study group had a median age 30.5 yr (range 19.7-69.8), two thirds were female and 71.5% were Hispanic. In all there were 77 episodes, which included 104 events involving 50 of 728 calcifications, which corresponds to 5 calcifications/person (1-280), 2 involved calcifications/person (1-11) and 3 events/persons (1-32)[(data are median (range)]. In 64 evaluable episodes, symptoms were seen in 70.3% and were mostly focal and/or generalized seizures. No symptoms were reported in 29.7% of episodes, a high proportion that may be the result of the relatively large numbers of MRIs performed in asymptomatic patients. Other findings will be presented. Our data demonstrate that recurrent episodes involving multiple calcifications can occur over decades causing significant morbidity. Many episodes are asymptomatic suggesting that the number of episodes may be significantly greater than estimated from symptomatic cases.

570

NEUROCYSTICERCOSIS AT A LARGE ACADEMIC CENTER IN SOUTH FLORIDA

Rosemary C. Iwunze[1], Susanne Doblecki-Lewis[2], Katherine Doktor[1], Aileen Chang[2], Maria Alcaide[2], Paola Lichtenberger[3]

[1]University of Miami/Jackson Memorial Hospital, Miami, FL, United States, [2]University of Miami Miller School of Medicine, Miami, FL, United States, [3]Miami Veterans Affairs Healthcare System/University of Miami Miller School of Medicine, Miami, FL, United States

Neurocysticercosis (NCC) is a neglected parasitic disease with an estimated mortality rate of 2-9.8% in the United States of America (USA). Florida accounted for 6.3% of NCC deaths in the USA between 1990 and 2002, yet there are no major NCC studies for the region. This is a retrospective study with the aim of characterizing the population diagnosed with NCC at 2 large tertiary medical centers in South Florida within Miami-Dade County, where 51.3% of the population is foreign born. Seventy-seven patients met criteria for study: 62.3% female, and 67.5% uninsured. The largest region of origin was Central America (50.6%), followed by the Caribbean (32.5%). The largest nationality was Haitian at 28.6% in the study, yet 7% of the foreign born population are Haitian in Miami-Dade county, and only 5% of cases were Mexican. 93.5% met diagnostic criteria for definitive and probable NCC, 67-78% had no serology or stool study to support radiologic evidence of NCC. 68.8% had parenchymal NCC, 31% had extraparenchymal NCC, and only 52% of extraparenchymal cases underwent resection of cyst. Five cases had mention of treating close contacts of patients or giving case patient praziquantel to target possible intestinal disease. There was a correlation between symptom improvement and increasing length of therapy, lesion type and NCC lesion resolution, but not symptom improvement and NCC lesion resolution. Nationalities represented differ from what has been reported in other studies, and disproportional to the foreign born populations in Miami-Dade County. This study shows that South Florida has conditions for the autochthonous acquisition of NCC, identifies Haitians has a high-risk group for NCC in the USA, variations in care and the need for treatment guidelines.

571

PREVALENCE AND FACTORS ASSOCIATED WITH INTESTINAL TAENIASIS IN PATIENTS WITH CYSTICERCOSIS AND THEIR RELATIVES

Katherine A. Sota[1], Javier A. Bustos[1], Carmen Taquiri[1], Armando E. Gonzalez[2], Robert H. Gilman[3], Juan Jimenez[1], Isidro Gonzales[4], Hector H. Garcia[1], for the Cysticercosis Working Group in Peru

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Johns Hopkins School of Public Health, Baltimore, MD, United States, [4]National Institute of Neurological Science, Lima, Peru

Neurocysticercosis, common parasitic disease of the central nervous system, is a leading cause of seizures worldwide. Identification and treatment of tapeworm carriers is key to block further infections and reduce the burden of disease of this zoonosis. In this study we evaluated the prevalence and associated factors of taeniasis in patients with cysticercosis and their close relatives (people living in the same house). Patients with a serological diagnosis of cysticercosis (positive on enzyme-linked immunoelectro transfer blot [EITB, western blot] assay) attending the Cysticercosis Unit in the Institute of Neurological Sciences, a referral center in Lima, Peru, and their relatives were routinely asked to provide at least one stool sample to rule out teniasis by microscopy using a tube sedimentation technique. This retrospective analysis had as its primary outcome the proportion of taeniasis in patients and relatives. Additionally age, sex and place of residence (living or not in Lima, capital of Peru) were evaluated in a logistic regression model to assess their role as associated factors. A total of 4,563 new patients with serological diagnosis of cysticercosis were identified in our unit between June-1999 and December-2010. From them only 3,405 patients and 4,217 relatives provided stool samples. The average age in patients was 36.2 years (SD 18.8) and 26.4 years (SD 18.0) in relatives. The proportion of males among patients was higher than relatives, 49.3% (95%CI ±1.68) and 44.55% (95% CI±1.5) respectively. The prevalence of microscopically confirmed taeniasis among patients was 2.3% (95%CI ±0.5) and 0.8% (95% CI±0.3) in relatives. In the logistic regression including sex age and place of residences as covariates we found that only younger age (OR 0.98 p<0.01) and living outside of Lima (OR 1.83, p=0.059) are associated to taeniasis. The prevalences found both in cysticercosis patients and in their relatives are similar to levels reported in highly endemic areas. Taeniasis should be actively ruled out in patients with positive results to western blot to cysticercosis especially in young population and in people who live outside of Lima.

572

ASSOCIATION BETWEEN EDEMA PERI-CALCIFICATION AND EPILEPTIC SEIZURES: A CASE-CONTROL STUDY IN ENDEMIC AREA FOR CYSTICERCOSIS IN THE NORTHERN COASTAL OF PERU

Luz Maria Moyano Vidal[1], Percy Vilchez[2], Fernando Urizar[3], Exgar Oliva[2], Viterbo Ayvar[3], Javier Bustos[4], Hector H. Garcia[5], For the Cysticercosis Working Group of Peru

[1]Universidad Peruana Cayetano Heredia, Center For Global Health, UMR 1094 Inserm Neuroépidémiologie Tropicale, Institut d'Epidémiologie et de Neurologie Tropicale, Université de Limoges, Research Unit, Hospital Regional II-2 TUMBES, Tumbes, Peru, [2]Universidad Peruana Cayetano Heredia, Center for Global Health, Tumbes, Peru, [3]Universidad Peruana Cayetano Heredia, Center For Global Health, Tumbes, Peru, [4]Unidad de Cisticercosis, Institute of Neurological Sciences, Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, Lima, Peru, [5]Universidad Peruana Cayetano Heredia, Center for Global Health, Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, Unidad de Cisticercosis, Institute of Neurological Sciences, Lima, Peru

Neurcysticercosis (NCC) is a helminthic infection of the Central Nervous System due to larval stage of ***Taenia solium*** and one of the most important contributor of late-onset epilepsy in resources poor-region around the world .Between 30% and 42% of overall epileptic seizures can be attributed to NCC in rural Peru. A previous study performed in patients with calcified NCC and seizures showed that 34.5% presented peri-lesional edema at MRI evaluation. The main objective of this case-control study was to evaluate the association between peri-calcification brain edema and seizures in field conditions in an endemic region for cysticercosis This study was performed in health centers in rural villages of the northern coastal of Peru (Tumbes) where people with epilepsy (PWE) receive monthly their antiepileptic treatment. Fifty-eight PWE with calcified images associates with NCC were included, 29 PWE (case group, CG) were matched by age (+/- 4 years) and sex with their control group (CC), PWE and calcified NCC with more than 02 year without seizures In a window-time of seven days after the last seizure an MRI (axial slides of T1, T2 and Flair protocol) was performed in cases and controls. Females were 17/29 (58.62%), history of partial seizure were more frequent CG compare to CC, 27/29 (93.1%) vs. 17/29 (58.62%), p= 0.0237), Peri-lesional edema was found in 34.48% (10/29) vs. 10.34% (3/26), p=0.028; other variables were not significative. The OR 6.71 [(95%CI 1.18-38.05), p=0.031] to develop an epileptic seizure was higher in PWE with calcified lesions associated with edema in CG compare to CC. In conclusion, edema Peri-calcification is strongly associate to epileptic seizures in PWE and Calcified NCC in field conditions.

573

ASSOCIATION BETWEEN INDIVIDUAL- AND VILLAGE-LEVEL FACTORS AND THE PREVALENCE OF CURRENT INFECTION WITH *TAENIA SOLIUM* CYSTICERCOSIS IN 60 VILLAGES OF BURKINA FASO

Hélène Carabin[1], Rasmané Ganaba[2], Athanase Millogo[3], Pierre Dorny[4], Cici Bauer[5], Ida Sahlu[5], Jean-Bosco Ouédraogo[6], Sarah Gabriel[4], Assana Cissé[6], Zékiba Tarnagda[6]

[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK, United States, [2]AFRICSanté, Bobo Dioulasso, Burkina Faso, [3]University of Ouagadougou, Bobo Dioulasso, Burkina Faso, [4]Institute of Tropical Medicine, Antwerp, Belgium, [5]Brown University, Providence, RI, United States, [6]Research Institute in Health Sciences, Bobo Dioulasso, Burkina Faso

Taenia solium cysticercosis is an infection with great potential to be controlled using One Health. The goal of this study was to use the baseline data from a community-based randomized controlled trial conducted in

60 villages of Burkina Faso to explore the association of environmental- and individual-level variables and human cysticercosis prevalence. Between February 2011 and January 2012, 60 individuals living in 60 villages located in three provinces of Burkina Faso were selected using clustered random sampling. One individual was sampled per compound. The chief of the household, housewife and the participant answered questionnaires about socio-demographic characteristics, sanitation, hygiene, pig management and pork consumption. Blood samples were drawn by venipuncture and the sera were tested for circulating antigens of ***T. solium*** metacestodes. Between March and November 2014, soil texture and pH were measured in each village. A Directed Acyclic Graph was developed to assess the structure of variables affecting environmental contamination and exposure to eggs. Bayesian hierarchical log-binomial models were fitted with individual and village level variables, with village- and province-level random-effect intercepts. Diffuse priors were used. Circulating antigens were detected in 120 of 3609 participants. The prevalence of current cysticercosis infection varied considerably across provinces and ranged from 0% to 11.5% across villages. At the individual level, being aged between 18 and 49, male, and eating pork outside the household were associated with increased prevalence while having access to a latrine and living in a more wealthy household decreased prevalence. At the village level, restraining pigs some of the time, a higher percentage of silt texture and higher pH in the soil decreased the prevalence. This study demonstrates that at the individual level young males who eat pork outside of the home show higher prevalence of cysticercosis. The highly clustered nature of cysticercosis could be explained in part by the soil texture which may impact survival of taeniid eggs in the environment.

574

TH-17 CELLS ARE ASSOCIATED WITH DISEASE ACTIVITY AND PATHOLOGY IN HUMAN ALVEOLAR ECHINOCOCCOSIS

Tuerhongjiang Tuxun[1], Shadike Apaer[1], Hai-Zhang Ma[1], Heng Zhang[2], Hao Wen[2], Amina Aierken[3], Ren-Yong Lin[2]

[1]Department of Liver and Laparoscopic Surgery, Digestive and Vascular Surgery Centre, First Affiliated Hospital of Xinjiang Medical University, Urumqi, China, [2]State Key Laboratory Incubation Base of Xinjiang Major Diseases Research and Xinjiang Key Laboratory of Echinococcosis, First Affiliated Hospital of Xinjiang Medical University, Urumqi, China, [3]Department of Ultrasonography,The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China

Echinococcus multilocularis infections, which usually cause alveolar echinococcosis, are often clinically silent, but some individuals develop severe pathological reactions. In several disease processes, T-helper 17 (Th17) cells have been linked to tissue injuries, while regulatory T cells (Tregs) are thought to down modulate inflammatory reactions. We assessed whether disease activity and pathology in human ***E. multilocularis*** infection is related to the balance of Th17 cells and Tregs. We used a murine model of ***E. multilocularis*** infection to further investigate whether the peripheral profiles reflected ongoing events in tissues. We characterized T-helper cell subsets in the peripheral blood and different hepatic tissue of alveolar echinococcosis patients in an endemic area and in the peripheral blood, spleen, and abdominal cavity of ***E. multilocularis***–infected C57BL/6 mice. Hepatic alveolar echinococcosis patients with active stage had a significantly higher percentage of Th17 cells than those without pathology. Moreover, the Th17 related cytokines and transcription factor were highly elevated in infected hepatic tissue compare with normal tissue. Percentages of interleukin 17–producing cells and related transcription factors were significantly higher in spleen and abdominal cavity of infected mice compare to non-infected mice. This difference was also reflected in the peripheral blood. Our study indicates that Th17 cells may be involved in the pathogenesis of human alveolar echinococcosis.

575

PERFORMANCE COMPARISON OF THREE RAPID DIAGNOSTIC TESTS FOR THE SERODIAGNOSIS OF HEPATIC CYSTIC ECHINOCOCCOSIS IN HUMANS

Francesca Tamarozzi[1], Ilaria Covini[2], Mara Mariconti[3], Roberta Narra[4], Carmine Tinelli[5], Annalisa De Silvestri[5], Federica Manzoni[5], Adriano Casulli[6], Enrico Brunetti[7]

[1]University of Pavia, Department of Clinical Srgical Diagnostic and Pediatric Sciences,World Health Organization Collaborating Centre on Clinical Management of Cystic Echinococcosis, Pavia, Italy, [2]University of Pavia, Pavia, Italy, [3]San Matteo Hospital Foundation, Division of Infectious and Tropical Diseases,World Health Organization Collaborating Centre on Clinical Management of Cystic Echinococcosis, Pavia, Italy, [4]University of Pavia, Department of Clinical Surgical Diagnostic and Pediatric Sciences, WHO Collaborating Centre on Clinical Management of Cystic Echinococcosis, Pavia, Italy, [5]San Matteo Hospital Foundation, Clinical Epidemiology and Biometry Unit, Pavia, Italy, [6]Istituto Superiore di Sanita', Department of Infectious, Parasitic and Immunomediated Diseases, Roma, Italy, [7]University of Pavia, Department of Clinical Surgical Diagnostic and Pediatric Sciences, San Matteo Hospital Foundation, Divison of Infectious and Tropical Diseases,World Health Organization Collaborating Centre on Clinical Management of Cystic Echinococcosis, Pavia, Italy

The diagnosis of cystic echinococcosis (CE) is based on imaging, in particular ultrasound (US) for abdominal CE, complemented by serology when US features are unclear. In rural endemic areas, where expertise in US diagnosis of CE may be scant and conventional serology techniques are unavailable due to the lack of laboratory equipment, Rapid Diagnostic Tests (RDTs) are appealing. However, the performances of immunoassays are heterogeneous and influenced by many variables, and the interpretation of results may be difficult. We evaluated the performances of 3 commercial RDTs for the diagnosis of hepatic CE. Sera from 59 patients with single hepatic CE cysts (38 active, 21 inactive) and 25 patients with non-parasitic cysts were analysed by RDTs VIRapid HYDATIDOSIS (Vircell, Spain), Echinococcus DIGFA test (Unibiotest, China), ADAMU-CE (ICST, Japan), and by RIDASCREEN Echinococcus IgG ELISA (R-Biopharm, Germany). Sensitivity, specificity and ROC curves were compared with McNemar and t-test. For VIRapid and DIGFA, correlation between semiquantitative results and ELISA OD values was evaluated by Spearman's coefficient. Reproducibility was assessed on 16 randomly selected sera with Cohen's Kappa coefficient. Se and Sp of VIRapid (74%, 96%) and ADAMU-CE (57%, 100%) did not differ from ELISA (69%, 96%) while DIGFA (72%, 72%) did (p=0.045). ADAMU-CE was significantly less Se in the diagnosis of active cysts (p=0.019) while DIGFA was significantly less Sp (p=0.014) compared to ELISA. All tests were poorly Se in diagnosing inactive cysts (33.3% ELISA and ADAMU-CE, 42.8% DIGFA, 47.6% VIRapid). ROC curves of VIRapid (AUC 0.851) and DIGFA (AUC 0.722) were significantly different (p=0.042). The reproducibility of all RDTs was good to very good. Band intensity of VIRapid and DIGFA correlated with ELISA OD values (r=0.76 and r=0.79 respectively, p<0.001). RDTs may be useful in resource-poor settings to complement US diagnosis of CE in doubtful cases. In this regard, VIRapid test appears to perform best among the examined kits, but all tests are poorly Se in presence of inactive cysts, which may pose considerable problems of differential diagnosis.

576

GEOPHAGY IS ASSOCIATED WITH ENVIRONMENTAL ENTEROPATHY AND IMPAIRED GROWTH IN CHILDREN IN RURAL BANGLADESH

Christine M. George[1], Lauren Oldja[1], Shwapon Biswas[2], Jamie Perin[1], Gwenyth O. Lee[1], Margaret Kosek[1], Bradley Sack[1], Shahnawaz Ahmed[2], Shahnawaj Ali[2], Rashidul Haque[2], Tahmina Parvin[2], Ishrat J. Azmi[2], Sazzadul Islam Bhuyian[2], Kaisar A. Talukder[2], Abu G. Faruque[2]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Undernutrition is estimated to be an underlying cause of over half of all deaths in young children globally. There is a growing body of literature indicating an association between stunting and environmental enteropathy, a disorder thought to be caused by repeated exposures to enteric pathogens. Environmental enteropathy is thought to arise from unsanitary environmental conditions leading to repeated exposure to enteric pathogen causing infections. To investigate the relationship between exposure to enteric pathogen through geophagy, consumption of soil, environmental enteropathy, and stunting, we conducted a prospective cohort study of 216 children under five years of age in Bangladesh. Geophagy was assessed at baseline using direct observation and caregiver reports. Stool was analyzed at baseline for fecal markers of intestinal inflammation: alpha-1-antitrypsin, myeloperoxidase, and neopterin combined to form an environmental enteropathy disease activity (EE) score, and calprotectin. Eighteen percent of children had observed geophagy events and 28% had caregiver reported events in the past week. Nearly all households had ***Escherichia coli*** (97%) in soil, and 14% had diarrheagenic ***E. coli***. Children with caregiver reported geophagy had significantly higher EE scores (0.72 point difference, 95% confidence interval (CI): 0.01, 1.42). Furthermore, at the 9 month follow-up the odds of being stunted (height for age z-score <-2) was double for children with caregiver reported geophagy (OR: 2.27, 95% CI: 1.14, 4.51). These findings suggest that geophagy may be an important unrecognized risk factor for environmental enteropathy and stunting in susceptible pediatric populations.

577

ESCHERICHIA COLI CONTAMINATION OF COMPLEMENTARY FOODS AND ASSOCIATION WITH DOMESTIC HYGIENE IN RURAL BANGLADESH

Sarker Masud Parvez[1], Laura Kwong[2], Ayse Ercumen[3], Amy Janel Pickering[2], Probir Kumar Ghosh[1], Musarrat Jabeen Rahman[1], Leanne Unicomb[1], Stephen Luby[2]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Stanford University, Stanford, CA, United States, [3]University of California Berkeley, Berkeley, CA, United States

Consumption of contaminated food is particularly harmful for children <2 years who have immature immune systems and are vulnerable to infection. Fecal indicator organisms and pathogens have been detected in children's complementary food in Bangladesh. This study aimed to identify the frequency and concentration of ***Escherichia coli*** in child complementary food and its association with domestic hygiene practices in rural Bangladesh. It was nested within the control arm of a large-scale randomized-controlled trial of water, sanitation, hygiene and nutrition interventions. Field workers collected stored complementary food samples from 608 households with children <2 years, performed spot checks on domestic hygiene and measured the ambient temperature in the food storage area using AcuRite 00325 monitor. Food samples were analyzed using the IDEXX most probable number (MPN) method with Colilert-18 media to detect ***E. coli***. We calculated adjusted prevalence ratios (APR) to assess the relationship between ***E. coli*** and domestic hygiene using modified poisson regression, adjusting for mother's education, household wealth, number of children and number of households in the compound. 58% of stored complementary food was contaminated with ***E. coli*** and high levels of contamination (>100 MPN/dry g food) were found in 12% of samples. High levels of ***E. coli*** contamination was more prevalent in food that was stored uncovered rather than covered (APR=2.0, 95% CI=1.2-3.2), transferred from the storage pot to serving dish by hand rather than utensil (APR=2.0, 95% CI=1.3-3.2), stored at higher ambient temperatures (26-40°C vs. 14-25°C; APR=2.7, 95% CI=1.5-4.7) and stored for longer periods of time (>4 hours vs. ≤4 hours; APR=2.5, 95% CI=1.5-4.2). Food container location, presence of flies and feces in the food storage area, presence of animals in the compound and utensil cleanliness were not significantly associated with high levels of ***E. coli*** contamination. Interventions to keep stored food covered, reduce storage temperatures, avoid hand contact while serving food and reduce storage time would be expected to reduce the concentration of ***E. coli*** in complementary foods.

578

PARASITIC CONTAMINATION OF VEGETABLES FROM SELECTED ORGANIC AND CONVENTIONAL FARMS IN THE PHILIPPINES: ITS IMPLICATIONS TO PUBLIC HEALTH

Kathleen Ordonez, Vachel Gay Paller

Institute of Biological Sciences, Los Banos, Philippines

This is a study on parasitic contamination of vegetables from selected farms in the Philippines. A total of 248 freshly harvested vegetable samples from organic and conventional farms were collected by systematic random sampling. The vegetable samples were processed by means of sedimentation technique. Results showed that 35 out of 248 (14%) vegetable samples were contaminated with eggs/cysts of parasites. The parasites found were ***Ascaris*** sp., ***Toxocara*** sp., ***Trichuris*** sp., ***Balantidium coli***, ***Isospora*** sp. ***Taenia*** sp. and hookworm/strongylid. ***Ascaris*** sp. was considered as the most prevalent parasite in raw vegetables (5.95%) while ***Toxocara*** sp. had the highest mean density of 16 eggs/kg of vegetables. Also, contamination rate was higher in organic farms (15%) than in conventional farms (11%). Lettuce, showed the highest contamination rate among the sampled vegetables in both types of farms. Farming practices and texture of vegetables were some of the factors that contributed to parasite contamination. These findings have important implications on food safety and on public health. The goal of the report is not to scare consumers but to aid regulatory agencies in their efforts to prevent contamination and improve food safety. Hence, proper authorities should address and review policies in certifying organic farms to address these issues.

579

USAGE OF CARBON-FINANCED ("LIFESTRAW") WATER FILTERS BY RURAL KENYAN HOUSEHOLDS

Amy J. Pickering[1], Benjamin F. Arnold[2], Holly Dentz[3], John M. Colford, Jr.[2], Thomas F. Clasen[3], Clair Null[3]

[1]Stanford University, Palo Alto, CA, United States, [2]University of California Berkeley, Berkeley, CA, United States, [3]Emory University, Atlanta, GA, United States

In early 2011, 877,505 Lifestraw family water filters were distributed freely to >4.5 million people residing in Kenya's Western Province by Vestergaard Fransen. The company registered the "Carbon for Water" project under the Gold Standard voluntary market; carbon credits are awarded based on semi-annual audits. This program overlapped a large RCT ("WASH Benefits") evaluating the impacts of water, sanitation, hygiene, and nutrition interventions among households with newborns in rural villages in Kakamega and Bungoma counties. To characterize baseline water management practices and drinking water quality in the study population, we conducted independent household surveys of Lifestraw ownership and usage at 6 (n=499), 12 (n=344) and 18-24 (n=8,224) months post filter distribution; we also sampled stored drinking water to assess levels

of E. coli contamination. We found 90.8% of the surveyed households had received a filter and 93.6% reported that a local Lifestraw behavior promoter had visited in the past 6 months. Reported filter use on currently stored drinking water declined progressively (31.8% at 6-mo, 12.0% at 12-mo, and 8.8% at 18-24mo). Although the percent of households that reported any filter use was higher, it also declined over time (62.7% at 6-mo, 44.0% at 12-mo, and 23.8% at 18-24mo). Few respondents obtained water directly from the filter when asked to fetch a glass of water for a young child (1.1% at 6-mo, 0.7% at 12-mo, 0.4% at 18-24 mo). Microbial quality was improved in Lifestraw filtered vs. unfiltered stored water, but typically still reflected ***Escherichia*** coli contamination (geometric mean 21 vs. 28 ***E. coli*** per 100mL, p=0.021). Half (49.5%) of households reported filters were not functioning after 18-24 mo. Our data suggest carbon-financed water filters have not contributed to improved water quality among households in Kenya's Western Province. While carbon credit financing has been promoted as an innovative means to finance water treatment for low-income populations, our data suggest the program is consistent with other studies showing poor adoption of household water treatment interventions provided programmatically.

580

EFFECTS OF COMPLEX HANDWASHING INSTRUCTIONS ON ADHERENCE AMONG SCHOOL CHILDREN IN A LOW INCOME URBAN COMMUNITY OF DHAKA, BANGLADESH

Nuhu Amin[1], Dawn D. Sagerman[2], Fosiul A. Nizame[1], Kishor K. Das[1], Mohammad Nuruzzaman[1], Jihnhee Yu[2], Leanne Unicomb[1], Stephen P. Luby[3], Pavani K. Ram[2]

[1]International Centre for Diarrhoeal Diseases Research, Bangladesh, Dhaka, Bangladesh, [2]University of Buffalo, Buffalo, NY, United States, [3]Stanford University, Stanford, CA, United States

Interventions to improve handwashing include instructions on how and when to wash hands. Instructions vary in complexity, with some recommending multiple steps. To assess whether increasingly complex handwashing instructions changed adherence among school-aged children, we conducted a randomized trial in a low-income area in Dhaka, Bangladesh. We randomly assigned each child to one of three different handwashing instruction sets: simple, moderate, or complex. The simple instructions had 3 steps: wet, lather, and rinse hands, moderate included the simple instructions plus steps to scrub palms, backs of hands, and dry hands by waving in the air. Complex instructions included the moderate instructions plus steps to scrub between fingers, under nails, and lather for 20 seconds. Fieldworkers observed baseline handwashing practice and then taught participants the handwashing instructions. Participants demonstrated handwashing immediately after intervention, then after two days, and after two weeks. Adherence was defined as the demonstration of all steps prescribed to the assigned group. Fieldworkers collected information from 134 (31%) children in simple, 148 (35%) in moderate and 147 (34%) in complex instruction groups. The mean age of the children was 7.5 years. At baseline, 68% children performed steps included in the simple, 6.7% in moderate and <2.7% in complex instructions. After the intervention, adherence to simple instructions increased to >99% at 3 follow-up time points (immediately after the intervention, after two days and after two weeks). Adherence to all 3 sets of handwashing instructions significantly increased at each follow-up compared to baseline (mean difference: baseline vs. after two weeks= 31% [p<.001] for simple, 32% [p<.001] for moderate and 36% [p<.001] for complex instructions). Although adherence to moderate and complex handwashing instructions was low at baseline, children in all groups adhered to the assigned set of instructions two weeks after the intervention. These results suggest that complex handwashing instructions can be included in school handwashing programs for better hand hygiene.

581

MOBILITY UP AND DOWN THE SANITATION LADDER IN RURAL COMMUNITIES OF ZAMBIA FOLLOWING COMMUNITY-LED TOTAL SANITATION TRIGGERING

Scott Russpatrick[1], Jillian Berkowitz[1], Oswell Katooka[2], Chinyama Lukama[3], Abel Manangi[2], Laurie Markle[1], Selenia Matimelo[2], Paul Mboshya[2], Tumba Mupango[1], Leonard Mukosha[2], Engervell Musonda[2], Anne Mutunda[1], Joseph Ngambi[3], Nicolas Osbert[3], John Pinfold[3], Amy Tiwari[1], Benjamin Winters[1], David A. Larsen[4]

[1]Akros, Lusaka, Zambia, [2]Ministry of Local Government and Housing, Lusaka, Zambia, [3]UNICEF Zambia Country Office, Lusaka, Zambia, [4]Syracuse University, Syracuse, NY, United States

The sanitation ladder consists of different stages of sanitation that correlate with increasing or decreasing risk of the transmission of diarrheal disease and soil-transmitted helminthes. Open defecation lies at the bottom rung of the ladder and is the most detrimental to health; the ladder progresses upward toward flush toilets. Between open defecation and flush toilets different types of latrines and latrine attributes are all associated with decreasing risk of disease transmission: a lid covering the hole; a smooth, cleanable floor; and a hand washing station with water and soap or ash. Using mobile-to-web community-led total sanitation (CLTS) data we explored the temporal stability of the three parameters (lid, smooth cleanable floor and hand washing station) across 13,000 communities over 1.5 years and determined factors that lead to ascending and descending the sanitation ladder. Before CLTS implementation an estimated 69.5% of households had access to any latrine; following CLTS implementation an estimated 89.1% of households had access to any latrine. Approximately 5.1% of communities (592) were open defecation free at the beginning of mobile-to-web CLTS, and 31.2% of communities (3650) were open defecation free 1.5 years later. Among villages with any type of latrine coverage the different components of adequate sanitation per latrine in use went from 66.2%, 87.5%, 56.4% before intervention roll-out to 86.9%, 95.0%, 81.4% following intervention rollout for lid, smooth cleanable floor, and hand washing station, respectively. As communities climbed the sanitation ladder toward open defecation free temporal instability was noted in latrine access and all three parameters. Approximately half of villages reported backsliding down the sanitation ladder at some point in their push toward ODF. Progress up the sanitation ladder appears to be unstable, with gains made in climbing the sanitation ladder subject to temporary setbacks. Continuous monitoring is helpful for the reinforcement of latrine construction and ensuring that adequate latrine components are present.

582

BEHAVIORAL IMPACT OF PROMOTING WATERLESS HAND CLEANSING WITH CHLORHEXIDINE DURING THE PERINATAL PERIOD: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

Pavani Kalluri Ram[1], Farzana Begum[2], Anne Weaver[1], Christina Crabtree-Ide[1], Dostogir Harun[2], Jelena Vujcic[1], Swapna Kumar[1], Sharifa Nasreen[2], Stephen P. Luby[3], Shams El Arifeen[2]

[1]University of Buffalo, Buffalo, NY, United States, [2]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]Stanford University, Palo Alto, CA, United States

One-quarter of neonatal deaths are attributable to infections. Observational data suggest that maternal handwashing with soap prevents neonatal mortality but maternal handwashing is difficult to increase in the neonatal period. We conducted a randomized controlled trial to test the impact of a chlorhexidine-based waterless hand cleansing promotion on behavior of mothers and other household members. In a demographic surveillance area in Bangladesh, we randomized consenting pregnant women at 32-34 weeks gestation to intervention or control. In the intervention arm, behavior change communicators promoted chlorhexidine

hand cleansing to pregnant women and their household members, and provided a bottle of 4% chlorhexidine lotion. Using data from structured observations, we compared hand cleansing with chlorhexidine or handwashing with soap before baby care among mothers and household members in the intervention arm to those in the control. Chlorhexidine was observed in the baby's sleep space in 97% of 130 intervention homes, compared to soap in 59% of 128 control homes. Hand cleansing before baby care was observed 5.6 times more frequently among mothers in the intervention arm, compared to controls (95% CI 4.0 - 7.7). Hand cleansing was observed at 34% of baby care events among women other than the mother in the intervention arm and 3% in the control arm (RR 10.9, 95% CI 5.1 - 23.1). Girls in the intervention arm cleansed hands before baby contact 37.0 times more frequently than those in the control arm (95% CI 5.2 - 263.7). Men and boys in the intervention cleansed hands before 29% and 44% of baby care events, compared to 0% for each in the control arm. A waterless hand cleansing option using chlorhexidine resulted in substantial increases in hand cleansing behavior among mothers who have greatest contact with neonates. Other household members, particularly children who may introduce new organisms to the neonate's environment, had far greater increases in hand cleansing in the intervention arm than mothers. The impact of chlorhexidine hand cleansing among mothers and other household members on neonatal infections should be evaluated.

583

RETROSPECTIVE LONGITUDINAL GENOMIC SURVEILLANCE OF *PLASMODIUM FALCIPARUM* MALARIA PARASITES DOCUMENTS THE EMERGENCE OF ARTEMISININ RESISTANCE IN THAILAND

Gustavo C. Cerqueira[1], Ian H. Cheeseman[2], Shalina Nair[2], Marina McDew-White[2], Alexander Melnikov[1], Francois Nosten[3], Timothy J. Anderson[2], Daniel E. Neafsey[1]

[1]Broad Institute of Massachusetts Institute of Technology and Harvard, Cambridge, MA, United States, [2]Texas Biomedical Research, San Antonio, TX, United States, [3]Shoklo Malaria Research Unit, Mahidol University, Mae Sot, Thailand

Artemisinin-based combination therapies (ACT) are the first line treatment for ***Plasmodium falciparum*** infections worldwide, but resistance to artemisinin (ART) has risen rapidly in prevalence in Southeast Asia over the last decade. Mutations in the gene encoding the kelch protein (PF3D7_1343700) located on chromosome 13 of ***P. falciparum*** have been associated with ART resistance. However, this locus eluded several efforts to identify resistance genes using genome wide association studies and scans for signals of natural selection, and it is still unclear if mutations in other genes also contribute to ART resistance. To explore the power of a longitudinal genomic surveillance approach to detect a resistance signal in ***kelch*** and other loci that potentially contribute to ART resistance, we retrospectively sequenced and analyzed the genomes of 148 ***P. falciparum*** isolates collected from patients from two sites in Northwest Thailand between 2001 to 2012, bracketing the era in which there was a rapid increase in ART resistance in this region. We employed hybrid selection to enrich the fraction of parasite DNA in samples collected in 2008 or earlier, which were not white cell depleted prior to DNA extraction. This dataset enabled us to observe changes of SNP allele frequencies genome-wide during the process of acquisition of resistance to ART, including alleles in ***kelch*** now known to be associated with this phenotype and other candidate biomarkers. We evaluated multiple statistical metrics of temporal change in the frequency of individual SNPs or the diversity profile of genes. Assuming that SNPs associated with resistance should exhibit a change in frequency proportional to the increase in ART resistance over this time period, the resistance-associated C580Y mutation in ***kelch*** exhibits the strongest signal of any variant in the genome. However, other loci exhibit temporal signatures nearly as strong, and warrant further investigation. This analysis demonstrates the potential of a longitudinal genomic surveillance approach to detect resistance loci and improve our mechanistic understanding of how resistance develops.

584

MODELING MALARIA GENOMICS REVEALS TRANSMISSION DECLINE AND REBOUND IN SENEGAL

Rachel Fath Daniels[1], Stephen F. Schaffner[2], Edward A. Wenger[3], Joshua L. Proctor[3], Hsiao-Han Chang[1], Wesley Wong[1], Nicholas Baro[1], Daouda Ndiaye[4], Fatou Ba Fall[5], Médoune Ndiopg[5], Mady Ba[5], Danny A. Milner[6], Terrrie E. Taylor[7], Daniel E. Neafsey[2], Sarah K. Volkman[1], Philip A. Eckhoff[8], Daniel L. Hartl[9], Dyann F. Wirth[1]

[1]Harvard School of Public Health, Boston, MA, United States, [2]Broad Institute, Cambridge, MA, United States, [3]Institute for Disease Modeling, Bellevue, WA, United States, [4]University Cheikh Anta Diop, Dakar, Senegal, [5]Programme National de lutte contre le Paludisme, Dakar Fann, Senegal, [6]Brigham and Women's Hospital, Boston, MA, United States, [7]Michigan State University, East Lansing, MI, United States, [8]Institute for Disease Modeling, Boston, MA, United States, [9]Harvard University, Cambridge, MA, United States

We examined a set of 1,007 ***Plasmodium falciparum*** samples collected in Thiès, Senegal between 2006 2013 in order to study the effects of malaria-control interventions on parasite population genomics. We genotyped these parasite samples using our 'molecular barcode' of 24 single-nucleotide polymorphisms and observed that about 35% of the single-genome samples grouped into subsets with identical barcodes, varying in size by year and even persisting across dry seasons. The barcodes also formed networks of related groups that were similar to those also identified by analysis of 164 completely sequenced parasites that revealed extensive sharing of genomic regions. In at least two cases we found first-generation recombinant offspring of parents whose genomes were similar or identical to genomes also present in the sample. We applied an epidemiological model that tracks parasite genotypes and reproduced these patterns of barcode subsets. Quantification of likelihoods in the model strongly suggests reduced transmission from 2006-2010, with a significant rebound in Thiès in 2012-2013. The reduced transmission and rebound was directly confirmed by incidence data from Thiès and was not found in Senegal overall. These findings imply that intensive intervention to control malaria results in rapid and dramatic changes in parasite population genomics. The results also suggest that genomics combined with epidemiological modeling may afford prompt and continuous tracking of progress toward malaria elimination.

585

DIFFERING POPULATION STRUCTURE AND GENOMIC SIGNATURES OF SELECTION IN SYMPATRIC WESTERN CAMBODIAN *PLASMODIUM VIVAX* AND *P. FALCIPARUM* POPULATIONS: IMPLICATIONS FOR ELIMINATION AND VACCINE DEVELOPMENT

Christian M. Parobek[1], Eric J. Barnett[2], Jessica T. Lin[2], Chanthap Lon[3], Charlotte Lanteri[4], Sujata Balasubramanian[2], Michele D. Spring[4], Char Meng Chour[5], David L. Saunders[4], Jeffrey A. Bailey[6], Jonathan J. Juliano[2]

[1]Curriculum in Genetics and Molecular Biology, University of North Carolina, Chapel Hill, NC, United States, [2]Division of Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, [3]U.S. Army Medical Component, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, and Phnom Penh, Cambodia, Bangkok, Thailand, [4]U.S. Army Medical Component, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [5]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, [6]Division of Transfusion Medicine and Program in Bioinformatics and Integrative Biology, University of Massachusetts School of Medicine, Worcester, MA, United States

Plasmodium vivax and ***P. falciparum*** populations circulating in Cambodia are being shaped by intense selective forces. To provide a comprehensive comparison of the genes under selection in sympatric

Cambodian ***P. vivax*** and ***P. falciparum*** populations, we whole-genome sequenced (WGS) 70 ***P. vivax*** and 75 ***P. falciparum*** clinical isolates, which were collected from three provinces during 2009-2013 as part of an ongoing antimalarial drug-susceptibility study. Based on our WGS data, ***P. vivax*** infections were commonly multiclonal with no population structure, while ***P. falciparum*** infections were monoclonal and demonstrated strong population structure within and between provinces. This suggests that recent demographic events - eg. selection and migration - have not affected admixture within the ***P. vivax*** population to the same degree as ***P. falciparum***. To better understand how these demographic events have shaped antigenic selection within Cambodian ***P. vivax*** and ***P. falciparum*** populations, we used coalescent simulations to model the effect of these forces for >90% of all ***P. falciparum*** and ***P. vivax*** genes. ***P. vivax*** and ***P. falciparum*** populations showed overall negative gene-wise Tajima's D values, consistent with a purifying selective event followed by population expansion. Among the minority of genes with signatures of balancing selection, erythrocytic stage vaccine candidates in both species were over-represented (eg. AMA-1, MSP-1). However, the protein domain under selection frequently varied between orthologs, suggesting that critical antigenic moieties vary between species. In addition, vaccine-candidate antigens expressed during non-erythrocytic stages - eg. CSP and TRAP - showed species-specific differences in selection, with ***P. falciparum*** antigens exhibiting higher diversity and stronger balancing selection. As the first genome-wide comparison of sympatric ***P. falciparum*** and ***P. vivax*** populations, our data demonstrate profound differences in population structure and orthologous vaccine candidates while providing insights into how control interventions and vaccine design must be tailored to address each species.

586

IDENTIFICATION AND FUNCTIONAL CHARACTERIZATION OF AN ESSENTIAL RNA-BINDING PROTEIN IN *PLASMODIUM FALCIPARUM*

Alejandra Falla, Suresh M. Ganesan, Jeffrey C. Wagner, Jacquin C. Niles

Massachusetts Institute of Technology, Cambridge, MA, United States

Malaria remains a major global health problem for which new drugs and effective vaccines are urgently needed for prevention, treatment and disease eradication. These efforts are significantly hindered, however, by a poor understanding of the parasite's biology. About 50% of ***Plasmodium falciparum*** genes are of unknown function, as few tools previously existed for doing robust functional genetics studies in ***P. falciparum.*** RNA-binding proteins (RBPs) are an important, yet poorly understood, class of proteins that are putatively involved in regulating various aspects of RNA metabolism in the parasite. However, most of the annotated RBPs have no described function. Since RBPs participate in processes essential for parasite survival, they may represent a novel class of therapeutic targets. To test this idea, we used a highly efficient CRISPR/Cas9 genome editing method to achieve conditional regulation of a putative RBP candidate gene by an anhydrotetracycline-inducible translation control system we previously developed. Protein expression profiling revealed tight regulation of expression. In growth assays, we find that knocking down expression of this RBP severely impairs parasite asexual growth after two generations; strongly indicating this protein is essential for intraerythrocytic development. We are presently carrying out various biochemical, cell biology and RNA-Seq experiments to characterize this protein and elucidate its mechanism of action. We believe that the integrated approach we have taken here will enable efficient identification of targets for potential antimalarial therapies and vaccines.

BRIDGING EPIGENETIC AND GENETIC CONTROLS IN MALARIAL ANTIGENIC VARIATION WITH EVOLUTIONARILY CONSERVED NONCODING ELEMENTS

Chengqi Wang, Swamy Rakesh Adapa, Stephen Sutton, Rays H. Y. Jiang

University of South Florida, Tampa, FL, United States

Antigenic variation in ***Plasmodium falciparum*** depends on the tight transcriptional regulation of var multi-copy gene family. To escape host immune detection, restricted subset of var genes are expressed few at a time. This mutually exclusive expression pattern is primarily controlled by modifications of chromatin structure as well as DNA regulatory elements associated with each var gene. However, the relationship between epigenetic and genetic control remains to be established. Here, we showed the intron region of each var gene always keeps a 'poised' epigenetic state, which have high potential to bind transcriptional factor (TF). The presence of stable transcripts for different var gene family is associated with this 'poised' potential. We further delineated a set of specific sequence elements located on the edge of intron region that play a key role for 'anchoring' this poised state. Interestingly, this Conserved Noncoding Element (CNE) is conserved in the introns of kir genes in ***P. knowlesi*** - which is another malaria parasite exhibiting antigenic variation. Taken together, our work showed the regulatory element binding potential in intron region is involved in the control mechanism of var gene expression and is differentially regulated among different var genes mediating antigenic variation.

CYP2D6 GENOTYPES AND *PLASMODIUM FALCIPARUM* GAMETOCYTE CLEARANCE AFTER SINGLE-DOSE PRIMAQUINE IN BURKINA FASO

Helmi E. Pett[1], Chris Drakeley[2], Bronner Goncalves[2], Alfred B. Tiono[3], Kjerstin Lanke[1], Mikko Neuvonen[4], Robert Sauerwein[1], Sodiomon B. Sirima[3], Mikko Niemi[4], Teun Bousema[1]

[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, [4]Department of Clinical Pharmacology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland

Genetically determined cytochrome P450 2D6 (CYP2D6) metabolizer phenotype may determine primaquine (PQ) efficacy by influencing its biotransformation into active metabolite(s). While there is evidence that ***CYP2D6*** genotype influences primaquine efficacy against ***P. vivax*** hypnozoites, it has not been shown that the same holds true for the gametocytocidal activity of PQ on ***P. falciparum***. As part of a dose-finding study, Burkinabè children (aged > 2 and < 15 years) with asymptomatic malaria infection were randomized to receive artemether-lumefantrine (AL) with primaquine (0.25 or 0.4 mg/kg single dose) or placebo at the time of the fifth dose of AL. Gametocyte carriage at days 0 and 7 was determined by ***Pfs25*** quantitative nucleic acid sequence based amplification (QT-NASBA) on nucleic acids from 50µL blood samples. DNA was extracted from EDTA-anticoagulated whole blood samples and genotyped for 19 ***CYP2D6*** sequence variants using custom TaqMan genotyping OpenArrays on a QuantStudio 12K Flex Real-Time PCR system. ***CYP2D6*** copy number was determined using two TaqMan copy number variation assays. In preliminary analyses 90/109 samples were successfully genotyped for ***CYP2D6***. CYP2D6 metabolizer status was inferred from the genotypes with the classical method, yielding predicted phenotypes for all but one of the genotyped individuals. The number of poor metabolizers (PM) and ultrarapid metabolizers (UM) in this Burkinabè cohort was low (PM=3%, UM=4%), but 34% (30/89) of the children were intermediate metabolizers (IM). Data for gametocyte prevalence on both days 0 and 7 was available for 77/89. Preliminary data for both PQ treatment arms were combined

and indicated that 72% (36/50) of extensive metabolizers (EM) and UMs had cleared gametocytes by day 7 compared to only 48% (13/27) of IMs and PMs (p=0.038). Data collection is currently ongoing; our preliminary data suggest an important role for CYP2D6 metabolizer phenotype in determining the ***Plasmodium falciparum*** transmission-blocking properties of primaquine.

GENOME WIDE ASSOCIATION AND COPY NUMBER VARIATION IN CHILDREN WITH SEVERE MALARIAL ANEMIA

Prakasha Kempaiah[1], Zachary S. Karim[1], Gavin Pickett[2], Christophe G. Lambert[1], John M. Ong'echa[3], Douglas J. Perkins[1]

[1]Center for Global Health, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, [2]Keck-UNM Genomics Resource, University of New Mexico School of Medicine, Albuquerque, NM, United States, [3]University of New Mexico/KEMRI, Kisumu, Kenya

Infectious diseases, such as malaria, exert strong natural selection on the human genome as evidenced by genetic variability and altered susceptibility to diseases in different ethnic groups in Africa. To date, studies examining the influence of genetic variability on malaria have largely taken a candidate gene approach. The use of genome-wide association studies (GWAS) is rapidly becoming the favored approach to unravel genetic variations involved in the complex biology of malarial immunity. Although GWAS typically utilizes phenotypically well-defined homogenous populations with large sample sizes, we utilized an approach with a reduced sample size in which polarized extremes were enriched from a homogenous population with ***Plasmodium falciparum*** in Western Kenya (n=1,654). To identify markers associated with susceptibility to severe malarial anemia [SMA, hemoglobin (Hb)<5.0 g/dL)], we investigated genetic variation in children with malaria who had exceedingly low Hb levels (n=22, avg. Hb=4.1, case) versus and those with high Hb levels (n=26, avg. Hb=10.8, control). Children with HIV-1, bacteremia, HbAS, and G6PD deficiency were excluded from selection. The GWAS was performed using Illumina®'Human(Omni2.5) beadchip' with >2.45M markers to profile both SNPs and copy number variants (CNVs). Variants were selected using the GenomeStudio® genotyping module. A full regression model was created (controlling for covariates and Bonferroni correction) using SNP and Variation Suite (SVS). SNP analysis identified 1,007 variants across 339 genes with ***P*** values between 4.01×10^{-7} to 9.99×10^{-4}. CNV analysis identified 315 genes with increased copy numbers (>2) and 940 genes with decreased copy numbers (≤1). Additionally, functional canonical pathway networks generated using GeneGo® identified 7 networks with high significance ($P < 1.0 \times 10^{-19}$) for genes associated with the host-immune response, signal transduction, and hematopoiesis. This strategy demonstrates that individuals representing polarized extremes from a larger population can be utilized to identify novel variants associated with malaria susceptibility.

590

ASYMPTOMATIC HUMANS TRANSMIT DENGUE VIRUS TO MOSQUITOES

Louis Lambrechts[1], Veasna Duong[2], Richard Paul[1], Sowath Ly[2], Srey Rath Lay[2], Kanya C. Long[3], Chantha Ngan[4], Arnaud Tarantola[2], Thomas W. Scott[3], Anavaj Sakuntabhai[1], Philippe Buchy[2]

[1]Institut Pasteur, Paris, France, [2]Institut Pasteur in Cambodia, Phnom Penh, Cambodia, [3]University of California, Davis, CA, United States, [4]National Dengue Control Program, Ministry of Health, Phnom Penh, Cambodia

Dengue is a self-limiting, systemic infection caused by RNA viruses transmitted by ***Aedes*** mosquitoes. Close to 400-million dengue virus (DENV) infections are estimated to occur each year throughout the tropics, of which about 75% are clinically inapparent. Symptomatic DENV infections cover a wide range of disease manifestations from mild febrile illness to severe and fatal disease. People with mildly symptomatic and clinically inapparent DENV infections are generally assumed to inefficiently infect mosquitoes and, therefore, to not be important contributors to DENV transmission. We used cluster sampling around confirmed cases to identify 182 people with natural, active DENV infections and quantify human-to-mosquito transmission across a wide spectrum of disease manifestations, including 14 people with no detectable symptoms and 42 viremic people prior to the onset of symptoms. Despite their lower average level of plasma viremia, the contribution of asymptomatic people to mosquito infection was similar to those with symptomatic infections, due to their higher relative infectiousness. At a given level of viremia, people with asymptomatic and presymptomatic DENV infections are markedly more infectious to mosquitoes than when a person's infection was symptomatic. Because DENV infected people with mild or undetectable symptoms may be exposed to more mosquitoes than sick people through their undisrupted daily routine and they represent the majority of DENV infections, our data indicate that mild and inapparent infections contribute significantly more to DENV transmission than previously recognized. This finding fundamentally changes the current paradigm of DENV transmission dynamics, which is based on people with apparent infections.

591

TRENDS IN CASES OF DENGUE IN INFANTS: INSIGHTS INTO SEROTYPE DIFFERENCES IN DISEASE IN NAÏVE AND NON-NAÏVE INDIVIDUALS AND POPULATION TRANSMISSION DYNAMICS

Hannah E. Clapham[1], Ananda Nisalak[2], Siripen Kalayanarooj[3], Butsaya Thaisomboonsuk[2], Chonticha Klungthong[2], Stefan Fernandez[2], Anon Srikiatkhachorn[4], Louis R. Macareo[2], Justin T. Lessler[1], Derek A. Cummings[1], In-Kyu Yoon[2]

[1]Department of Epidemiology, Johns Hopkins School of Public Health, Baltimore, MD, United States, [2]Department of Virology, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]Queen Sirikit National Institute of Child Health, Bangkok, Bangkok, Thailand, [4]Division of Infectious Diseases and Immunology, Department of Medicine, University of Massachusetts Medical School, Worcester, MA, United States

Infants with maternally acquired antibody to dengue provide unique insight into dengue pathogenesis in immune modulated infections. This age group may also provide important information on population level transmission dynamics. Using serotype specific dengue case data from Queen Sirikit National Institute of Child Health over 40 years (1973-2012), we compared infant (<1 year old) dengue cases to other paediatric dengue cases (both primary and secondary). The serotype distribution of cases in infants (proportions DENV1-4: 0.37, 0.32, 0.27, 0.04) was more similar to the serotype distribution of secondary cases (0.35, 0.31, 0.22, 0.12), than the distribution of primary cases (0.57, 0.05, 0.37, 0.01). This is consistent with intrinsic differences between serotypes in the ability to cause disease in immune-naïve and non-naïve individuals. For cases of all serotypes, the mean age in the under 1s was 6.7 months (95% CIs; 6.6, 6.9). The mean age was 7.3 months (6.9, 7.5) for DENV1 and DENV3, 6.7 months (6.5, 7) for DENV2 and 5.9 months (5 to 6.5) for DENV4. These differences between serotypes could be explained by previously reported serotype differences in maternal antibody decline (with DENV1 the slowest and DENV4 the fastest), leading to differences at which protection ends and enhancement starts. We show that trends over time in the mean age of under 1s mirror trends in mean age of cases in the general paediatric population, suggesting transmission dynamics at a population level are reflected in trends in age of infant cases. We observe that as the mean age of cases increases, a smaller proportion of cases occurs in the under 1s. This is consistent with a decrease in the force of infection leading to an increase in the mean age, and more infections after the age of 1 leading to a reduction in the risk of severe disease upon first infection. We conclude that cases in infants give insight into dengue pathogenesis and transmission dynamics. An understanding of disease in infants will be of increasing importance after the introduction of a dengue vaccine, particularly a vaccine that will not be given to this group, or one which reduces disease but not infection.

592

INTRAHOST SELECTION PRESSURES DRIVE RAPID DENGUE VIRUS MICROEVOLUTION IN ACUTE HUMAN INFECTIONS

Poornima Parameswaran[1], Chunling Wang[1], Surbhi B. Trivedi[1], Meghana Eswarappa[1], Magelda Montoya[1], Angel Balmaseda[2], **Eva Harris**[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Centro Nacional de Diagóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Dengue, caused by infection with one of the four serotypes of dengue virus (DENV-1 to DENV-4), is the most prevalent mosquito-borne viral disease in humans. Yet, the selection pressures driving DENV evolution within human hosts ('intrahost') remain unknown. We employed a whole-genome segmented amplification approach coupled with deep sequencing to profile DENV-3 intrahost diversity in 68 peripheral blood mononuclear cell (PBMC) and 31 plasma samples from 77 dengue patients from a hospital-based pediatric dengue study in Nicaragua. DENV-3 intra-human diversity in acute dengue appears to be directed by the immune repertoire, with reduced variation observed in individuals with pre-existing immunity (secondary infection) in contrast to patients with primary DENV infection. In addition, we detected distinct DENV variant populations in plasma compared to PBMC samples, suggesting that cell-free circulating virions were derived from replication sites distinct from PBMCs. We also identified one hotspot for variation in the Envelope gene (E-315) and two linked hotspots in the pre-Membrane gene (prM-100,101 and prM-101) that were present in 60-78% of the patients. These variants arose via convergent viral microevolution, as determined by the manifestation of these hotspots in four distinct haplotype backgrounds spanning the prM-100,101 and E-315 hotspots. Furthermore, we constructed infectious clones with the E-315 or prM-100,101 mutations and demonstrated that the dominant intrahost variants exhibited reduced replicative fitness and altered epitope accessibility profiles. Dengue is thus a salient example of an acute human infection in which selection pressures within infected individuals drive rapid intrahost virus evolution. The immune pressures driving DENV microevolution could provide additional insights into dengue pathogenesis and disease outcome, as well as the efficacy of vaccines and therapeutics.

593

FORMULATION AND EVALUATION OF A REAL-TIME CLIMATE-BASED DENGUE FEVER FORECAST MODEL FOR THAILAND IN 2015

Stephen A. Lauer[1], Nicholas G. Reich[1], Krzysztof Sakrejda[1], Derek A. Cummings[2], Paphanij Suangtho[3], Hannah Clapham[2], Suthanun Suthachana[3], Soawapak Hinjoy[3], Sopon Iamsirithaworn[3], Justin Lessler[2]

[1]University of Massachusetts, Amherst, Amherst, MA, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Thai Ministry of Public Health, Bangkok, Thailand

Dengue is a mosquito-borne infectious disease that places an immense public health and economic burden upon Thailand. Annual outbreaks of varying sizes provide a particular challenge to the public health system because treatment of severe cases requires significant resources. Advanced warning of increases in incidence could help public health authorities allocate resources more effectively and mitigate the impact of epidemics. In collaboration with the Thai Ministry of Public Health (MoPH) and Bureau of Epidemiology, we have developed a statistical model for infectious disease surveillance that uses data from across Thailand to give early warning of developing dengue epidemics in real time. For each province, the forecast is based on (1) seasonal dynamics of dengue in the focal province, (2) observed case counts at recent time-points from the focal province and neighbors demonstrated to be relevant through model selection using historical data, and (3) short-term weather patterns provided by NOAA weather grids and stations. Beginning in April 2014, we created updated forecasts every two weeks based on the most current data from the Thai MoPH database. We will present the results of this real-time forecasting exercise, including evaluating the performance of different forecasting models in predicting different features of the 2014 and 2015 dengue season in each Thai province. Additionally, we will introduce a suite of evaluation metrics designed to measure the accuracy of different aspects of the prediction model, including the model's ability to detect the timing of and magnitude of outbreaks.

594

ESTABLISHING THE WMEL STRAIN OF WOLBACHIA IN *AEDES AEGYPTI* POPULATIONS PREDICTED TO REDUCE THE DISEASE BURDEN FROM DENGUE BY AT LEAST TWO-THIRDS

Neil M. Ferguson[1], Natsuko Imai[1], Gemma Nedjati-Gilani[1], Ilaria Dorigatti[1], Duong Thi Kien[2], Vu Tuan Trung[2], Peter A. Ryan[3], Scott L. O'Neill[3], Cameron P. Simmons[4]

[1]Imperial College London, London, United Kingdom, [2]Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, [3]Monash University, Melbourne, Australia, [4]University of Melbourne, Melbourne, Australia

In recent work we have shown that stably infecting ***Aedes aegpyti*** mosquitoes with the wMel strain of Wolbachia substantially reduces their competence as vectors for dengue viruses, such that establishment of wMel across the ***A. aegypti*** population of an area is predicted to reduce the reproduction number, R0, of dengue by at least 2/3 within the treated zone. Here we examine the potential impact of widescale use of wMel as a vector control measure on the burden of disease arising from dengue infection. We developed a mathematical model of the transmission dynamics of the four dengue viruses and calibrated the model to dengue surveillance data from South East Asia and to the phase III trial results of the Sanofi dengue vaccine candidate. The model was designed to model a wide range of potential interventions measures, including release of Wolbachia-infected mosquitoes, other vector control measures and the introduction of vaccination. We explored the potential impacts of large-scale release and establishment of wMel-infected ***A. aegypti*** on dengue transmission dynamics and disease burden. In all transmission settings, the sudden reduction in the reproduction number of dengue induced by wMel release is predicted to interrupt dengue transmission for a minimum of 5 to 10 years. After that time, in high transmission intensity settings (R0>3), dengue transmission is predicted to resume as a result of the gradual build-up of susceptible individuals (through births) in the population. However, transmission rates are predicted to be substantially lower than prior to the introduction of wMel, leading to a long term reduction in disease burden from dengue of at least two-thirds. In low to moderate transmission settings (dengue R0<3), wMel introduction reduces the reproduction number of dengue below 1, leading to elimination of endemic transmission. A higher intensity of density dependent regulation of larval mosquito populations than typically seen is predicted to reduce the impact of wMel on dengue transmission, but impact predictions are robust to uncertainty regarding the efficiency of vertical transmission of the wMel strain.

595

THE GLOBAL BURDEN OF SEVERE DENGUE

Oliver J. Brady[1], Leon Ochiai[2], Maina L'Azou[2], Simon I. Hay[1]

[1]University of Oxford, Oxford, United Kingdom, [2]Sanofi Pasteur, Lyon, France

Dengue is a tropical disease of global public health importance with symptomatic manifestations that range from mild fever to severe haemorrhage and death. In 2013, the first evidence-based attempt to estimate the global burden of dengue suggested 390 million (95% credible interval 284-528) infections occur each year. Only a small proportion of these infections, however, will manifest as severe dengue cases that are at the highest risk of mortality and place a

disproportionately high burden on the healthcare system. Since the publication of these first estimates, the number of cohort studies that measure dengue incidence have been nearly doubled through on-going research efforts and the addition of the control arm results of the multi-centre Sanofi Pasteur Asian and Latin American vaccine efficacy trials. By monitoring over 10,000 individuals in 34 sites using a common experimental design these cohort studies provide the first reliable estimates of the proportion of severe dengue cases among symptomatic dengue virus infections. Here we provide updated estimates of the global burden of dengue infections and, for the first time, include estimates of severe dengue burden. These estimates reflect significant updates to the database describing dengue's global distribution and incidence with new covariates in an improved and expanded modelling framework. Global and national estimates of severe dengue burden are essential for measuring progress towards the WHO's global strategy goal of reducing dengue morbidity by 25% between 2010 and 2020. Furthermore, these estimates will form an important part of the evidence base for national and international funders to support important resource allocation decisions for dengue control.

596

ESTIMATING WITHIN-HOST DYNAMICS OF DENGUE VIRUS SEROTYPES USING TWELVE YEARS OF INDIVIDUAL-LEVEL LONGITUDINAL SEROLOGICAL DATA

Robert C. Reiner[1], Steven T. Stoddard[2], Brett M. Forshey[3], Carolina Guevara[4], Robert Hontz[4], Eric S. Halsey[4], Amy Morrison[2], Tadeusz J. Kochel[4], Thomas W. Scott[2]

[1]Indiana University, Bloomington, IN, United States, [2]University of California Davis, Davis, CA, United States, [3]U.S. Department of Defense, Washington, DC, United States, [4]U.S. Naval Medical Research Unit - 6, Lima, Peru

Dengue, which is caused by any of four related but antigenically distinct virus serotypes, has increased its incidence and geographic range considerably in the past 50 years. Infection with a DENV serotype induces lifelong immunity to that serotype and a short-term, temporary cross-immunity (TCI) to the other serotypes. Despite a century of research, the strength and duration of TCI remains uncertain because it is difficult to estimate using disease surveillance data. With data from large, longitudinal serological studies, on the other hand, we can evaluate the relative change in infection risk immediately following a DENV infection. We used a 12-year dataset from Iquitos, Peru to estimate the strength and duration of TCI in an endemic population. The dataset contained information from 14,335 individuals whose blood was assayed by PRNT every 6-9 months (38,416 total samples). There were 3,854 interval-censored, serotype-specific infections. We applied a novel modeling approach to simultaneously estimate interactions between serotypes as well as the time-varying intensity of transmission for each serotype (force of infection). We identified significant variation in the duration of TCI and the strength of heterologous protection_ depending on data cleaning assumptions and the functional form of TCI. The presence of individuals that were infected several times over the course of the study (422 with 2 infections, 39 with 3 and 5 who were infected with all 4 serotypes during their time in the cohort) provides strong evidence indicating that TCI is either short-lived or imperfect. The average time between seroconversions for these individuals was 449 days, but 250 occurred in between three sequential assays. We are conducting sensitivity analyses to evaluate model assumptions. Additional analyses are assessing the possibility of within-host interactions that could boost or dampen infectiousness during second, third or fourth infections. Assumptions about TCI in dengue virus transmission play a critical role in disease models. Our findings inform the design of appropriate models, which will be used to guide disease intervention strategies.

597

IMPACT OF INTERMITTENT MASS SCREENING AND TREATMENT (IMSAT) FOR MALARIA ON INCIDENCE OF INFECTION IN AN AREA OF HIGH MALARIA TRANSMISSION IN WESTERN KENYA

Meghna Desai[1], Aaron M. Samuels[1], Wycliffe O. Odongo[2], John Williamson[1], Norbert Awino Odero[2], Kephas Otieno[2], George Okoth[2], Ya P. Shi[1], S. Patrick Kachur[1], Mary J. Hamel[1], Simon Kariuki[2], Kim Lindblade[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya

Malaria burden remains high in western Kenya (population parasite prevalence=39%) despite widespread ITN coverage. Interventions targeting asymptomatic infections, at least one-third of all infections in this area, could help reduce transmission. We implemented the first multi-year community-based, cluster-randomized controlled trial of intermittent mass screening and treatment (iMSaT) for malaria in an area of high transmission. Participants aged 1–75 years were recruited from 10 intervention and 10 adjacent control areas within 3 km of 10 study clinics. Participants in the intervention area (n>27,000) received three rounds of iMSaT annually; they were tested with combination HRP2/pLDH rapid diagnostic tests (RDTs,and those testing positive were treated with dihydroartemisinin-piperaquine. Malaria infection incidence by RDT was estimated through passive case detection at study clinics beginning 6 months prior to iMSaT through 12 months after implementation. Data were analyzed as an interrupted time series. A total of 514 participants were enrolled in the incidence cohort in year 1. Coverage (proportion of intervention population screened at each round) was 73% in September 2013, 80% in January 2014, and 75% in April 2014. Malaria infection incidence at baseline in the intervention and control areas was comparable, 28.1/1000 and 24.2/1000 person-months, respectively (p=0.35). Compared with baseline, there was a 14% (incidence rate ratio [IRR]=0.39 vs 0.46, p=0.046), 16% (IRR=1.17 vs 1.39, p=0.02), and 10% (IRR=1.04 vs 1.15, p=0.22) relative reduction in incidence of malaria infection after the first, second, and third round, respectively. In the first year of follow-up, the crude median time to first infection was 232 days (7.6 months) in the intervention arm and 200 days (6.5 months) in the control arm; hazard ratio of 0.86 (95% CI 0.69-1.07, p=0.16). These preliminary data suggest iMSaT is not associated with a decline in incidence of malaria infection and time until first infection among recipients of iMSaT compared with participants in control villages. Age-specific and second year data will be available in August, 2015.

598

IMPACT, INTERACTIONS AND LIMITATIONS OF LARVICIDING, WINDOW SCREENING, BED NETS AND HUMAN BEHAVIOR FOR PREVENTING MALARIA IN AN AFRICAN CITY WITH READILY AVAILABLE ARTEMISININ-BASED COMBINATION THERAPY AND RAPID DIAGNOSTIC TESTS

Kiware[1], Ying Zhou[2], Neil Lobo[2], Silas Majambere[3], Khadija Kannady[4], Stefan Dongus[3], Nicodem J. Govella[1], Prosper P. Chaki[1], Christopher J. Drakeley[5], **Gerry F. Killeen**[3]

[1]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [2]Notre Dame University, South Bend, IN, United States, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]Ministry of Health and Social Welfare, Dar es Salaam, United Republic of Tanzania, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

In the city of Dar es Salaam in Tanzania, programmatic distribution of insecticide-treated nets and application of mosquito larvicides, as well as provision of artemisinin-based combination therapy and rapid diagnostic

tests, have been complemented by commercial sale of window screening. After a decade of progressively improving coverage with all these interventions, vector populations which remained pyrethroid-susceptible became sparse and lower malaria infection risk became evenly distributed across all ages but stable transmission persisted. High estimated proportion of potential vector exposure occurring indoors (ϖh,i) was protective against malaria among the majority of residents (85.8%) living in houses with window screens (OR [95%CI]= 0.73[0.60,0.90], P=0.0040 and 0.64[0.49,0.83],P=0.00094 for highest and middle versus lowest terciles, respectively) but not in unscreened houses ($P \geq 0.51$). Residents of houses with window screening who spent most night hours indoors (middle and high terciles of ϖh,i) were protected against malaria infection (OR [95% CI]=0.71 [0.59,0.85],P=0.00013) but not those spending even a few hours outdoors in the evening and early morning (P=0.433). Malaria risk among residents with unscreened houses (14.2%) increased with vector density (P=0.0093) and was reduced by larvicide application (OR[95% CI] = 0.42 [0.23,0.74], P=0.0033), but was unaffected by either factor among residents with screened houses (P=0.23 and 0.19, respectively). Only small fractions of persisting malaria infections could be attributed to houses lacking window screens (4.1%), spending time outside screened houses (5.8%), or gaps in larviciding coverage, (15.8%), respectively. Despite high coverage of effective nets, screening and larviciding in this urban context with very sparse populations of pyrethroid-susceptible vectors, malaria transmission persists and further improving coverage and adherence for these interventions are therefore only likely to prevent a minority of remaining cases. New or improved transmission control measures are required to enable elimination of malaria from Dar es Salaam.

FACTORS ASSOCIATED WITH INSECTICIDE TREATED NET USE AND PROTECTION FROM MALARIA INFECTION AMONG SCHOOL-AGED CHILDREN IN MALAWI: A MULTIPLE CROSS-SECTIONAL STUDY

Andrea G. Buchwald[1], Jenny A. Walldorf[1], Lauren M. Cohee[1], Jenna E. Coalson[2], Nelson Chimbiya[3], Andy Bauleni[3], Kondwani Nkanaunena[3], Andrew Ngwira[3], Atupele Kapito-Tembo[3], Don Mathanga[3], Terrie E. Taylor[3], Miriam K. Laufer[1]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]University of Michigan School of Public Health, Ann Arbor, MI, United States, [3]University of Malawi College of Medicine, Blantyre, Malawi

Recent data from Malawi suggests that school-aged children (SAC), aged 5 to 15 years, have the highest prevalence of ***Plasmodium falciparum*** parasitemia among all age groups. They are the least likely group to utilize bed nets, the most commonly used intervention to prevent malaria in Africa. This study examined the effects of a universal mass net distribution campaign in Malawi on net usage among SAC and the duration of the impact. We identified factors that influence net usage among SAC and the protective effect of bed nets in this age group. Six cross-sectional surveys using cluster random sampling were conducted in the rainy and dry seasons in southern Malawi from 2012 to 2014. Mass net distribution occurred between the first and second surveys. Data were collected on household ITN usage as well as demographic variables. Blood samples for detection of ***P. falciparum*** infection were obtained from all household members who were present. Statistical analyses used generalized linear mixed models to account for clustering at the household and neighborhood level. There were 7,296 observations from SAC. SAC used ITNs significantly less frequently than the rest of the population (odds ratio=0.26 [0.24, 0.28]). The OR did not change significantly following mass net distribution. The campaign did lead to a statistically significant population-wide increase in net use, however net use returned to near baseline within 3 years. Lower ratio of people to nets in a household and higher proportion of nets that were hanging at the time of survey were the most important predictors of ITN usage. Older SAC (11-15 yrs) were significantly less likely to use nets than younger SAC (5-10 yrs) (OR=0.24 [0.21, 0.28]). Net use was highly protective against ***P. falciparum*** infection during the dry seasons (OR=0.42 [0.31, 0.59]), but had no significant effect during the rainy seasons. This study suggests that one time net distribution campaigns are not sufficient to increase net usage among SAC. New and targeted interventions are needed to address the high prevalence of infection in SAC.

RISK FACTORS ASSOCIATED WITH MALARIA EPIDEMIOLOGY IN ZANZIBAR: A PRE-ELIMINATION SETTING

Humphrey Raphael Mkali[1], Abdul-wahid Habiba Al-mafazy[2], Mike McKay[3], Issa Garimo[1], Shabbir Lalji[1], Mahdi Ramsan[1], Wahida Hassan[4], Mohamed Ali[4], Abdullah Ali[4], Jeremiah Ngondi[1]

[1]RTI International, Dar Es Salaam, United Republic of Tanzania, [2]Zanzibar Malaria Elimination Programme, Unguja, United Republic of Tanzania, [3]RTI International, Nairobi, Kenya, [4]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania

Imported cases by travelers to and from Zanzibar tend to make up the majority of reported cases. Travel therefore, poses a great challenge in malaria epidemiology and must be addressed if the country is to achieve malaria elimination. This study aimed to identify the risk factors associated with malaria epidemiology in Zanzibar. Malaria surveillance data were collected between August, 2012 and September, 2014. For each case, a message was sent from health facility to a Central server which generated an SMS alert to the District Malaria Surveillance Officer's (DMSO) mobile phone and tablet. Data included patients' names and villages, which enabled the DMSO to follow up patients to their households. All household members of the index cases were tested for malaria using rapid diagnostic tests (mRDT). Household members testing malaria positive were treated with artemisinin-based combination therapy (ACT). Data was subjected to univariate and multivariate analysis, logistic regression model was used to identify the risk factors. Among 18,640 patients followed, 6.2% (1,158) were malaria positive, of which 17.9% (207) were aged below 5 years. Among positive cases significantly increased odds of malaria positivity were found in people aged 5-14 years (odds ratio [OR] 1.6; 95% CI: 1.4-1.9) and who didn't sleep under treated net previous night (OR 1.4; 95% CI: 1.2-1.7). In addition, those with history of fever in the last 2 weeks (OR: 23.2; 95% CI: 19.7-27.4), who had travelled outside Zanzibar in the past one month (OR: 9.8; 95% CI: 8.3-11.6) and patients without nets (OR: 1.3; 95% CI: 1.1-1.6) were found to have significantly increased odds of malaria positivity. Failure to use nets and travel are major drivers of malaria cases in both high and low transmission periods. Identification of gaps in gaps in net use, knowledge and relevant types of human movement, and development of strategies addressing travel is highly recommended.

601

SEROLOGICAL EVIDENCE OF A SUSTAINED REDUCTION IN MALARIA TRANSMISSION 2004-2012 IN BIOKO ISLAND, EQUATORIAL GUINEA

Jackie Cook[1], Chris Drakeley[1], Chris Schwabe[2], John Bradley[1], Daniel Vargas[3], Andrea Rehman[1], Luis Segura[3], Guillermo Garcia[3], Lou Herman[1], Feliciano Monti[3], Immo Kleinschmidt[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Medical Care Development International, Silver Spring, MD, United States, [3]Medical Care Development International, Malabo, Equatorial Guinea

Following comprehensive malaria control interventions since 2004, malaria prevalence in Bioko island, Equatorial Guinea, has reduced substantially. However, the effects of the interventions have been heterogeneous across the island, resulting in residents of some regions remaining at relatively high risk of infection. To determine which regions were experiencing the highest burden of infection and to investigate changes in transmission over time, parasitological and serological measures were compared from two island-wide surveys undertaken in 2008 and 2012. Parasite prevalence, as measured by rapid diagnostic test, decreased from 18.0% to 11.1% between 2008 and 2012 ($p<0.001$), with wide variations by sentinel site.

The change in parasite prevalence between 2008 and 2012 correlated strongly with the change in seroprevalence in children aged 5 and under (r2 0.6, p<0.001). The 2012 data indicated that the seroconversion rate, which is a proxy for the force of infection, has reduced by approximately 80% since interventions began. Spatial analysis suggested transmission had become less heterogenous between 2008 and 2012 but indicated new ***foci*** of transmission had appeared in the South East region. Whilst it appears that interventions were still relatively effective in Bioko, the highlighted hotspots in the South East region, coupled with a lack of further reduction in parasitological and serological measures between 2008 and 2012 in this area, were a cause for concern and indicated that interventions needed to be adapted. This resulted in a concentrated response by the program which has led to a reduction in parasite prevalence in the South East in the subsequent malaria indicator surveys.

602

MEASURING THE IMPACT OF SEASONAL MALARIA CHEMOPREVENTION AS PART OF ROUTINE MALARIA CONTROL IN KITA, MALI

Fatou Diawara[1], **Laura Steinhardt**[2], Almahmoudou Mahamar[1], Halimatou Diawara[1], Tiangoua Traore[1], Douda Kone[1], Ibrahim Diarra[1], Beh Kamate[3], Drissa Outtara[3], Diakalia Diallo[4], Mouctar Diallo[1], Issaka Sagara[1], Aboubacar Sadou[5], Jules Mihigo[6], Erin Eckert[7], Alassane Dicko[1]

[1]Malaria Research and Training Center, Bamako, Mali, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Save the Children, Bamako, Mali, [4]National Malaria Control Program, Bamako, Mali, [5]United States Agency for International Development/US President's Malaria Initiative, Bamako, Mali, [6]Centers for Disease Control and Prevention/US President's Malaria Initiative, Bamako, Mali, [7]United States Agency for International Development/US President's Malaria Initiative, Washington, DC, United States

Seasonal malaria chemoprevention (SMC), the administration of complete therapeutic courses of antimalarials to all children during the malaria transmission season, is a new strategy recommended by WHO in areas of highly seasonal transmission. Although randomized controlled trials (RCTs) have shown SMC to be highly effective, evidence and experience from routine implementation of SMC are limited. This study aimed to evaluate reductions in malaria and anemia when SMC is delivered through routine programs and existing community health workers. A non-randomized pre-post design was used, with one intervention district (Kita), where 4 rounds of SMC with SP+AQ took place in August-November 2014, and one comparison district (Bafoulabé). Children aged 3-59 months from 15 selected localities per district, sampled with probability proportional to size, were surveyed and blood samples collected for malaria blood smears and hemoglobin (Hb) measurement in two cross-sectional surveys, one prior to SMC (July 2014) and one after SMC (December 2014). Difference-in-differences regression models were used to assess and compare changes in malaria and anemia in the intervention and comparison districts. During round 1, 84% of targeted children received at least the first SMC dose, but coverage declined to 67% by round 4. Across the 4 treatment rounds, 54% of children received 4 complete SMC courses. Prevalence of parasitemia and malaria disease (fever+parasitemia) was similar in intervention (23.4%) and control (29.5%) districts prior to SMC (p=0.34). After SMC, parasitemia prevalence fell to 18% in the intervention district and increased to 46% in the control district (Difference-in-differences (DD) OR=0.35; 95% CI: 0.20-0.60). SMC also significantly reduced the odds of malaria disease (DD OR=0.20; 95% CI: 0.04-0.94) and moderate anemia (Hb<8 g/dL) (DD OR=0.26, 95% CI: 0.11-0.65). Routine implementation of SMC in Mali substantially reduced malaria and anemia, with reductions of similar magnitude to those seen in previous RCTs. Improving coverage could further strengthen SMC impact.

603

CHANGES IN MALARIA TRANSMISSION AND IMMUNITY AND THE EMERGENCE OF ARTEMISININ RESISTANCE IN THAILAND FROM 2001-2011

Ricardo Ataíde[1], Rosanna Powell[1], Kerryn Moore[1], Aung Pyae Phyo[2], Alistair McLean[1], James G. Beeson[1], Julie A. Simpson[3], François Nosten[4], Freya J. Fowkes[5]

[1]Burnet Institute, Melbourne, Australia, [2]Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot, Thailand, [3]Centre for Epidemiology and Biostatistics, University of Melbourne, Melbourne, Australia, [4]Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University and Centre for Tropical Medicine, Nuffield Department of Medicine, University of Oxford, Mae Sot, Thailand, [5]Burnet Institute and Monash University, Melbourne, Australia

Over the past decade a series of anti-malaria interventions and control efforts have led to a significant decline in malaria morbidity and mortality globally. A major contributor to this reduction was the introduction of artemisinin derivatives as first line treatment for malaria. Despite this success, resistance to artemisinin derivatives is now well established in western Cambodia, western Thailand, southern Myanmar and southern Vietnam. Resistance to artemisinin, taken as an increase in blood-stage parasite clearance time, has recently been linked to mutations in the ***kelch13*** giving us a potential molecular marker for resistance. However, little is known about how much naturally acquired immunity to blood-stage malaria parasites contributes to the observed clearance times, especially in a scenario of declining transmission and potentially declining immunity. The aim of this study was to quantify the impact of changing immunity in a population from Thailand where transmission is declining, and further assess its impact on parasite clearance and to assess the emergence of resistance to artemisinin derivatives. We obtained dried blood spots and plasma samples from 1,585 hyperparasitaemic patients admitted to clinics of the Shoklo Malaria Research Unit along the northwestern border of Thailand between 2001-2011. Levels of antibodies to the ***Plasmodium falciparum*** merozoite antigens AMA1, $MSP1_{42}$, MSP2 and $EBA140_{RII}$ were measured by ELISA. Polymorphisms in the ***kelch13*** gene were obtained after PCR amplification of the full sequence of the gene. We show that immunity declines between 2001-2004 and is followed shortly by the appearance of mutations in the ***kelch13*** gene which increase in prevalence from 0% to 67.4%. Levels of immunity were lower in patients with slower parasite clearance times, compared to those with faster parasite clearance times. Immunity is therefore an important confounder in the evaluation of resistance to artemisinin when using parasite clearance, particularly in the context of changing malaria transmission.

604

DEVELOPMENT OF AN TRICHURIASIS VACCINE; STARTING FROM THE BEGINNING

Leroy Versteeg

Baylor College of Medicine, Houston, TX, United States

Estimations say that 604 to 795 million people are infected worldwide with ***Trichuris trichuria,*** which causes Trichuriasis. ***T. trichuria*** infects the large intestine and disease transmission occurs by ingestion of the eggs, which are found in feces of infected patients. Symptoms vary from minor to severe with painful passage of the stool, while children may suffer from growth retardation and impaired cognitive development. Although anti-helminthic drugs are available, to many poor people these remain inaccessible. An affordable preventive treatment is needed to prevent infections and reduced transmission of the disease. By using the mouse ***T. muris*** laboratory model, ES antigens from live ***T. muris*** adult worms were extracted and AKR mice were vaccinated with the ES antigens and ISA720 adjuvant subcutaneously. Mice cohorts were as follows: cohort

A was only vaccinated once, cohort B was vaccinated twice, cohort C was vaccinated once and challenged with 300 ***T. muris*** eggs, and cohort D was vaccinated twice and challenged with 300 ***T. muris*** eggs. After sacrificing the animals, immunogenicity studies included antibody analysis of ES specific IgG, IgG1 and IgG2a by ELISA, and cytokine responses of splenocytes which were re-stimulated with ES antigens are currently analysed. It was observed that both one and two vaccinations boosted the ES specific total IgG and IgG1 titers, while the ES specific IgG2a titer remained low. Results also suggested that when challenged with ***T. muris*** eggs, two vaccinations were required to maintain high levels of ES specific IgG and IgG1 and a low-titer of IgG2a. Results from the worm counts in the GI tract showed a reduction of worms in animals vaccinated twice compared to non-vaccinated animals (mean 4.8 vs 50.2 respectively). Data from these studies suggest a T_H2-mediated immune response was induced by the vaccine, and correlated with a decreased worm burden. These results suggest that vaccination can be successful means of eliciting a protective immune response against ***Trichuris.*** Recombinant protein candidate antigens are being identified for vaccine development and their immunogenicity and efficacy evaluated.

605

GROUP 2 INNATE LYMPHOID CELLS ARE EARLY RESPONDERS THAT SUPPORT TH2 EFFECTORS AFTER HELMINTH INFECTION

Jesse C. Nussbaum, Steven J. van Dyken, Ari B. Molofsky, Hong-Erh Liang, Richard M. Locksley

University of California San Francisco, San Francisco, CA, United States

Helminth infections are associated with a modified type 2 immune response, characterized by T helper type 2 (Th2) cell-derived IL-4, IL-5, IL-13, and IL-9. In inflamed tissues, these cytokines recruit and activate innate effector cells, which in turn alter the local environment to repel intruders and repair damage. Modulating immunity to treat and prevent disease requires a more complete understanding of the basic pathways involved. We and others have identified Group 2 Innate Lymphoid Cells (ILC2) as an important novel source of type 2 cytokines in mice and humans. In models of acute and chronic intestinal nematode infection, ILC2 increase in number and in cytokine production, corresponding with eosinophilia and Th2 cell induction. Analysis of cytokine expression in an IL-5/IL-13-dual reporter strain showed different expression patterns in different effector cell types. Deletion of ILC2 and live imaging of inflamed tissue revealed a unique role for these cells in recruitment of other effector cells that persist in chronic infection. We surmise that ILC2 are "first responders," uniquely poised from early development to detect tissue stress and shape ensuing T cell responses. Our data support a highly cooperative innate-adaptive relationship at the initiation of type 2 immunity. Further characterization of these interactions is ongoing, with the goal of identifying novel targets in treating human disease.

606

PHASE 1 TESTING OF THE NA-GST-1/ALHYDROGEL HOOKWORM VACCINE IN BRAZILIAN AND AMERICAN ADULTS

David Diemert[1], Vanderson Valente[2], Janaina Freire[2], Carlo G. Fraga[2], Frederico Talles[2], Shannon Grahek[1], Doreen Campbell[1], Victoria Periago[2], Jill Brelsford[1], Anna Yakovleva[1], Maria F. Gazzinelli[3], Rodrigo Correa-Oliveira[2], Peter Hotez[4], Jeffrey Bethony[1]

[1]George Washington University, Washington, DC, United States, [2]Centro de Pesquisas René Rachou, Belo Horizonte, Brazil, [3]Federal University of Minas Gerais, Belo Horizonte, Brazil, [4]Baylor College of Medicine, Houston, TX, United States

Necator americanus glutathione S-transferase-1 (***Na***-GST-1) is a 24-kDa protein produced by adult hookworms that is thought to play a role in detoxifying heme and other breakdown products of the hookworm blood digestion pathway. Vaccination of laboratory dogs and hamsters with recombinant GST-1 resulted in reduced hookworm fecal egg counts and reduced adult worm burden following challenge with infective larvae. Recombinant ***Na***-GST-1 was expressed in ***Pichia pastoris*** and formulated on Alhydrogel. Two Phase 1 trials were conducted: one in the USA (n=40) and a second in Brazil (n=102). In both studies, healthy adults were vaccinated with 1 of 3 different dose concentrations of ***Na***-GST-1 (10, 30 or 100 µg) either with or without the point-of-injection addition of an aqueous formulation of glucopyranosyl lipid A [GLA-AF], a synthetic Toll-like receptor-4 agonist. Subjects received 3 intramuscular injections at 2-month intervals. In Brazil, the trial was conducted in both hookworm-unexposed volunteers in an urban center and in hookworm-exposed adults (including recently treated) at a rural trial site. In both the US and Brazil studies, the vaccine was well tolerated: common adverse events included mild to moderate injection site pain and tenderness, headache, and nausea. No differences were observed in adverse events between dose groups or GLA formulations. Anti-***Na***-GST-1 IgG antibody levels as measured by qualified indirect ELISA were modest after the 2nd vaccination, but increased significantly from baseline after the 3rd vaccination in those who received 30 or 100 µg ***Na***-GST-1. For each dose concentration of ***Na***-GST-1, the increase in IgG levels was not significantly different in those who received formulations containing GLA-AF. In the Brazilian subjects, the antigen-specific IgG response consisted mainly of the IgG1 subclass whereas in the US subjects, both antigen-specific IgG1 and IgG3 were detected. These first-in-human trials of the ***Na***-GST-1 hookworm vaccine demonstrate that it is well tolerated and immunogenic in both unexposed and exposed adults and justifies further clinical testing of this vaccine.

RNAI COMPETENCY IN ADULT *ASCARIS SUUM* - POTENT, PERSISTENT AND REPRODUCIBLE KNOCKDOWN

Ciaran J. McCoy[1], Neil D. Warnock[2], Louise E. Atkinson[2], Erwan Atcheson[2], Richard J. Martin[3], Alan P. Robertson[3], Nikki J. Marks[2], Aaron G. Maule[2], Angela Mousley[2]

[1]University of Georgia, Athens, GA, United States, [2]Queen's University Belfast, Belfast, United Kingdom, [3]Iowa State University, Ames, IA, United States

The development of anthelmintic resistance threatens the primary mode of helminth parasite control. Whilst the utility of RNA interference (RNAi) for the validation of drug targets in nematode parasites is widely accepted, issues with their variable sensitivity to RNAi have undermined the development of robust gene silencing platforms. ***Ascaris suum*** is an important veterinary-parasite, a zoonotic pathogen and a close relative of the prevalent human parasite, ***Ascaris lumbricoides***. The large size of adult ***A. suum*** has facilitated its development as a tractable model for nematode parasite biochemistry, neurobiology and physiology research. The recent completion of the ***A. suum*** genome has prompted the development of functional genomics tools in this species. Whilst RNAi has been reported in the L3 larval stages of ***A. suum***, it has not been demonstrated in adults, limiting the utility of this gene silencing technique. Here we report efforts to develop an RNAi platform for adult ***A. suum*** through the direct delivery of double stranded (ds)RNAs into the pseudocoelomic cavity of adult female worms. RNAi success was determined through qPCR transcript analysis, and by monitoring encoded protein expression and worm phenotype. The data presented highlight: (i) the dynamics associated with the rate of induction of RNAi in ***A. suum***; (ii) the ability to induce RNAi in tissues distant from the site of dsRNA injection; and (ii) the consistency of RNAi across a range of gene targets expressed in a variety of therapeutically relevant tissues. Despite achieving specific, robust and reproducible transcript knockdown for all target genes, no post-RNAi phenotypes were recorded over the course of these investigations. This was in spite of efforts to: (i) target putatively essential genes; (ii) improve the RNAi trigger delivery methodology; and (iii) employ a highly quantitative electrophysiology-based phenotypic assay. The data described here highlight an opportunity for the development of a functional genomics platform that supports organism-, tissue- and cell-based biology in a model nematode parasite.

608

METHYLPREDNISOLONE ACETATE INDUCES *STRONGYLOIDES STERCORALIS* HYPERINFECTION IN NSG MICE

John B. Patton[1], Sandra Bonne-Annee[2], Jessica Hess[1], April Torigian[1], Erica Hart[1], Thomas J. Nolan[3], James B. Lok[3], David Abraham[1]

[1]Thomas Jefferson University, Philadelphia, PA, United States, [2]National Institutes of Health, Bethesda, MD, United States, [3]University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA, United States

Strongyloides stercoralis infected patients, immunosuppressed with corticosteroids, develop hyperinfection, which if left untreated, has a mortality rate approaching 90%. While immunocompetent mice are resistant to infection with ***S. stercoralis***, we have demonstrated that highly immunodeficient NSG mice support the development of all life stages of this parasite. Interestingly, hyperinfection is not observed in NSG mice, even though they lack macrophages, B, T- and NK cells. In this study we tested the hypothesis that treating NSG mice infected with ***S. stercoralis*** with methylprednisolone acetate (MPA), a synthetic glucocorticoid, would lead to hyperinfection. NSG mice were infected with 5,000 infective third-stage larvae and treated with MPA for 6 weeks. Approximately 50% of infected mice treated with MPA died prior to the conclusion of the experiment. MPA treatment caused a significant increase in the number of parasitic female ***S. stercoralis*** recovered from 61±33 in untreated mice to 708±684 in treated mice. In addition, auto-infective third-stage larvae, which initiate hyperinfection, were not observed in NSG mice but were found in high numbers in MPA treated mice. Despite their severe immune deficiencies NSG mice retain neutrophils and eosinophils. Consequently, we hypothesized that MPA treatment exerted its effect by decreasing granulocyte function, which eliminated immune control of hyperinfection. To test this, NSG mice were treated with monoclonal antibody RB6-8C5 to eliminate granulocytes, however, although the granulocytes were abolished, hyperinfection did not develop in these mice. In conclusion, using a ***S. stercoralis*** hyperinfection model in NSG mice treated with MPA that we developed, we show that hyperinfection is not due to the action of glucocorticoid on B, T, NK cells or granulocytes, leaving open the possibility that these compounds may be acting directly on the parasite.

609

A NOVEL PHARYNGEAL NICOTINIC ACETYLCHOLINE RECEPTOR FORMED BY EAT-2 AND EAT-18 AS A POTENTIAL DRUG TARGET

Alan Robertson, Shivani Choudhary, Samuel Buxton, Richard Martin

Iowa State University, Ames, IA, United States

There is a compelling need for research to develop new anthelmintic targets and drugs. Nicotinic agonists are effective and widely used agents. The nicotinic agonists target nicotinic acetylcholine receptors (nAChRs) found at the nematode neuromuscular junction, causing depolarisation and hyper contraction of the parasite. Previous studies have demonstrated the nAChRs on the nematode pharynx are insensitive to current cholinomimetic drugs. This study was aimed at identifying the potential of EAT-2, a pharyngeal nAChR subunit and EAT-18, a small transmembrane protein, as chemotherapeutic targets. EAT-2 and EAT-18 have been reported to be involved in pharyngeal pumping in ***C. elegans***, hence affecting feeding behaviour. Using molecular techniques, we expressed EAT-2 and EAT-18 from ***C. elegans*** in ***Xenopus laevis*** oocytes. To study the pharmacology of the receptor we used the two electrode voltage-camp technique. Expression of either EAT-2 or EAT-18 alone did not produce a functional nicotinic ion channel. When expressed in combination, EAT-2 and EAT-18 produced a functional receptor that responded robustly to acetylcholine in a concentration-dependent manner. The rank order potency of agonists on this receptor was acetylcholine ≈ nicotine > methacholine > carbachol ≈ butyryl choline > epibatidine > oxantel. However, there was no response to levamisole, cytisine, pyrantel, and tribendimidine. Various nicotine analogues including alpha-cotinine, nornicotine, anabasine, altinicline failed to produce any agonistic activity. Also, alpha-bungarotoxin did not show any significant antagonistic effect on the expressed nAChR. It is worthy of note that EAT-2 is not an nAChR alpha subunit. In conclusion, we report the ability of a non-alpha subunit to express as a functional homomer in oocytes for the first time. The pharmacology of this previously uncharacterised receptor appears to be different from other nAChR's characterized in nematodes. Thus, this subunit offers a possibility for being used as a potential target site for developing new anthelmintic compounds.

610

SPECIES-SPECIFIC ASSOCIATIONS BETWEEN HELMINTHS AND MICRONUTRIENTS IN VIETNAMESE SCHOOLCHILDREN

Brechje de Gier[1], Tran Thuy Nga[2], Pattanee Winichagoon[3], Marjoleine A. Dijkhuizen[4], Nguyen Cong Khan[5], Maiza Campos Ponce[1], **Katja Polman**[6], Frank T. Wieringa[7]

[1]VU University Amsterdam, Amsterdam, Netherlands, [2]National Institute of Nutrition, Ministry of Health, Hanoi, Vietnam, [3]Institute of Nutrition, Mahidol University, Bangkok, Thailand, [4]Copenhagen University, Copenhagen, Denmark, [5]Ministry of Health, Hanoi, Vietnam, [6]Institute of Tropical Medicine, Antwerp, Belgium, [7]Institute de recherche pour le developpement, Montpellier, France

Several different associations between helminth infections and micronutrient status in children have been reported. We aimed to study associations between specific STH species and micronutrients in schoolchildren. Vietnamese children (n=510) aged 6-9 years were recruited from two primary schools. STH infections were determined in stool samples. In blood samples, hemoglobin, ferritin, retinol and zinc were measured, as well as CRP to control for inflammation. Iodine excretion was measured in urine. Associations of single and multiple ***Ascaris lumbricoides, Trichuris trichiura,*** or hookworm infections and micronutrients were estimated by regression techniques. ***Ascaris*** infections showed a specific and dose-dependent relationship with vitamin A. Trichuris and hookworm infections were associated with lower hemoglobin concentration, but not with plasma ferritin. Trichuris-infected children had zinc deficiency less often than uninfected children. The different life cycles of STH species might have specific effects on the absorption or loss of specific micronutrients.

611

VARIATION IN RELAPSE FREQUENCY, SEASONALITY, AND THE TRANSMISSION POTENTIAL OF *PLASMODIUM VIVAX* MALARIA

Michael White

Imperial College London, London, United Kingdom

There is substantial geographical variation in the relapse frequency of ***Plasmodium vivax*** malaria with fast relapsing phenotypes observed in tropical areas with year round transmission and relapses with long-latency observed in temperate areas with seasonal transmission. We hypothesise that much of the global phenotypic diversity in ***P. vivax*** relapses has been generated by the evolution of time to next relapse to optimise transmission potential in a given environmental niche. We develop a mathematical model of ***P. vivax*** relapses incorporating competition between strains with different relapse frequency, and the evolution of strains to optimise their transmission potential. The model was validated using data on the seasonal suitability for malaria transmission (determined by temperature, rainfall and mosquito abundance) and datasets on time to first relapse collected from a large number of geographical locations. In high transmission tropical zones, transmission potential is optimised by strains with time to first relapse of 1 to 3 months - slower relapsing strains will be out-competed. In low transmission tropical areas, transmission

potential is optimised by strains with time to first relapse of 4 to 5 months - long enough for the primary infection to clear. In highly seasonal settings characteristic of temperate zones, transmission potential is optimised by strains with time to first relapse of 8 to 10 months - long enough for hypnozoites to survive winter in the human liver. These findings will have consequences if ***P. vivax*** transmission is lowered through sustained control where we may see the emergence of slower relapsing strains to optimise transmission potential in the new lower transmission setting. In settings where ***P. vivax*** elimination is being pursued, the potential increase in the time to next relapse may introduce additional challenges for the detection and treatment of the last few cases of malaria.

612

PREDICTING MALARIA REINTRODUCTION RISK IN AN AGENT-BASED MODELLING FRAMEWORK TO UNDERSTAND THE IMPACT OF GLOBAL, PATCH-LEVEL, AND INDIVIDUAL VARIANCE

Nick Warren Ruktanonchai[1], Trevor T. Caughlin[2], Amit Verma[3], Tom Bird[1], Chris Lourenco[1], Corrine W. Ruktanonchai[1], David L. Smith[4], Andrew J. Tatem[1]

[1]University of Southampton, Southampton, United Kingdom, [2]University of Florida, Gainesville, FL, United States, [3]Emory University, Atlanta, GA, United States, [4]University of Oxford, Oxford, United Kingdom

Recent research highlights spatial targeting of malaria elimination resources as a potential way to ensure limited resources are used most efficiently. Targeting intervention efforts to reduce costs and achieve regional elimination requires an accurate picture of heterogeneity in transmission intensity and parasite spread across the landscape. Spatially resolved estimates of transmission intensity are often uncertain, however, as source data can be highly clustered or noisy. Quantifying human-facilitated parasite spread is also difficult, as people move for a variety of reasons, vary in movement patterns, and data on movement can be difficult to obtain. Understanding how these uncertainties affect predictions of parasite spread is critical for assessing what data must be obtained for effective spatial targeting, and which factors are the most important predictors. In this study, we use an agent-based modelling approach to quantify the effects of these uncertainties on predictions of malaria spread. We simulate malaria transmission within Namibia using a map of transmission intensity with corresponding estimates of uncertainty, and simulate parasite spread between patches using anonimized mobile phone call data records to inform human movement patterns. Our simulations incorporate uncertainty in the transmission intensity map, demographic stochasticity, and individual-level variation in movements. We partition the variance in malaria spread using a global sensitivity framework to yield the relationships between global uncertainty, patch-level transmission characteristics, and individual-level movement patterns in driving number of cases from a reintroduction event over time. We also found that patch-level transmission intensity alone was a poor predictor of parasite spread, and that network context must be considered with transmission intensity to accurately predict whether particular patches are at high risk for a malaria outbreak.

613

MODELING THE IMPACT OF TRANSMISSION-BLOCKING ACTIVITY ON THE COMPOSITION AND DYNAMICS OF THE MALARIA INFECTIOUS RESERVOIR

André Lin Ouédraogo, Jaline Gerardin, Caitlin A Bever, Philip A Eckhoff, Edward A Wenger

Institute for Disease Modeling, Bellevue, WA, United States

In malaria endemic settings, only infectious gametocyte carriers are responsible for mosquito's infection allowing subsequent transmission of the disease. This fact strongly suggests that a comprehensive understanding of the human infectious reservoir becomes a key prerequisite for malaria control and elimination efforts although limited resources make it challenging to generate required data in several of endemic countries. Anti-gametocyte immunity can influence gametocyte infectiousness and may allow predictions of the infectious reservoir as well as future transmission blocking vaccine testing. The ultimate impact of this type of immunity on the composition and dynamics of the infectious reservoir has never been studied. Here, we use data from an area of intense malaria transmission to calibrate the EMOD agent-based mechanistic model and assess the impact of naturally acquired anti-gametocyte immunity on the composition and dynamics of the infectious reservoir. Repeated measurements were carried out at distinct transmission seasons (start-wet, peak-wet and dry season) and provided data on Pfs48/45 and Pfs230 specific antibody responses as anti-gametocyte immunity. Data on low-density gametocyte infections and their infectiousness were obtained using an ultra-sensitive molecular method and mosquito feeding assays respectively. To predict the composition (high and low-density infection) and the dynamics of the infectious reservoir, model simulations were run accounting for anti-gametocyte immunity or not. A model solution of the age and temporal changes in the infectious reservoir could be obtained when anti-Pfs48/45 and anti-Pfs230 immune responses parameters were accounted for; and not when they were turned off. Our mathematical simulations indicate that anti-gametocyte immunity may be as representative of transmission blocking activity and a key factor for predicting and understanding the composition and the dynamics of the infectious reservoir.

614

IMPACT OF IRS ON MALARIA BURDEN WHEN COMBINED WITH LLIN IN ETHIOPIA: MODELLING THE 2015-2017 MALARIA NATIONAL STRATEGY

Emilie Pothin[1], Olivier Briet[1], Hiwot Solomon[2], Seife Basaye[2], Thomas Smith[1]

[1]Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]National Malaria Control Program, Ministry of Health, Addis Ababa, Ethiopia

The Ethiopian malaria strategy is stratified on transmission level with full coverage of long lasting insecticidal nets (LLINs) in all malarious woredas (sub-districts), supplemented in some woredas by indoor residual spraying (IRS) using carbamate. Simultaneous LLIN and IRS deployment is planned only in epidemic-prone woredas and those with high transmission. Fine scale simulation of multiple scenarios can help to assess the likely impact of such approaches, especially where local data are limited. We simulated malaria transmission, prevalence and burden for each of these woredas using the OpenMalaria platform. Transmission levels were derived from recent annual parasite incidence and parasite prevalence data. National estimates of access to healthcare, historical intervention coverage and malaria seasonality were used to parameterize the simulations further. The national strategic plan for 2015-2017 was simulated accounting for variable levels of effective LLIN usage, access to healthcare and pyrethroid resistance. The predicted incremental benefit of IRS decreases with levels of effective usage of LLINs and of pyrethroid resistance. Changes in mosquito resting/biting behaviour, prevalence of ***Plasmodium vivax*** and LLIN deployment delays would contribute to a higher impact of IRS. The simulations of the different scenarios indicate the expected impact of the interventions in Ethiopia and can be used during decision making process, for example in cost effectiveness analysis. They can also help to understand what would happen when interventions are deployed if all factors influencing malaria transmission intensity could be controlled. Deviations from the predictions could be used to identify where implementation differs from what was anticipated in the plan and hence where additional efforts are required.

615

MODELLING THE POTENTIAL INCREMENTAL VALUE OF INTERMITTENT SCREENING AND TREATMENT IN SUB-SAHARAN AFRICA

Patrick Walker[1], Jessica Floyd[1], Feiko ter Kuile[2], Matt Cairns[3]

[1]MRC Centre for Outbreak Analysis and Modelling, London, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]MRC Tropical Epidemiology Group, London School of Hygiene & Tropical Medicine, London, United Kingdom

We combine estimates from recent trials of the effectiveness of Intermittent Screening and Treatment during pregnancy (ISTp) relative to that of Intermittent Preventative Therapy with sulfadoxine-pyrimethamine (IPTp-SP) with data on how the accuracy of the rapid diagnostic test used in ISTp is likely to vary throughout pregnancy and according to differing levels of immunity, in order to assess the relative effectiveness of ISTp and IPTp-SP across the range of transmission settings in Africa. This work suggests that, as a result of the imperfect sensitivity of the diagnostic and the additional prophylactic value of presumptive therapy, ISTp will not be as effective a strategy for reducing the burden of malaria in pregnancy in areas where the parasite remains sensitive to sulfadoxine-pyrimethamine (SP). Then, using data on the geographical distribution of molecular markers of SP resistance and their relationship to the reduced effectiveness of SP, we mapped how resistance to SP is likely to impact upon the relative effectiveness of the two interventions. Our estimates suggest ISTp is only likely to be more effective than IPTp in areas of "super-resistance", those with substantial prevalence of the A581G sextuple mutation. We estimate that in 2010 these areas represented only 10% of pregnancies across Africa, and only 8% of those pregnancies estimated to have a malaria-attributable LBW baby in the absence of intervention. In areas of intermediate levels of SP resistance, representing much of East Africa, we estimate that an alternative strategy of presumptive therapy with an effective artemisinin combination drug would successfully provide better protection for pregnant women from infection.

616

MODELING THE DYNAMICS OF IMMUNOLOGICAL MEMORY TO MALARIA

Lauren M. Childs, Caroline Buckee

Harvard T.H. Chan School of Public Health, Boston, MA, United States

Each year nearly 200 million people are infected with the malaria parasite, ***Plasmodium falciparum***. One of the most notable features of infection with malaria is the inability of individuals to acquire sterilizing immunity to the parasite. Even with multiple exposures as is common in areas of high endemicity, individuals remain semi-immune avoiding disease but not the presence and persistence of parasites. The failure of protection is almost certainly in part due to parasite strategies to avoid and limit host immune response including antigenic variation. Recent evidence, however, suggests that in addition to parasite-mediated strategies there may be deficiency in the ability of the immune system itself to create long-lived protection against ***P. falciparum***. Conflicting reports of the levels of long-lived malaria-specific antibodies may be the result of the method and timing of measuring antibodies compared to the timing of infection. Here, we develop a mathematical model of the generation and maintenance of B cell and antibody response to ***P. falciparum***. We analyze simulated output to understand the origin of protective as well as ineffective immune responses in the presence of a multitude of varied proteins as well as antigenically varying proteins. We find that the level of persistent antibodies depends upon assumptions on the relative production of different type of antibody producing cells. Understanding the development and maintenance of protective immune responses to malaria is key in the on-going push towards elimination and eradication.

617

OPTIMAL POPULATION-LEVEL DEPLOYMENT OF ARTEMISININ COMBINATION THERAPIES

Tran Dang Nguyen[1], Piero Olliaro[2], Arjen M. Dondorp[3], J. Kevin Baird[4], Ha Minh Lam[1], Jeremy Farrar[5], Guy E. Thwaites[1], Nicholas J. White[3], Maciej F. Boni[1]

[1]Oxford University Clinical Research Unit, Wellcome Trust Major Overseas Programme, Ho Chi Minh City, Vietnam, [2]UNICEF/UNDP/World Bank/ World Health Organization Special Programme for Research and Training in Tropical Disease, Geneva, Switzerland, [3]Mahidol-Oxford Research Unit, Wellcome Trust Major Overseas Programme, Bangkok, Thailand, [4]Eikman-Oxford Clinical Research Unit, Jakarta, Indonesia, [5]Wellcome Trust, London, United Kingdom

Artemisinin combination therapies (ACTs) are used worldwide as first-line treatment against confirmed or suspected ***Plasmodium falciparum*** malaria. ACTs together with vector control, individual protective measures against mosquitoes, prophylactic drug use, and improvements in health care capacity form the basis of modern malaria control and its elimination. Despite the recent success of these strategies at reducing the global burden of malaria, emerging resistance to artemisinin threatens those gains. Countering the onset of resistance may require deliberate tactics aimed at slowing the decline in ACT effectiveness. Using an individual-based microsimulation of regional malaria transmission, we revisit a classical dilemma in evolutionary epidemiology: how to apply a therapy as widely as possible without also accelerating the erosion of its efficacy by drug resistance. We compare the simultaneous distribution of multiple first-line therapies (MFT) against strategies where ACTs would be cycled or used sequentially, either on a fixed schedule or when population-level efficacy reaches the WHO-threshold level of 10% treatment failure. We show that deploying multiple first-line therapies reduces the long-term number of treatment failures when compared to strategies where a single first-line ACT is recommended. We show that this result is robust to various epidemiological, pharmacological, and evolutionary features of malaria transmission. Additionally, we analyze the benefits of including a single non-ACT therapy in an MFT strategy and predict that this approach would have significant benefits in reducing the pressure on artemisinin-resistance evolution, delaying its emergence and slowing its spread. Adjusting national antimalarial treatment guidelines to encourage the simultaneous use of multiple first-line therapies is likely to extend the useful therapeutic life of currently available antimalarials resulting in long-term beneficial outcomes for patients.

618

ACCEPTABILITY OF THEORETICAL IMPLEMENTATION OF MINIMALLY INVASIVE AUTOPSIES IN DIFFERENT CULTURAL AND GEOGRAPHICAL CONTEXTS

Maria Maixenchs[1], Rui Anselmo[2], Mamudo R. Ismail[3], Carla Carrilho[3], Paola Castillo[1], Emily Zielinski-Gutiérrez[4], Frank Odhiambo[4], Shujaat Zaidi[5], Zulfiqar A. Bhutta[5], Rokiatou Dembele[6], Samba Sow[6], Selidji T. Agnandji[7], Bertrand Lell[7], Eusebio Macete[2], Jaume Ordi[1], Clara Menendez[1], Quique Bassat[1], **Khatia Munguambe**[2]

[1]ISGlobal, Barcelona Ctr. Int. Health Res. (CRESIB), Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, [2]Centro de Investigação em Saúde da Manhiça, Manhiça, Mozambique, [3]Hospital Central de Maputo, Maputo, Mozambique, [4]Centers for Disease Control and Prevention/Kenya Medical Research Institute (Research and Public Health Collaboration), Kisumu, Kenya, [5]Department of Pediatrics and Child Health, Aga Khan University, Karachi, Pakistan, [6]Centre pour le Développement de Vaccins in Mali, Bamako, Mali, [7]Centre de Recherches Médicales de Lambaréné, Albert Schweitzer Hospital, Lambaréné, Gabon

Complete diagnostic autopsies (CDAs), the gold standard method for cause of death (CoD) ascertainment, are not routinely performed in low and middle income countries for several reasons, including scarcity

of human and technical resources, and poor acceptability. Minimally invasive autopsies (MIAs), a fine-needle based approach to obtain post-mortem tissues, are being investigated as an alternative to CDA. For MIA implementation, its feasibility and acceptability assessment in diverse cultural, religious and geographical backgrounds is essential. We studied the willingness to know the CoD and the theoretical acceptability of MIAs in Mozambique, Mali, Gabon, Kenya and Pakistan. Five-hundred interviews with key informants (151), health workers (158) and next of kin of recently deceased people (191) were conducted. A thematic analysis was performed. Seventy five percent of interviewees desired to know the CoD of their relative. Theoretical MIA acceptance rates from family members of the deceased at different time-points after death were high, at 71% (15/21) within 24 hours after death, 73% (56/77) in those interviewed 1 to 7 days; and 66% (61/93) between 30 and 40 days. MIA was perceived as acceptable by the majority of participants because of its simplicity, rapidity and avoiding the mutilation of the body. Participants believed that MIA could help to prevent contagious diseases and to address hereditary diseases. Respondents also noted that knowing the CoD could avoid witchcraft accusations and conflicts within the family. Concerns were raised regarding confidentiality for the CoD, fear of organ removal and MIA's compatibility with religious beliefs. A few participants questioned MIA's usefulness, as the person was already dead. Health professionals were more reluctant, with concerns about MIA´s accuracy, or fears related to the questioning of their previous clinical diagnoses. In conclusion, MIA's real acceptability will depend on community's engagement and consideration of potential barriers: confidentiality, delivery of clear messages about the need of knowing the CoD, and sensitization and collaboration of health workers.

619

INTEGRATING TRANSMISSION DYNAMICS IN THE MODELLING OF VACCINATION IMPACT AGAINST YELLOW FEVER IN AFRICA

Kévin Jean[1], Neil M. Ferguson[1], Maria D. Van Kerkhove[2], Sergio Yactayo[3], Wiliam Perea[3], Joseph Biey[4], Messeret E. Shibeshi[5], Tini Garske[1]

[1]MRC Centre for Outbreak Analysis and Modelling, Imperial College, London, United Kingdom, [2]Center for Global Health, Institut Pasteur, Paris, France, [3]World Health Organization, Geneva, Switzerland, [4]AFRO West Africa Inter-country Support Team, Ouagadougou, Burkina Faso, [5]AFRO Eastern and Southern Africa Inter-country Support Team, Harare, Zimbabwe

Yellow fever is a vector-borne flavivirus infection, whose major burden is concentrated in the African inter-tropical area. Eradication is not possible due to the existence of a wildlife reservoir, but a high level of control is achievable as an efficacious and safe vaccine conferring long-lasting immunity is available. After a period of resurgence due to low vaccination coverage, preventive mass vaccination campaigns for yellow fever have been implemented since 2007 in the 12 most affected countries in Africa to curb the rising burden and control future outbreaks. In order to evaluate the burden of Yellow Fever and to assess the impact of recent vaccination campaigns, we developed a comprehensive estimation method based on generalized linear regression models accounting for location of reported outbreaks, surveillance quality, environmental variables and parameters of transmission intensity estimated from serological surveys. We have now further developed this model by integrating a transmission dynamic component. This allowed us to estimate the basic reproduction number R0 at the province level and to account for the indirect protective effect of vaccination due to "herd immunity" enabling us to estimate, at the province level, critical vaccination coverages (CVC) needed to prevent outbreaks. We estimated very low R0 values in numerous provinces in Eastern Africa, but values up to 3.9 [95% CI 1.9-6.9] in Senegal, corresponding to CVC ranging from 0% to 74% [95% CI 48 - 85%]. As of 2012, 19 of the 34 African countries endemic for Yellow Fever had already achieved critical vaccination coverage in ≥90% of their provinces, including 10 of the12 countries with recent mass vaccination campaigns. We identified several provinces with substantial risk of outbreak (R0>1.25) but where <50% of the CVC was achieved, particularly in Mauritania and Guinea-Bissau neither of which have benefited from the recent vaccination activities. Integrating dynamic transmission processes in an existing model allows more comprehensive impact estimates of past and future vaccination campaigns, producing parameters directly useful for disease control strategies.

ASSESSMENT OF MOBILE PHONE SHORT MESSAGE SERVICE (SMS) AS A POST-TRAINING APPROACH IN UGANDA

Ruth Nakaboga Kikonyogo[1], Umaru B. Ssekabira[1], Chime Mukwakwa[2], Paul Oboth[3], Geoffrey Oguma[4], Delanie Ricketts[5]

[1]Infectious Diseases Institute, Kampala, Uganda, [2]Stop Malaria Project, Kampala, Uganda, [3]Busitema University, Kampala, Uganda, [4]School of Public Health, Kampala, Uganda, [5]TechnoSave, California, CA, United States

In Uganda, the population coverage for mobile telephony is close to 100%, while geographical coverage is about 65% according to the Uganda Communication Commission. The Infectious Diseases Institute, through the Stop Malaria Project, assessed the effectiveness of using mobile phone SMS to measure retention of knowledge amongst 95 laboratory personnel from rural health centers. These personnel had previously attended a three-day training on laboratory diagnosis of malaria using microscopy and rapid diagnostic tests (RDT). Six weeks after the training, all 95 alumni began receiving follow-up quiz questions via SMS. The alumni were asked to reply to a toll free SMS platform which instantly acknowledged receipt of response and provided feedback on whether the answer was correct or not. Alumni were asked a total of 25 questions – 21 multiple choice and four free response – over the course of 13 weeks. The questions covered the topics of phlebotomy; preparing, examining, and reporting blood smears; differentiating malaria species; and performing RDTs. A toll free phone line was also used to provide reminders and receive technical queries in relation to the SMS. 71% of the trainees responded to the SMS quiz questions. Multiple choice questions had an average response rate of 74% while free response questions were at 51%. Of the trainees that responded, 75% submitted the correct response. Challenges that hindered responses included busy work schedules, poor network coverage, and lack of battery power. The high percentage of responses in general, and specifically the high percentage of correct responses, shows that SMS is effective as a post-training approach to measure knowledge retention. The results also emphasized that multiple choice questions are more appropriate for SMS post-training follow-up compared to free response questions.

621

CROWDSOURCING HIV TESTING: A PRAGMATIC, NON-INFERIORITY RANDOMIZED CONTROLLED TRIAL IN CHINA

Joseph D. Tucker

University of North Carolina School of Medicine, Guangzhou, China

Crowdsourcing, the process of shifting individual tasks to a large group, may enhance HIV testing interventions. We conducted a non-inferiority, pragmatic randomized controlled trial to compare first-time HIV testing rates among men who have sex with men (MSM) and transgender individuals who received a crowdsourced HIV test promotion intervention to a group who received a health marketing intervention. Participants were recruited through three large Chinese MSM web portals. We randomly assigned 721 MSM and transgender individuals (≥16 years old, never before tested for HIV) to one of two video interventions. The crowdsourced video was developed using an open contest and formal transparent judging while the evidence-based health marketing video was designed by experts. Study objectives were to measure HIV test uptake within four weeks and cost per new HIV test and diagnosis. Overall, 624/721 (87%) participants completed the study from 31 provinces in 217

Chinese cities. HIV test uptake was similar between the crowdsourced arm (37%, 114/307) and the health marketing arm (35%, 111/317). The risk difference between crowdsourced and health marketing intervention was 2.1% (95% confidence interval, -5.4 to 9.7%). Sensitivity analysis using imputation supported the similarity of the two interventions. Among those tested, 31% (69/225) reported a new HIV diagnosis. The crowdsourced intervention cost substantially less than the health marketing intervention per first-time HIV test ($131/person vs. $238/person) and per new HIV diagnosis ($415/person vs. $799/person). Crowdsourcing may be a cost saving tool to enhance community engagement and improve tropical medicine campaigns.

622

VIGILANCIA COMUNITARIA: IMPROVING COMMUNITY-BASED INFECTIOUS DISEASE SURVEILLANCE IN NICARAGUA USING A LOW- COST MHEALTH TOOL FOR DATA COLLECTION AND DECISION SUPPORT

Heather Zornetzer[1], Lionel Gresh[1], Josefina Coloma[2], Eva Harris[2], William Avilés Monterrey[1]

[1]Sustainable Sciences Institute, Managua, Nicaragua, [2]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

In Nicaragua, a critical data source for early detection of infectious disease outbreaks comes from the community level. Nicaragua has an extensive network of 20,000+ community-based volunteers, trained by the Ministry of Health (MoH), who provide important community-level data to the public health system. Over several years working in close collaboration with the Information Systems Office and the Office of Epidemiology and Surveillance at the central and state levels of the MoH, we developed, tested, fine-tuned and helped to implement a community-based mobile surveillance tool called Vigilancia Comunitaria (VC) for use on low-cost Android mobile phones. VC is based on the open source software platform Open Data Kit and was designed as a disease tracking and case referral tool for community health workers (CHWs). The goal of this tool is to help increase efficiency and quality of infectious disease surveillance at the community and municipal levels, while also providing near-real time information via an interactive web-based dashboard alert system to supervisors and disease surveillance personnel in prevention and control activities at the municipal, state and national levels. VC allows CHWs to document and maintain a dynamic community census and to track and monitor the health of individuals (as well as aggregate information at the household level) for probable cases of dengue, leptospirosis, leshmaniasis, malaria, cholera, acute diarrheal and respiratory diseases, poisoning and intoxication events. VC also includes modules for infant mortality and high-risk pregnancies. By late 2014, >1200 CHWs were trained on the use of VC on phones in 4 Northern states in Nicaragua. In 2015, an additional module with family planning methodology and reproductive health outreach information will be added. We present a mixed methods impact evaluation of the VC tool and its capacity as it scales up nationally to 1) increase the efficiency and quality of CHW data collection, reporting and referrals, and 2) improve access by state and national decision-makers to timely and reliable information about disease outbreaks.

623

THE BOSTON COMBINED RESIDENCY PROGRAM PEDIATRIC GLOBAL HEALTH FELLOWSHIP: EDUCATING PEDIATRICIANS FOR CAREERS IN GLOBAL HEALTH RESEARCH

Rachael E. Bonawitz[1], Matthew P. Fox[1], Donald M. Thea[1], Jonathon L. Simon[1], Robert J. Vinci[2], Julie M. Herlihy[3]

[1]Boston University School of Public Health, Boston, MA, United States, [2]Boston University School of Medicine, Boston, MA, United States, [3]University of California Davis, School of Medicine, Sacramento, CA, United States

In recent years, demand for global health (GH) training and experience has risen dramatically in medical education programs in the United States. There has been a proliferation of GH residency tracks and post-graduate fellowships, few of which are designed to prepare medical trainees for careers in global health research. In 2009, a unique GH track for residents was established at the Boston Combined Residency Program in Pediatrics (BCRP), a pediatrics residency co-sponsored by Boston Medical Center and Boston Children's Hospital. One pediatric resident, after completion of their intern year, is selected to extend training by one year, in order to undertake mentored GH research in partnership with the Center for Global Health and Development at the Boston University School of Public Health. The goal is to prepare pediatricians for careers in global health research or service delivery. Since inception, there are four graduates of the BCRP GH program, but their experiences and track record of the fellowship are illustrative: 2 Directors of Pediatric Global Health at their respective academic institutions, 1 Bill & Melinda Gates Foundation Program Officer, and 1 Director of Transitional Medicine at a managed care organization who is also a Director of the Welbodi Partnership NGO in Sierra Leone. With 6 years' experience administering the fellowship, challenges have included ensuring funding, meeting diverse needs of residents entering training for GH activities, and an evolving future job market. Future directions include solidifying funding for this distinctively integrated, GH research skills-focused fellowship, and partnering with other clinical departments to leverage the collective interest in GH training. The BCRP Pediatric Global Health Research Fellowship remains unique in that it is the only training program integrated with an established pediatric residency that provide trainees the skills necessary for a career in pediatric global health research, with potential lessons to provide to other leaders in GH education.

PREDICTING AND MITIGATING OUTBREAKS OF INFECTIOUS DISEASE BY USING NASA SATELLITE REMOTE SENSING TECHNOLOGY AND MODELS

John A. Haynes[1], Sue Mathews Estes[2]

[1]NASA, Washington, DC, United States, [2]NASA/UAH, Huntsville, AL, United States

The presentation is designed to present progress in the effort to predict and mitigate infectious disease using remote sensing parameters. The speaker will discuss models developed by NASA and their partners for application of the research results for improved prevention and prediction of outbreaks. The presentation will focus on using satellite remote sensing of to fill the gaps of environmental, spatial, and temporal data for tracking disease. Satellite earth observations provide a wealth of health applications for the imaginative investigator. The session is directly related to Global Environmental Health Surveillance and will present research results of the remote sensing environmental observations of earth and health applications, which can contribute to the tropical medicine research. This presentation will show the advancements that have occurred over the past years and new research that has not been presented. The use of NASA technology to benefit society on earth is a very important topic. For years NASA had been at the forefront of technology in space now we are at the forefront on studying science here on Earth. The will presentation will

show how remotely sensed data has been used to predict and mitigate diseases such as Dengue Fever, Malaria, Oyster Norovirus Outbreaks, West Nile Outbreaks and other Vector Borne Diseases.

IRON DEFICIENT RBCS ARE RESISTANT TO GROWTH AND INVASION BY *PLASMODIUM FALCIPARUM*: A FIELD STUDY

Morgan M. Goheen[1], Bakary Darboe[2], Ebrima Danso[2], Mamadou M. Bah[2], Muna Affara[3], Amat Bah[2], Rita Wegmuller[2], Andrew M. Prentice[4], Carla Cerami[1]

[1]University of North Carolina Chapel Hill, Chapel Hill, NC, United States, [2]MRC-GAMBIA, Keneba, Gambia, [3]MRC-GAMBIA, Fajara, Gambia, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom

Iron Deficiency Anemia (IDA) and malaria are interconnected public health concerns and both cause significant morbidity in Sub-Saharan Africa. Anemia, predominantly IDA, affects up to 50% of pregnant women and 40% of preschool children in the developing world, significantly impacting perinatal and developmental health. The World Health Organization has previously recommended iron supplementation for at risk populations in areas with prevalent malnutrition. However, clinical studies have revealed that iron deficiency protects against malaria, and that administration of iron to iron-deficient individuals increases the risk of malaria. This has complicated recommendations for universal supplementation in malaria endemic regions. Our previous ***in vitro*** work, which has focused on the red blood cell (RBC) stage of the malaria infection, has confirmed these clinical observations: we have shown malaria parasite growth in and invasion of IDA RBCs is impaired, using iron deficient blood donors from our U.S.-based clinic and standard laboratory ***P. falciparum*** strains. Now we have now extended these studies to a real world setting where malaria and iron deficiency are prevalent. Specifically, we show that ***P. falciparum*** growth is directly proportional to hemoglobin status in RBCs from iron deficient Gambian children and pregnant women; ***P. falciparum*** invasion is reduced in iron deficient RBCs from Gambian children; and Gambian field isolates of ***P. falciparum*** exhibit the same phenotype of reduced invasion and growth in IDA RBCs from Gambian children. Our overall goal is now to understand the mechanisms by which iron deficiency protects individuals from malaria, in order to develop safe iron supplementation guidelines in malaria endemic areas.

626

UPSA AND DC8 PFEMP1 VARIANTS ARE ASSOCIATED WITH SEVERE ADULT MALARIA IN INDIA

Maria Bernabeu[1], Marina Vaz[2], Jayashri Walke[3], Thurston Herricks[3], Andrew J. Brazier[1], Jennifer Maki[3], Ligia Pereira[3], Anjali Mascarenhas[3], Edwin Gomes[2], Laura Chery[3], Marion Avril[1], Pradipsinh K. Rathod[3], Joseph D. Smith[1]

[1]Seattle Biomedical Research Institute, Seattle, WA, United States, [2]Department of Medicine, Goa Medical College, Bambolim, Goa, India, [3]Department of Chemistry, University of Washington, Seattle, WA, United States

Expression of a particular subset of ***Plasmodium falciparum*** var genes/PfEMP1 proteins, termed DC8 and DC13, has been linked to severe pediatric malaria. This finding has important implications in disease pathogenesis because DC8 and DC13 PfEMP1 bind Endothelial Protein C Receptor (EPCR), a receptor that plays a key role in regulating endothelial cells permeability, coagulation and blood vessel inflammation. Although the clinical presentation of severe malaria differs significantly between children and adults, almost nothing is known about the var expression profile in severe adult malaria. To better understand the origin of these differences, we analyzed the var profile of infected adult populations in India. Parasites from severe patients significantly overexpressed UpsA var transcripts and DC8 variants, but not DC13s. In addition, an identical DC8 var tag was detected in multiple patients with distinct severe malaria complications. By expressing the DC8 CIDRα1 adhesion domain from patients with high DC8 expression, we found that Indian CIDRα1 domains differed in EPCR binding strength and presented phenotypic differences in the extent of APC blockade. Our findings demonstrate that DC8 PfEMP1 are associated with adult severe malaria and reveal considerable heterogeneity in the CIDRα-EPCR binding phenotype that may contribute to the different disease outcomes observed in adult patients with severe malaria.

627

INCREASED TOTAL BODY ARGININE FLUX AND DECREASED NITRIC OXIDE SYNTHESIS IN SEVERE FALCIPARUM MALARIA

Matthew P. Rubach[1], Salvatore Florence[2], Haoyue Zhang[1], Nicholas M. Anstey[3], Tsin W. Yeo[4], David S. Millington[1], J. Brice Weinberg[1], Esther D. Mwaikambo[2], Donald L. Granger[5]

[1]Duke University, Durham, NC, United States, [2]Hubert Kairuki Memorial University, Dar es Salaam, United Republic of Tanzania, [3]Menzies School of Health Research and Charles Darwin University, Darwin, Australia, [4]Lee Kong Chian School of Medicine, Singapore, Singapore, [5]University of Utah, Salt Lake City, UT, United States

We have previously demonstrated that nitric oxide (NO) is protective against the development of severe falciparum malaria (SM). Our prior work showed that plasma arginine, NO metabolites, PBMC NO synthase (NOS) protein and RNA, and the NOS cofactor tetrahydrobiopterin are low in children and adults with SM compared to healthy controls (HC), while plasma arginase is elevated. To determine whether low nitric oxide in malaria is due to increased degradation of arginine by arginase (arginine urea + ornithine citrulline) or due to decreased synthesis via NOS (arginine NO + citrulline), in this study we measured arginine metabolic flux and calculated total body NO synthesis by administering primed infusions of $^{13}C_6$,$^{15}N_4$-labeled arginine to 10 children with SM and 10 HC children (age 4 to 8 years). Isotopic-enrichment of arginine and citrulline was measured at 0, 90, 120, 150, and 180 minutes post-infusion. Plasma amino acid levels were measured using an amino acid analyzer, and isotope ratios using UPLC-MSMS with selected ion monitoring. By tracing the isotopic enrichment and measuring total plasma citrulline levels, the concentrations of the enriched forms of citrulline were determined, which enabled us to distinguish citrulline produced from arginine via arginase vs. citrulline produced from arginine via NOS. Plasma arginine levels were lower in SM than in HC [mean (range) 43 (25-78) vs. 74 (32-112) μM; p=0.001]. Isotopic equilibrium in arginine was attained within 180 minutes. We noted that arginine flux was higher in children with SM than in HC children [mean (range) 106 (83-167) vs. 81 (65-101) μmol/kg/hour at 120 minutes; p=0.026]. A+9 citrulline (derived from NOS action) was significantly lower in children with SM than in HC children [mean (range) 0.019 (0.008-0.037) vs. 0.040 (0.019-0.129) μM; p=0.045]. Overall, our results definitively demonstrate that children with SM have increased arginine flux and decreased total body NO production (based on the low measurement of citrulline derived from actions of NOS). This new knowledge should help guide development of adjunctive therapies that increase NO in patients with SM.

POLYMORPHIC MOLECULAR SIGNATURES IN *PLASMODIUM FALCIPARUM* VAR2CSA ARE ASSOCIATED WITH VIRULENCE IN PLACENTAL MALARIA

Eldin Talundzic[1], David S. Peterson[2], **Julie M. Moore**[2], Venkatachalam Udhayakumar[1], Naomi W. Lucchi[1], Stephen Scott[2], Simon O. Owino[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]University of Georgia, Athens, GA, United States

Plasmodium falciparum-infected erythrocytes accumulate within the placenta by expressing VAR2CSA, a variant of the highly polymorphic erythrocyte membrane protein-1 (PfEMP1) family that has unique specificity for a low-sulfated form of chondroitin sulfate A (CSA) found

only in this tissue. The resulting syndrome, placental malaria (PM), has important repercussions for the health of both mother and fetus, with the first and second pregnancies being at highest risk for placental pathology and maternal and fetal morbidity and mortality. Partial immunity against VAR2CSA, and therefore protection against pathogenesis, is achieved after multiple PM-exposed pregnancies, making this protein a leading vaccine target. However, the extent to which VAR2CSA diversity contributes to immune evasion and parasite virulence remain poorly understood. In this study the genetic complexity of the DBL3X domain of var2csa in ***P. falciparum***-infected placental blood samples from Kenyan women was characterized. Higher copy numbers of var2csa were found in multigravidae, which may indicate gravidity-associated selection for parasites with inherently greater capacity for immune evasion. Deep sequencing revealed a remarkably high number of unique DBL3X sequences in some individuals, with histologically-confirmed chronic placental infection, but not gravidity, being a significant predictor. Scrutiny of the sequences, however, unveiled divergent, gravidity-biased sequence patterns, with unique types that are more prevalent among primigravidae being associated with high density parasitemia and low birth weight. These results provide for the first time compelling evidence that previous exposure to PM induces selection for multiple copies of unique VAR2CSA types that have reduced virulence and should redirect vaccine efforts to further identify and target antigen types associated with poor birth outcomes.

629

ACUTE KIDNEY INJURY IN UGANDAN CHILDREN WITH SEVERE MALARIA: A PROSPECTIVE COHORT STUDY

Andrea L. Conroy[1], Michael Hawkes[2], Robyn E. Elphinstone[1], Catherine Morgan[2], Sophie Namasopo[3], Robert O. Opoka[4], Chandy C. John[5], W. Conrad Liles[6], Kevin C. Kain[1]

[1]University of Toronto, Toronto, ON, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]Jinja Regional Referral Hospital, Jinja, Uganda, [4]Makerere University, Kampala, Uganda, [5]Indiana University, Indianapolis, IN, United States, [6]University of Washington, Seattle, WA, United States

Acute kidney injury (AKI) is a common complication of severe malaria in adults, but rarely reported in the context of pediatric populations. Using a new consensus definition of AKI (Kidney Disease: Improving Global Outcomes (KDIGO) Acute Kidney Injury Work Group), we evaluated the incidence of AKI in a cohort of Ugandan children with severe malaria.180 children aged 1 to 10 years with a rapid diagnostic test positive for both ***Plasmodium falciparum*** histidine rich protein 2 and lactate dehydrogenase, and at least one of the following criteria for severe malaria: repeated seizures, impaired consciousness, and respiratory distress were enrolled in the study. Renal function was monitored daily for four days using serum creatinine measured by iSTAT. AKI was defined retrospectively by KDIGO. Baseline data were available for 178 children. The day 14 mortality rate was 9.0% (n=16), but AKI was only assessed in 168, as 10 children died before a repeat creatinine measurement. Overall, 63.7% of children (n=107/168) met the criteria for AKI with 55.1% (59/107) staged as "risk", 28.0% (30/107) as "injury", and 16.8% (18/107) as "failure". There was an increase in mortality across stages of AKI (p=0.004) with the mortality rate reaching 16.7% in children with KDIGO-staged renal failure. Overall, 78.6% of children had their creatinine levels peak within the first two days of admission. To evaluate the nature of renal dysfunction in children with AKI we assessed the BUN:creatinine ratio and found 84.2% of children had a BUN:creatinine>20, suggestive of prerenal injury. Since the majority of study deaths occurred before a repeat creatinine measure on day 2, we evaluated the association of renal biomarkers at admission with outcome. There were no differences in creatinine levels between survivors and non-survivors (p=0.1858), but there was an increase in BUN in non-survivors (p=0.0066). These data suggest that renal dysfunction may be more common in pediatric populations with severe malaria than previously assumed and is associated with increased mortality.

630

METABOLOMICS OF *PLASMODIUM VIVAX* RELATED ANEMIA FROM THE BRAZILIAN AMAZON

Jorge L. Salinas[1], Karan Uppal[1], Fernando F. Val[2], Wuelton M. Monteiro[2], Gisely C. Melo[2], Belisa Magalhães[2], Andre M. Siqueira[2], Dean P. Jones[1], Mark P. Styczynski[3], Mary R. Galinski[1], Marcus V. Lacerda[2]

[1]Emory University, Atlanta, GA, United States, [2]Fundaçao de Medicina Tropical Doutor Heitor Vieira Dourado, Manaus, Brazil, [3]Georgia Institute of Technology, Atlanta, GA, United States

Anemia is one of the most common complications of ***Plasmodium vivax*** malaria. Multiple host and pathogen factors are involved, as well as nutritional and environmental exposures. Currently, the field of metabolomics uses sophisticated machine learning approaches able to analyze small number of samples while accounting for multiple possible confounding variables. We hypothesized that metabolomic analyses of plasma samples from patients would help us better understand the complex metabolic host-pathogen interactions occurring in ***P. vivax*** anemia in the Brazilian Amazon. We recruited 150 patients (age ≥18 years) with PCR confirmed ***P. vivax*** monoinfection at the Fundação de Medicina Tropical Heitor Vieira Dourado in Manaus, Brazil during 2011-2012. Samples underwent randomization followed by Liquid Chromatography/ Mass Spectrometry. Each sample was run in triplicate and data was extracted using xMSanalyzer. 16,791 unique ***m/z*** and retention times were obtained in all patients. Analyses were restricted to ***m/z*** present in at least 70% of all samples with adjustment for multiple hypothesis testing by the Benjamini-Hochberg false discovery rate method ($p<0.05$). A regression model for hemoglobin levels as a continuous variable was created using partial least squares (PLS) regression with variable importance in projection scores ≥2. We obtained 141 significant ***m/z*** from PLS regression and used them for pathway enrichment analyses with mummichog, an algorithm for pathway-level annotation of metabolomics data. Top altered pathways included butyric acid metabolism (p=0.02) and the carnitine shuttle (p=0.03); metabolite confirmation is under way. Butyric acid and carnitine have been previously implicated in sickle cell and end stage renal disease related anemia, respectively, and both are considered alternative treatments for each of these conditions. These pathways are likely altered as a result of the host-pathogen interaction rather than arising from the host or the pathogen alone. Although not evidence of causality, our efforts yielded potential biochemical pathways associated with ***P. vivax*** related anemia from the Brazilian Amazon.

631

STRUCTURE OF PLASMEPSIN V COMPLEXED WITH AN INHIBITOR THAT BLOCKS PROTEIN EXPORT AND MALARIA TRANSMISSION TO MOSQUITOES

Anthony N. Hodder[1], Brad E. Sleebs[1], Peter E. Czabotar[1], Michelle Gazdik[1], Charlie Jennison[1], Matthew T. O'Neill[1], Sash Lopaticki[1], Annie Yang[1], Jennifer S. Armistead[1], Brian J. Smith[2], Alan F. Cowman[1], **Justin A. Boddey**[1]

[1]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]LaTrobe University, Melbourne, Australia

Every day around the world, over 1 million people are infected with malaria parasites. These infections are caused when female Anopheles mosquitoes feed on the blood of infected humans and themselves become infected with gametocytes, followed weeks later by biting another individual and depositing sporozoites into the new host. For the global burden of malaria to be reduced, this transmission cycle needs to be blocked. We have developed a new small molecule that potently inhibits the malarial export protease, plasmepsin V, with an IC_{50} 1 nM. The compound blocks the ability of the most virulent parasite of humans, ***Plasmodium falciparum***, to export proteins that would normally commandeer the infected erythrocyte for parasite survival, and the parasites subsequently die. Treatment of gametocytes, the parasite

form that exits humans and infects mosquitoes, with the compound kills them and a sub-lethal dose blocks their transmission to Anopheles mosquitoes. This establishes plasmepsin V as an essential protein in gametocytes, in addition to the asexual stage, and an attractive drug target for reducing malaria transmission. We have used the inhibitor to obtain diffractable crystals and solved the structure of liganded plasmepsin V to 2.37 Angstroms. This provides a clear basis for the strict requirements for substrate and inhibitor binding of this protease, and unveiled both a plant-like fold and a malaria-specific helix-turn-helix motif that are unique to plasmepsin V and likely to be important in its function in cleavage of effector substrates for export.

THE PIRNA PATHWAY AND STRESS IN *ANOPHELES STEPHENSI*

Vanessa M. Macias[1], William A. Dunn III[2], Anthony A. James[1]

[1]University of California Irvine, Irvine, CA, United States, [2]Yale University, New Haven, CT, United States

Stress-induced mobilization of transposons is well-documented in many organisms. The piRNA pathway is an RNA interference pathway responsible for repressing transposon mobilization in germ-line tissues of the fruit fly, ***Drosophila melanogaster***. The genes encoding the components of the piRNA pathway, Piwi, Aubergine (Aub) and Argonaut 3 (Ago3), were identified and characterized in the malaria vector mosquito, ***Anopheles stephensi***. Preliminary experiments show that they are induced in embryos following short-duration heat stress. Current experiments are designed to assay the effects of prolonged heat and cold stress on the expression levels of the mosquito orthologs of the heat-shock protein genes, hsp70 and hsp90, as well as Piwi, Aub and Ago3 and putative endogenous transposon transcripts identified from ***An. stephensi*** RNA sequencing data. Additionally, mosquitoes mutant for Piwi, Aub and Ago3 are being generated using Cas9-mediated site-specific genome targeting that will be tested for a phenotype affecting the temperature stress response. The results of this work are expected to inform the development of transposon-based gene-drive systems for introgressing beneficial traits into vector mosquitoes.

633

A KEY REPRODUCTIVE GENE INFLUENCES *PLASMODIUM* DEVELOPMENT IN THE MAJOR MALARIA VECTOR *ANOPHELES GAMBIAE*

Perrine Marcenac[1], Adam South[1], W Robert Shaw[1], Emily Lund[1], Abdoulaye Diabate[2], Serge Yerbanga[2], Thierry Lefevre[3], Flaminia Catteruccia[1]

[1]Harvard TH Chan School of Public Health, Boston, MA, United States, [2]Institut de Recherche en Sciences de la Sante/Centre Muraz, Bobo-Dioulasso, Burkina Faso, [3]UMR MIVEGEC, Montpellier, France

In the major malaria vector ***Anopheles gambiae***, male-female molecular interactions following mating are important determinants of fertility and fecundity. Intriguingly, an increasing amount of evidence points to reproductive processes playing an important role in ***Plasmodium*** parasite development. Male transfer of the steroid hormone 20-hydroxyecdysone (20E) during mating activates the transcription of a ***Mating-Induced Stimulator of Oogenesis*** (***MISO***) gene that transduces the mating signal into an increase in egg development. Silencing ***MISO*** by RNA interference reduces egg development to levels observed in virgin females. This phenotype is caused in part by improper release of 20E from the mating plug in the absence of MISO, leading to disregulation of genes important for oogenesis. In particular, silencing ***MISO*** reduces expression of yolk protein precursors (YPPs) and impairs lipid accumulation in the oocyte. Previous research shows that the same YPPs essential for lipid accumulation in the developing mosquito egg help parasites escape the immune system. We show evidence that MISO depletion impacts both ***Plasmodium falciparum*** and ***P. berghei*** infection in ***A. gambiae;*** however, the effects in these ***Plasmodium*** species differ, enabling us to further reconstruct the molecular pathways linking egg development and ***Plasmodium*** infection. Our studies suggest ***MISO*** may modulate aspects of mosquito biology that are relevant to anopheline vector competence.

634

INVESTIGATING MOSQUITO MOLECULAR FACTORS THAT CONTROL GUT MICROBIOTA VARIABILITY IN *AEDES AEGYPTI*

Sarah M. Short, Octavio C. Talyuli, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

The ***Aedes aegypti*** mosquito midgut microbiota can alter mosquito susceptibility to dengue virus, and understanding factors that shape it could explain field transmission dynamics and contribute to development of novel dengue control strategies. In the current study, we aimed to identify mosquito molecular factors that control bacterial load of the midgut and contribute to within-species variability in gut microbial load. We reared multiple strains of ***A. aegypti*** in a controlled laboratory environment and used culture-dependent and -independent techniques to assess bacterial load in the midguts of sugar and blood fed females from each strain. We then compared genome-wide gene expression in response to blood feeding and bacterial ingestion between two strains showing the greatest difference in microbial load. We identified genes that showed strain-specific patterns of up- or down-regulation and used Gene Ontology and KEGG analyses to identify pathways enriched in a strain-specific manner. Finally, we used RNAi to knock down candidate genes to validate their role in influencing gut microbial load. We found significant variation between strains in gut bacterial load. Our transcriptome analysis revealed that an unexpectedly high number of metabolism-implicated genes were differentially expressed between strains. We also identified strain-specific variation in the mRNA abundance of multiple immunity genes. Preliminary data from RNAi knock down experiments suggests that the immunity gene galectin 1 as well as genes involved in valine, leucine and isoleucine degradation are implicated in controlling proliferation of gut bacteria in a strain-specific manner. Taken together, these data suggest that metabolic activity in the mosquito gut may act to control bacterial load and that variability in metabolic activity has the potential to control within-species variation in gut microbial load.

A PROTEOMIC-BASED "SHOTGUN" APPROACH OPENS NEW PERSPECTIVES TO MOSQUITO AGE-GRADING

Immacolata Iovinella[1], Beniamino Caputo[1], Elena Michelucci[2], Francesca Dani[2], **Alessandra della Torre**[1]

[1]University of Rome, Sapienza, Rome, Italy, [2]University of Florence, Florence, Italy

Information on age structure of wild mosquito populations is fundamental to assess impact of control measures and vectorial capacity of species implicated in transmission of malaria or arboviroses. Transcriptional studies on major disease vectors, such as ***Anopheles gambiae*** and ***Aedes aegypti***, have highlighted age-related variations in some genes which have been exploited to develop quantitative reverse transcriptase-PCR age-grading methods. However, due to low RNA stability, these qRT-PCR approaches require a careful manipulation and preparation of samples and relatively high-tech and expensive equipment. In this work we applied a proteomic-based "shotgun" approach to identify and quantify proteins from carcasses of laboratory reared Aedes albopictus belonging to six different age-groups and different physiological stages. Proteins were extracted from heads and thoraxes and the same total protein content of each group was processed for a nanoLC-nanoESI-MS/MS analysis on an Ultimate 3000 HPLC coupled to a LTQ Orbitrap mass spectrometer. Protein intensities across samples was evaluated using a LFQ (label-free quantitation) method. Approximately 600 proteins/age-group were identified, 4 of which (i.e. an hemocyanin protein; an insect cuticle

protein; a glutathione S-transferase; and a not yet annotated protein) were shown to strongly decrease with age in all biological and technical replicates carried out to exclude possible technical biases. Antibodies against two of these proteins have been produced and are being exploited to develop ELISA or Western Blotting age-grading protocols to be applied on Ae. albopictus, a species whose longevity is difficult to assess due to lack of specific molecular approaches. In fact, these approaches are expected to be more manageable and cheaper than the currently used qRT-PCR approaches, thus allowing a larger scale assessment of longevity in epidemiological studies as well as in the evaluation of the efficacy of control strategies. This study represents a proof-of concept for the development of similar methods to tropical vectors of malaria and arbovirosis.

636

MOLECULAR MECHANISMS MEDIATING INNATE IMMUNE PRIMING IN *ANOPHELES GAMBIAE* MOSQUITOES

Jose Luis Ramirez[1], Giselle de de Almeida Oliveira[1], Eric Calvo[1], Jesmond P. Dalli[2], Romain A. Colas[2], Charles N. Serhan[2], Jose Ribeiro[1], **Carolina Barillas-Mury**[1]

[1]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, [2]Center for Experimental Therapeutics and Reperfusion Injury, Brigham and Women's Hospital, Harvard Institutes of Medicine, Boston, MA, United States

An innate immune priming response is triggered when ***Plasmodium*** ookinetes invade the mosquito midgut and the microbiota comes in direct contact with injured cells. This is a long-lasting response that confers the mosquito enhanced ability to control subsequent ***Plasmodium*** infections. The immune priming response involves hemocyte differentiation, in particular an increase in the granulocyte population. A hemocyte differentiation factor (HDF) is released into the hemolymph and transfer of cell-free hemolymph from challenged mosquitoes can induce hemocyte differentiation and enhanced immunity in recipient naïve mosquitoes. In this study, we have characterized the biochemical nature of HDF. We discovered that this factor consists of a Lipoxin / Lipocalin complex. RNAi-based silencing of the lipocalin (Evokin) component abolished the release of HDF activity in the hemolymph extract, indicating that it is a critical component of the immune priming response. In turn, LC/MS/MS analysis showed that the HDF lipid component is an eicosanoid (Lipoxin). Injection of synthetic lipoxin recapitulates the phenotype observed in ***Plasmodium***-infected mosquitoes as well as those observed when transferring cell-free hemolymph from challenged to naïve mosquitoes. In summary, we show that innate immune priming involves a persistent increase in expression of Evokin, and in the ability of mosquitoes to convert arachidonic acid to lipoxins, predominantly Lipoxin A4.

637

AN ENDOSYMBIONT-REGULATED TSETSE ODORANT BINDING PROTEIN MEDIATES HOST IMMUNE SYSTEM MATURATION PROCESSES

Brian L. Weiss[1], Joshua B. Benoit[2], Aurelien Vigneron[1], Yineng Wu[1], Serap Aksoy[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Department of Biological Sciences, University of Cincinnati, Cincinnati, OH, United States

Endosymbiotic bacteria serve important functions within their animal hosts, including maintenance of immune system homeostasis. Little is known about the mechanisms that enable these bacteria to induce host immunity-related phenotypes during development and into adulthood. Tsetse flies (***Glossina*** spp.) house 3 distinct endosymbiotic bacteria that are vertically transmitted from mother to offspring during this insect's unique viviparous mode of reproduction. When intrauterine tsetse larvae mature in the absence of their endogenous microbiota (referred to as 'aposymbiotic'), subsequent adults present a highly compromised cellular immune system that is characterized by the absence of phagocytic hemocytes. We demonstrate that an odorant binding protein-encoding gene (***obp6***) is expressed at 22x higher levels in wild-type versus aposymbiotic larvae. Expression of this gene is reduced significantly in wild-type larvae when their lactating moms are microinjected with gene-specific short interfering RNAs (siRNAs). Offspring that imbibe anti-***obp6*** siRNAs exhibit phenotypes consistent with the presence of a reduced or dysfunctional population of crystal cells, which are responsible for initiating the melanization cascade via the release of prophenoloxidase. Our findings provide valuable insight into molecular pathways that underlie symbiont-mediated immune system maturation in tsetse.

638

IMPACT OF INCREASED INSULIN SIGNALING IN THE FAT BODY OF *ANOPHELES STEPHENSI* AND *AEDES AEGYPTI* MOSQUITOES ON INNATE IMMUNITY, LIFESPAN AND REPRODUCTION

Lewis Hun[1], Michael Riehle[1], Anam Arik[1], Kendra Quicke[2], Patricia Scaraffia[3], Hemant Badgandi[1], Michael Piatt[1], Yan Lee[1]

[1]University of Arizona, Tucson, AZ, United States, [2]Emory University, Atlanta, GA, United States, [3]Tulane University, New Orleans, LA, United States

The World Health Organization (WHO) estimates that 2.5 billion people live in dengue-endemic areas and are at daily risk of infection. Thus, there is an urgent need for new innovative strategies to ease the burden of dengue transmission. One strategy is to genetically engineer the primary mosquito vector, ***Aedes aegypti***, to be resistant to dengue infection and with improved fitness to replace wild, susceptible mosquito population. In mosquitoes, the insulin/insulin growth factor 1 signaling (IIS) cascade regulates lifespan, reproduction, and innate immunity. To better understand the impact of IIS in mosquitoes, we induced IIS in the fat body of transgenic ***Ae. aegypti*** mosquitoes by expressing an active form of ***Ae. aegypti*** Akt (AeagAkt), a key component of the IIS cascade. The mosquito's fat body is the main tissue responsible for antimicrobial production and has been shown to serve as "signaling center" for the IIS pathway. In early studies we found that active AeagAkt transcript and protein expression occurred in a fat body and blood meal specific manner, as expected for a transgene regulated by the vitellogenin promoter. Furthermore, we were able to demonstrate increased activation of downstream IIS molecules indicating activation of the IIS cascade. We also observed changes in vitellogenin protein levels, but surprisingly did not observe any change in egg production. Most importantly, we observed a significant extension in the lifespan of the myr-AeagAkt transgenic ***Ae. aegypti***. This increase in lifespan opens intriguing possibilities for manipulating the fitness of transgenic virus resistant mosquitoes.

639

COMPARISON OF DOXYCYCLINE, MINOCYCLINE, DOXYCYCLINE PLUS ALBENDAZOLE AND ALBENDAZOLE ALONE IN THEIR EFFICACY AGAINST ONCHOCERCIASIS

Ute Klarmann-Schulz[1], Linda Batsa[2], Sabine Specht[1], Alexander Y. Debrah[3], Jubin Osei-Mensah[2], Nana K. Ayisi-Boateng[4], Yusif Mubarik[2], Louise Ford[5], Peter Konadu[6], Mark J. Taylor[5], Achim Hoerauf[1]

[1]Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany, [2]Kumasi Centre for Collaborative Research, Kumasi, Ghana, [3]Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [4]University Hospital of Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]Komfo Anokye Teaching Hospital, Kumasi, Ghana

In search of new macrofilaricidal drugs against onchocerciasis that lead to regimens shorter than the current macrofilaricidal "gold standard" doxycycline (Doxy) 200mg/d given for 4 weeks, preclinical studies within the A·WOL consortium showed that minocycline (Mino) had an efficacy superior to Doxy. Further studies suggested that a combination treatment with Doxy and albendazole (Alb) increased the effect of Doxy alone. Therefore a randomized, open-label, pilot trial was carried out in an area in Ghana endemic for onchocerciasis, comprising 5 different regimens: the standard regimen Doxy 200mg/d for 4 weeks (Doxy 4w), the experimental regimens Mino 200mg/d for 3 weeks (Mino 3w), Doxy 200mg/d for 3 weeks plus Alb 800mg/d for 3 days (Doxy 3w + Alb 3d), Doxy 200mg/d for 3 weeks (Doxy 3w) and Alb 800mg for 3 days (Alb 3d). Of 156 volunteers, 136 (87.2%) completed the treatment according to protocol. Of these, 99 (72.8%) were present for the surgical extirpation of their onchocercomata 6 months after treatment onset. Histological analyses of the adult worms in the extirpated nodules revealed absence of Wolbachia in 98.8% (Doxy 4w), 81.4 % (Doxy 3w + Alb 3d), 72.7% (Mino 3w), 64.1% (Doxy 3w) and 35.2% (Alb 3d) of the female worms. All 4 treatment regimens showed superiority to Alb 3d ($p < 0.001$, $p < 0.001$, $p = 0.002$, $p = 0.008$, respectively). Additionally, Doxy 4w showed superiority to all other treatment arms (vs. Doxy 3w + Alb 3d $p = 0.005$, vs. Mino 3w $p = 0.002$, vs. Doxy 3w $p < 0.001$). The observed differences regarding the absence of Wolbachia between the 3-week regimens did not reach statistical significance. Furthermore Doxy 4w and Doxy 3w + Alb 3d showed a higher amount of female worms with degenerated embryogenesis compared to Alb 3d ($p = 0.028$, $p = 0.042$, respectively). These results confirm earlier studies that Doxy 4w is sufficient for Wolbachia depletion and the desired parasitological effects. The data further suggest that there is an additive/synergistic effect of Alb (3 days) on top of that of Doxy 3w alone, and that Mino 3w has a stronger potency than Doxy 3w. These latter two results are preliminary and need confirmation in a full randomized controlled phase 2 trial.

DEVELOPMENT OF NOVEL SEROLOGIC TOOLS TO STUDY *ONCHOCERCA VOLVULUS* POPULATION GENETICS

Carmelle T. Norice[1], Jose' Ribeiro[2], Sasisekhar Bennuru[1], Thomas B. Nutman[1]

[1]Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, [2]Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

The ongoing public health and socioeconomic impact of onchocerciasis requires a better understanding of ***Onchocerca volvulus*** biology that can be translated into innovative methods for improved surveillance, diagnosis, and treatment. In particular, studies of ***O. volvulus (Ov)*** population genetics may help elucidate its transmission, spread, emergence of drug resistance, and persistence despite control measures. Currently, studies of ***O. volvulus*** population genetics are significantly limited because the extraction of parasite tissue from hosts requires invasive and painful procedures. Therefore, we are developing a novel approach to help advance our understanding of ***O. volvulus*** allele diversity and spatial distribution using well-characterized serum and available parasite material. We have identified non-synonymous single nucleotide polymorphisms (SNPs) in the coding sequences of 9 of the 14 most highly immunogenic ***Ov*** proteins: Ov7, Ov16, OvASP1, OvCHI1, OvM3, OvALT1, OvB8, OvFAR1, and OvRAL1. Moreover, we have confirmed these SNPS, using PCR-based genotyping and applied these genotyping assays to individual skin snip samples from patients with onchocerciasis (e.g. Ov7 S29F and Ov16 R180P). Using KLH-linked synthetic peptides that each contain one or the other SNP variant for each of these antigens, we have developed serum-based immunoassays to genotype ***O. volvulus*** infecting strains using Ov-infected patient sera. We plan to investigate the diversity and distribution of ***O. volvulus*** populations over geographical space and time without the need for parasite material. The results are expected to shed light on features of ***O. volvulus*** population genetics that may facilitate elimination efforts.

641

CAN WE USE SIMPLE PHYSICAL MEASURES TO DETECT COVERT LYMPHEDEMA IN ADOLESCENTS AND YOUNG ADULTS INFECTED WITH LYMPHATIC FILARIASIS?

Janet Douglass[1], Susan Gordon[1], Patricia Graves[2]

[1]James Cook University, Townsville, Australia, [2]James Cook University, Cairns, Australia

Lymphedema after infection with lymphatic filariasis (LF) and lymphedema after treatment for cancer have differing causes but similar chronic manifestations. In both conditions only a portion of those at risk will develop chronic disease and in both cases early detection and intervention can result in reversal of symptoms or even complete recovery, whereas progression to later stages prevents any possibility of cure and reduces opportunity for improvement. Devices used to detect and assess cancer related lymphedema were used in an LF early detection study in a highly endemic area in Central Myanmar (Amarapura Township). Participants aged between 10 and 21 years were screened by ICT (n=315) and positive cases were age and gender matched with negative cases and invited into a longitudinal study. Physical measures were taken on 104 participants before and after the annual MDA campaign. Infection rate was 17.8% in younger people (aged 10-17) and 23.08% in older participants (aged 18-21). Of the 95 participants who returned for follow up measures there was conversion from negative to positive and vice versa in 5 and 1 participants respectively. Physical measures included limb circumference and tissue tonicity at the mid-point of the anterior and posterior thigh and the calf. Bio impedance spectroscopy was used to assess segmental fluid load in the whole leg, thigh and upper thigh. The results will assess the usefulness of physical measures for early detection of covert lymphatic changes in young people infected with LF and the impact of MDA on early lymphatic dysfunction.

642

MEASURING THE IMPACT OF LYMPHOEDEMA ON PATIENT MOBILITY USING GPS DATA LOGGERS: A CASE-CONTROL STUDY OF PATIENTS IN CHIKWAWA, MALAWI

Michelle C. Stanton[1], Square Z. Mkwanda[2], Masato Yamauchi[1], Charles Mackenzie[1], Louise A. Kelly-Hope[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Ministry of Health, Lilongwe, Malawi

Lymphoedema, one of the most common clinical manifestations of lymphatic filariasis, is known to have a significant impact on a patient's quality of life by restricting mobility both day-to-day due to the swelling of the limb, and during acute attacks during which the patients is often completely incapacitated. This can impact both their economic and mental

stability, and perpetuates poverty in endemic areas. This purpose of this study was to directly measure the physical and socio-economic impact of lymphoedema on affected individuals and their carers in an endemic area of Malawi by comparing a group of lymphoedema patients (cases) to a group without the condition (controls). There were three components to this project: (i) a self-assessment questionnaire, including questions on mobility, self-care, assistance received and daily activities, (ii) observed mobility tests and (iii) a diary and GPS data logger study. Components (i) and (ii) involved 30 cases and 30 controls, whereas a subset of 10 cases and 10 controls were asked to complete a daily activity sheet over a three week period, and further to wear a GPS logger to track their movements over the same period. The self-assessment questionnaire required participants to score each question. Participants indicated their score using a graphical representation of stacked blocks was used, as opposed to a more traditional written scale in order to produce more accurate self-assessed responses. Individual scores were summed to produce an overall disability score. Observed mobility tests included a timed 10 metre walk, and a timed 'up and go' test during which the time required to stand up from a chair, walk 3 metres, then return to a seated position was calculated. The GPS logger component allowed the average distance and travelling speed to be calculated over the three week period for each case and control, and further to identify mobility patterns. The disability score, observed mobility test times, daily activities and mobility patterns were then compared between cases and controls to obtain a more accurate understanding of the relative impact of lymphoedema on affected individuals.

643

ABL-KINASE TARGETING OF FILARIAL PARASITES BY IMATINIB IMPAIRS EMBRYOGENESIS AND SHEATH/CUTICLE INTEGRITY: STRUCTURAL STUDIES IN *BRUGIA MALAYI*

Elise M. OConnell[1], Sasisekhar Bennuru[1], Aaron Bell[2], Sara Lustigman[2], Thomas B. Nutman[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]Lindsley F. Kimball Research Institute, New York Blood Center, New York City, NY, United States

Unanticipated severe side effects (including death) in ***Loa loa*** (Ll)-endemic regions of Central Africa caused by ivermectin use in mass drug administration (MDA) campaigns for onchocerciasis and lymphatic filariasis elimination has resulted in cessation of MDA. The severity of these post-ivermectin treatment reactions has been found to be proportional to the number of Ll microfilariae (MF) and is thought to result from rapid MF killing. Thus, there is a need for new drugs that either kill MF more slowly or only target adult worms. We have previously shown a high degree of sequence identity between the human c-Abl protein and Abl-like proteins expressed by ***Brugia malayi*** (Bm), ***Onchocerca volvulus***, ***Wuchereria bancrofti***, Ll, and ***Mansonella perstans*** at the imatinib binding site. Imatinib also kills Bm ***in vitro*** at concentrations achievable in humans after a single oral dose. Prior to full scale human trials, it is important to understand the mechanism by which imatinib is acting on the MF and the other parasite stages to anticipate possible efficacy and safety. First, we used RNAseq data to quantify the relative expression of Abl-like proteins. These data showed that the highest Abl-like expression was found in the adult female (AF)(246 RPKM), followed by MF (125 RPKM), and lastly by L3 (68 RPKM) and by adult males (AM)(63 RPKM). Confocal microscopy was next performed and demonstrated that fluorescently labeled rabbit anti-human c-Abl showed extensive staining of the cuticle in both AM and AF and in the uterine lining of AF. Moreover, the MF sheath stained brightly. Compared to untreated control parasites, transmission electron microscopy of imatinib-treated AF showed an arrest in development of embryogenesis, with only immature ova/embryos visible with pyknotic nuclei. The cuticles of the AM and AF were markedly disturbed, and the MF revealed complete loss of internal architecture. Scanning electron microscopy of MF demonstrated a thinning and loss of sheath integrity. These data suggest that imatinib inhibits filarial embryogenesis, and effects mobility and survival of MF and AF/AM by its disruption on the sheath and cuticle, respectively.

EXPERIMENTAL ANTI-WOLBACHIAL THERAPY OF FILARIASIS WITH COMBINATIONS OF REGISTERED ANTIBIOTICS SUGGESTS TREATMENT SUCCESS IS ACHIEVABLE WITHIN SEVEN DAYS

Sabine Specht[1], Kenneth Pfarr[1], Sandra Arriens[1], Ute Klarmann-Schulz[1], Louise Ford[2], Mark Taylor[2], Achim Hoerauf[1]

[1]IMMIP, University Hospital Bonn, Bonn, Germany, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Filarial parasites can be targeted by antibiotic treatment due to their unique endosymbiotic relationship with Wolbachia bacteria. This finding has led to successful treatment strategies in both, human onchocerciasis and lymphatic filariasis. A 4-6 week treatment course using doxycycline results in long-term sterility and ultimately death of the parasite. However, current treatment times and doxycycline contraindications in children and pregnant women preclude administration of doxycycline in mass chemotherapy within public health control programs; therefore, establishing of shorter anti-wolbachial regimens is a focus of ongoing research. We have used a sensitive rodent model of ***Litomosoides sigmodontis***, for compound screening, which allows us to quickly provide initial evidence for ***in vivo*** efficacy. In this model, combinations of registered antibiotics were tested. Administration of rifamycins (Rifampin or Priftin® /rifampicin or rifapentine) in combination with doxycycline for 7 days successfully depleted Wolbachia by > 2 log (99% reduction) and thus resulted in a significant reduction of the treatment duration. Using a triple combination of a tetracycline (doxycycline or minocycline), a rifamycin and a fluoroquinolone (moxifloxacin) given ip led to an even greater shortening of the treatment time to approx. 4 days. Both alone or in the triple combination rifapentine showed superiority to rifampicin. Reduction of treatment time was similar when administration was by oral gavage instead of ip. Testing all double combinations that could be built out of the triple combinations revealed that the combination of rifapentine (15mg/kg) and moxifloxacin (2 x 200mg/kg) showed the best efficacy. For both administration routes (oral or ip) it could be proven that the rifapentine plus moxifloxacin combination was equivalent to the triple combination (>99% Wolbachia reduction). These investigations suggest that it may be possible to shorten anti-wolbachial treatment times to 7 days or less in humans, in accordance with the currently favoured TPP for macrofilaricidal drugs.

645

TYLOSIN ANALOGS AS ANTI-FILARIAL AGENTS, PART B: PRE-CLINICAL EVALUATION IN RODENT MODELS OF LYMPHATIC FILARIASIS AND ONCHOCERCIASIS"

Joseph D. Turner[1], Louise Ford[1], Hayley Tyrer[1], Hanna Sjoberg[1], Joanne Gamble[1], Darren Cook[1], Thomas Von Geldern[2], Kennan Marsh[3], Samuel Wanji[4], Stephen Ward[1], Dale Kempf[3], Mark J. Taylor[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Franciscan Institute for World Health, Steubenville, OH, United States, [3]AbbVie, Chicago, IL, United States, [4]University of Buea, Buea, Cameroon

Onchocerciasis and lymphatic filariasis (LF) are priority neglected tropical diseases targeted for elimination. The causative agents of LF and onchocerciasis harbor a symbiotic endobacterium, Wolbachia. Targeting Wolbachia with doxycycline has delivered curative outcomes and is safe to administer in loiasis co-infection. Contraindications and long treatment courses required for efficacy limit doxycycline scale-up for widespread programmatic use. Orally bioavailable analogs of the veterinary antibiotic, tylosin A (TylA): A-1535469 and A-1574083, are potent anti-Wolbachia

agents ***in vitro***, with promising pharmacokinetic profiles. We tested the anti-Wolbachia effect of TylA analogs in rodent models of LF and onchocerciasis. During ***Brugia malayi*** intraperitoneal filarial infections of mice, oral A-1535469 and A-157083 effectively depleted Wolbachia from larval tissues. Testing at 50 mg/kg, A-1535469 dosing for 14 days mediated comparable anti-Wolbachia efficacy to parenteral TylA and superior activity compared to doxycycline (99.3% vs 98.3%, P<0.001). Seven day dosing of A-1535469 or A-1574083 induced 99.3% and 98.8% reductions in Wolbachia, both superior to 7-day doxycycline treatment (27.6%, P<0.001). Against pre-fecund ***B. malayi*** female worms, A-1535469 administered for 14 days at 50 mg/kg or 7 days at 250 mg/kg mediated equipotent Wolbachia depletion compared with 28-day dosing with the second generation tetracycline, minocycline, (90% vs 93% and 98.3% vs 95.5%, respectively). In gerbils, A-1574083 dosed for 14 days at 10 or 50 mg/kg were equipotent to 21 day high-dose doxycycline (200 mg/kg) in depletion of Wolbachia from mature female ***B. malayi*** (99.4 / 99.8% vs 99.1%). Further, 50 mg/kg dosing of A-1574083 significantly depleted microfilariae compared with control infections (99.64% reduction, P=0.039). In conclusion, orally bioavailable TylA analogues can achieve >90% Wolbachia depletion ***in vivo*** following 7-14 day dosing, a threshold validated as predictive of curative outcome in both human LF and onchocerciasis. 'TylAMac' compounds are now being advanced into full-scale pre-clinical development.

646

BUSINESS TRAVEL AND ILLNESS: ANALYSIS OF DATA FROM THE GEOSENTINEL SURVEILLANCE NETWORK

Lin H. Chen[1], Karin Leder[2], Kira A. Barbre[3], Jay S. Keystone[4], Patricia Schlagenhauf[5], Eli Schwartz[6], Michael Libman[7], Bradley A. Connor[8], Marc Mendelson[9], Philippe Parola[10], Effrossyni Gkrania-Klotsas[11], Susan MacDonald[12], Anne McCarthy[13], Marc Shaw[14], Vanessa Field[15], Jakob Cramer[16], Davidson H. Hamer[17], Mary E. Wilson, for the GeoSentinel Surveillance Network[18]

[1]Mount Auburn Hospital and Harvard Medical School, Cambridge, MA, United States, [2]Monash University and Royal Melbourne Hospital, Melbourne, Australia, [3]Division of Global Migration and Quarantine, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Toronto General Hospital and University of Toronto, Toronto, ON, Canada, [5]University of Zurich, Zurich, Switzerland, [6]Sheba Medical Center, Tel Hashomer and Sackler Faculty of Medicine, Tel Aviv University, Tel Hashomer, Israel, [7]J.D. MacLean Centre for Tropical Diseases, McGill University, Montreal, QC, Canada, [8]Weill Cornell Medical College, New York, NY, United States, [9]University of Cape Town, Cape Town, South Africa, [10]Aix-Marseille University, Marseille, France, [11]University of Cambridge, Cambridge, United Kingdom, [12]Medicine and Quality, Interior Health, Kelowna, BC, Canada, [13]University of Ottawa, Ottawa, ON, Canada, [14]Worldwise Travellers Health Centres and James Cook University, Auckland, New Zealand, [15]InterHealth, London, United Kingdom, [16]Bernhard-Nocht-Institute for Tropical Medicine, Hamburg, Germany, [17]Center for Global Health and Development; Boston University School of Public Health, Boston, MA, United States, [18]Harvard Chan School of Public Health, Boston, MA, United States

There are ≥150 million international business trips annually; business travelers represent 14-21% of travelers reported in the literature. Illness in business travelers has economic consequences for both employee and employer. We used data from the GeoSentinel Surveillance Network to describe health problems in business travelers seen at GeoSentinel clinics in 26 countries. Specifically, we describe the demographics of business travelers evaluated after travel, review their illnesses and severity based on hospitalization, and determine prominent diagnoses. From 1997 through 2014, a total of 14,041 business travelers presented with a travel-related illness to a GeoSentinel clinic (16,697 total diagnoses). The vast majority (94%) were adults aged 20-64 years; most (75%) traveled from Western Europe or North America, and two-thirds were male. Most (86%) were seen as outpatients. Fewer than half (44%) reported a pre-travel encounter. Frequent regions of exposure were sub-Saharan Africa (33%), Southeast Asia (13%), South Central Asia (13%), South America (6%), and North East Asia (6%). The most frequent diagnoses were acute unspecified diarrhea (7%), viral syndrome (5%), acute bacterial diarrhea (4%), chronic unknown diarrhea (4%), and falciparum malaria (4%). Species was specified for 933 (84%) of 1116 malaria patients and included 657 ***Plasmodium falciparum***, 177 ***P. vivax***, 52 ***P. ovale***, 29 ***P. malariae***, 1 ***P. knowlesi***, and 17 with two species. Of 598 (54%) with chemoprophylaxis information, 92% took none or incomplete courses. Also underestimated, 17 malaria cases were drug resistant. Over half of malaria patients were hospitalized. There were 116 patients with severe malaria. Sixteen deaths occurred in business travelers, of which 8 were from malaria. Our analysis identifies gastrointestinal diagnoses as the most common problems related to business travel and raises concern for malaria in business travelers, including death and acquisition of resistant strains. These results indicate the need to promote pre-travel health through public health messages as well as for improved messages regarding safe food and drinks, and malaria prevention.

647

TRENDS IN IMPORTED INFECTIONS IN THE UNITED KINGDOM: 2000-2015

Michael E. Marks[1], Margaret Armstrong[2], Christopher Whitty[1], Justin F. Doherty[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Hospital for Tropical Diseases, London, United Kingdom

We established a prospective database to capture all admissions with tropical infections at a large tertiary referral infectious diseases and tropical medicine unit in the United Kingdom. The database allows analysis of cause and length of admission, region of travel and time between travel and admission. We will present data on over 2,200 consecutive admissions, from almost 2,000 patients between August 2000 to February 2015. Between them these admissions resulted in 12,962 bed days. Falciparum malaria was the single commonest reason for admission (n = 1,115, 50.1%) but contributed only 30.5% of the total number of bed days. Conversely leishmaniasis and leprosy were the reason for admission in only 269 (11.9%) and 106 (4.7%) patients respectively but contributed 27.4% and 12.3% of the total number of bed days. Although the total number of cases of malaria in the United Kingdom remained steady, the number of admissions at our site fell significantly over the study period from an average of 120 cases per year between 2001 to 2004 to only 34 cases a year between 2011-2014, Africa was the most common region of travel (n=1,303, 57.4%), followed by Asia (n=419, 18.5%) and the Americas (n=242, 10.7%). As expected the majority of falciparum malaria arose following travel to West Africa (n=726) followed by East Africa (n=247). Falciparum malaria (84.9%), enteric fever (5.3%) and dengue (6.5%)were the most common presentation in individuals presenting within 3 months of travel. In patients presenting more than 3 months after travel, chronic conditions, in particular leishmaniasis (57.8%), non-falciparum malaria (12.6%), leprosy (9.4%), and neurocystericosis (8.2%) were more common. These data, collected prospectively over almost 15 years, represent the most comprehensive data available on the trends in imported infections seen in the United Kingdom and will help be of value to all clinicians in high income settings involved in delivering care to returning travellers.

648

EFFECTIVENESS OF LOPERAMIDE MONOTHERAPY FOR SELF-TREATMENT OF MODERATE OR SEVERE ACUTE WATERY DIARRHEA

Tahaniyat Lalani[1], Mark Riddle[2], Mark D. Johnson[3], Anuradha Ganesan[1], Heather Yun[4], Jamie Fraser[1], Edward Grant[5], Timothy Burgess[6], David Tribble[1]

[1]Infectious Disease Clinical Research Program, Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Naval Medical Research Center, Silver Spring, MD, United States, [3]Naval Medical Center, San Diego, San Diego, CA, United States, [4]San Antonio Uniformed Services Health Education, Fort Sam Houston, TX, United States, [5]IDCRP, Bethesda, MD, United States, [6]Walter Reed National Military Medical Center, Bethesda, MD, United States

Standard guidelines recommend the use of antibiotics and loperamide for self-treatment of moderate or severe travelers' diarrhea (TD). However, recent data suggests that the use of antibiotics during travel may be associated with acquisition of extended spectrum-beta-lactamase producing gram negative rods, suggesting the need for judicious use of antibiotics for self-treatment. We evaluated the effectiveness of loperamide alone, versus antibiotics with or without loperamide for self-treatment of moderate or severe acute watery diarrhea (MS-AWD). Travelers presenting to 4 US military travel clinics were prospectively enrolled. Participants completed a diary, post-travel survey and follow-up surveys documenting any diarrhea during travel, self-treatment taken, duration of symptoms, and symptoms of irritable bowel syndrome (IBS). Standard definitions were used to assess for MS-AWD and IBS. We compared the duration of diarrhea in days and clinical cure at 72 hours among travelers who took loperamide alone vs. antibiotics alone or antibiotics plus loperamide for MS-AWD. 2232 participants were enrolled between 2010 and 2015, of whom 204 met criteria for MS-AWD and completed the diary/survey. The median number of stools during a 24 hour period was 4 stools (IQR: 3-7 stools); 48 participants used no self-treatment, 48 used loperamide alone, and 108 used either antibiotics alone or in combination with loperamide for self-treatment. No difference in the duration of diarrhea (1.1 days vs. 1.5 days) or 72 hour cure rate (90% vs. 90%) was observed among participants who used loperamide alone, vs. antibiotics alone or in combination with loperamide. There was no significant difference in the incidence of PI-IBS at 12 months (7.7% [2/26] vs. 5.3% [3/57]) between the two treatment groups. Loperamide alone was as effective as antibiotics with or without loperamide in shortening the duration of MS-AWD, in this observational pilot study based on self-reported symptom duration. This suggests that using loperamide alone for MS-AWD may be a reasonable option. Further effectiveness studies aimed at judicious use of antibiotics during travel are needed.

649

GASTROINTESTINAL POLYPARASITISM: POTENTIAL IMPACT ON HOST RESPONSE AND PERSISTENCE OF INFECTIONS

Jill E. Weatherhead[1], Andrea Arévalo Cortés[2], Carlos Sandoval[2], Maritza Vaca[2], Martha Chico[2], Sophia Loor[2], Peter Hotez[1], Philip J. Cooper[2], Rojelio Mejia[1]

[1]National School of Tropical Medicine, Baylor College of Medicine, Houston, TX, United States, [2]Centro de Investigación en Enfermedades Infecciosas, Pontificia Universidad Católica del Ecuador, Quito, Ecuador

Over 30% of the human population is infected with gastrointestinal parasites. Quantitative Real-Time PCR (qPCR) has allowed for easier detection of helminth and intestinal protozoa co-infection. Co-infection can alter the host immune response. Protozoa stimulate a T-helper cell-1 (Th1) polarized response and helminths stimulate a polarized Th2 response. The immune response to one parasite may directly influence the immune response to another parasitic infection and alter clearance of infection. We hypothesized that co-infected children with intestinal helminth (***Ascaris lumbricoides***) and protozoa (***Giardia lamblia***) would have evidence of Th2 cytokine polarization with a reduction in Th1 cytokines compared to singly infected children with either ***Ascaris*** or ***Giardia***. Fecal and plasma samples were collected from 39 randomly selected 3 year-old asymptomatic children living in Ecuador of whom 11 children infected only with ***G. lamblia***, 7 with only ***A. lumbricoides***, 13 with both ***A. lumbricoides*** and ***G. lamblia***, and 8 with no parasites (controls). Parasitic infections were detected using qPCR of stool samples. Plasmas were used to measure cytokines using BioRad Luminex MagPix. Children with co-infections had a significantly increased IL-10/IFN-γ ratio compared to uninfected controls (0.48 vs. 0.16, $p < 0.05$) and compared to ***Ascaris*** only infections (vs. 0.17, $p < 0.05$) and a non-significant increase compared to ***Giardia*** only infections (vs. 0.26, $p = 0.09$). Children with co-infections compared to those with ***Giardia*** only infections had significantly reduced levels of Th1 cytokines (IL-2 [3.83 vs. 8.08 pg/mL; $p < 0.05$], IL-12 [4.72 versus 14.89 pg/mL; $p < 0.05$], TNF-α [1.52 versus 2.58 pg/mL; $p < 0.05$]). Our data provide evidence that children with co-infections (i.e. ***A. lumbricoides*** and ***G. lamblia***) have reduced plasma levels of Th1 cytokines and relatively increased levels of the immune regulatory cytokine, IL-10. An increase in immune regulation in the context of reduced Th1 responsiveness associated with ascariasis may be permissive to chronic carriage of intestinal protozoa such as ***Giardia***.

650

DISCREPANCIES BETWEEN TEST RESULTS, DIAGNOSIS, AND TREATMENT OF FEBRILE ILLNESS IN KENYAN CHILDREN

Anneka M. Hooft[1], Bryson Ndenga[2], Francis Mutuku[3], Dunstan Mukoko[3], John Vulule[2], Angelle Desiree LaBeaud[4]

[1]University of California San Francisco Benioff Children's Hospital Oakland, Oakland, CA, United States, [2]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [3]Division of Vector Borne and Neglected Diseases, Kenyan Ministry of Health, Nairobi, Kenya, [4]Department of Pediatrics, Division of Infectious Diseases, Stanford University School of Medicine, Stanford, CA, United States

In low resource settings where malaria is prevalent, accurate diagnosis of the etiology of febrile illness in children can be challenging. The WHO currently recommends laboratory-confirmed diagnosis of malaria, if available, prior to starting antimalarials in patients who are stable. Given the increasing prevalence of other febrile illnesses such as dengue and chikungunya viruses, plus ongoing high risk of bacterial infections such as diarrheal illness and pneumonia, we chose to investigate trends in clinical practice in four Kenyan hospitals. These hospitals rely on clinical assessment and blood smears for malaria to differentiate illness and determine management in children who present with febrile illness. This study examined factors present on presentation in a cohort of acutely febrile Kenyan children at 4 hospital sites over a 33 week period. Clinical officers at each site completed a comprehensive intake form for each child including components of history, physical exam, malaria smear results, diagnosis and treatment. We examined the correlation of malaria smear results and diagnosis with treatment. In a cohort of 598 febrile children, preliminary data indicates that 56.8% (95% CI 51.2-62.2%) of those with a negative malaria smear were given a primary diagnosis of malaria. Of patients who were malarial positive with no additional viral or bacterial diagnosis, 30% (95% CI 23.2-37.8%) were given antibiotics. Of patients who were malaria smear negative and diagnosed with viral illness, 70.6% (95% CI 64.1-76.3%) were given antibiotics. In a cohort of acutely ill Kenyan children, malarial test results and diagnosis did not correlate over half of the time. In addition, antibiotics were given to a large percentage of cases diagnosed with either malarial or viral illness. More thorough investigation, including qualitative analysis on the principles, practices, and knowledge of these clinical officers is needed to understand if there are discrepancies between evaluation and appropriate treatment of these children in a resource-poor setting. Further analysis is needed to examine various factors that influence management decisions.

651

DETERMINING THE SAFETY OF LUMBAR PUNCTURE IN COMATOSE MALAWIAN CHILDREN: A RETROSPECTIVE CASE-CONTROL STUDY

Christopher Moxon[1], Lei Zhao[2], Chenxi Li[2], Karl Seydel[2], Peter Diggle[1], Ian MacCormick[3], Terrie Taylor[2], **Douglas Postels**[2]

[1]University of Liverpool, Liverpool, United Kingdom, [2]Michigan State University, East Lansing, MI, United States, [3]Malawi-Liverpool-Wellcome Trust, Blantyre, Malawi

Coma is a common clinical presentation for critically ill children in sub-Saharan Africa, where major differential diagnoses include cerebral malaria, viral encephalitis, and bacterial and tuberculous meningitis. Lumbar puncture (LP) is a crucial diagnostic test to distinguish between these etiologies and determine optimal treatment. However, clinicians may be hesitant to perform an LP due to concerns of precipitating herniation and death, particularly in environments where pre-procedure neuroimaging is unavailable. This concern may be compounded by a recent major study demonstrating that substantial brain swelling occurs in children with cerebral malaria and is strongly associated with fatal outcome. We performed a retrospective case-control study of the safety of LP in comatose Malawian pediatric inpatients recruited over consecutive rainy seasons from 1999-2013. Our goal was to assess whether performing an LP changed the odds of mortality within the first 12 hours after the procedure. Propensity score matching was used to estimate the independent effect of LP on outcome. Nine hundred thirty-three children were in coma and had data on all key covariates, of which 718 (77%) had an LP and 215 (23%) did not. Following propensity score matching, all baseline characteristics were balanced between matched pairs of children who did and did not have LPs. After matching, 12 hour mortality was not significantly different between children who did and did not receive lumbar punctures (average treatment effect of receiving an LP was to reduce mortality by 5.3%; 95% CI: -1.1% to 11.6%; P=0.11). Logistic regression, stratification on propensity scores, and inverse probability weighting analyses all showed a trend towards a lower mortality in the group that received an LP. In our study population of African children in coma, performing a diagnostic LP in the absence of prior neuroimaging was not associated with increased mortality risk.

652

CURRENT BURDEN OF LIVER ABSCESS AND FACTORS AFFECTING PATIENT SURVIVAL IN THAILAND: NATIONWIDE STUDY

Kittiyod Poovorawan[1], Wirichada Pan-ngum[2], Ngamphol Soonthornworasiri[2], Chatporn Kittitrakul[1], Polrat Wilairatana[1], Sombat Treeprasertsuk[3], Bubpha Kitsahawong[4], Kamthorn Phaosawasdi[4]

[1]Department of Clinical Tropical Medicine, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]Department of Tropical Hygiene, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand, [4]Vichaiyut Hospital and Medical Center, Bangkok, Thailand

We aimed to evaluate the burden of liver abscess in Thailand, using information from the 2009-2013 Nationwide Hospital Admission Data, the National Health Security Office (NHSO), Thailand. All patients with a primary diagnosis of pyogenic liver abscess and amoebic liver abscess (ICD10-K750, A064) were included. Epidemiological data, baseline characteristics, hospital course and survival were analyzed. 11,296 admissions comprised of 8,423 patients from 844 hospitals across Thailand were eligible for analysis. The mean age was 52±17 years and 66.1% of patients were male. Most pyogenic liver abscess patients were from the northeastern part of the country (3,157/7,975, 39.6%), and patients with amoebic liver abscess were mostly from the south (205/448, 45.8%). The highest incidence of liver abscess occurred in the rainy season (June to November, p<0.01). The median length of hospital stay was 8 days (IQR 4 to 13 days), and mean cost of hospitalization was 846±1,574 USD. The overall in-hospital mortality rate was 2.8%. Etiology of pyogenic liver abscess could be determined in 1,029 cases. Most common pathogens causing pyogenic liver abscess were ***Burkholderia pseudomallei*** (56.5%), ***Klebsiella*** pneumonia (22.2%), and ***Escherichia coli*** (10%). Of these, ***E. coli*** posed the highest risk of in-hospital mortality (HR 3.38; 95% CI, 1.69-6.76; p=0.001). HIV infection was found to be one of the most significant comorbidities associated with increasing in-hospital mortality (HR 6.57; 95% CI, 3.81-11.33; p<0.001). Overall long-term survival was significantly higher among patients with amoebic liver abscess compared to pyogenic liver abscess (HR 0.54; 95% CI, 0.42-0.68; p<0.001). Incidence of amoebic liver abscess decreased over the five-year study period, while incidence of pyogenic liver abscess increased (p<0.01). Treatment outcomes did not significantly change (p=0.68) but the cost of treatment gradually increased over the five-year period (p<0.01). Direct cost of hospitalization was estimated to 10 million USD. The burden of liver abscess remains a public health problem in Thailand, with an overall mortality rate of 2.8%.

653

COMMUNITY BARRIERS FOR THE IMPLEMENTATION OF A MASS DRUGS ADMINISTRATION FOR MALARIA IN THE GAMBIA

Susan Dierickx[1], Charlotte Gryseels[1], Julia Mwesigwa[2], Sarah O'Neill[1], Fatou Jaiteh[2], Melanie Bannister-Tyrrell[1], Julia Irani[1], Maya Ronse[1], Jane Achan[2], Umberto D'Alessandro[2], Koen G. Peeters[1]

[1]Institute of Tropical Medicine, Antwerp, Belgium, [2]Medical Research Council Unit, Fajara, Gambia

With some countries in Sub-Saharan Africa documenting a decline in malaria transmission, the feasibility of Mass Drug Administration (MDA) for malaria elimination is being reconsidered. For this strategy to work, participation of the target population in excess of 80% is needed. Hence, understanding community perceptions of MDA and response to the intervention is fundamental to ensure its effectiveness. This anthropological study is ancillary to a study aiming to understand the heterogeneity of malaria transmission in the Gambia. Within this study, MDA took place before the rainy season in 12 villages throughout the Gambia. Research was carried out during the MDA and its direct aftermath. Several barriers were identified that influenced the uptake of and adherence to MDA:(i) long and short-term mobility of individuals and groups; (ii) perceived adverse drug reactions and related rumors, (iii) size and taste of the medication, (iv) waiting time and (v) public pregnancy tests to exclude pregnant women. MDA refusers often did not attend the sensitization meetings and misinterpreted essential information about the MDA. Personal characteristics of the distribution team and the level of trust between this team and locals were key factors for participation and adherence. Although community involvement was aimed for during this trial, the lack of active involvement in the set-up of the trial extravagated internal frictions within communities and may have led to refusal to participate or lack of adherence to the medication Formative research may be a useful approach when developing and implementing new interventions as it allows for the identification of potential constraints and enabling factors at community level. By taking into account local perceptions about the roll-out of MDA, treatment preferences and rumors caused by perceived side effects and internal divisions within local communities, the implementation of trials may be improved and internal conflicts enhanced by MDA procedures prevented.

654

ANTIMALARIAL TREATMENT-SEEKING AND USE IN SOUTHERN MALAWI: CHALLENGES TO INTERRUPTION OF *PLASMODIUM* TRANSMISSION

Jenna E. Coalson[1], Lauren M. Cohee[2], Jenny A. Walldorf[2], Kondwani Nkanaunena[3], Nicole F. Dear[1], Atupele Kapito-Tembo[3], Karl Seydel[4], Don P. Mathanga[3], Terrie E. Taylor[4], Miriam K. Laufer[2], Mark L. Wilson[1]

[1]University of Michigan, Ann Arbor, MI, United States, [2]University of Maryland Baltimore, Baltimore, MD, United States, [3]Malaria Alert Centre, University of Malawi College of Medicine, Blantyre, Malawi, [4]Blantyre Malaria Project, University of Malawi College of Medicine, Blantyre, Malawi

Antimalarial treatment is key for clearing ***Plasmodium*** infections, which can persist for months. We studied treatment-seeking in southern Malawi to assess the proportion of the infectious reservoir that seeks and obtains treatment. School-aged children (6-15 yrs) have the highest infection prevalence in this area. Each of four cross-sectional surveys over two years included ~3,000 people from 900 households. All members were asked about fever and treatment-seeking in the past two weeks; those present had blood sampled for PCR testing for ***P. falciparum***. Multilevel logistic regression was used to analyze predictors of whether febrile people sought treatment, did so at government/private clinics vs. other sources (shops, community health workers, etc.), and reported taking antimalarials. Of 12,652 interviewed, 87.1% reporting recent fever sought treatment, but the proportion decreased with older age. School-aged children and adults (≥16 yrs) were less likely to attend government/private clinics than young children (≤5 yrs). Antimalarial use was more common among febrile people who visited government/private clinics (42.5%) than those going to other sources (7.9%), with diagnostic testing performed on 47.5% of people at government/private clinics and only 2.8% at other sources. These treatment patterns may contribute to high infection prevalence in school-aged children. Afebrile people rarely sought treatment (5.5%); of 1,616 people who were PCR-positive for ***P. falciparum*** when interviewed, only 24.4% sought treatment in the past two weeks. Of people who sought treatment but did not receive antimalarials, 6.9% from government/private clinics and 16.8% from other sources were PCR-positive for ***P. falciparum*** when surveyed. Treatment of symptomatic malaria is common in southern Malawi, but current practices miss a substantial portion of human infectious reservoirs. Encouraging treatment at government/private clinics, especially among school-aged children, could help reduce the high prevalence in this group and potentially decrease transmission; additional intervention will be needed to address the asymptomatic reservoir.

EVALUATING HIGH-RISK VENUE-BASED MALARIA SURVEILLANCE USING TIME-LOCATION SAMPLING IN NAMIBIA

Jerry Jacobson[1], Carmen Cueto[1], Jenny Smith[1], Davis Mumbengegwi[2], Kathryn Roberts[1], Hugh Sturrock[1], Roly Gosling[1], **Adam Bennett**[1]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]University of Namibia, Windhoek, Namibia

While Namibia has experienced a rapid decline in reported malaria cases, from 538,512 cases in 2001, to 3163 cases in 2012, low transmission persists in the north of the country. As part of efforts to eliminate malaria by 2020, targeted active surveillance strategies are being evaluated to identify risk factors and undiagnosed and asymptomatic infections, which may serve as a reservoir driving ongoing transmission. We developed a novel active, venue-based surveillance strategy to target individuals who congregate outdoors or partially outdoors at specific locations ("venues") during evening and morning mosquito biting hours. Venues were selected within the catchment areas of 6 randomly selected health facilities in the Zambezi Region, which borders Zambia and Angola. Focus groups and interviews were conducted with community members to develop an exhaustive map of venues in the selected areas, estimate peak attendance times, and elicit recommendations on study design. Mapping identified 24 shabeens (bars), 6 churches, and one fishing camp with regular evening or morning attendance. Drawing on these findings, a sample frame of venue-day-time intervals (VDTs) was constructed. Local field teams visited randomly selected VDTs and recruited a random selection of 750 venue-goers over a 2 month period. Study participants completed an interviewer-assisted survey, provided dried blood spot samples, received testing by RDT, and treatment if positive. In this presentation we discuss the feasibility of this active surveillance strategy by exploring participation rates, self-reported venue attendance patterns, prevalence of infection by RDT and PCR, and socioeconomic and behavioral risk factors. Estimates were adjusted for probability of selection and clustering by VDT. Prevalence of infection and risk factors are compared to a contemporaneous household survey of 10% of households in the same catchment areas. These methods provide a potentially simple surveillance strategy for accessing individuals at high risk of malaria transmission who may be missed by household level surveillance.

MALARIA ELIMINATION IN ACEH, INDONESIA: USING LAMP IN REACTIVE CASE DETECTION TO INCREASE INFECTION DETECTION

Chris Cotter[1], Farah Coutrier[2], Herdiana H. Basri[3], Iska Zarlinda[2], Yusrifar K. Tirta[2], Asik Surya[4], Brittany Zelman[1], Alanna Schwartz[5], Bryan Greenhouse[5], Iveth J. Gonzalez[6], William A. Hawley[3], Rintis Noviyanti[2], Roly D. Gosling[1], Michelle S. Hsiang[1]

[1]Global Health Group at the University of California San Francisco, San Francisco, CA, United States, [2]Eijkman Institute for Molecular Biology, Jakarta, Indonesia, [3]United Nations Children's Fund, Aceh, Indonesia, [4]National Malaria Control Programme - Indonesian Ministry of Health, Jakarta, Indonesia, [5]Department of Medicine, University of California San Francisco, San Francisco, CA, United States, [6]Foundation for Innovative New Diagnostics, Geneva, Switzerland

Reactive case detection (RACD), whereby household members and neighbors of passively-detected malaria cases are screened for infection, is a WHO-recommended strategy for malaria elimination, however there are limited data to guide practice, particularly from mixed ***Plasmodium*** species settings. We introduced the use of molecular detection for RACD of malaria in Aceh Besar District, Aceh Province, Indonesia and compared infection detection to currently used RACD practices based on microscopy. Microscopy-confirmed index cases identified at five sentinel health facilities received a follow-up investigation in their home, and family members and neighbors were targeted for blood testing by microscopy and the collection of dried blood spots for testing by high sensitivity ***Plasmodium***-specific loop-mediated isothermal amplification (LAMP). From June 2014 to March 2015, we enrolled 21 index cases which led to the screening of 778 household members and neighbors (median 38/index case, mean 35/index case). Positivity rate by microscopy was 0.4% (3/778) versus 0.6% (5/778) by LAMP (p=0.16), with LAMP detecting 1.5 fold more infections than microscopy alone. Compared to passive surveillance alone, whereby 21 cases were identified, RACD using microscopy increased the detection of infections by 1.1 fold, and RACD using LAMP increased the detection of infections by 1.2 fold. Of the five additional infections found by slide and/or LAMP from RACD, speciation by species-specific PCR showed 1 ***Plasmodium falciparum***, 3 ***P. vivax***, and 1 ***P. knowlesi***. The speciation for three infections (1 Pf, 1 Pv and 1 Pk) matched that of the index case infection and two did not (1 Pv was associated with a Pf index case and 1 Pv was associated with a Pk index case). Although the difference was not significant, RACD using LAMP, compared to RACD using microscopy, increased the detection of infections in a low transmission, mixed ***Plasmodium*** species setting. The study is ongoing and further enrollment of subjects may strengthen findings and potentially show declines in incidence.

WHAT MAKES A MALARIA HOTSPOT A HOTSPOT? EXAMPLE FROM ZANZIBAR

Jackie Cook[1], Mwinyi Khamis[2], Lugano Daimon[3], Ulrika Morris[4], Berit Aydin-Schmidt[4], Silas Majambere[5], Khamis Haji[2], Mwinyi Msellem[2], Ali Abass[2], Waziri Nyoni[3], Iveth Gonzalez[6], Andreas Martensson[4], Rob Ainslie[3], Anders Bjorkman[4], Abdullah Ali[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, [3]Johns Hopkins Center for Communication Programs, Dar es Salaam, United Republic of Tanzania, [4]Karolinska Institutet, Stockholm, Sweden, [5]Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, [6]Foundation for Innovative New Diagnostics, Geneva, Switzerland

Health facility based, passive case detection surveillance systems have been in place in Zanzibar since 2007. Spatial analysis of this data revealed ***foci*** of clinical malaria cases which were present every transmission season. In order to investigate why these areas consistently record higher numbers of malaria cases, a cross-sectional Knowledge, Attitudes, Practices and Behaviour (KAPB) study was undertaken in all 30 hotspot villages (N of households=1,036), as well as from 30 randomly selected control villages (N of households=1,117). In order to determine current prevalence all household members were tested using rapid diagnostic test (RDT) or RDT and loop-mediated isothermal amplification (LAMP), to assess the proportion of low-density parasitemias present. Entomological indices were also collected. Analyses are still ongoing. Prevalence of infection was low (0.3% by RDT, 1.6% by LAMP) and did not differ in hotspots and controls. Preliminary results show that 60% of study participants reported sleeping under a net the previous night. Coverage and usage of nets did not differ between hotspot villages and controls. Households in hotspot villages were more likely to have been sprayed in the previous 6 months (55% compared to 31%, p<0.001), highlighting the targeted nature of spray campaigns in Zanzibar. People living in hotspot villages were more aware of malaria (transmission season, symptoms, causes) but appeared to have less faith in the protective effect of sleeping under nets and were more likely to wait more than 2 days before presenting to a health facility with a fever (p=0.02). More Anopheline mosquitoes were found in hotspot households than controls, with outdoor biting prominent in both. Examining KAPB of residents living within malaria ***foci*** may help to elucidate reasons for the higher burden of infection and subsequently enable interventions to be adapted or targeted as required.

658

WHEN SUSTAINABILITY FAILS: THE IMPACT ON ELIMINATION

Rajendra Maharaj, Natashia Morris

Medical Research Council, Durban, South Africa

As many countries now target elimination of malaria, whole regions are harmonising policies and regimens in order to present a united front in pushing back the frontiers of malaria distribution. This is most apparent in southern Africa where a number of multi-country initiatives are in place to increase the pace for elimination. The Lubombo Spatial Development Initiative (LSDI) was one such initiative. It aimed to accelerate socio-economic development in parts of South Africa, Swaziland and Mozambique but malaria was an impediment to this goal and the LSDI malaria control component was established. During its lifetime, the LSDI achieved remarkable results but unfortunately the programme was not sustainable and terminated after 12 years, affecting the elimination efforts in South Africa and Swaziland. To examine the impact of this failure in sustainability, retrospective data from the LSDI era was compared to current data (when no LSDI initiatives were implemented). Indoor Residual Spray (IRS) coverage gave an indication of the effectiveness of the vector control intervention in place. Impact was measured as the parasite prevalence rate in Mozambique and the incidence rate in South Africa and Swaziland. During the life of the LSDI, there was a rapid decline in prevalence in Mozambique from an average prevalence of 70% in 2000 to 5% in 2010. The area under control increased and the IRS implemented was at a high rate of coverage. In South Africa and Swaziland, the incidence of malaria also decreased by 98% within 3 years. When IRS was no longer implemented in Mozambique, the malaria cases rose from 5% up to 14% in three years and the incidence increased to >1% in districts of Mpumalanga and Limpopo Provinces. In South Africa and Swaziland, imported malaria increased and resulted in focal outbreaks of malaria. Malaria cases decreased when IRS was implemented in a co-ordinated manner. However when the interventions were no longer applied, the malaria cases reached the same level as pre-intervention prevalence. Failure of control in one country can hamper the elimination agenda of surrounding countries.

659

REACTIVE CASE DETECTION WITH TARGETED MASS DRUG ADMINISTRATION FOR MALARIA ELIMINATION IN NORTHWESTERN PERU

Fernando A. Quintana[1], Elke L. Mendoza[1], Rommel V. Gonzales[1], Juan Arrasco[2], Yenny O. Herrera[3], **Antonio M. Quispe**[4]

[1]Epidemiology General Directorate, Tumbes, Peru, [2]Dirección Ejecutiva de Vigilancia Epidemiológica, Dirección General de Epidemiología, Lima, Peru, [3]Dirección de Saneamiento Básico, Higiene Alimentaria y Zoonosis, DISA Lima Sur, Lima, Peru, [4]Johns Hopkins Bloomberg School of Public Health, Lima, Peru

Reactive case detection (RCD) with targeted mass drug administration (tMDA) has been proposed as an effective strategy for malaria elimination, although little is know about its effectiveness. In this study, we estimated the effectiveness attributable to RCD/tMDA as compared to passive case detection (PCD) on reducing the incidence of malaria to zero in Tumbes, Peru. During years 2009-2010 we piloted a malaria-elimination programme based on RCD/tMDA in the two most malaria-endemic districts in Tumbes; then, during years 2011-14 we scaled up to the other 11 districts in Tumbes. Under RCD/tMDA every malaria case that was detected passively was followed within the first 24 hours to census and treat each of his/her household contacts, excluding elders, pregnant women, and chronically-ill subjects. Then each eligible subject was treated with chloroquine (25mg/kg, total dose) over 72 hours plus primaquine (0.5mg/kg) taken orally for 7 days. The primary study endpoint was a 50% reduction in the annual parasite incidence (API = total malaria cases/ 1,000 inhabitants) at the surveillance-reporting units level, analyzed by intention to treat. The Peruvian Ministry of Health sponsored the study and the Ecuadorian government donated 20,000 vivax malaria treatments. During the pilot study we treated a total of 8,243 subjects, including 7376 household contacts. The estimated reduction in the mean API across intervened and non-intervened reporting units was 86.2% (95% CI 72–100) at 12-mo and 97.9% (93–100) at 24 months, and -230.9% (95% CI -395–-66) at 12-mo and -19% (-87– 49) at 24-mo, respectively. When comparing those mean API reductions we found that in both cases, at 12-mo (p=0.02) and at 24-mo (p=0.04) the differences were statistically significant. Any antimalarial adverse events were reported during study period. After scaling up, the APIs dropped to 3.1 and 0.4 in years 2011 and 2012, with zero cases in year 2013, and one imported case in year 2014. Hereby, we concluded that RCD/tMDA represent an effective strategy to support malaria elimination initiatives in region with high predominance of vivax malaria such in northwestern Peru.

RATS FOR SALE: INVESTIGATING THE SCOPE AND PUBLIC HEALTH CONSEQUENCES OF RODENT CONSUMPTION IN NORTHERN VIETNAM

Thinh D. Nguyen[1], Duoc Vu Trong[1], Sinh Vu Nam[1], Chi Nguyen Yen[2], Karen Saylors[3], Heiman Wertheim[2], **Juliet E. Bryant**[2]

[1]National Institute Hygiene and Epidemiology, Hanoi, Vietnam, [2]Oxford University Clinical Research Unit, Hanoi, Vietnam, [3]Global Viral, San Francisco, CA, United States

In Vietnam, rodents are frequently trapped on rice fields before and after harvesting and are sold live in wet markets for food consumption. The rodent trade in the southern Mekong Delta is vigorous, with an estimated 3300-3600 tonnes of rodent meat sold per year. We hypothesize the presence of significant regional differences in rodent trade between northern and southern Vietnam, reflecting differences in rodent density, rodent species diversity, seasonality, culinary traditions, and variable risk perceptions. As part of a larger study on zoonotic disease transmission at the human-animal interface in Vietnam, we have conducted a systematic survey of wet markets in the northern province of Hanoi, to identify sites where rodents are sold for human consumption; determine the common species sold in markets, and estimate the volume of trade; characterize seasonality and fluctuations in rodent trade over the course of one year; and to obtain samples from epidemiologically linked humans and rodents for further molecular and serological analysis of microbial ecology. To date, although our results from various study sites in Vietnam confirm low-to-moderate levels of endemic circulation of rodent-borne viruses and bacterial agents (e.g. hantaviruses, flaviviruses, parechovirus, Bartonella, Leptospira), there is little evidence to suggest a public health risk associated with rodent meat consumption. These ongoing investigations and analyses will be discussed.

ANTHROPOGENIC DISTURBANCE, SPECIES DIVERSITY AND RISK OF RODENT-BORNE DISEASES IN MADRE DE DIOS, PERU

Catherine Dupont[1], M. Claudia Guezala[1], Gabriela Salmon-Mulanovich[1], Christian B. Albujar[1], Victor Pacheco[2], Valerie Paz-Soldan[3], Stella Hartinger[4], Lineth Garcia[5], Philip Cooper[6], Xiangming Xiao[7], A. Townsend Peterson[8], James Mills[9], Daniel G. Bausch[3]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]Museo de Historia Natural "Javier Prado", Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [4]Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Universidad Mayor de San Simon, Cochabamba, Plurinational State of Bolivia, [6]Pontificia Universidad Catolica del Ecuador, Quito, Ecuador, [7]University of Oklahoma, Norman, OK, United States, [8]University of Kansas, Lawrence, KS, United States, [9]Emory University, Atlanta, GA, United States

Anthropogenic disturbance of natural ecosystems may result in biodiversity loss with altered rodent population dynamics and risk of rodent-borne disease to humans. Influencing factors include rodent population density, environmental conditions and food availability, and human behavior. Here we describe the preliminary findings of a 5-year study on the effects of anthropogenic habitat perturbation and risk of rodent-borne diseases in 4 communities along a highway recently built through the Madre de Dios Region in the southern Amazon Basin of Peru. At each site, live traps were placed in six 7x7m grids (49 trap stations per grid) selected, with the assistance of satellite imagery, to represent varied habitat disturbance: 2 in non-disturbed forest, 1 in disturbed areas (crop field, pasture or other) and 3 in edge areas. Trapping was conducted every 4 months to cover dry, rainy and mid-seasons. Blood was taken before marking and releasing rodents, with the exception of the last day of trapping, when necropsies were performed and organs obtained. From the first 4 trapping sessions, a total of 732 animals were captured, of which 129 were recaptures. The 603 individual rodents captured comprised 10 genera and 16 species, including ***Oligoryzomys microtis*** (43.4%), ***Necromys lenguarum*** (10.4%), ***Euryoryzomys nitidus*** (10.0%) and ***Hyaleamys perenensis*** (8.9%). We found ***E. nitidus*** more frequently in edge areas (51/75), similarly to ***N. lenguarum*** (40/78) and ***O. microtis*** (250/324), in contrast to ***H. perenensis*** which was more frequently found in non-disturbed areas (42/67). Simpson's biodiversity indices were higher for edge areas. The highest trap success was in the dry season, when scarce food availability likely led rodents to extend foraging into traps. Laboratory testing for pathogens is underway but, notably, three of the captured rodent species have been previously reported to carry hantaviruses. Full results will be presented at the meeting.

662

THE EPIDEMIOLOGY OF Q FEVER IN HUMANS AND CATTLE, WESTERN KENYA

Nicola A. Wardrop[1], Elizabeth A. Cook[2], William A. de Glanville[2], Lian Thomas[2], Peter M. Atkinson[1], Claire N. Wamae[3], Eric M. Fevre[4]

[1]University of Southampton, Southampton, United Kingdom, [2]University of Edinburgh, Edinburgh, United Kingdom, [3]Kenya Medical Research Institute, Nairobi, Kenya, [4]University of Liverpool, Liverpool, United Kingdom

Evidence suggests that the intracellular bacterial pathogen Coxiella burnetii (which causes Q fever) is widespread, with a near global distribution. While there has been increasing attention to Q fever epidemiology in high-income settings, a recent systematic review highlighted significant gaps in our understanding of the prevalence, spatial distribution and risk factors for Q fever infection across Africa. This research aims to provide a One Health assessment of Q fever epidemiology in western Kenya in cattle and humans. A cross-sectional survey was conducted: serum samples from 2113 humans and 983 cattle in 416 homesteads were analysed for C. burnetii antibodies. Questionnaires covering demographic, socio-economic and husbandry information were also administered. These data were linked to environmental datasets based on geographical locations (e.g. land cover). Multilevel regression analysis was used to assess the relationships between a range of socio-economic, demographic and environmental factors and sero-positivity in both humans and animals. The overall sero-prevalence of C. burnetii was 2.5% in humans and 10.5% in cattle. Multilevel modelling indicated the importance of several factors for exposure to the organism. Cattle obtained from market (as opposed to those bred in their homestead) and those residing in areas with lower precipitation levels had the highest sero-prevalence. For humans, the youngest age group had the highest odds of seroprevalence, variations were observed between ethnic groups, and frequent livestock contact (specifically grazing and dealing with abortion material) was also a risk factor. These results illustrate endemicity of C. burnetii in western Kenya, although prevalence is relatively low. The analysis indicates that while environmental factors may play a role in cattle exposure patterns, human exposure patterns are likely to be driven more strongly by livestock contacts. The implication of livestock markets in cattle exposure risks suggests these may be a suitable target for interventions.

663

MAPPING LEPTOSPIROSIS HOTSPOTS IN FIJI USING ENVIRONMENTAL, SOCIOECONOMIC AND LIVESTOCK DATA: AN ECO-EPIDEMIOLOGICAL APPROACH TO EMERGING INFECTIOUS DISEASE CONTROL

Colleen L. Lau[1], Conall H. Watson[2], John H. Lowry[3], Michael C. David[1], Mike Kama[4], Eric J. Nilles[5]

[1]The University of Queensland, Brisbane, Queensland, Australia, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]School of Geography, Earth Science and Environment, The University of South Pacific, Suva, Fiji, [4]Fiji Centre for Communicable Disease Control, Suva, Fiji, [5]Emerging Diseases Surveillance and Response, World Health Organization, Suva, Fiji

Leptospirosis is an emerging infectious disease in the Pacific Islands. In Fiji, two successive cyclones and severe flooding in 2012 resulted in outbreaks associated with 10% case-fatality. A seroprevalence study was conducted in 2013 to better understand environmental drivers of leptospirosis emergence in Fiji. Antibodies indicative of previous leptospirosis infection were found in 19.4% of 2152 participants (82 communities on the 3 main islands). Questionnaires and geographic information systems data were used to assess risk factors related to individual behavior, exposure to animals, socioeconomics, land use, and natural environment. Significant individual-level risk factors include male, ethnicity, working outdoors, swimming in rivers, and physical contact with rodents. A multivariable logistic regression model was able to correctly classify the presence/absence of previous infection in >80% of participants using only six community-level variables: rainfall in the wettest month (OR 1.004 per mm, p <0.01); living <100m from a major river (OR 1.46, p <0.01); poverty rate (OR 1.46 for the poorest 25%, p 0.03); living in rural area (OR 1.75 compared to urban, p <0.01), pigs in community (OR 1.64, p <0.01); and cattle density in district (OR 1.03 per head/sqkm, p 0.02). The model was used to predict community-level seroprevalence, and produce a predictive risk map of leptospirosis for Fiji to identify hotspots and inform public health interventions. Predicted community seroprevalence was highly correlated with levels observed in the 2013 field study (cor coeff 0.73). Leptospirosis transmission in Fiji is complex and multifactorial, disproportionately affecting the poorest. Predictive accuracy of the model highlights the importance of environmental and socioeconomic drivers of transmission. With global climate change, extreme rainfall and cyclones are expected to intensify in the South Pacific. Livestock farming and commercial agriculture are also expected to increase with population growth. These factors could combine to drive increasing incidence of leptospirosis if risks are not properly managed and mitigated against.

664

CHAGAS DISEASE EPIDEMIOLOGY AND OUTREACH IN HIGH-RISK HUMAN AND CANINE POPULATIONS ALONG THE U.S.-MEXICO BORDER

Sarah Hamer[1], Italo Zecca[2], Rachel Curtis-Robles[1], Ann Millard[2], Daniel Goldberg[1], Cecilia Giusti[1], Charles Criscione[1], Gabriel Hamer[1]

[1]Texas A&M University, College Station, TX, United States, [2]Texas A&M University, McAllen, TX, United States

Chagas disease is a cardiac disease of humans and dogs caused by the parasite ***Trypanosoma cruzi***. The disease is most prevalent across Latin America in areas where the Triatomine 'kissing bug' vectors colonize the home. Despite the recognition of established enzootic cycles of parasite transmission involving wildlife in the southern United States, the human and veterinary health burden of Chagas disease in this area is largely unknown, although there are increasing diagnoses in immigrants and locally-exposed persons as well as privately-owned, stray, and working dogs. With a One Health framework involving collaborators from the medical, veterinary, agriculture, architecture, geoscience, and science colleges, we studied the epidemiology of Chagas disease in medically-underserved human and canine populations in the south Texas colonias. Colonias are impoverished communities along the US-Mexico border that lack some of the most basic living necessities, such as sewer systems, electricity, and sanitary housing, and may therefore be at high risk for vector exposure. During the summer activity season of kissing bugs, we conducted a cross-sectional study to determine the associations among human and animal infection, vector occurrence, and socioeconomic and environmental features. We collected human and canine blood samples in four colonias using a door-to-door approach that also allowed the opportunity for characterization of the peridomestic environment. Additionally, we implemented a kissing bug citizen science program including a new kissing bug mobile app, given the widespread use of smart phones in these communities, to empower the public with Chagas disease knowledge while allowing them to submit kissing bugs for identification and testing. Preliminary data from the area indicate over 6% of local dogs arriving at the major animal shelter in the region were exposed to ***T. cruzi***. Our citizen science program has resulted in over 2,000 bugs submitted across Texas, characterized by >60% infection prevalence. Key findings, including risk factors for human and canine ***T. cruzi*** infection will be presented.

665

HAS RIFT VALLEY FEVER VIRUS EVOLVED TO INCREASED VIRULENCE IN HUMAN POPULATION AFTER EXISTENCE FOR A CENTURY IN EAST AFRICA?

Marycelin M. Baba[1], Jandouwe Villinger[2], Rosemary Sang[2], Daniel Masiga[2]

[1]University of Maiduguri, Maiduguri, Nigeria, [2]International Centre of Insect Physiology and Ecology, Nairobi, Kenya

Rift Valley Fever (RVF) outbreaks have occurred across East African countries from 1912 to 2010 in cycle of 4-15 years. RVF virus becomes enzootic/endemic once it is introduced into a certain permissive ecologies, causing periodic outbreaks with the potential to spread further to non-endemic/enzootic environments with favorable conditions. In Kenya, of 22 RVF outbreaks from 1912 to 2007, 14 were national affecting 3 -38/69 districts while 8 were localized to 1 - 2/69 districts. Unlike other parts of Africa, most of these outbreaks were epizootics in early 1900s and were not accompanied by significant epidemics in human populations in East Africa. However, in 1998, RVF outbreaks in the horn of Africa led to 478 deaths, followed by further epidemics a decade later, in 2006-2007, during which 1,107 human cases were reported with 350 deaths. In 2008, comparable epidemics occurred in Sudan (698 human cases; 222 deaths) and Mozambique (412 human cases, 17 deaths). Comparisons between isolates from different outbreaks reveal specific genetic mutations and reassortments that have diversified RVF virus genomes over the past century. Although genetic diversity of RVF virus appears to be low (~5%), these changes in combination with the accumulation of mutational changes over the years could have influenced RVF virus host preference and virulence in human populations. Factors such as underreporting, lack of appropriate diagnostic kits, under-recognition of clinical signs, changes in case definitions could have influenced paucity of information on human RVF in early 1900s. However, the explosive nature and pronounced RVF epidemics in humans in recent decades became so overwhelming to attribute the obvious changes to improvement in the above mentioned factors. We speculate that the evolutionary diversification of the virus could have resulted in distinct lineages with increased and possibly increasing virulence and pathogenicity in humans. The emerging infectious disease threats posed by the modern RVF virus strains to humans increases the potential public health and socio-economic impacts of future RVF epidemics.

RETROSPECTIVE ANALYSIS OF HUMAN-BONOBO ZOONOTIC PATHOGEN TRANSMISSION IN THE DEMOCRATIC REPUBLIC OF CONGO

Aleah C. Bowie[1], Chelsea McMullen[1], Raphael Belais[2], Claudine André[2], Fanny Minesi[2], Anne-Marie Ngalulua[2], Lawrence Park[1], Anne Rimoin[3], Suzanne Kennedy-Stoskopf[4], Brian A. Hare[1], Christopher W. Woods[1]

[1]Duke University, Durham, NC, United States, [2]Lola Ya Bonobo Sanctuary, Kinshasa, Democratic Republic of the Congo, [3]University of California, Los Angeles, Los Angeles, CA, United States, [4]North Carolina State University, Raleigh, NC, United States

Forest destruction and the rampant bushmeat trade in the Democratic Republic of Congo (DRC) have increased proximity between human and African great ape populations. Because humans and great apes are genetically similar, known and emerging pathogens can opportunistically transmit between hosts in close contact, further endangering remaining ape populations and potentially instigating human epidemics that could weaken the DRC's already fragile healthcare infrastructure. Zoonotic transmissions are well documented between chimpanzees and humans, but few data exist on transmission between humans and bonobos (Pan paniscus), To introduce bonobos, found only in the DRC and the least studied of the great apes, into the growing body of zoonotic disease research, we examined fifteen years of veterinary records from 125 rescued orphan bonobos rehabilitated at a sanctuary outside the densest city in the DRC. Common clinical syndromes described in the records included gastrointestinal illnesses, skin infections, and injury. Respiratory illness accounted for 52% of the 1,481 reports and 31% of all deaths (n=16) since the sanctuary's inception. In contrast, respiratory illness is infrequent among wild bonobo populations with limited human contact. Temporal correlations between bonobo and human respiratory outbreaks reported through Ministry of Health surveillance from 2006 to 2011 suggest transmission of respiratory pathogens from humans to bonobos. The results of this study have implications for increased safety and hygiene practices at rehabilitative sanctuaries to reduce the introduction and spread of respiratory pathogens, with larger implications for limiting the increasingly inevitable contact between humans and wild bonobo populations as the landscape of the DRC continues to change.

INNOVATIVE 2-D AND 3-D *IN VITRO* CULTURING SYSTEMS FOR *ONCHOCERCA VOLVULUS*

Sara Lustigman[1], Nancy Tricoche[1], Olena Kolesnichenko[1], Judy A. Sakanari[2], Michael T. Suderman[3]

[1]New York Blood Center, New York, NY, United States, [2]University of California, San Francisco, CA, United States, [3]Cell Systems-3D, LLC, Kemah, TX, United States

Elimination of Onchocerciasis where mass drug administration with ivermectin is not sufficient (loasis co-endemic regions or areas where suboptimal responses to ivermectin are observed) will require a drug that kills adult ***Onchocerca volvulus*** worms (macrofilaricidal drugs). The macrofilaricidal drug discovery efforts are limited in part by having access to only surrogate filarial adult worms isolated from infected animals (e.g. cows: ***O. ochengi***, ***O. lienalis***, ***O. gibsoni*** or ***O. gutterosa***; gerbils: ***Brugia malayi***, ***B. pahangi***). Thus far, the life cycles of ***Onchocerca*** and ***Brugia*** spp. have not been completed ***in vitro***. At most, partial molting of the infective third-stage larvae (L3) to the fourth-stage larvae (L4) has been attained ***in vitro;*** within a week for ***O. volvulus*** and 2 weeks for ***Brugia***. To address the lack of access to adult ***O. volvulus*** worms, we developed a 2-Dimensional (2-D) ***in vitro*** monolayer culture and an innovative 3-D culturing system that provided supportive microenvironments for the growth and development of ***O. volvulus*** L3 to the L5 adult female and male stages. Four human cell lines (HUVEC, NHEK, HDFB, and HSMC) supported the growth and development of ***O. volvulus*** L3 (~350 µm) to female and male L5 worms after 100 days in 2-D cultures. These worms ranged in length from 1400-1800 µm and most likely consisted of both sexes since male worms are generally shorter in length compared to female worms. The 3-D scaffold was made of PET fibers infused with NHNDF, MVE and LMVE dermal cells and supported the growth of L3s to L5s that were >2,000 µm in length after 100 days. Initial screening of repurposed drugs with such L5s demonstrated that these pre-adult ***O. volvulus*** could be used to identify novel macrofilaricidal drugs. Once the culture system is optimized, we anticipate that we will be able to provide large quantities of adult ***O. volvulus*** worms to routinely screen for novel macrofilaricidal drugs and thereby accelerating the drug discovery program aimed to support the elimination of onchocerciasis.

TRANSCRIPTOMIC ANALYSIS FOR IVERMECTIN-TREATED ADULT *BRUGIA MALAYI*

Cristina Ballesteros[1], Lucienne Tritten[1], Maeghan O'Neill[1], Erica Burkman[2], Weam Zaky[3], Steven Williams[3], Jeff Xia[1], Patrick Flaherty[4], Andy Moorhead[2], Timothy G. Geary[1]

[1]McGill University, Ste-Anne-de-Bellevue, QC, Canada, [2]University of Georgia, Athens, GA, United States, [3]Smith College, Northampton, MA, United States, [4]Worcester Polytechnic Institute, Northampton, MA, United States

Lymphatic filariasis (LF) is a disabling and disfiguring neglected tropical disease caused by three filarial nematodes (***Wuchereria bancrofti***, ***Brugia malayi*** and ***B. timori***) which are transmitted by mosquitos. The presence of adult worms in the lymphatic system can lead to progressive damage and pathology. Presently, 120 million people are infected and 1.4 billion people are targeted for annual mass drug administration (MDA) in an attempt to eliminate this disease by 2020. The MDA strategy is to block parasite transmission by using combinations of albendazole and diethylcarbamazine or, in areas co-endemic for onchocerciasis, albendazole and ivermectin. Paralysis of pharyngeal pumping by ivermectin could result in deprivation of essential nutrients, inducing a wide range of starvation responses, including altered gene expression and biochemical activities, alternative developmental states in intrauterine larvae and altered physiological responses. Previous studies have shown that ivermectin treatment significantly reduces microfilariae release from females within four days of exposure; however, the mechanisms responsible for reduced microfilaria production are not well understood. In this study, we analyzed transcriptomic profiles from ivermectin-treated and -untreated ***B. malayi*** adult females using Next Generation RNA Sequencing technology at different concentrations (100 nM, 300 nM and 1 uM) and time points (24, 48, 72, and 120 hours). Our analysis revealed altered expression of multiple genes involved in fertility, embryogenesis and larval development, which were significantly down-regulated as early as 24 hours post-exposure. These changes reflect and provide insight into the mechanisms involved in ivermectin-induced reduction in microfilaria output and impaired embryogenesis. RNA interference phenotypes of the homologs of these genes in C. elegans include maternal sterile, embryonic lethal, larval arrest, larval lethal, reduced brood size and egg shape variable.

RATIONAL DESIGN FOR OXAMNIQUINE DERIVATIVES THAT KILL SCHISTOSOMES

Stacey R. Stahl[1], Alexander B. Taylor[1], Xiaohang Cao[1], P. John Hart[1], Stanton F. McHardy[2], Ambrosio Lopez[2], Frédéric D. Chevalier[3], Timothy J. Anderson[3], **Philip T. LoVerde**[1]

[1]University of Texas Health Science Center, San Antonio, TX, United States, [2]University of Texas San Antonio, San Antonio, TX, United States, [3]Texas Biomedical Research Institute, San Antonio, TX, United States

Human schistosomiasis is a disease caused by species of the genus ***Schistosoma***, which globally affects over 200 million people. The major species affecting humans are ***S. mansoni***, ***S. haematobium***,

and ***S. japonicum***. There is currently only one method of treatment (monotherapy), the drug Praziquantel. Constant selection pressure through mass chemotherapy - this year alone will see the administration of over 250 million doses - has yielded evidence of resistance to PZQ. This has been observed in both the laboratory and field. The goal of this research is to develop a second drug for use in conjunction with PZQ. Previous treatment of ***S. mansoni*** included, among others, the use of oxamniquine (OXA), a prodrug that is enzymatically activated in ***S. mansoni*** but is ineffective against ***S. haematobium*** and ***S. japonicum***. The OXA activating enzyme was identified, described, and crystallized by our laboratories as being a sulfotransferase (SmSULT). The focus of this research is to reengineer OXA to be effective against ***S. haematobium*** and ***S. japonicum***. In this regard we isolated the ***S. haematobium*** (ShSULT) and ***S. japonicum*** (SjSULT) sulfotransferases. Thirty OXA derivatives were synthesized, of which eight showed schistosomicidal activity as good as or better than OXA that may potentially be used to treat schistosomiasis mansoni. ***In vitro*** tests demonstrated that some of these 8 derivatives had activity against ***S. haematobium*** and ***S. japonicum***. This iterative process of using structural data to inform chemical synthesis of derivatives, which are then tested ***in vitro***, continues to provide us with novel compounds with improved anti-schistosomal activity. The information gleaned from these early studies will be used to optimize OXA derivative design. The most active derivatives will be used in an ***in vivo*** model of schistosomiasis to evaluate efficacy before moving to safety and toxicity studies.

670

STAGE-SPECIFIC PROFILING OF THE SOMATIC PROTEOMES AND SECRETOMES OF *ONCHOCERCA VOLVULUS*

Sasisekhar Bennuru[1], Jose M.C. Ribeiro[1], Fidelis Cho Ngwa[2], David Abraham[3], Sara Lustigman[4], Thomas B. Nutman[1]

[1]National Institutes of Health, Bethesda, MD, United States, [2]Biotechnology Unit, Faculty of Science, University of Buea, Buea, Cameroon, [3]Thomas Jefferson University, Philadelphia, PA, United States, [4]Lindsley F. Kimball Research Institute, New York Blood Center, New York, NY, United States

Stage-specific proteomes of filarial parasites have thus far been limited to ***Brugia malayi*** and ***Onchocerca ochengi*** as a surrogate for ***O. volvulus*** (Ov) - the causative organism of onchocerciasis ('river blindness'). Here we report the stage-specific somatic proteomes of the adult male and female worms, embryonic stages (EMB), microfilariae, infective L3 larvae, larvae undergoing molting and L4 larvae along with the secretomes of adult male (OvAM) and adult female parasites (OvAF). Global proteomic analyses were performed using Thermo Easy nLC 1000 UPLC interphased via a Thermo Easy Spray ion source to a Thermo Q-Exactive quadrupole-Orbitrap mass spectrometer. Spectral matching with combined databases of predicted proteomes of Ov, its endosymbiont Wolbachia (wOv) and humans resulted in the identification of ~56% (6821) of the predicted proteome of ***O. volvulus*** and ~69% (571) of wOv proteome. Though relative abundance varied, a small fraction ~ 5% (327) of the identified proteins were commonly found across all stages. Preliminary analyses suggest immunologically related, detoxification and protein modification associated proteins to be differentially expressed and enriched in the L3, adult females and microfilarial stages respectively. Surprisingly, despite EMB being derived from the adult female uterus, they had the highest degree of discrimination power among stages (384) with very few proteins unique to both EMB and OvAF being identified (58). Developmentally, stage-specific expression of 127 proteins were identified during the L3 to L4 molting process, some of which are well-characterized cysteine proteases, cystatins and serpins. More importantly, over 200 proteins were identified as specific to OvAF, proteins that were also identified in the secretome of OvAF. These data not only provide a comprehensive proteomic resource for understanding host-parasite interactions, but also provide a platform for the interrogation of candidate proteins that can support the ongoing quest for biomarkers (particularly for viable OvAF) during post-control surveillance in Ov-endemic areas.

671

"EXTREME" QTL METHODS FOR GENETIC MAPPING FOR DRUG RESISTANCE AND HOST SPECIFICITY IN SCHISTOSOME PARASITES

Frédéric D. Chevalier[1], Winka Le Clec'h[1], Philip T. LoVerde[2], Timothy J. Anderson[1]

[1]Texas Biomedical Research Institute, San Antonio, TX, United States, [2]University of Texas Health Science Center, San Antonio, TX, United States

Classical quantitative trait locus (QTL) analyses, using controlled genetic crosses or natural pedigrees, together with phenotyping and genotyping of parents and progeny, has been used for QTL localization for almost a century and has been applied to multiple species ranging from yeast to humans. Extreme QTL (X-QTL) methods, developed by researchers working on yeast and malaria parasites, takes several short cuts to simplify QTL mapping. Instead of phenotyping, pooled F2 progeny are selected for the trait of interest, while instead of genotyping individual progeny, pools of selected or unselected progeny are quantitatively genotyped (or sequenced) to measure allele frequencies genome-wide. We first applied X-QTL to examine the genetic basis of drug resistance in a multicellular parasite, ***Schistosoma mansoni***, which infects an estimated 67 million people in Sub-Saharan Africa and South America. We conducted genetic crosses between oxamniquine resistant and sensitive parasites, and selected pools of F2 progeny with oxamniquine while controls were left untreated. Surviving drug-treated and control pools were then sequenced to high read depth (mean = 95-366×) across the genome using exome capture, Illumina sequencing and allele frequencies at 14,489 variants were compared between pools. We observed dramatic enrichment of alleles from the resistant parent in a small region of chromosome 6 in drug-treated male and female pools (combined analysis: Z = 11.07, p = 8.74 × 10-29). This region contains Smp_089320 a gene encoding a sulfotransferase recently implicated in oxamniquine resistance using classical linkage mapping methods, directly validating X-QTL methods for schistosomes. Encouraged by this success, we are currently applying the X-QTL approach to identify the genes underlying host specificity of larval schistosomes to the aquatic snail host.

672

SCHISTOSOMA MANSONI EXPOSURE MODIFIES PLASMA EXOSOMAL MIRNAS INTERCELLULAR COMMUNICATIONS BETWEEN PARASITE AND HOST

Wannaporn Ittiprasert[1], Andre' Miller[1], Chutima Kumkhaek[2], Josanne Logan[1], Sarah Li[1], Margaret Mentink-Kane[1], Michael Hsieh[1]

[1]Biomedical Research Institute, Rockville, MD, United States, [2]National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, MD, United States

Schistosomiasis is a water-borne parasitic disease of major public health importance. More than 4.5 million disability adjusted life years (DALYs) are lost each year worldwide due to schistosome infection. More than 90% of reported cases are from sub-Saharan Africa where both ***Schistosoma mansoni*** and ***S. haematobium*** infections are endemic. The major of control programs use the antihelminthic drug praziquantel for mass drug administration. MicroRNAs are small non-coding RNAs transported in exosomes, and as such schistosome miRNAs may serve as an efficient cell-to-cell communication system linked to the host. miRNAs also have potential as novel therapeutic tools for diseases associated with inflammatory responses. Here we show differential expression of schistosome exosomal miRNAs in ***S. mansoni***-infected mouse plasma, including miR71, bantam, miR125 and miR-new 1, at various time point post exposure up to 7 weeks. Given that ***S. mansoni*** infection-associated inflammation is thought to potentially increase risk of colorectal cancer, we are currently evaluating the expression of putative miRNA biomarkers for inflammation/cancer, e.g. miR-let 7a, miR-150, and miR 21. We have

found that exosome-associated miRNA profiles shift significantly in mice at 2 weeks post exposure. Schistosome-specific miRNAs (miR-bantam and miR125) were increased after 2 weeks. On the other hand, miRNA let-7a and miRNA 150 were increased during chronic parasite infection. These results strengthen the notion that schistosomes secrete miRNA-containing exosomes into the host circulation, and that miRNAs may be highly sensitive biomarkers for infection status, including ***in vivo*** schistosome growth, development, and egg production. Our ongoing work may facilitate the development of highly sensitive diagnostics, miRNA-based blockade of schistosomiasis transmission, and even nanotechnology-centered therapeutics. Moreover, a deeper understanding of exosomal miRNAs as cancer markers would be useful for identifying new therapeutic targets for inflammation-induced carcinogenesis in chronic schistosomiasis and other helminth infection-associated malignancies.

673

MEASURING POPULATION HEALTH: COSTS FOR ALTERNATIVE SURVEY APPROACHES IN THE NOUNA HEALTH AND DEMOGRAPHIC SURVEILLANCE SYSTEM IN RURAL BURKINA FASO

Henrike Lietz[1], Lingani Moustapha[2], Ali Sié[2], Rainer Sauerborn[1], Aurélia Souares[1], Yesim Tozan[3]

[1]University of Heidelberg, Heidelberg, Germany, [2]Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso, [3]New York University, Steinhardt School of Culture, Education and Human Development and Global Institute of Public Health, New York, NY, United States

To improve data quality and collection efficiency in the Nouna Health and Demographic Surveillance System (HDSS) in Burkina Faso, stand-alone data collection activities of the HDSS and the Household Morbidity Survey (HMS) were integrated, and the paper-based questionnaires were consolidated into a single tablet-based questionnaire, namely the Comprehensive Disease Assessment (CDA). This study aims to assess the comparative implementation costs of the two different survey approaches to measure health at the population level. Financial costs of stand-alone (HDSS and HMS) and integrated (CDA) surveys were estimated from the perspective of the implementing agency. Fixed and variable costs of survey implementation and key drivers of costs were identified, and costs per household visit were calculated for both survey approaches. While fixed costs of survey implementation remained similar across the two survey approaches, there were significant variations in variable costs, resulting in an estimated annual cost-saving of about US$45,000 with the integrated survey approach. This was primarily because costs of data management for the tablet-based CDA survey were significantly lower than the paper-based stand-alone surveys. The integrated survey approach was estimated to reduce the cost per household visit from US$25 to US$21 to collect the same amount of information from 10,000 HDSS households. In conclusion, the CDA survey appears to be a feasible and efficient method of data collection in the Nouna HDSS in rural Burkina Faso. The tablet-based data collection platform is likely to increase the quality of population and health data collected and this should be further explored.

674

THE MILLENNIUM DEVELOPMENT GOALS AND DEVELOPMENT ASSISTANCE FOR HEALTH, 1990-2014

Joseph L. Dieleman, Lavanya Singh, Elizabeth Johnson, Maxwell Birger, Casey Graves, Annie Haakenstad

Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States

Millennium Development Goals (MDGs) four, five and six focus on health in low- and middle-income countries. This presentation will present findings related to tracking the development assistance for health (DAH) and explore the relationships between the establishment of the MDGs, the scale-up in funding, and the attainment of the health targets. We extract data from the Institute for Health Metrics and Evaluation's Financing Global Health 2014 report. This report systematically tracks DAH from 1990 to 2014. We assess the allocation of DAH across 15 health focus areas, and compare the DAH received by countries likely to achieve each MDG to the DAH received by countries that are unlikely to achieve them. We use linear regression to test whether the onset of the MDGs was associated with a systematic shift in DAH disbursements. Since 2000, $227.9 billion of DAH has been provided for the MDG health focus areas, amounting to $24.3 billion in 2014 alone. DAH disbursements for the MDG causes grew by 13.9% annually between 2000 and 2010, while annual growth for these same health focus areas was only 7.4% from 1990 through 2000. DAH for HIV/AIDS grew 15.8% over 2000 to 2014, amounting to $10.9 billion in 2014. DAH for malaria and tuberculosis funding increased annually at 17.4% and 17.7% over the same period, reaching $2.4 billion and $1.4 billion, respectively. DAH for maternal, newborn, and child health grow at an annualized rate of 6.2%, with spending of $9.7 billion in 2014. Countries expected to achieve each goal have received on average more DAH for the associated health focus areas than those not expected to achieve a given MDG. Linear regression shows that in 2000 the annual increase of MDG-related DAH amounted to 324%, a statistically significant change. Still, growth slowed in 2010. If DAH had continued to climb from 2011 to 2014 as it had the decade prior, an additional $27.4 billion of DAH would be available for the MDG health focus areas. With the post-MDG era in sight, these trends and the concurrent evolution in burden of disease hold lessons for future global health ambitions.

675

THE SOCIOECONOMIC IMPACT OF INTERNATIONAL AID: A QUALITATIVE STUDY OF AID AND HEALTHCARE RECOVERY IN POST-EARTHQUAKE HAITI

Maxwell Kligerman

Stanford University, Menlo Park, CA, United States

International aid spending for healthcare has nearly quadrupled over the last two decades, but how these efforts are perceived by the recipient country in post disaster settings remains unclear. We assessed healthcare provider perspectives of international aid four years after the Haiti Earthquake to better understand the impact of aid on the Haitian healthcare system and learn best practices for recovery both in Haiti and future disaster contexts. We conducted 22 semi-structured interviews with the directors of local, collaborative, and aid-funded healthcare facilities in Leogane, Haiti, which was the epicenter of the 2010 Earthquake. We coded and analyzed the interviews using an iterative method based on a grounded theory approach of data analysis. We found that healthcare providers identified aid as benefitting the community via acute emergency relief, increased long-term healthcare access, and increased referral options for local healthcare providers. However, we also found that aid had many negatively perceived impacts, including episodes of poor quality care, internal brain drain, competition with local facilities, decrease in patient flow to local facilities, and forced emigration of Haitian doctors to abroad due to loss of economic revenue. As Haiti continues to recover, it is imperative for aid institutions and local healthcare facilities to develop a more collaborative relationship to transition acute relief to sustainable capacity building. Based on our findings, in future disaster contexts, we advocate for the use of both acute and long-term quality of care metrics, NGO Codes of Conduct, Master Health Facility Lists, and sliding scale payment schemes as policies to guide and improve future disaster response.

676

"WOMEN IN CONTROL FOR TSETSE CONTROL"-COMMUNITY LED INTERVENTION INVOLVING INNOVATION

Vanja Kovacic[1], Johan Esterhuizen[1], Michael Lehane[1], Tawona Mangwiro[2], Alexandra Shaw[3], Inaki Tirados[1], Stephen Torr[1], Helen Smith[4]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Bindura University of Science Education, Bindura, Zimbabwe, [3]AP Consultants, Andover, United Kingdom, [4]University of Manchester, Manchester, United Kingdom

Community-based approaches are widely employed in efforts to control a variety of neglected tropical diseases (NTDs). Some of the earliest attempts at community-based control of NTDs were concerned with controlling tsetse flies, the vector of human African trypanosomiasis (HAT). However, this approach was never widely adopted and no community-based interventions against tsetse have been reported in the past decade. Recent developments of cost-effective and simple-to-use tools, particularly 'tiny targets', provide a new opportunity for communities affected by sleeping sickness in Africa. The traditional roles of women (water collecting, washing) regularly bring them into the riverine habitats where vectors of the Gambian form of HAT concentrate. Women may therefore be able to play an important role in community-based interventions against tsetse. We used action research to implement and evaluate an intervention led by women in two villages in a sleeping sickness area of NW Uganda. Feasibility, sustainability, cost-effectiveness and participants' perceptions of managing this intervention were assessed. We ran mentoring meetings over three phases: preparation, action (target deployment) and evaluation. The community-led intervention was compared with a separate operation conducted by an 'expert' team in an adjacent area. The community deployed 194 targets of which 38% were still functional after 6 months: comparable to the professional operation. The women demonstrated good planning, leadership and management skills and their perception of ownership and empowerment increased during the process. Excluding the research component, a community intervention would cost $67 compared to $85 per km2 for the expert team operation. Women's attitudes towards the innovation were positive: they were motivated, confident and resourceful partners in interventions against tsetse. We suggest that promoting their involvement is feasible and will improve sustainability and cost-effectiveness of tsetse control. More broadly, women should be actively involved in the planning, execution and evaluation of disease control programmes.

677

BETTER DATA INTEGRATION AND SHARING CAN ACCELERATE RESEARCH AND POLICY FOR GLOBAL POPULATION HEALTH

Willem G. Van Panhuis[1], Proma Paul[1], Claudia Emerson[2], Richard Wilder[3], Abraham J. Herbst[4], David Heymann[5]

[1]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, United States, [2]St. Michael's Hospital, Toronto, ON, Canada, [3]Bill & Melinda Gates Foundation, Seattle, WA, United States, [4]The Africa Centre for Health and Population Studies, University of KwaZulu-Natal, Somkhele, South Africa, [5]Chatham House, London, United Kingdom

The vast amount of data that is currently collected by researchers and health agencies around the world creates new opportunities to improve global population health. Most of these data are stored across thousands of different data systems and may never be used for new research because data cannot be easily accessed and integrated. Despite a global commitment to improve the use and sharing of global health data, this can be challenging in reality. We described the entire web of barriers to global health data sharing, and evaluated data availability and consistency for one example disease: dengue. We systematically reviewed documents that described barriers to global health data sharing, identified individual barriers, and grouped these in a taxonomy of major categories. We also integrated dengue surveillance data provided online by various WHO sources. We assessed the availability and consistency of WHO data across sources and compared WHO data to data provided online by two example countries: Brazil and Indonesia. We identified 20 potential barriers to global health data sharing and classified these in six categories: technical, motivational, economic, political, legal and ethical. The first three categories are deeply rooted in well-known challenges of health information systems for which structural solutions have yet to be found; the last three have solutions that lie in an international dialogue on policies and instruments for data sharing. Dengue data from 100 countries were available from WHO representing 23 million dengue cases and 82 thousand deaths reported to WHO since 1955. We found 84% agreement between WHO data sources, representing a discrepancy of almost half a million cases. The simultaneous effect of multiple interacting barriers greatly complicates access and integration of global health data for research and policy. The increasing complexity of this data landscape causes an urgent need for global coordination to standardize, integrate, and disseminate data. A new financial and operational framework should ensure the sustained availability of high quality data to improve global population health.

678

BIOMEDICAL GRADUATE EDUCATION AND CDC WEBSITES PROMOTE INFECTIOUS DISEASES IN THE MEDICAL SCHOOL CURRICULUM AT THE JOHN A. BURNS SCHOOL OF MEDICINE, HONOLULU, HAWAII

Kenton Kramer, Jourdan Posner, Brooks Mitchell, Nelson Lazaga, Glen Chew, Yuki Lloyd, William Gosnell

University of Hawaii, Honolulu, HI, United States

Biomedical scientists bridge the gap between the basic sciences and clinical medicine. Teaching medical microbiology to medical students in a Problem Based Learning curriculum can be challenging. Appropriate information must be conveyed at the appropriate time for maximal learning. Although major infectious organisms are covered in health care problems and in didactic lectures, many organisms of importance in travel and tropical medicine are not covered in the pre-clerkship curriculum (Years 01 & 02). To overcome this barrier, we introduced the concept of "Parasite of the Week" based on the CDC website: DPDx - Laboratory Identification of Parasitic Diseases of Public Health Concern (www.cdc.gov/dpdx).1 Introduction of relevant parasitic organisms was held during normally held pathology laboratory sessions. Before each session, a clinical case relevant to the parasitic organism is sent to the students. During the laboratory session informational material is offered covering biological and clinical aspects that included: 1) a large poster summarizing the main aspects of the life-cycle, pathology, diagnosis and therapeutic options, 2) informational handouts covering the material in greater depth for future reference and 3) microscopic and macroscopic specimens to solidify learning. Graduate students are present to explain the material and answer questions. The success of these sessions led to the graduate students in the Department of Tropical Medicine to developed informational material on bacterial infections of importance to travel and tropical medicine based on CDC's Yellowbook (http://wwwnc.cdc.gov/travel/page/yellowbook-home-2014/). We believe these sessions greatly increase medical student exposure to concepts of infectious diseases while providing productive interactions between medical and biomedical graduate students. 1. Use of visual displays to teach medical microbiology in the preclerkship years. WGEA conference, Honolulu, Hawaii. March 23-25, 2014

PREDICTIVE STATISTICAL MODELLING TO INFORM TUBERCULOSIS PREVALENCE ESTIMATIONS

Sandra Alba[1], Ente Rood[1], Masja Straetemans[1], Mirjam Bakker[1], Charalambos Sismandis[2]

[1]Royal Tropical Institute (KIT), Amsterdam, Netherlands, [2]World Health Organization, Amsterdam, Netherlands

A total of 22 nationally representative tuberculosis (TB) prevalence surveys have been conducted between 1990 and 2013, providing direct estimates of TB burden. In countries without surveys the World Health Organization (WHO) currently estimates prevalence indirectly from estimated incidence and disease duration. In order to provide WHO with alternative indirect estimates of TB prevalence, an ecological predictive statistical model was developed to predict prevalence in low and middle-income countries without survey data with an estimated prevalence over 0.1%. We included 13 nationally representative surveys, 2 district level surveys in India and subnational estimates for 5 surveys conducted between 2007 and 2013 resulting in 30 datapoints for model development (training set). Ecological predictors included TB surveillance and programmatic data, co-morbidities and socio-environmental factors extracted from online data repositories. We fitted a random effects multivariate binomial regression and predicted bacteriologically confirmed TB prevalence in 74 low to middle income countries across Africa, Asia and South America in 2013. Out of the 166 ecological predictors considered 37 were retained for model building (due to incompleteness or collinearity) and 7 were found significant in univariate analyses. The final multivariate model included 3 predictors: climate score, laboratory confirmed TB notification rates per 100,000 population and BCG vaccination coverage. Cross-fold validations in the training set suggested average fit (R-sq = 0.57). Out of sample predictions (all forms all ages) were on average consistent with WHO estimates (average difference -10 cases per 100,000), albeit with considerable scatter. Predictive ecological modelling can provide useful complementary estimates for TB burden and can be considered alongside other methods in countries with limited TB data. The predictive power of the model may be improved by including (sub)national estimates of 5 surveys which will become available in the coming year and more complex spatial correlation structures to the model currently presented.

INSTITUTIONALIZATION OF QUALITY OF CARE IN HEALTH FACILITIES IMPROVES MANAGEMENT OF MALARIA IN PREGNANCY IN TANZANIA

Jasmine W. Chadewa, Rita Mutayoba

Jhpiego, Dar es Salaam, United Republic of Tanzania

Malaria in Pregnancy (MiP) is one of the contributors to maternal mortality in Tanzania which persists at a ratio of 410/100,000 live births. Tanzania implements WHO's three-pronged approach to prevent MiP (use of insecticide treated bed-nets (ITNs), intermittent preventive treatment (IPTp) with sulfadoxine-pyrimethamine (SP) and prompt diagnosis and treatment). Efforts are on-going to improve IPTp and ITN coverage which is 33% and 75%, respectively. Jhpiego, in collaboration with the Ministry of Health and Social Welfare, worked in 251 health facilities to improve the quality of maternal and neonatal health by building the capacity of health care providers through training, supportive supervision, mentoring and coaching. A total of 7,181 providers and 400 tutors were trained on MiP prevention and treatment. A quality of care study used the same methodology and sampling approach in 2010 and 2012, combining observations of women during antenatal care, inventory and record review as well as health worker knowledge. A team of MNH experts underwent clinical updates, training and orientation to the study tools. Data collection teams visited facilities, made observations and entered data into smart phones. The study was conducted in 12 regional hospitals and 38 lower level facilities in 12 regions including Zanzibar with a total of 391 and 366 ANC observations made in 2010 and 2012, respectively. Between 2010 and 2012, the percentage of women receiving an ITN increased by 26% (p-value = <0.0001); the change observed was due to a 33% increase in offering ITN vouchers at health centers and dispensaries. A slight improvement was seen in provision of IPTp-SP from 62% in 2010 to 65% in 2012. In Tanzania, application of the quality improvement approach contributed to improving MiP services. Moving forward, there is a need for the Ministry to continue strengthening ANC with effective monitoring and routine supervision to increase coverage of MiP prevention. Districts management teams and facilities need to ensure availability of SP and provide regular technical updates on the national service standards including counseling at ANC and birth preparedness.

681

ASSOCIATION BETWEEN MALARIA CONTROL SCALE-UP AND MICRO-ECONOMIC OUTCOMES: EVIDENCE FROM A RETROSPECTIVE ANALYSIS IN ZAMBIA

Anthony Leegwater[1], Alison Comfort[2], Sharon Nakhimovsky[1], Benjamin Johns[1], Lauren Olsho[2], Martin Alilio[3], Henry Kansembe[4], Benson Bwalya[5], Kelley Ambrose[2], Busiku Haminza[6]

[1]Abt Associates, Inc., Bethesda, MD, United States, [2]Abt Associates, Inc., Cambridge, MA, United States, [3]President's Malaria Initiative/United States Agency for International Development, Washington, DC, United States, [4]Ministry of Health, Lusaka, Zambia, [5]Abt Associates, Inc., Lusaka, Zambia, [6]National Malaria Control Center, Lusaka, Zambia

While substantial attention has been devoted to understanding the effectiveness of malaria control strategies on health outcomes, there has been less focus on understanding the economic impact of malaria control interventions. As malaria control interventions are scaled up and malaria episodes decrease, households may experience economic benefits such as improved household income and consumption, worker productivity, schooling attendance, and poverty status. This study assesses the associations between malaria control scale-up and micro-economic indicators in Zambia, where significant progress has been made in scaling up effective malaria control strategies, but also where malaria continues to be an important public health concern. Using data from 2006 to 2010 on the distribution of insecticide-treated nets (ITNs) and indoor residual spraying (IRS), this study examines whether the scale-up of these activities in Zambia is associated with improved micro-economic outcomes at the household level. Specifically, do these activities affect household spending on food, household spending on medical care, schooling attendance, agricultural production, and household savings and borrowing? To answer these questions, we will use secondary data collected by multiple Zambian ministries and the National Malaria Control Center (NMCC) to conduct retrospective, multivariate analyses to match districts at baseline in 2006. We will then compare micro-economic outcomes of nearly 20,000 households at endline in 2010, as a function of malaria control activities conducted during that year and preceding years. Study findings are expected by August 2015. Particularly in a context of limited resources, the results of the study will inform policymakers, donors, and development practitioners on the returns to investing in malaria control by considering the micro-economic benefits of these strategies.

682

ONGOING NEONATAL MORTALITY AUDITS IN MALAWI HELP FOCUS MEDICAL AND NURSING EDUCATION

Joshua Grahe[1], Yasmin Bahora[1], Megan Coe[2], Margot Anderson[1], Ajib Phiri[3], Rhoda Chifisi[4], Julie Anathan[5], Elizabeth Cunningham[6], Sadath Sayeed[7], Patricia Daoust[5], Vanessa Kerry[8], Rachel Mlotha[3]

[1]Global Health Service Partnership and University of Malawi College of Medicine, Lilongwe, Malawi, [2]Global Health Service Partnership and Kamuzu College of Nursing, Lilongwe, Malawi, [3]Kamuzu Central Hospital and University of Malawi College of Medicine, Lilongwe, Malawi, [4]Kamuzu Central Hospital, Lilongwe, Malawi, [5]Seed Global Health and Massachusetts General Hospital Center for Global Health, Boston, MA, United States, [6]Seed Global Health, Boston, MA, United States, [7]Seed Global Health, Harvard Medical School, and Boston Children's Hospital, Boston, MA, United States, [8]Seed Global Health, Massachusetts General Hospital Center for Global Health, and Massachusetts General Hospital Division of Pulmonary and Critical Care, Boston, MA, United States

The WHO estimates a critical shortage of 7.2 million healthcare workers globally. Malawi has 2 physicians and 34 nurses/midwives per 100,000 people, limiting quality of care for patients and quality of training and supervision for healthcare students. In Malawi, neonatal mortality accounts for 34% of deaths in children under 5 and are a vital target for reducing child mortality. Kamuzu Central Hospital (KCH), in Lilongwe, Malawi, is a teaching hospital for the University of Malawi College of Medicine and Kamuzu College of Nursing, and a placement site for volunteers with the Global Health Service Partnership (GHSP), a US-based public-private partnership that places US faculty in medical and nursing schools for one-year. At KCH, the neonatal unit admits more that 2000 sick newborns annually. Each month a pediatric intern, together with an intern from the obstetrics department, presents the perinatal morbidity and mortality data. These presentations have informed educational priorities and helped the team focus trainings and protocols on core needs. The most common admission diagnoses in 2014 were prematurity (37%), birth asphyxia/meconium aspiration (27%), neonatal sepsis (14%), and congenital anomalies (9%). The average neonatal mortality rate was 20%, with prematurity and asphyxia accounting for 75% of deaths. These findings highlight the need to emphasize staff training on protocols such as neonatal resuscitation, CPAP, kangaroo care, and antibiotic management. These skills are also emphasized in both medical and nursing students' curricula, and additional intern trainings have been introduced to ensure ongoing quality improvement in the care of neonates. By understanding current neonatal mortality statistics at KCH, physician and nurse educators can target classroom and clinical education to improve the care of neonates and reduce neonatal mortality at our teaching hospital as well as impact the care given by our graduates. Additionally, due to the heavy toll of birth asphyxia and prematurity, improved outcomes for neonates cannot be accomplished without the combined efforts of both the pediatric and obstetrics departments.

683

ANTENATAL AND DELIVERY CARE RECEIVED BY WOMEN IN BUNGOMA COUNTY, WESTERN KENYA

Peter O. Okuma[1], Vincent O. Were[1], Mary J. Hamel[2], Florence A. Were[1], Meghna Desai[1], Ann M. Buff[3], Simon K. Kariuki[1]

[1]Kenya Medical Research Institute/Centers for Disease Control and Prevention, Kisumu, Kenya, [2]Malaria Branch, Centers for Disease Control and Prevention, Kisumu, Kenya, [3]United States President's Malaria Initiative, Nairobi, Kenya, Kisumu, Kenya

Maternal mortality remains high in sub-Saharan Africa. The Millennium Development Goal for maternal health aimed to reduce maternal mortality by three-quarters by 2015. However, most countries including Kenya fell short of achieving these targets. We describe the status of prenatal and delivery care for women in Bungoma county, western Kenya. Between September and November 2013, we conducted a household cross-sectional survey of women who had given birth within the last 4 months in Bungoma County, western Kenya. Using a structured questionnaire, data were collected on antenatal care (ANC) visits, delivery location and service satisfaction of a random sample of women from a demographic surveillance system. A total of 748 women had a recent birth; 89% (n=667) consented and were interviewed. Ninety-two percent (n=622) visited ANC clinic at least once, and 33% (n=223) made the recommended four ANC visits. Sixty-one percent (n=278) made the first ANC visit in the second trimester. Women who made the first ANC visit in the first trimester were more likely to complete ≥4 ANC visits (83.6%; 56/67) compared to those starting ANC visits in the second or third trimesters (27.3%; 151/557; p=0.0001). There was no significant difference observed in the percentage of women making ≥4 ANC visits among those who started ANC in the second or third trimesters (p=0.68). Only 45% (n=301) of women delivered at a health facility. Satisfaction with ANC services was 67% (415/622); satisfaction with health facility-based delivery services was 67% (203/301). Of the 205 women who made ≥4 ANC visits, 64.4% delivered in facilities compared to 37.9% of women who made fewer visits (p<0.0001). As the deadline for the Millennium Developmement goal for maternal mortality gets closer, Kenya did not achieve the stated targets. Over a third of women reported dissatisfaction with ANC and delivery services, which might contribute to low service utilization. Strategies to increase satisfaction with ANC and delivery services might positively impact utilization and improve maternal mortality so as to achieve the newly promulgated International health Development Goals.

684

HEALTH FACILITY CASELOAD CHANGES DURING THE INTRODUCTION FOR COMMUNITY CASE MANAGEMENT FOR MALARIA IN SOUTH WESTERN UGANDA - AN INTERRUPTED TIME SERIES APPROACH

Sham Lal[1], Richard Ndyomugyenyi[2], Mylene Lagarde[1], Neal D. Alexander[1], Lucy Paintain[1], Pascal Magnussen[1], Daniel Chandramohan[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]London School of Hygiene & Tropical Medicine, London, Uganda

Many malaria endemic countries are scaling-up community case management (CCM) programmes, which increase access to malaria testing and treatment to communities with limited access to health facilities. To date, evaluations of CCM programs have centred on community health workers (CHWs) compliance to guidelines, but broader effects on utilisation of health centres (volume and case mix) have not been documented. This analysis was conducted during a community case management intervention in Rukungiri District Western Uganda. Out-patient department (OPD) visit data for children under 5 was collected for one year before the trial started (pre-intervention) and during the 20-month trial (intervention-period) from three health centres serving the intervention area. An interrupted time series analysis with segmented regression models was used to compare the trends in all-cause and malaria-specific OPD visits during the pre-intervention and intervention periods. The introduction of the CCM intervention was followed by increases in the frequencies of diagnosis of diarrhoeal diseases, pneumonia and helminths and fewer malaria diagnoses. In the first month after the CCM intervention began all-cause OPD utilisation decreased by 63% compared to the pre-intervention period (p<0.001). Malaria-specific visits also saw a dramatic drop shortly after the intervention began, with 27 fewer visits per month during the intervention-period compared with the pre-intervention period (p<0.05). The declines in all-cause and malaria visits were sustained for the entire intervention period. In conclusion, introduction of a community-treatment programme for malaria reduced the total caseload seen at local health centres. The subsequent impact for health workers and patients in terms of reduced total working hours, increased time spent per consultation and/or other health centre duties, as well as required changes in stock management and financing, warrants further examination in order to fully document the effect of community case management programmes on the functioning of health systems.

685

INTEGRATING GLOBAL HEALTH SURVEILLANCE DATA: AN EXAMPLE APPLICATION TO MALARIA SURVEILLANCE IN UGANDA

Kate Zinszer[1], Anya Okhmatovskaia[1], Arash Shaban-Nejad[1], Lauren Carroll[2], Neil Abernethy[2], David L. Buckeridge[1]

[1]McGill University, Montreal, QC, Canada, [2]University of Washington, Seattle, WA, United States

The growing volume of data generated by systems around the world presents a tremendous opportunity for global health surveillance. These data, however, are fragmented in many ways, across diseases, countries, governmental and non-governmental organizations, and clinical institutions. This fragmentation poses a barrier to analyses that could benefit from using multiple data sources as the data must be integrated manually for each analysis, requiring a considerable amount of effort. Malaria surveillance, including the monitoring and evaluation of malaria control activities, is an example of how data fragmentation can hinder analyses. Matching effective interventions to specific factors in each area requires epidemiological analysis of data integrated across multiple sources. This type of data is generally not available to malaria control and elimination activities due to the challenges in identifying, accessing, and integrating data hosted within the wide range of organizations contributing to malaria control efforts. SDIDS (Scalable Data Integration for Disease Surveillance) is a software application designed to enable the integration and analysis of data across multiple scales to support global health decision-making. In this presentation, we present a prototype of SDIDS and show how it can be used to integrate malaria surveillance data collected by multiple organizations in Uganda. SDIDS is a web-based, ontology-driven software platform that automates the integration of heterogeneous data from multiple sources, and supports visualization, analysis, and sharing of these data. A central characteristic of SDIDS is its ability to scale-up and integrate data from other geographical regions and for other priority diseases. This scalability means that a wide range of data sources can be mapped once to SDIDS and then accessed and analyzed repeatedly by a wide range of global health users and applications.

686

INTEGRATED COMMUNITY CASE MANAGEMENT DATA QUALITY IN MALAWI

Jennifer Yourkavitch[1], Kirsten Zalisk[1], Debra Prosnitz[1], Misheck Luhanga[2], Humphreys Nsona[3]

[1]ICF International, Rockville, MD, United States, [2]Independent Consultant, Lilongwe, Malawi, [3]Ministry of Health, Lilongwe, Malawi

ICF conducts annual data quality assessments of WHO RAcE projects to review accuracy, availability, completeness, reliability, integrity, confidentiality and precision of iCCM data and to recommend ways to improve data quality. The first RAcE data quality assessment was conducted in Malawi in January, 2014. We focus here on findings from the data tracing part of the assessment with supporting information from the systems assessment and key informant interviews. ICF randomly selected 10 health facilities from all four RAcE project districts, and collected quantitative data with an adapted and comprehensive tool which included tracing selected indicators through the reporting system. We calculated averages of data agreement between reporting levels for three indicators. ICF also conducted key informant interviews with Health Surveillance Assistants (HSA), and facility, district and central Ministry of Health staff. Data availability was generally high except for supervision data. The data verification process identified gaps in completeness, integrity, and reliability, particularly in HSA's record keeping. Cross-checks revealed that data recorded by HSAs for new cases and referrals in their registers usually did not match the data they reported to health facilities. New cases are generally reported accurately from one level to the next in the system (e.g. within 10% difference between data at health facilities and districts), but referrals and stockouts are underreported from one level to the next. There were substantial differences between the number of new cases and referrals initially recorded by HSAs and the corresponding number reported through the system (ranges: -51 to 183 and -3 to 102, respectively). The system lacks some quality controls, including data entry verification, a protocol for addressing errors, and written procedures for data collection, entry, analysis and management. Staff at all levels would like more training in data management. We recommend prioritizing data management with documented protocols, additional training, and efficient supervision practices to improve iCCM data quality.

687

BURDEN AND DISTRIBUTION OF MALNUTRITION IN GUAYAQUIL, ECUADOR: RESULTS FROM THE ECUADORIAN NATIONAL HEALTH AND NUTRITION SURVEY (ENSANUT-ECU)

Winnie Chu[1], Sadie J. Ryan[2], Wilma B. Freire[3], Anna M. Stewart-Ibarra[4], Washington B. Cárdenas[5], Julia L. Finkelstein[1]

[1]Cornell University, Ithaca, NY, United States, [2]Department of Geography and Emerging Pathogens Institute, University of Florida and Center for Global Health and Translational Science, SUNY Upstate Medical University, Gainesville, FL, United States, [3]Ministry of Health of Ecuador and the Universidad San Francisco de Quito, Ecuador, Quito, Ecuador, [4]SUNY Upstate Medical University, Syracuse, NY, United States, [5]Escuela Superior Politecnica del Litoral, Guayaquil, Ecuador

Guayaquil is the largest urban center in Ecuador (2.3 million), but there is little published nutritional data for this population. This study was conducted to examine the burden and distribution of malnutrition in Guayaquil, using data from the Ecuadorian National Health and Nutrition Survey (ENSANUT-ECU). Socio-demographic and anthropometric data (n=1,738) and venous blood samples (n=900) were collected. The prevalence of anemia, micronutrient deficiencies (zinc, vitamin A, iron, vitamin B12, folate), and stunting (LAZ<-2), underweight (WAZ<-2), wasting (WLZ1), and obesity (BMIZ>2) were calculated and mapped in ArcGIS. Binomial and linear regression models were used to examine the associations of socio-demographic characteristics with nutritional outcomes. Micronutrient deficiencies were common, including zinc deficiency (Zn<65.0 µg/dL; 50%) and anemia (Hb<11.0 g/dL; 13%), and the prevalence was significantly higher than the national level data ($p<0.01$). The prevalence of anemia was highest in children (29%; RR: 2.35, 95%: 1.55-3.59, $p<0.01$) and women of reproductive age (22%; RR: 2.50, 95%: CI 1.77-3.50, $p<0.01$), compared to all other age groups. Children also had the highest prevalence of vitamin A deficiency (serum retinol<20.0 µg/dL; 19%; RR: 3.53, 95% CI: 1.87-6.65, $p<0.01$), compared to all other age groups. Women of reproductive age in Guayaquil had lower hemoglobin, zinc, erythrocyte folic acid, and serum folic acid levels, compared to the national level data ($p<0.01$). The prevalence of overweight and obesity were high in adults; women were less likely to be overweight compared to men (46% vs. 37%; RR: 0.71, 95% CI: 0.55-0.90, $p=0.004$), however women were more likely to be obese (30% vs. 21%; RR: 1.60, 95% CI: 1.20-2.10, $p=0.001$). The burden of malnutrition is high in Guayaquil Ecuador, including anemia, zinc deficiency, and vitamin A deficiency, particularly among women of reproductive age and young children. Further understanding of the dual burden of malnutrition and its distribution in this population is needed to inform preventive interventions and public health approaches in Ecuador.

688

HEALTHCARE CAPACITY BUILDING IN HAITI: TRAINING HEALTHCARE AND NON-HEALTHCARE PROVIDERS IN BASIC CARDIOPULMONARY RESUSCITATION

Jerry L. Livingston, Anthony M. Pickrell, Ashkita Kumar, Ruth L. Bush, David M. Vanderpool

Texas A&M College of Medicine, Bryan, TX, United States

Following the devastating 2010 earthquake in Haiti, the need for health care and support increased as medical schools and hospitals were destroyed or severely damaged. Outreach educational programs are crucial to decreasing the uneven geographical distribution of healthcare workers or skilled laypersons in this impoverished country. A pilot program was implemented in 2015 to provide necessary emergency training in the basics of adult and infant cardiopulmonary resuscitation (CPR). The purpose of this study is to describe our experience establishing an innovative educational opportunity for basic skills training in Haiti. A team of 4 U.S. providers developed a basic emergency provider program including a written guidebook with a French translation and utilized standard CPR manikins for training. This program was supported by the Haitian government and taught in 2 hour sessions. Training included adult and infant CPR and suffocation/ chocking treatment (Heimlich maneuver). Competency was assessed via direct observation and oral testing. Over 4 days, 80 healthcare providers, lay persons, and governmental security staff were trained by the international team. Local translation was available. At the completion of training, the participants were able to demonstrate skills competency and pass an oral quiz. Satisfaction ratings were high as well as performance confidence. The need for healthcare capacity building in Haiti is well recognized both locally and internationally. This pilot skills training program received positive evaluations from trainers and participants. Teaching basic healthcare skills and competencies to native Haitians will augment the availability of basic services and improve access to quality healthcare services to this most vulnerable of populations. Development of additional healthcare educational initiatives and curricula are underway as well as expansion of this program.

SUITE FOR AUTOMATED GLOBAL ELECTRONIC BIOSURVEILLANCE (SAGES): SIMPLIFYING INSTALLATION AND IMPROVING USE AND SUSTAINABILITY

Timothy C. Campbell, Aaron T. Katz, Charles J. Hodanics, Zarna S. Mistry, Richard A. Wojcik, Jacqueline S. Coberly, Shraddha V. Patel, Sheryl A. Lewis

Johns Hopkins University Applied Physics Laboratory, Laurel, MD, United States

SAGES is a collection of open source software tools designed to create or enhance existing electronic disease surveillance systems in resource-limited settings. The SAGES architecture uses mobile and web-based methods to collect structured data via SMS, Wi-Fi, and Internet connected devices. The primary data analysis tool, OpenESSENCE, provides a web-based interface for data analysis, visualization, and reporting for disease surveillance. Development of SAGES began in 2008, but significant advancements in open source software, data collection technology, and user needs instigated a re-engineering of the system. During initial development of SAGES customized systems were developed for each user. While this technique supplied a near-perfect fit for each installation, it also required significant technical support from the SAGES design team during installation. It also made independent configuration of SAGES tools by the users more difficult. An analysis of alternatives was done for both new front-end and back-end open source solutions for SAGES. The results suggested that creation of a base set of tools that would meet most users' disease detection needs and was ready 'out of the box' would increase the utility and usability of the SAGES software. However, this more generic version of SAGES also needed to leverage industry standard technologies to facilitate expansion of the generic system by users and by the SAGES development team. This presentation will describe the re-engineering of SAGES that began in 2013. The aim was to improve ease of installation, configuration, and use of the system, and to create a system that would meet the needs of 80% of users but be flexible enough to allow users to expand the system as needed. Particular attention will be paid to the trade-offs between designing customized systems versus designing 'out of the box' ready systems suitable for most users. The challenges of designing systems when technology is changing rapidly and where early design decisions have long term, and often unexpected, impacts will also be discussed, as will the challenges of designing tools for use in resource-limited setting.

690

TRAUMA EDUCATION FOR MEDICAL STUDENTS: IMPACTING THE TRAUMA BURDEN IN ETHIOPIA WITH UNDERGRADUATE MEDICAL EDUCATION REFORM

Malena A. Outhay[1], Isa I. Wismann-Horther[1], Lucy C. Unger[1], Amina I. Merchant[1], Milliard Derbew[2], Kelly McQueen[1]

[1]Vanderbilt University School of Medicine, Nashville, TN, United States, [2]Addis Ababa University School of Medicine, Addis Ababa, Ethiopia

Ethiopia is a developing nation with a significant trauma burden and a lack of policy, infrastructure, and emergency medical services to address this burden. Though injury is one of the top causes of mortality in Ethiopia, trauma education and management training is not standardized across the country. Ethiopian medical school graduates are required to serve rural populations as general practitioners, and they often lack skilled hospital personnel to assist in managing critical trauma management. The purpose of our study is to determine the feasibility of implementing a basic trauma triage and resuscitation course for Ethiopian medical students, a population that will address trauma in locations where access to supplies is limited. Furthermore, we investigate the utility of this course as a teaching tool to expand the capacity to impact the trauma burden in low-resource settings. This modified ATLS-based course focused on the ABCD (airway, breathing, circulation, and disability) management of emergency care in low-resource settings. The educational session included a pre-test, educational intervention, and post-test. Two groups of participants, medical students (N=39) and laypersons (N=39), completed the entirety of the course. Both groups demonstrated an improvement in test scores following the education intervention. The medical school students had a mean post-intervention test score of 92% (SD = 8) and laypersons had a mean score of 75% (SD = 12). A t test for equal variances demonstrated significant difference between the post-intervention scores for the two groups ($p = 0.01$), and all 78 participants demonstrated significant difference between their pre- and post-test scores based on a paired t test ($p = 0.01$). Furthermore, all 78 participants were able to demonstrate the basic skills of the primary and secondary survey in ATLS. Based on this study, a basic trauma-training course provides new information for all participants and can be used to train a supply of teachers for less skilled hospital personnel and laypersons.

691

PREDICTIVE STATISTICAL MODELLING TO INFORM TUBERCULOSIS MORTALITY ESTIMATES

Ente J. Rood[1], Sandra Alba[1], Masja Straetemans[1], Mirjam Bakker[1], Charalambos Sismanidis[2]

[1]KIT- Royal Tropical Institute, Amsterdam, Netherlands, [2]World Health Organization, Geneva, Switzerland

The global task force on tuberculosis (TB) impact measurement is mandated to periodically review and update methods to estimate TB incidence, prevalence and mortality. This study investigates the value of predictive ecological modelling to estimate TB mortality in low-income countries. A predictive ecological model was built using civil registration and vital statistics (CRVS) data with standard coding of cause of death

to World Health Organization (WHO) from 128 countries with quality CRVS systems collected between 2004-2012. Independent predictors of TB mortality, including TB program performance, TB co-morbidities, socio-environmental and climatic factors were extracted from online data repositories. A two-step procedure was used to select variables. Firstly, the association of each variable to TB mortality was assessed by fitting a univariate negative binomial model to the data. When predictor variables correlated > 80% the best fitting variable was retained. Secondly, a stepwise information based procedure was used to identify the multivariate model which best fit the data. Predictions were cross-validated by comparing model predictions to the WHO measurements. Out of the 166 ecological predictors initially considered, 19 were found to be uncorrelated and significantly associated to TB mortality in the univariate analysis. The multivariate model included 11 predictors including male life-expectancy, number of new sputum-smear positive cases, proportion population living in urban settings, proportion multidrug resistant TB cases among all TB cases notified, national health expenditure, prevalence of diabetes, HIV positivity rate among all TB cases notified, BCG vaccination coverage, percent of TB retreatments among all TB cases notified, treatment success rate among retreatments, annual precipitation. Predictive statistical modelling is shown to be valuable to estimate TB mortality in countries with limited availability of TB data. The predictive power of the model may be improved by considering more complex covariate correlation structures (random) to account for region specific variations to the model currently presented.

692

GLOBAL QUEST FOR QUALITY AND MRIGLOBAL

Jolanta S. Jacobs, Cao Shi-Nian, Joanne M. Horn

MRIGlobal, Frederick, MD, United States

Laboratory and health care quality is becoming synonymous with competency and reliability; accreditation and certification are sought after by increasing numbers of facilities in many countries. In January 2008, representatives from World Health Organization, US PEPFAR, US Centers for Disease Control and Prevention, World Bank, several universities and 33 countries issued The Maputo Declaration recognizing the need to strengthen laboratory services and systems in developing countries. WHO and US CDC subsequently issued a statement calling for countries with limited resources to establish a path towards laboratory accreditation to ISO 15189 standard; as a result, in 2009, WHO AFRO launched Stepwise Laboratory Improvement Process Towards Accreditation in the African Region (SLPTA) program, making accreditation more accessible, affordable and sustainable for African countries. In other regions, Thailand and Argentina have been hailed as great examples of developing national laboratory quality programs. Republic of Kazakhstan in Central Asia is another example of a country that understands the need for accreditation and is making great strides in this arena. MRIGlobal, registered to the ISO 9001 and accredited to ISO 17025, with several ASQ Certified Quality Auditors, has contributed to the incorporation of QMS elements and ISO 15189 laboratory quality standard into the curricula of the Kazakhstani National Medical University in the Republic of Kazakhstan. After a thorough review of the Medical University curricula, MRIGlobal has worked with faculty and administrators to formulate a roadmap to achieve the integration of laboratory QMS with medical school coursework. This project has enabled the stakeholders to introduce international quality standards into clinical laboratory education, which will result in a sustainable laboratory quality in RoK.

694

ENGAGING STUDENTS IN ADVOCACY, EDUCATION, AND RESOURCE MOBILIZATION TO SUPPORT THE EFFORT TO CONTROL AND ELIMINATE NEGLECTED TROPICAL DISEASES: THE END7 CAMPAIGN MODEL

Emily Conron

Sabin Vaccine Institute, Washington, DC, United States

In January 2012, the Global Network for Neglected Tropical Diseases launched END7, an international advocacy campaign to raise the awareness and funding necessary to control and eliminate the seven most common neglected tropical diseases (NTDs) through targeted engagement with grassroots supporters. Undergraduate and graduate students at universities around the world have become a key constituency advancing END7's goals. Through its student engagement program, END7 seeks to develop the next generation of scientists, researchers, and advocates needed to see the NTD control and elimination effort to its completion. END7 works to engage students in the campaign, develop their leadership skills, and equip them with the resources necessary to plan advocacy, education, and fundraising events on campus. A specific theme, ranging from "NTDs and WASH" to "NTDs and Human Rights," is selected for each month of the academic year. The campaign blends digital organizing with traditional constituent engagement, complementing social media promotion, webinars, online petitions, and other digital tools with personal communication with student leaders, on-campus presentations, and support for student leaders to attend conferences and policy events. This online/offline approach has mobilized a large and growing community of students to support the campaign from universities across the United States, Europe, and the Middle East. Student groups at more than fifty universities have raised nearly $50,000 for NTD treatment programs and completed more than 2,500 targeted advocacy actions, ranging from online petitions urging the United Nations to include an NTD-specific target in the Sustainable Development Goals to meeting with members of Congress to advocate for an increase in funding for the United States Agency for International Development NTD Program in the U.S. federal budget. Through regular access to experts in the field, END7 student leaders develop a sophisticated understanding of the science underlying the WHO NTD Roadmap and the policy and resource mobilization targets that will need to be met in order to implement it - connecting science, policy, and program implementation.

695

'A PEACEFUL PREGNANCY': THE INFLUENCE FOR CULTURAL SCHEMAS ON INTERMITTENT PREVENTION FOR MALARIA IN PREGNANCY IN MALI

Emily Hurley, Namratha Rao, Meredith Klein, Steven A. Harvey

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Research on intermittent preventative treatment of malaria in pregnancy has identified health system, cultural and individual barriers to uptake. Few studies have focused on links between such barriers and cultural schemas, culturally-shared cognitive systems that influence individual decision-making. Our study sought to understand Malian cultural schemas of pregnancy and their effect on local concepts of IPTp. We conducted interviews and focus groups with women, husbands, mothers-in-law and health workers in 4 rural villages in Sikasso and Koulikoro. We also observed antenatal care in health centers at each site. Women state that malaria is a significant threat to a healthy or "peaceful" pregnancy. For prevention, informants mention long-lasting insecticidal nets (LLINs), hygiene, nutrition and avoiding heavy work. Few mention IPTp spontaneously. When prompted, some recall receiving pills that fit the description of sulfadoxine pyrimethamine, but most are unsure of their purpose. During observations, SP was administered with little or no patient counseling. Some women asked about free LLINs, but none mentioned

IPTp or SP. In contrast nearly all recall receiving iron tablets and describe them as a key ANC element. Many link them to a Bambara ethnomedical concept about the importance of "strong" blood in pregnancy. In ANC consults, clinicians often refer to FeSO4 using a local Bambara term consistent with this concept. No analogous local term exists for SP or IPTp: Clinicians; if they mention it at all, use French. Existence of a linked Bambara term and construct may help explain why FeSO4 salience is so much higher than that of IPTp, despite women's view of malaria as a serious threat to pregnancy. Rebranding SP to tie it more closely with the cultural schema of "peaceful" pregnancy may help increase its salience and uptake. Strategies could include coining a meaningful local term for SP, administering it concurrent with LLIN distribution, and publicly promoting it as a free and valuable benefit. Raising SP's profile within the cultural narrative of "peaceful" pregnancy could increase demand for IPTp, thus reducing Mali's MIP burden.

696

EPISAMPLE: AN ANDROID APP FOR POPULATION-BASED EPIDEMIOLOGICAL SURVEYS

Belendia Serda[1], Tim McDonald[2], John Miller[3]

[1]PATH, Addis Ababa, Ethiopia, [2]Widenet Consulting, Bellevue, WA, United States, [3]PATH, Lusaka, Zambia

Household surveys are required for benchmarking many national and global indicators such as those used for Millennium Development Goals or national malaria control programs. Survey sampling is a critical component for household surveys to ensure representativeness but can be difficult and expensive for field implementation. EpiSample is an Android-based application that builds off of ODK 2.0 tools and offers additional census, sampling, and survey interviewing capabilities to facilitate the implementation of population-based epidemiological surveys using Android devices. Features are grouped into the following categories: census, sampling, navigation, surveying, and data aggregation. Census features include: (a) efficient census listings including the use of GPS coordinates of target points, (b) in-field aggregation of lists collected on multiple devices onto one device for sampling without the need for a laptop, (c) data connection, or cables, and (d) the ability to capture additional points of interest that can be excluded from the sampling. Sampling features include the application of a random sampling algorithm to a listing of points to select: (a) primary points to survey, (b) additional or oversampled points (if needed), and (c) replacement points that can be used to replace a primary or additional point that cannot be surveyed. The number of points selected can be defined in advance and locked down via a password-protected configuration or can be defined during field implementation. EpiSample allows surveying of points collected in the field and sample selection using a random sampling feature or points imported from a csv file. Points can be filtered or sorted in various combinations based on the type of point, distance from the device, time of data entry, interviewer name, Android device identification number, or point location. EpiSample can be used to open and manage ODK Survey-based questionnaires. All census and survey data collected can then be sent to a central server where it is aggregated and stored using ODK 2.0 tools. EpiSample will be used to conduct national malaria indicator surveys in Zambia and Ethiopia in 2015.

697

GEOSPATIAL COVARIATES AVAILABLE IN GOOGLE EARTH ENGINE FOR DISEASE MODELING

Daniel J. Weiss[1], Harry Gibson[1], Matthew D. Hancher[2], Allison Lieber[2], Peter W. Gething[1]

[1]University of Oxford, Oxford, United Kingdom, [2]Google, Inc., Mountain View, CA, United States

The Malaria Atlas Project (MAP), University of Oxford has compiled a suite of geospatial covariates useful for characterizing the spatiotemporal patterns of malaria prevalence via their relationships with vector ecology. The covariates consist of metrics that quantify environmental factors (e.g., temperature, moisture, and vegetation) known to affect the prevalence of numerous infectious diseases. To make these datasets available to the wider health research community MAP and Google have partnered to add them to the Google Earth Engine platform, which provides an online processing environment, data repository, and data distribution system that maximizes the utility and exposure of MAP covariates. Currently available covariates consist of global grids of land surface temperature (day, night, and diurnal flux), enhanced vegetation index, and brightness and wetness indices, with a 2.5 arc-minute (~5 km) spatial resolution and a monthly temporal resolution, for 2000-2014. These datasets were derived from MODIS satellite imagery and gap-filled to remove the effects of cloud contamination, thus producing wall-to-wall spatial coverage for the full 15-year time-series.

698

TESTING DRUG QUALITY AT ALL POINTS IN THE SUPPLY CHAIN: INTEGRATION OF TECHNOLOGY AND HEALTH SYSTEM

Nga T. Ho[1], Darash Desai[1], Andrea Fernandes[1], Wolfgang Krull[2], Alfred Banahene[3], Geoffrey Togoh[3], Lukas Roth[4], Kennedy M. Chibwe[4], Muhammad H. Zaman[1]

[1]Boston University, Boston, MA, United States, [2]Center for Integration of Medicine and Innovative Technology, Boston, MA, United States, [3]Center for Pharmaceutical Advancement and Training, United States Pharmacopeia, Accra, Ghana, [4]Promoting the Quality of Medicine, United States Pharmacopeia, Rockville, MD, United States

Substandard and counterfeit medicines are a major public health threat, not only because they cause loss of life and financial burden, but also because they lead to long-term drug resistance in vast areas affecting millions of people. With the growing global challenges in combat substandard and counterfeit medicines, there is an urgent and dire need to come up with tools that are not only affordable, but also quantitative, easy to use and are able to test drug ingredient and dissolution rapidly at multiple points within the health system. Current tools, unfortunately, are too cumbersome, expensive or qualitative and hence ill-suited for testing drugs at all points in the supply chain. We have developed, within our PharmaChk platform to test drugs, rapid luminescent and fluorescent assays to quantify Artesunate (ATS) and Amodiaquine in mono and combination therapies and are now extending our work to other life saving commodities including oxytocin. Here, we will discuss the design of the technology, laboratory tests, our field trials in Ghana focusing on both tablet and injectable formulations and our overall results which show excellent agreement with the gold standard method (HPLC) despite orders of magnitude cost difference in the two technologies. Overall, our lab results, combined with field studies show high performance and substantial improvement over field based methods, both in precision and accuracy, of our drug testing platform, PharmaChk. Finally, we will also identify areas of growth and improvement and also how we are working with partners both in and outside Ghana to integrate the technology within the healthcare system to substantially improve drug quality and save precious lives.

GENOMICS APPROACH TO IDENTIFY THE IMMUNODOMINANT *BABESIA MICROTI* ANTIGENS FOR THE DIAGNOSTICS AND VACCINE USE

Nitin K. Verma, Hong Zheng, Ankit Puri, Catherine Bradley, Sanjai Kumar

Laboratory of Emerging Pathogens, Division of Emerging and Transfusion Transmitted Diseases, Office of Blood Research and Review, Center for Biologics Evaluation and Research, Food and Drug Administration, Silver Spring, MD, United States

Babesiosis, caused by infection of erythrocytes by parasitic protozoans of genus ***Babesia***, is a major public health concern in many parts of the world. In United States, ***B. microti*** is the dominant species and about 1200 clinical cases of babesiosis are reported annually, mostly in the endemic areas in Northeastern, Mid-Atlantic and upper Midwestern states. In addition, disease is highly underreported and misdiagnosed. There is no FDA-licensed diagnostic test or vaccine for ***B. microti***. We have applied a genomics approach to identify the novel immuno-dominant ***B. microti*** antigens to develop novel diagnostic tests and evaluate their efficacy as vaccine candidate. Using the ***B. microti*** genome sequence database (www.piroplasm.org) and ***B. microti*** Peabody sequence available in the Kumar laboratory, we have identified over 300 genes by bioinformatics analyses that meet the criteria for immuno-dominance (surface expression, repeat units, high copy number etc.) for recombinant expression, antigenic characterization and evaluation as diagnostic and vaccine candidate. In addition, in a parallel approach, we have developed more than 14 unique monoclonal antibodies using spleen cells from mice immunized by repeated infections with live ***B. microti*** parasites. The characterization of these mAbs for antigenic recognition by Western Blot and IFA, and finer epitope mapping by the phage display library approach is in progress. Whole-genome-fragment-phage-display libraries (GFPDL) expressing the open reading frames of ***B. microti*** genome were constructed. Each GFPDL contains more than 10^9 individual phages expressing ***B. microti*** sequences of 50-250 amino acids as fusion proteins with the pIII coat protein of the M13 bacteriophage. Anti-***B. microti*** monoclonal antibodies will be used to 1) identify the immuno-dominant ***B. microti*** antigens, and 2) develop a ***B. microti*** antigen detection assay for application in acute diagnosis and to screen blood donors with low-grade asymptomatic infections. Details of these studies will be presented.

700

ECTOPARASITES FROM DOMESTIC ANIMALS DEVOID FOR RICKETTSIAL AGENTS, CUZCO, PERU

Carmen Flores-Mendoza[1], David Florin[2], Steev Loyola[1], Frederick Stell[1], Allen L. Richards[3]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [3]Naval Medical Research Center, Siver Spring, MD, United States

In order to develop effective control measures against arthropod-borne diseases, it is very important to identify the pathogens and their vectors. In southern Peru, there have been few studies on domestic animal ectoparasites and their pathogens. However, there has been evidence of spotted fever group of rickettsial infections in patients from the same region. The purpose of this study was to detect and identify rickettsial agents of ectoparasites collected from domestic animals in southern Peru. Ectoparasite collections were performed in 14 sites in Cuzco, Peru during August 2013. The study sites were located between 2,938 and 4,014 m.a.s.l. On average, the min and max temperatures were registered between 2C and 24C. All visible ectoparasites were removed with fine forceps, preserved in 95% ethanol and transported to NAMRU-6 where they were identified using morphological keys. Each specimen was cut in half and one half was used for DNA extraction with PrepMan™ Ultra, followed by detection/identification using a genus -specific qPCR assay for ***Rickettsia*** targeting the 17-kD antigen gene. A total of 222 animals from twelve types of domestic animals (donkeys, burrows, horses, cows, pigs, chicken, goats, guinea pig, sheep, llama, alpaca, and vicuña) were sampled. From 122 animals, 1657 lice, 39 ticks, and 1 flea were collected. A total of 400 (24%) qPCR reactions were performed with DNA from: ***Melophagus ovinus*** (19.3%, 300), ***Haematopinus eurysternus*** (80%, 4), ***Bovicola bovis*** (83%, 10), ***Otobius megnini*** (89.7%, 35), ***Bovicola caprae*** (75%, 3), ***Linognathus stenopsis*** (89.5%, 17), ***Bovicola equinus,*** (80%, 8), ***Tunga penetrans*** (100%, 1), and ***Haematopinus suis*** (50%, 22). All samples tested were negative for rickettsial DNA. ***M. ovinus*** was the most common ectoparasite (98%, 1563), which was collected from sheep (93%, 1551) and donkeys (0.8%, 12), and the other nine species of ectoparasites made up only 2% of all the ectoparasites collected. There is a possibility that the austere environment (high elevation, and low temperature and humidity) may have played an important role in the lack of rickettsial agents encountered in the ectoparasites assessed from Cusco.

701

EMERGENCE FOR LYME DISEASE IN NORTH DAKOTA: HOW DID IT GET THERE AND HOW IS IT BEING SUSTAINED?

Jefferson A. Vaughan, Michael W. Dougherty, Chad A. Stromlund, Robert A. Gaultney, Catherine A. Brissette

University of North Dakota, Grand Forks, ND, United States

Northeast North Dakota is highly agricultural with large amounts of acreage devoted to industrial scale farming. But lying within the expanse of field crops are islands of forested areas. Since 2010, breeding populations of deer tick, Ixodes scapularis, have consistently been present in the larger (>200 hectares), disjunct 'forest islands'. So far, the field infection rates of ***Borrelia burgdorferi*** (agent of Lyme disease) and ***Anaplasmosis phagocytophilum*** in North Dakota deer ticks have been relatively low (3 to 5%) compared to endemic regions to the east. Analyses of the mitochondrial DNA of deer ticks collected from different forest islands revealed a high haplotype diversity (Hd=0.80), suggesting that the forest islands were being colonized continuously from multiple sources. The likeliest host candidate to explain such pattern would be birds. Therefore in 2014, birds were collected in northwest Minnesota - the geographically closest area of Lyme disease endemicity. Of 104 passerine birds examined, five (4.8%) tested positive by PCR and sequencing for ***B. burgdorferi***, supporting our hypothesis of avian introduction of infected ticks into northeastern North Dakota. Nearly half of the small mammals captured in forest islands were white-footed mice (***Peromyscus*** - known reservoir of Lyme disease) and half were red-backed voles (***Myodes gapperi***). Both voles and mice were parasitized by immature deer ticks. A small percentage (ca. 6%) of engorged ticks pulled from voles and mice tested positive by PCR for ***Borrelia*** and ***Anaplasma***. To determine whether voles served as reservoirs for Lyme disease or conversely, as dead-end hosts (i.e., dilution hosts), a laboratory colony of red-backed voles was established. F-1 voles were injected with ***B. burgdorferi*** s.s. and at 2 and 4 weeks, the voles were infested with larval deer ticks. Engorged ticks were allowed to molt to nymphs and the nymphs were re-fed on naïve laboratory mice to determine if the larval ticks got infected and, as nymphs, were able to transmit the borreliae. At the time of this writing (April 2014), final data are still forthcoming and will be presented at the meeting.

702

CONTROL FOR VISCERAL LEISHMANIASIS: PERCEPTIONS, ACCEPTANCE AND WEAKNESSES FOR INDOOR INSECTICIDE SPRAYING (IRS) CAMPAIGN

Paritosh Malviya

Banaras Hindu University, Varanasi, India

Visceral Leishmaniasis (VL) is a fatal vector born infectious disease transmitted by ***Phlebotomus argentipes*** sand flies. The disease is highly endemic in Muzaffarpur district of India. The elimination program targets

on vector control by indoor residual spraying (IRS) using DDT twice a year. The IRS coverage increased from 17% in 2010 to 70% in 2013. However, even in the villages with 100% coverage vector density did not reduce significantly. With the objectives of determining the perception and acceptance by the community and Identifying weaknesses in the current IRS practical execution, we conducted 16 focused group discussions (FGD) among villagers and spray team members in the five endemic villages: three with low coverage (<60%) and two with higher coverage (>85%). Male and female households' heads representing wider section of the community in terms of socio-economic status, education, and caste formed heterogeneous groups. Our FGDs identified several ditches between the planning and monitoring of IRS program including poor quality of insecticide, diluted solution, inadequate spraying of wall and peri-domiciliary areas and no spraying in remote houses. IRS was done only once in a year. Pungent bad odour, stain on the walls, contamination of food items and occasional illicit demands from spray team were the main factors for the non-acceptance in the low coverage villages. Denial of spraying in washrooms, no prior information, unknown team members and purdah by the rural women were other common reasons. Spray team complaints about refusal by the well-built houses, and resistance from Musahar caste. Both the community and the spray team advocated for awareness campaign and prior announcement, involvement of ASHAs/ ANMs in IRS activities, spraying at least twice a year and improving quality of spray solutions. The spray team demanded increased and timely payment and upgraded equipment. We did not observe major trouble and discomfort in the community towards the IRS program, however people felt IRS grossly ineffective. The program should immediately focus on improving IRS campaign as deficient coverage may develop resistance against the insecticide.

703

PREVALENCE OF RICKETTSIAE IN FLEAS AND MITES COLLECTED FROM WILD RODENTS IN KENYA

David C. Abuom[1], Beth Mutai[1], Daniel Ngonga[1], Bernard Agwanda[2], Derek Monthei[1]

[1]Kenya Medical Research Institute/ United States Army Medical Research Unit Kenya, Kisumu, Kenya, [2]National Museums of Kenya, Nairobi, Kenya

Rodent-borne diseases pose a public health threat and rodents serve as hosts for a number of parasites linked to zoonotic disease. Identifying and understanding the epidemiology of rodent-borne diseases associated with ectoparasites is important when instituting mitigation strategies. Rickettsiae cause significant acute febrile illnesses especially in developing countries. Ticks have been incriminated as vectors of rickettsiosis (scrub typhus, murine typhus, and tick typhus). Rodent parasites such as fleas and mites are also possible vectors that can transmit rickettsiae and could possibly play an active role in maintaining and transmitting rickettsiae in the absence of livestock. Rodents were collected across three sites with varying habitat conditions. Ectoparasites were removed by combing with a fine tooth nit comb. The parasites were identified and pooled per rodent and per species. Fleas and mites were pooled and total nucleic acids extracted from them. The DNA was screened for evidence of rickettsiae nucleic acid using two quantitative real time PCR assays that were specific to the Rickettsiae genus and Rickettsia felis. A total of 208 rodents and small mammals comprising 12 different species were collected. The rodents were groomed and 187 mites and 124 fleas were collected. Fleas were identified as ***Dinopsyllus lupus*** (85/124; 68.5%), ***Xenopsyllus cheopis*** (35/124; 28.2%) and Leptsylla spp. (4/124; 3.5%). Mites were identified as ***Haemolaelaps*** spp. Mites had the highest prevalence of rickettsiae (13.9%) compared to fleas (10.5%). Several species of rickettsiae have been identified in Kenya including ***Rickettsia typhi***, ***R. africae***, and ***R. felis***. It is possible that rodents provide stable reservoirs for rickettsiae. Detection of rickettsiae in rodents indicates that control of rodents could be a possible way of controlling rickettsiae. More genetic analysis needs to be conducted to characterize rickettsiae species in fleas and mites in addition to studies conducted during over overlapping seasons to establish seasonal patterns.

704

UTILITY OF MATHEMATICAL MODELLING OF VECTOR-BORNE DISEASE

Steven D. Haenchen, Heidi E. Brown

University of Arizona, Tucson, AZ, United States

Mathematical epidemiology provides a useful toolbox for understanding and modeling transmission of vector-borne diseases. By definition, the reproduction number, R_0, and vectorial capacity present the scientific community with easily identified critical thresholds for when cases of disease are expected to increase or decrease. However, these models make three key assumptions regarding the mechanisms by which transmission occurs that may fail to match reality: 1) a single host, single vector system, 2) consistency of model parameters over time, and 3) homogenous mixing of hosts and vectors. While most disease systems will not behave in manner that is as clear and easily interpretable as these mathematic equations, the degree to which any individual system breaks these assumptions varies. We utilize a complex vector-borne disease system, plague in mammalian populations, to demonstrate how each of these assumptions could prove invalid. This analysis shows that classic models of transmission are useful for making relative comparisons of the force of infection given specific differences in a disease system. However, the validity of applying these models rests strongly in the assumptions made. As a result, the interpretation needs to be carefully considered and explicitly presented within the limits of the assumptions. Despite these potential limitations, we present situations in which these models effectively represent the biological system being modeled and suggest alternative methodologies to model more complex disease systems.

705

SEROPREVALENCE AND RISK FACTORS FOR *RICKETTSIA* AND *LEPTOSPIRA* INFECTION IN PUERTO MALDONADO, PERU

Gabriela Salmon-Mulanovich[1], Mark Simons[1], M. Claudia Guezala[1], Carmen Flores[1], Tatiana Quevedo[2], Mariana Leguía[1], Steev Loyola[1], Enrique Canal[1], Matthew Kasper[3], Hugo R. Rázuri[4], Daniel G. Bausch[5], Allen L. Richards[6]

[1]Naval Medical Research Unit - 6, Lima, Peru, [2]Naval Medical Research Unit - 6, Puerto Maldonado, Peru, [3]Armed Forces Health Surveillance Center, Silver Spring, MD, United States, [4]McGill University Health Centre, Montreal, QC, Canada, [5]Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [6]Viral and Rickettsial Diseases Department, Naval Medical Research Center, Silver Spring, MD, United States

Rickettsiae and ***Leptospira*** are common but often under-recognized causes of acute febrile disease. ***Rickettsiae*** are characterized into spotted fever group ***Rickettsia*** (SFGR) and typhus fever group ***Rickettsia*** (TGR). The distribution of the two groups is closely related to the distribution of their arthropod vectors. Conversely, ***Leptospira*** comprise a diverse genus with global distribution and a wide variety of animal hosts. To determine the burden of ***Rickettsia*** and ***Leptospira*** infections in the Madre de Dios Region in the Peruvian Amazon, we evaluated the seroprevalence of these two pathogenic genera among participants of an existing community cohort study of respiratory disease in Puerto Maldonado, the capital city of Madre de Dios. ***Rickettsia*** exposure was assessed by ELISA and ***Leptospira*** by microscopic agglutination testing. We also assessed risk factors for infection associated with seropositivity, collected serum samples and ectoparasites from domestic animals, and captured rodents in and around households. The antibody prevalence in the 353 humans tested was 13.9% (95% CI: 10.4, 17.9) for SFGR, 6.4% (95% CI: 3.9, 9.3) for TGR, and 11.3% (95% CI: 8.2, 15.1) for ***Leptospira***. Associated risk factors for SFGR were contact with birds, working in agriculture, older age and male gender while the risk factor for TGR was increasing age. No specific risk factors were noted for ***Leptospira***. In 65 households we sampled 137 domestic animals (59 dogs, 37 chickens, 25 ducks and 16 cats), captured 30 rodents, obtaining 130 serum samples and 432

ectoparasites (45% fleas, 35% ticks, 18% lice and 1% rodent mites). The most common ectoparasite species were ***Ctenocephalides felis*** (34.0%) and ***Rhipicephalus sanguineus*** (32.5%). Testing of the samples obtained from household animals and ectoparasites is in progress and will be presented at the meeting. The study provides valuable information on the burden of ***Rickettsiae*** and ***Leptospira*** in the region as well as shedding light on possible transmission route from domestic animals to humans.

CRIMEAN-CONGO HEMORRHAGIC FEVER INVESTIGATION - GEORGIA, 2014

Ashley L. Greiner[1], Stephanie J. Salyer[1], Natia Kakutia[2], Kendra Stauffer[3], Marika Geleishvili[3], Nana Mamuchishvili[2], Khatuna Zakhashvili[2], Juliette Morgan[3]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]National Centers for Disease Control and Public Health, Tbilisi, Georgia, [3]Centers for Disease Control and Prevention, Tbilisi, Georgia

By September 2014, the country of Georgia's National Center for Disease Control and Public Health reported 22 cases of Crimean-Congo hemorrhagic fever (CCHF), the highest annual case count since surveillance began in 2009. CCHF is a highly-fatal hemorrhagic illness naturally transmitted by infected ticks and animal blood. We investigated the 12 rural villages reporting at least one CCHF case in 2014; the goals were to assess CCHF risk factors (i.e. ticks, husbandry, and slaughtering/butchering), document CCHF-related knowledge, attitudes, and practices (KAP), and determine seroprevalance. A calculated sample size of 904 participants was proportionally allocated to each village by population size; 457 households were randomly selected. We enrolled all consenting adults (≥18 years old) residing in the households for the preceding two months. We performed a KAP/risk factor survey in conjunction with an anti-CCHF IgM and IgG serosurvey. We used Epi Info™ for analysis. Of 634 people eligible and available to interview, 618 (97%) completed the survey. Mean respondent age was 54 years (Range: 18-101); 214 (35%) were male. Most (57%) were agricultural workers; 102 (17%) were herders. Of the 389 (63%) who had tick contact, 286 (74%) handled ticks bare-handed; 95 (33%) knew the associated risk. Of 605 respondents, 355 (59%) reported animal blood exposure; 32 (9%) knew the associated risk. The 349 (57%) respondents with CCHF risk factor knowledge were more likely to have risk factors than others surveyed (OR=3.07, p=0.006). Of 440 serum samples collected, 13 (3%) were positive (one IgM, 12 IgG); seven (54%) were male. Mean seropositive subjects' age was higher than mean seronegative subjects' (71 vs. 52 years, p<0.001). Eight (62%) seropositive subjects had tick contact and four (31%) had fever in the preceding four months. In these rural villages, CCHF risk factors are highly prevalent but knowledge is limited and does not lead to preventative practice; educational campaigns should target these issues. CCHF seroprevalence in these villages is similar to the region's (~3%), thus improved surveillance may account for the increased case detection in 2014.

707

CAN BED BUGS MEDIATE AN URBAN CHAGAS EPIDEMIC?

Sherrie Xie

University of Pennsylvania, Philadelphia, PA, United States

Chagas disease, a zoonotic and vector-borne disease caused by the protozoan ***Trypanosoma cruzi***, is endemic throughout much of Latin America and affects tens of thousands of people in the United States. Recently, a study conducted with laboratory mice determined bed bugs to be a competent vector of ***T. cruzi.*** In light of these results and the dramatic rise in bed bug prevalence in many US cities, we examine through mathematical modeling whether bed bugs could mediate a Chagas epidemic in an urban neighborhood. The probability of transmission occurring within a bed bug infested household was modeled through simulations in a discrete stochastic model of bed bug feeding and bed bug-mediated ***T. cruzi*** transmission. This intra-household model was then combined with a discrete SEIS contact network model of inter-household bed bug infestations to determine the conditions under which a transmission event between households might occur. Key parameters of the inter-household model include network connectivity, visitation rate between contacts, and bed bug prevalence. When possible, parameter values were drawn from laboratory studies and field observations, and where little data was available – parameter ranges were examined via sensitivity analysis. A major limitation of this study was a lack of data on human movements between households. Our preliminary results suggest intra-household transmission is highly probable, and inter-household transmission is probable in a neighborhood with a clustered contact network, a high contact rate and high bed bug prevalence.

708

INCIDENCE FOR TICK-BORNE INFECTIONS IN A COHORT FOR NORTH CAROLINA OUTDOOR WORKERS

Steven R. Meshnick[1], John Wallace[1], Meagan Vaughn[2], Sheana Funkhouser[1], Sangmi Lee[3], Madhavi Kakumanu[3], Loganathan Ponnusamy[3], Charles Apperson[3]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Rho, Inc., Chapel Hill, NC, United States, [3]North Carolina State University, Raleigh, NC, United States

Numerous cross-sectional studies have shown that outdoor workers, such as park and forestry rangers, have high seroprevalences of tick-borne infections. However, the incidences of these diseases in outdoor workers are rarely reported. Here, we report the incidence of tick-borne diseases in a cohort of North Carolina park and forestry rangers followed over a 2-year period with repeated serologies. A cohort of 159 outdoor workers from the North Carolina State Divisions of Forestry, Parks and Recreation, and Wildlife were followed for 2 years as part of a randomized controlled trial evaluating the effectiveness of permethrin-impregnated clothing. Antibody titers against ***Borellia burgdorferi***, ***Rickettsia parkeri***, ***R. rickettsii***, ***R. amblyommi*** and ***Ehrlichia chaffeensis*** were measured by immunofluorescence assay (IFA) or enzyme-linked immunosorbent assay (ELISA) at baseline (n=130), after one year 1 (n=82), and after 2 years (n=73). An incident infection was defined as a 4-fold increase in IFA titer over a 1 year period. At baseline, seroprevalence (IFA titers of 1:128 or greater) among the workers were ***R. parkeri***, 24%; ***R. rickettsia***, 19%; ***R. amblyomii***, 12%; and ***E. chaffeensis***, 4%. There were no subjects who were reactive to ***B. burgdorferi*** C6 antigen at any point in the study. Over 2 years, there was one clinically confirmed case of Ehrlichiosis and one of Spotted Fever Rickettsiosis. There were 50 total seroconversions among 37 individuals to ***R. parkeri*** (n=19), ***R. amblyomii*** (n=14), ***R. rickettsii*** (n=9), and ***E. chaffeensis*** (n=8). The risk of infection by any pathogen during the study period was 0.26. The risk of infection was lower in subjects wearing permethrin-impregnated clothing, but not significantly (RR=0.80; 95% CI: 0.47, 1.39). In summary, outdoor workers in North Carolina are at high risk of incident tick-borne infections most of which appear to be asymptomatic.

709

MOLECULAR DETECTION AND CHARACTERIZATION OF *'CANDIDATUS RICKETTSIA ASEMBOENSIS'* IN ECTOPARASITES FROM DOMESTIC ANIMALS IN IQUITOS, PERU

Steev Loyola[1], Melanie Melendrez[2], Claudine Kocher[1], Allen Richards[3], Mariana Leguia[1]

[1]U.S. Naval Medical Research Unit - 6, Callao, Peru, [2]Viral Diseases Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]Viral and Rickettsial Diseases Department, Naval Medical Research Center, Silver Spring, MD, United States

While studying rickettsial infections in Iquitos, Peru, we identified ***Candidatus Rickettsia asemboensis*** sequences in multiple fleas, ticks and lice collected from domestic cats, dogs and chickens. Candidatus

Rickettsia asemboensis was first isolated in samples from Kenya. Since then asemboensis-specific PCR diagnostics have been developed and the full bacterial genome has been sequenced. Following the Kenya isolation and its complete genomic characterization, there has been a single additional report of asemboensis in Ecuador. Specifically, partial fragments of the 16S rRNA (1387 bp), gltA (350 bp), and ompB (464 bp) genes were amplified by PCR and sequenced. We now report multiple asemboensis isolations from Peru that have been fully characterized by multilocus sequence typing (MLST) of the 16S rRNA (1506 bp), gltA (1308 bp), ompA (1047 bp), ompB (4305 bp), and sca4 (1035 bp) genes. We are using these sequences, along with additional genomic information derived from next-generation sequencing of the Peru asemboensis isolates, to infer phylogenetic relationships among asemboensis strains reported to date, and further, to infer the molecular timeline of asemboensis evolution in the context of other Rickettsial strains. This work should help us better understand Rickettsial infections, which are a leading cause of undifferentiated febrile illness commonly found throughout Latin America.

710

USE FOR A NOVEL REAL-TIME FRET PCR ASSAY FOR DETECTION FOR TICK-BORNE RELAPSING FEVER GROUP *BORRELIA* FROM *IXODES SCAPULARIS* TICKS COLLECTED IN WISCONSIN (2013-2014)

Harmony L. Tyner[1], Lynne M. Sloan[1], Susan M. Paskewitz[2], Diep K. Hoang Johnson[3], Xia Lee[2], Bobbi S. Pritt[1]

[1]Mayo Clinic, Rochester, MN, United States, [2]University of Wisconsin, Madison, WI, United States, [3]Wisconsin Division of Public Health, Madison, WI, United States

Tick-borne relapsing fever (TBRF) is caused by at least 15 members of the ***Borrelia*** genus including several species endemic to the United States. Although most species in this group are transmitted through the bite of a soft-bodied tick, ***Borrelia miyamotoi*** is transmitted by the hard tick ***Ixodes scapularis***, the same vector as ***B. burgdorferi***. Human infections with ***B. miyamotoi*** have been reported from Russia and the northeastern United States (US), and DNA has been detected in ticks from Japan, Canada and the northeastern and midwestern US. We describe a sensitive and specific real-time PCR assay for detection of TBRF ***Borrelia*** and the results from testing Ixodes scapularis field-collected ticks (2010, 2013, and 2014) from Wisconsin. The TBRF PCR utilizes primers and fluorescence resonance energy transfer (FRET) probes targeting a sequence of the GlpQ gene which is specific for ***Borrelia*** in the relapsing fever group and is not found in the ***Borrelia*** sensu lato complex. The assay utilizes post-amplification melting temperature (Tm) analysis to differentiate ***B. miyamotoi*** from other causes of TBRF. Assay validation experiments showed that the novel PCR is capable of detecting all TBRF agents tested (***B. turicatae, B. hermsii, B. parkeri***) and has a lower limit of detection of 1 gene target per microliter of extracted DNA. The assay did not detect 16 tested ***Borrelia*** sensu lato species, (including ***B. burgdorferi***) or multiple other bacterial, parasitic and viral tick-borne pathogens. Five of 257 I. scapularis tested (1.9%; 1 nymphs, 4 adults) were positive for ***B. miyamotoi*** which is similar to other reported rates of detection from the upper midwestern states. The presence of ***B. miyamotoi*** DNA in ticks collected in Wisconsin suggests that ***Borrelia*** species associated with Relapsing Fever may be endemic in Wisconsin in hard-bodied ticks and may be predictive of future disease in human populations. This newly described real-time PCR assay allows for sensitive detection of TBRF ***Borrelia*** species and is a useful diagnostic and research tool.

711

ASSESSING DISPERSAL AND DIETARY PATTERNS IN BED BUGS (*CIMEX LECTULARIUS*) FOR VECTOR RISK IN PHILADELPHIA, PA

Alexander S. Berry, Dylan M. Tracy, Michael Z. Levy

University of Pennsylvania, Philadelphia, PA, United States

Cimex lectularius, the common bed bug, is abundant across the globe, particularly in urban regions. ***C. lectularius*** feeds exclusively on blood, primarily from humans, posing a risk as a vector of disease. We conducted a door to door survey of bed bugs in row homes in Philadelphia. 596 residents participated, 66(11.1%) of whom reported recent bed bug infestations. We confirmed infestations in 15 of these homes by inspection and collected insects when possible. Spatial analyses including Ripley's L and Moran's I were conducted showing that bed bugs may spread to the immediate neighboring home (15m). The lack of significant clustering on city blocks, however, suggests that the active movement of insects between houses is limited, and the presence of insects throughout the study area suggests that the rate of active dispersal is overshadowed by the rate of passive dispersal. Because bed bugs are competent vectors of ***Trypanosoma cruzi***, the etiologic agent of Chagas disease, the high prevalence of the insect may facilitate disease transmission between human populations. Moreso, bed bugs may serve as a vector between animal reservoirs and human hosts by feeding on the various species in the same residence. We have used multiplex PCR to detect the presence of human, mouse, dog, and cat blood in the gut of each ***C. lectularius***. Using ***C. lectularius*** samples collected from houses in the survey in Southern Philadelphia we will identify the source of each bug's last blood meal. We will use the dispersal and dietary patterns to better assess and address the risk bed bugs pose as a vector of disease to Philadelphia residents.

712

THE EFFECT FOR LARVAL EXPOSURE TO METAL POLLUTION ON THE LIFE HISTORY AND INSECTICIDE RESISTANCE PHENOTYPE FOR THE MAJOR MALARIA VECTOR *ANOPHELES ARABIENSIS (DIPTERA: CULICIDAE)*

Shune Oliver, Basil Brooke

National Institute for Communicable Diseases, Johannesburg, South Africa

Anopheles arabiensis is one of the major malaria vectors of Southern Africa. This vector has been shown to shown to be strongly affected by agriculture, but in this study, the effects of metal pollution on ***An. arabiensis*** was assessed. In this study,laboratory strains of ***An. arabiensis*** strains were used to determine whether unselected and strains selected for insecticide resistant respond differently to metal pollution. The SENN strain is an unselected strain originating from Sennar, Sudan that displays baseline resistance. The SENN DDT is selected for DDT resistance and displays multiple resistance phenotypes, mediated by the kdr mutation and elevated metabolic detoxification enzymes. Hatchling larvae of both strains were raised at the maximum acceptable toxicant concentration (MATC) of cadmium chloride, copper nitrate and lead nitrate. Development, size and subsequent longevity was monitored. The comparative lethal doses of the three metals were determined for both strains. Larvae of both strains were reared at MATC and the LD50 values for malathion and deltamethrin of 4th instar larvae and compared to control larvae. Similarly, the effect of rearing SENN DDT larvae at MATC on the insecticide resistance phenotype was assessed. The effect of all three metals on detoxification and oxidative stress enzymes was assessed. These studies demonstrate a marked fitness advantage of the resistant SENN DDT strain over their non-susceptible counterparts. The relevance of these findings will be discussed in context of increased urban and industrial pollution in Africa.

SUBSTANTIAL FITNESS COSTS FOR WOLBACHIA INFECTION ON THE STARVATION RESISTANCE FOR *AEDES AEGYPTI* LARVAE

Perran A. Ross, Nancy M. Endersby, Ary A. Hoffmann

University of Melbourne, Parkville, Australia

The mosquito ***Aedes aegypti***, the principal vector of the dengue virus, has recently been experimentally infected with ***Wolbachia***: intracellular bacteria that possess enormous potential as dengue biological control agents. In order for ***Wolbachia*** to spread throughout mosquito populations and supress dengue transmission, infected mosquitoes must be able to compete with the native inhabitants for access to limited resources. ***Wolbachia*** depend on their hosts for a wide range of nutrients which they are unable to synthesize themselves. Consequently, competition between ***Wolbachia*** and their hosts for nutrients could negatively affect host survival and development under the resource-limited conditions commonly experienced by ***Ae. aegypti*** larvae in the field. We test the tolerance of ***Ae. aegypti*** larvae to starvation when infected with one of three experimentally-generated ***Wolbachia*** strains: ***w***Mel, ***w***MelPop and ***w***AlbB, and compare their survival to wild-type uninfected larvae. We find that all three ***Wolbachia*** infections reduce the starvation resistance of larvae relative to uninfected. Additionally, the relative costs to starvation resistance for each of the three infections are concordant with previously characterized fitness costs in other life stages; highly virulent strains that reduce adult lifespan and egg viability also substantially reduce the starvation resistance of larvae, while benign infections only have a small deleterious effect. A reduced ability of ***Wolbachia***-infected larvae to survive in resource-limited habitats will limit the potential for ***Wolbachia*** infections to establish in highly competitive ***Ae. aegypti*** populations and control the spread of dengue.

714

IS MALARIA VECTORS PEAK BITING TIME CHANGING? THE IMPLICATIONS FOR MALARIA CONTROL IN WESTERN KENYA

Lucy A. Abel

AMPATH, Eldoret, Kenya

Malaria is a major cause of morbidity and mortality in Kenya. Prevention strategies include vector control efforts such as ITNs and IRS which exploit the vectors behavior of feeding and resting indoors. However recent studies indicate malaria vectors biting and resting behavior may be changing in response to control measures. This study was set up to assess the biting pattern, species composition and genetic mutations associated with resistance amongst malaria vectors in western Kenya. Mosquitoes were collected at 2 hr intervals throughout the night using a rotating specimen collector attached to a CDC light trap set in a room with 2 sleeping spaces covered by ITNs. Collection continued for 11 months. Mosquitoes were collected every other week for 4 consecutive nights. The first cup collected mosquitoes from 6:30-8:30pm and rotated each 2 hr interval thereafter. The last cup remained open from 6:30am until 9:30am. A trap set before 6:30pm collected mosquitoes into 'Cup 0' until 6:30pm. Malaria vectors from each cup were identified and abdominal status determined. A total of 1082 mosquitoes were captured; 636 ***Anopheles*** and 446 ***Culex***. 627 of the ***Anopheles*** mosquitoes were female. 5% (31/619) of the females were fed and 39% (12/31) of those were gravid. Most mosquitoes were caught before 6:30pm and after 6:30am with a minor peak between 1030pm-1230am. 494 anopheles were identified as either ***Anopheles gambie*** ss (48%), ***An. funestus***(33%) or An. arabiensis(19%). >50% of ***An. gambiae*** ss and ***An. arabiensis*** were captured before 6:30pm and after 6:30am while 41% of ***An. funestus*** were captured between 1030pm-0430am. Sporozoite rate was 1%. 79% of An. gambaie were homozygous for kdr 1014S allele, associated with pyrethroid resistance. There was increased activity of malaria vectors between 6:30-8:30pm and 6:30-8:30am, which could suggest early and late biting as well as exophily and endophagy in malaria vectors. There are significant levels of pyrethroid resistance in ***An. gambiae***. This could greatly compromise the effectiveness of current vector control interventions and thus alternative efforts are needed to address this behavioural change.

715

EXPLOITING THE 'KIDNEYS' FOR MOSQUITOES FOR THE DEVELOPMENT FOR NOVEL INSECTICIDES

Peter M. Piermarini[1], Klaus W. Beyenbach[2], Jerod S. Denton[3]

[1]The Ohio State University, Wooster, OH, United States, [2]Cornell University, Ithaca, NY, United States, [3]Vanderbilt University, Nashville, TN, United States

New insecticides are needed to improve our capabilities for mosquito control due to the emergence of resistance to conventional control agents (e.g., pyrethroids). Here we describe our efforts to develop new insecticides that disrupt the renal functions of mosquitoes by inhibiting the activity of inward-rectifier K^+ (Kir) channels expressed in the Malpighian tubules. We show that the Malpighian tubules of adult female mosquitoes (***Aedes aegypti***) express 3 Kir subunits (Kir1, Kir2B, Kir3) that exhibit cell and membrane specific localizations within the epithelium. Furthermore, we report the discovery of small molecule inhibitors of mosquito Kir1 channels that disrupt the capacity of isolated Malpighian tubules to secrete fluid in a manner consistent with the disruption of Kir-mediated K^+ secretion. Lastly, we show that the small molecule inhibitors of Kir1 elicit toxic effects on adult female mosquitoes in part by disrupting their excretory capacity and/or regulation of hemolymph K^+ homeostasis. Our data indicate that the mosquito Malpighian tubules and Kir channels are valuable physiological and molecular targets, respectively, for the development of novel insecticides.

716

LABORATORY EVALUATION FOR A MIXTURE FOR CLOTHIANIDIN AND DELTAMETHRIN AGAINST TWO RESISTANT *ANOPHELES* STRAINS

Karin Horn, Dagmar Gasten

Bayer CropScience, Monheim, Germany

Resistance to currently available insecticides is a major threat to the continued success in the fight against malaria. There are few insecticides which exhibit desirable features for vector control in their own right; however insecticide mixtures present interesting alternatives to explore. A mixture containing the neonicotinyl, clothianidin, and the pyrethroid, deltamethrin was compared in bioassays against both insecticides applied alone at equivalent rates, on wood, concrete and mud. Efficacy was investigated with the ***Anopheles gambiae*** RSP-H strain (100% kdr pyrethroid resistant) and ***Anopheles funestus*** FUMOZ-R (elevated levels of P450 - resistant to pyrethroids and carbamates). Against FUMOZ-R; deltamethrin efficacy was between 60% and 80% on wood, concrete and mud at 7, 5, and 5 months, respectively. Clothianidin alone failed to fully control FUMOZ-R on any of the treated substrates and efficacy remained below 60% except for few readings at 9 months. The mixture achieved a higher level of mortality and better overall residuality across all tested surfaces with smaller variations between evaluations. The mixture achieved efficacy of 80%-100% for 9, 8, and 6 months on wood, concrete, and mud, respectively. Against RSP-H, deltamethrin performed surprisingly well, with efficacy above 80% up to 9 months on all surfaces; Clothianidin performed well initially on wood and remained between 60%- 80% (with high variability and few readings above 80%) for 7, 4 and 4 months on wood, concrete and mud, respectively however the mixture achieved 100% efficacy throughout 9 months on all surfaces. This study suggests that the mixture performs more reliably against pyrethroid resistant mosquito strains on a range of surfaces than either insecticide applied alone at equivalent rates. Further studies are underway to confirm

this finding in other mosquito strains and under field conditions. The implications and potential relevance of such a mixture for indoor residual spray application is discussed.

717

CHARACTERIZATION FOR GLUTATHIONE-S TRANSFERASE EPSILON 2 (GSTE2) ISOFORMS IN *ANOPHELES STEPHENSI*

Cherry L. Dykes[1], Mark J. Paine[1], Martin J. Donnelly[1], Om P. Singh[2]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]National Institute of Malaria Research, Delhi, India

Glutathione-***S*** transferase belongs to a multifamily gene responsible for metabolism and detoxification of endogenous and xenobiotic compounds by catalyzing the conjugation of glutathione (GSH) with electrophilic compounds resulting in products with greater water solubility easing excretion. Amongst the many cytosolic GST classes, Delta and Epsilon are specific to insects and show a relationship with resistance. Metabolization of DDT due to enhanced DDT dehydrochlorinase activity by enzyme glutathione-***S***-transferase (GST) is one of the mechanisms known in insecticide resistance, which is due to qualitative or quantitative changes, in particular, overexpression of GST epsilon2 (GSTe2) gene. Here we report the occurrence of multiple GSTe2 isoforms in the Asian malaria vector ***Anopheles stephensi.*** Cloning and sequencing of full GSTe2 gene from this vector revealed the presence of four isoforms. The two most abundant isoforms GSTe2_1 and GSTe2_2, differed by six amino acids arising from 12 bp insertion and four bases substitutions. These genes were expressed in ***E. coli*** for functional analysis. ***In vitro*** assays showed that these two recombinant isoforms are efficient in metabolizing DDT showing 83% and 68% DDT depletion, respectively, after 1 hour in the presence of cofactor glutathione. Other two isoforms (GSTe2.3 and GSTe2.4) are rare and found in DDT-susceptible mosquitoes.

718

DISTRIBUTION OF *ANOPHELES GAMBIAE* S.L. AND ITS INSECTICIDE RESISTANCE PROFILE IN TANZANIA: IMPLICATIONS FOR MALARIA VECTOR CONTROL

Bilali Kabula[1], Patrick Tungu[2], Johnson Matowo[3], Robert Malima[2], Bernard Batengana[2], William Kisinza[2], Stephen Magesa[4], Martin Donnelly[5], Franklin Mosha[3]

[1]Kilimanjaro Christian Medical University College/NIMR, Moshi, United Republic of Tanzania, [2]National Institute for Medical Research, Muheza, Tanga, United Republic of Tanzania, [3]Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, [4]RTI International, Dar es Salaam, United Republic of Tanzania, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The ***Anopheles gambiae*** species complex exhibits an enormous diversity in its biology which impacts greatly on its importance as a vector of malaria. This study investigated the distribution of members of the ***An. gambiae*** complex and their insecticide resistance profile relative to the ecological differences found across Tanzania. Indoor-resting ***Anopheles*** mosquitoes were collected from 14 districts located across various ecological settings of Tanzania. These were morphologically identified and tested for their susceptibility to deltamethrin, lambdacyhalothrin, permethrin, propoxur, fenitrothion and DDT using standard WHO methods. Molecular diagnostics were used to genotype mosquitoes and screen for resistance mechanisms. A total of 7,596 mosquitoes were morphologically identified as ***An. gambiae*** s.l. of which 2,947 were identified to their species level. Out of these, 69% and 31% were ***An. arabiensis*** and ***An. gambiae*** s.s. respectively. Overall ***An. arabiensis*** predominated and was distributed widely across all ecological zones. The distribution of resistance was not homogenous. The species complex was resistant to the three pyrethroids tested (mortality rate < 90%) in Moshi, Arumeru, Muheza and Muleba. Resistance to DDT was recorded in Dar es Salaam and Muleba (mortality rate< 90%). There was no resistance to propoxur or fenitrothion. Knock down resistance mutations L1014S and L1014F were detected in some parts of the country in both species with varying allelic frequencies (4-41%). L1014S mutations were found most frequently in ***An. gambiae*** s.s. ($p<0.05$). The cytochrome P450s; cyp6p3, cyp6m2, cyp6z1 and cyp6z3 were significantly overexpressed in ***An. gambiae*** s.s. resistant to DDT. We have demonstrated the predominance and wide distribution of ***An. arabiensis*** in Tanzania. We have also demonstrated that ***An. gambiae*** s.l. is becoming resistant to pyrethoids and DDT in several parts of the country. This appearance of resistance mandates close monitoring and adoption of rational resistance management strategies in the country if the gains so far made in malaria control are to be sustained.

719

BEHAVIORAL CHARACTERISTICS FOR MALARIA VECTORS IN A HIGH INSECTICIDE TREATED NET COVERAGE AREA FOR WESTERN KENYA

Andrew Obala[1], Judy Mangeni[1], Lucy Abel[2], Kristin Corey[3], Alyssa Platt[3], Daniel Aswa[2], Wendy O'Meara[4]

[1]Moi University, Eldoret, Kenya, [2]Academic Model Providing Access to Healthcare, Moi Teaching and Referral Hospital Complex, Eldoret, Kenya, [3]Duke Global Health Institute, Duke University, Durham, NC, United States, [4]Academic Model Providing Access to Healthcare, Moi Teaching and Referral Hospital Complex, Duke Global Health Institute, Duke University, Eldoret, Durham, NC, United States

The scale-up of ITN coverage to control malaria hasreturned mixed resultsdue to over exposure of malariavectors to insecticides. The aim of this study was to determine factorsresponsiblefor continued malaria transmission in spite of wide ITN coverage in western Kenya. Malaria vectors were captured usingCDC light trap, PSC and window exit traps. ***Anopheles gambiae*** group were identified to species using PCR while the sporozoites rate was determined by ELISA method, and kdr genotyping was used to determine L1014S and L1014F alleles. Window exit traps collected fewer mosquitoes; only 15 over 329 nights of collection compared to 1061 in 1598 nights of CDC light trap collections and 269 in 178 PSCcollections. Amongst anopheline vectors identified (n=1,044), 68.2% were ***An. gambiae***ss, 20.1% were ***An. arabiensis*** and ***An. funestus*** comprised 11.7%. The proportion of ***An. gambaiess*** was slightly higher in CDC light traps, althoughthese differences were not statistically significant (72% v 67%, p=0.27). 26.4% of anopheles mosquitoes were fed, but the sporozoite positivity was only 1%. There were significant differences in feeding status by type of collection technique; 70% of collections by PSC were fed compared to only 18% of those in the light trap. 255 ***An. arabiensis*** and 817 ***An. gambaie*** were genotyped at kdr allele as LL (wildtype), LS or LF (heterozygous resistant), and SS or FF (homozygous resistant). A small number of mosquitoes carried the F allele; 2.1% An. gambaie and 5.1% ***An. arabiensis*** were heterozygous LF and 0.4%***An. gambaiess***were homozygous FF. 67% of ***An. gambaiess*** were homozygous resistant (SS) compared to 14% ***An. arabiensis***. Homozygous resistant ***An. gambaiess*** were slightly more likely to have fed (30% vs. 23%, p=0.10), but homozygous resistant ***An. arabiensis*** were slightly less likely to have fed (18% vs. 40%, p=0.058). Low proportion of ***An. arabiensis*** captured indoors confirms this mosquito bites indoors but rests outdoors, which is a challenge to malaria control. We report both L1014S and L1014F kdr alleles; these could have negatively impacted vector competence and hence low sporozoite rate reported here.

720

EVIDENCE OF MIXED FUNCTION OXIDASES MECHANISM IN *ANOPHELES GAMBIAE* S.L. WITH PYRETHROID RESISTANCE IN MALI

Moussa Bm Cisse[1], Dereje Dengela[2], Bradford Lucas[2], Jules Mihigo[3], Allison Belemvire[4], Kristen George[4], Christen Fornadel[4], Suzanne Powell[5], Raymond Beach[5]

[1]PMI Africa Indoor Residual Spraying Project, Abt Associates, Mali, Bamako, Mali, [2]PMI Africa Indoor Residual Spraying Project, Abt Associates, Bethesda, MD, United States, [3]U.S. President's Malaria Initiative United States Agency for International Development, ACI2000, Bamako, Mali, [4]U.S. President's Malaria Initiative United States Agency for International Development, Washington, DC, United States, [5]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

There is a growing concern that the spread of vector resistance to pyrethroid insecticides (PYs) may compromise the effect of long lasting insecticidal nets (LLINs). The only alternative products available for use in areas of pyrethroid resistance (pyrR) are LLINs treated with PYs plus piperonyl-butoxide (PBO), a synergist that inhibits the activity of mixed function oxidases (MFOs) in the mosquitoes. Therefore the President's Malaria Initiative supported a field evaluation of LLINs with PYs plus PBO in Mali. One of the activities in this study was verifying the role of the MFO mechanism in ***Anopheles gambiae*** s.l. with pyrR. ***An. gambiae*** s.l. larvae were sampled in 38 villages from 2 Districts in southern Mali from August to September 2013. The distance of the villages in the same district is 5 to 10 Km. Local vector populations were screened with the Centers for Disease Control and Prevention bottle bioassay test for permethrin and deltamethrin resistance. Bottle assays with PBO as a synergist were used to determine the association between reduced survival and elevated levels of MFOs. Taxonomic identification to species as well as presence of the L1014F kdr (knock down resistance) mutation were determined by the polymerase chain reaction. According to WHO 2013 resistance classification there was evidence of high pyrR in all 38 villages tested. After exposure to PBO, the mortality increased significantly ($P<0.05$) in 18 out of 38 villages showing evidence of a MFO-based metabolic resistance mechanism involved in pyrR. There was high variability both in resistance and the effect of PBO on mortality from one village to another. The L1014F kdr allelic frequencies were also high: 25%-100% in ***An. coluzzii***, 69%-100% in ***An. gambiae*** s.s. This study confirmed the presence of high variability of the MFO mechanism in wild-caught mosquitoes with pyrR from one village to another in southern Mali.

721

ENHANCING ENTOMOLOGICAL MONITORING FOR THE NATIONAL MALARIA CONTROL PROGRAM IN THE DEMOCRATIC REPUBLIC OF CONGO

Seth Irish

Centers for Disease Control and Prevention, Atlanta, GA, United States

Since 2012, the United States President's Malaria Initiative (PMI) has supported the National Malaria Control Program (NMCP) in the Democratic Republic of Congo (DRC), one of the highest malaria burden countries, by financing malaria key interventions including entomological monitoring through the Africa Indoor Residual Spray (AIRS) Project. The NMCP has set the objective to regularly monitor vectors throughout the country, and be able to have in the near future a well-defined map with vectors classification, their behavior, density, and even resistance to insecticides. The (INRB), with the close support of PMI, has conducted this monitoring in sentinel sites throughout the Democratic Republic of Congo. In 2014, entomological monitoring was conducted in seven sites in five provinces: Kinshasa, Kisangani, Lodja, Tshikaji, Mikalayi, Fungurume, and Kapolowe. In each site, human landing catches and pyrethrum spray catches were conducted to determine biting rates and to find the species present in each site. Furthermore, resistance tests were conducted using WHO tube tests and mosquitoes were analyzed for presence of resistance mechanisms (specifically kdr). ***Anopheles gambiae*** s.l. was the primary malaria vector in DRC, but several other malaria vectors were collected (***An. funestus***, ***An. moucheti, An. nili***, and ***An. paludis***). The detection of large numbers of ***An. paludis*** has led to a separate study to evaluate its importance as a vector in Lodja. Resistance to dichlorodiphenyltrichloroethane (DDT) has been widely detected (as was resistance to permethrin in 2013), deltamethrin resistance was suspected in some cases, and little resistance to carbamates and organophosphates was found. The sentinel site system continues to be improved and harmonized with the epidemiological sentinel site system. The regular collection of entomological data provides useful information to the NMCP to inform its vector control decisions and research priorities. Results from the newly implemented surveillance system will be shown.

722

A NOVEL LARVICIDE DELIVERY SYSTEM FOR ARTHROPODS

Scott Matthews[1], Ivy Hurwitz[1], Julin Wang[2], Marcelo Ramalho-Ortigao[2], Ravi Durvasula[1]

[1]University of New Mexico School of Medicine, Albuquerque, NM, United States, [2]Kansas State University, Manhattan, KS, United States

For many of the world's most dangerous vector-borne diseases, larvicides are essential to effective disease control. Regrettably, larvicides in common use are limited by toxicity, degradation of aquatic resources, evolution of resistance, and cost. We have developed a novel approach to larval eradication designed to overcome these limitations: use of Baker's yeast (***Saccromyces cerevisae***) as a delivery vehicle for essential oils. Our method of loading essential oils produces a yeast cell continent to the entrapped oil but no longer viable. Essential oils are produced by plants to combat larval and adult insects and are not toxic to mammals. They are lethal to mosquito larvae at low concentrations (50 ppm), but have not been tested against the larvae of leishmaniasis vectors. We hypothesized that (a) larvae of the leishmaniasis vector ***Lutzomyia longipalpis*** would consume yeast loaded with an essential oil and (b) consumption of these loaded yeast cells would be fatal to the larvae. To test this hypothesis we fed 3rd instar ***L. longipalpis*** larvae yeast loaded with lemongrass oil, an essential oil with established cidal activity against mosquito larvae. We completed two trials, with experimental and control groups of approximately 30 larvae each. The experimental group was fed a mixture of loaded yeast cells and fish meal (95:5 w/w %). The control group was fed a mixture of yeast cells free of essential oils and fish meal in the same ratio. After 24 hours all larvae fed essential oil-loaded yeast had been killed, with only one death occurring in the control group. Although the sample size is small, these results argue lemongrass oil is cidal to ***L. longipalpis*** larvae and that essential oil entrapped in a yeast delivery vehicle merits investigation as a novel approach to disease control. It is worth noting that preparation of the essential oil-loaded yeast cells is low in cost, requiring no specialized equipment or technical skill. These attributes, combined with evidence that lemongrass oil is cidal to the larvae of multiple arthropods, suggest that the essential oil -yeast system may be a viable platform technology for control of multiple vector borne diseases.

723

FINE SCALE HETEROGENEITY OF KDR FREQUENCIES AND DELTAMETHRIN RESISTANCE IN *AEDES AEGYPTI* IN MEXICO

Anna Trett[1], Marissa Grossman[2], Anuar Medina-Barreiro[3], Edgar Koyoc-Cardena[3], Azael Che-Mendoza[4], Jo Lines[1], Pablo Manrique-Saide[3], Gonzalo Vazquez-Prokopec[2], Audrey Lenhart[5]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Emory University, Atlanta, GA, United States, [3]Universidad Autonoma de Yucatan, Merida, Mexico, [4]Secretaria de Salud de Yucatan, Merida, Mexico, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States

Insecticide resistance is a widespread concern in the control of vector borne diseases, including dengue fever. Insecticide resistance monitoring is most often carried out at sentinel sites, and outcomes are extrapolated to describe vector populations over a large geographical scale. The accuracy of these extrapolations can be called into question if insecticide pressures are heterogeneously applied on a finer scale, as is often the case with reactive insecticide spraying targeting ***Aedes aegypti*** around the houses of reported dengue cases in Mexico. To determine the scale at which heterogeneity could be detected in insecticide resistance phenotypes as well as kdr molecular markers, a cross-sectional entomological study was conducted in two small dengue-endemic towns located on the Yucatan peninsula of southern Mexico. Five blocks were sampled in each town. Ovitraps were placed in ten randomly selected houses on each side of the blocks, and a minimum of ten houses on each block were selected for adult mosquito collections. Adult female ***Ae. aegypti*** collected from inside houses were genotyped to determine kdr allele frequencies and insecticide bioassays were performed on mosquitos reared from field-collected eggs to determine phenotypic resistance. Significant differences between blocks were detected in deltamethrin susceptibility ($p<0.0005$) and F1534C allele frequency ($p<0.0001$). No significant evidence for the stability of heterogeneity was observed when comparing town level resistance data over the time period of a year ($p>0.1$). Fine scale variability of insecticide resistance is a particular concern from an operational perspective, since the ability to tailor vector control interventions at such a scale is limited for many vector control programmes. The operational implications of such fine-scale variability in ***Ae. aegypti*** insecticide resistance will be discussed, with particular reference to limitations in the ability of vector control programmes to conduct insecticide resistance management and monitoring on a small scale.

724

A NOVEL VIDEO-TRACKING SYSTEM TO RECORD BEHAVIOR FOR NOCTURNAL MOSQUITOES ATTACKING HUMAN HOSTS

Natalia Angarita-Jaimes[1], Josephine Parker[2], Mayumi Abe[2], Gregory Murray[2], Fabian Mashauri[3], Jackline Martine[3], Catherine E. Towers[1], **Philip J. McCall**[2], David Towers[1]

[1]Optical Engineering Group, School of Engineering, University of Warwick, Coventry, United Kingdom, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]National Institute for Medical Research, Mwanza, United Republic of Tanzania

The mosquitoes that transmit malaria and many other vectors spend most of their adult life within human homes. It is here that they bloodfeed and transmit infections and also where vector control, via residual insecticides, is most effective in preventing transmission. Knowledge of vector behavior in this environment is limited, particularly when describing how mosquitoes attack a human host and how insecticides impact on such behavior. This is partly because satisfactory technology for tracking these small nocturnal insects in traditional dwellings in disease endemic communities has never been available. As better knowledge of such behavior is a pre-requisite for rational design of novel interventions, we have developed a novel camera tracking system that allows the real-time observation of nocturnal mosquitoes and records their behavior when attacking human hosts, within or without a bednet. The system addresses the requirements for high resolution over a substantial volume (approximately 2.0 x 2.4 x 1.0m) under nocturnal conditions. We describe the data processing strategies required to extract individual mosquito trajectories and the algorithms to derive insights into mosquito behavior as they approach, search and interact with a bednet baited with a human host. The high resolution of the system has revealed different behavioral modes in mosquitoes attacking a human-occupied bednet, and enabled detailed quantification of flight activity, velocity and contact duration at precise locations. The complete tracking device has been deployed successfully at a remote location in rural Tanzania, enabling the behavior of wild mosquito populations to be investigated. The system has considerable potential for use in behavioral studies of mosquitoes and many other vector groups, and it may provide a new route for investigations ranging from fundamental questions on basic behavior to the evaluation of vector control tools.

725

LABORATORY STUDIES FOR VECTOR COMPETENCE OF *CULEX ERRATICUS* FOR EASTERN EQUINE ENCEPHALITIS VIRUS

Andrea Bingham[1], Nathan D. Burkett-Cadena[2], Hassan K. Hassan[3], **Thomas R. Unnasch**[3]

[1]Florida Department of Health, Tallahassee, FL, United States, [2]Florida Medical Entomology Laboratory, Vero Beach, FL, United States, [3]University of South Florida, Tampa, FL, United States

Field studies of the ecology of Eastern Equine Encephalitis virus (EEEV) in the Southeastern USA have demonstrated that ***Culex erraticus*** is among the most common mosquitoes at many EEEV endemic sites. ***Cx. erraticus*** is often infected with EEEV, implicating it as a potential vector in this area. However, the competence of ***Cx. erraticus*** for EEEV has not been explored in detail, though early data have suggested that it might serve as a vector. To further explore the competence of this mosquito species for EEEV, ***Cx. erraticus*** females were collected from wetlands in Tampa, Florida and used in laboratory transmission studies. To confirm that females were not previously exposed to EEEV in nature, mosquitoes were first allowed to feed upon a droplet of honey that was then tested for presence of EEEV. Females were then starved for 48 hours before being allowed to feed upon chickens infected with EEEV (log10 PFU = 4.17-5.39 PFU/ml). Blood-engorged mosquitoes were then placed into individual containers and maintained for 14d. The rearing containers contained honey droplets to provide nutrition for the mosquitoes and to monitor for the presence of EEEV in mosquito saliva. The honey was changed out every other day. At 14d post feeding, mosquitoes were frozen, dissected and examined for the presence of EEEV by RT-PCR and IFA. Nucleic acids were also extracted from the honey samples and screened for the presence of EEEV RNA. EEEV RNA was detected in 89% of the bodies of the infected ***Cx. erraticus*** and in the legs of 64% of the individuals, providing evidence of a disseminated infection. Of the 19 individuals that survived for the entire study period, 16 (84%) of the mosquito heads were IFA positive for EEEV antigen; of these EEEV RNA was detected in the honey from 15 (79%), indicative of EEEV in the saliva. Together, these data suggest that ***Cx. erraticus*** is a competent vector of EEEV.

726

EVIDENCE FOR *AEDES AEGYPTI* OVIPOSITION ON BOATS IN THE PERUVIAN AMAZON

Sarah Anne Guagliardo[1], Amy Morrison[2], Jose Luis Barboza[3], Dawn Wesson[4], Loganathan Ponnusamy[5], Helvio Astete[6], Gonzalo Vazquez-Prokopec[1], Uriel Kitron[1]

[1]Emory University, Atlanta, GA, United States, [2]University of California, Davis, CA, United States, [3]Universidad Nacional de la Amazonía Peruana, Iquitos, Peru, [4]Tulane University, New Orleans, LA, United States, [5]North Carolina State University, Raleigh, NC, United States, [6]U.S. Naval Medical Research Unit - 6, Iquitos, Peru

The dengue vector ***Aedes aegypti*** is invading peri-urban and rural areas throughout Latin America. Our previous research in the Peruvian Amazon has shown that river boats are heavily infested with immature and adult ***Ae. aegypti***, likely playing a major role in their long-distance dispersal and successful invasion. However, the presence of immature mosquitoes provides no information about the timing of oviposition, and whether it took place in the boats. Here, we used baited ovitraps deployed on river boats to test the hypothesis that ***Ae. aegypti*** oviposition occurs during boat travel. We deployed a total of 360 ovitraps on 60 different barges during August and October of 2013, and February of 2014 (with 20 barges sampled during each month). We found ***Ae. aegypti*** mosquitoes in 22 individual ovitraps from 15 out of 60 barges (Premise Index 25%) across all sampling dates. Further, the distribution of ***Ae. aegypti*** egg abundance was highly aggregated: 2.6% of traps (N=7) were responsible for 71.8% of eggs found, and 1.5% of traps (N=4) were responsible for all (100%) of the larvae found. Similarly, 5% of boats were responsible for 71.5% of eggs. To complement our findings that a few boats are responsible for most mosquito production and movement over long distances, we now add the observation that a few oviposition sites are responsible for much of the larval production. When oviposition data are considered together with transportation data, we found that 1) large barges are a significant source of propagule pressure (the frequency and intensity of new introductions) for ***Ae. aegypti*** mosquitoes at all life stages 2) potential mosquito introductions may occur more frequently at different times of the year, as human transit in the Amazon is seasonal (even though mosquito oviposition is not). Our results provide strong evidence that ***Ae. aegypti*** oviposition commonly occurs during boat travel, and that the whole life cycle may be completed during a large barge voyage. Baited ovitraps targeted to specific boats, sites within a boat, and times of year are a potential cost-effective means of monitoring and controlling mosquito populations on boats, and introduction to new sites.

727

INTEGRATED ENTOMOLOGIC, PARASITOLOGIC AND IMMUNOLOGIC SURVEILLANCE FOLLOWING CESSATION FOR MDA IN SENTINEL COMMUNITIES IN SIKASSO, MALI

Yaya I. Coulibaly[1], Siaka Y. Coulibaly[1], Housseini Dolo[1], Siaka Konate[1], Abdallah A. Diallo[1], Salif S. Doumbia[1], Lamine Soumaoro[1], Michel E. Coulibaly[1], Ilo Dicko[1], Moussa B. Sangare[1], Modibo Sangare[1], Massitan Dembele[2], Yeya T. Touré[3], Louise Kelly-Hope[4], Katja Polman[5], Dominique Kyelem[6], Sekou F. Traore[1], Moses Bockarie[4], Amy D. Klion[7], Thomas B. Nutman[7]

[1]International Center of Excellence in Research, Filariasis Unit, Bamako, Mali, [2]National Lymphatic Filariasis Elimination Program, Bamako, Mali, [3]World Health Organization, Geneva, Switzerland, [4]Liverpool School of Tropical Medicine, Centre for Neglected Tropical Diseases, Liverpool, United Kingdom, [5]Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp, Belgium, [6]Neglected Tropical Diseases Support Center, Task Force for Global Health, Decatur, GA, United States, [7]Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

After 7 years of annual albendazole/ivermectin mass drug administration (MDA) in 6 ***Wuchereria bancrofti*** (Wb) previously highly endemic villages in Mali when WHO stopping criteria were met in 2008, surveillance was instituted over the subsequent 5 years using a variety of methods that included; circulating filarial antigen (CFA) tests (both ICT and ELISA) and antibodies to the Wb-specific antigen (Wb123) in all 6-7 year old children. Entomological surveillance was also performed using dissection of ***Anopheles gambiae*** complex.vectors collected monthly (from July to December) by human landing catch (HLC) and an additional pyrethrum spray catch (PSC) mosquito collection that relied on screening pools of ***Anopheles gambiae*** complex.using reverse-transcriptase polymerase chain reaction (RT-PCR) for infection/infectivity. Data from the children demonstrated increases in CFA prevalences over time with 0% (0/289) in 2009, 2.7% (8/301) in 2011, 3.9% (11/285) in 2012 and 4.1% (13/318) in 2013(Trend Chi2= 10.19, p= 0.0014). In 2012 when Wb123 antibody was assessed concurrently, there was a reported prevalence of positive responses of 1.8% (5/285) that was similar to that of the CFA prevalence (5/285). For the entomologic assessments, over the various sampling times using HLC, only two Wb-infected ***Anopheles*** were observed despite 14,575 mosquitoes dissected. Using the PSC method and RT-PCR technique, no positive pools were observed.Although CFA positivity in children was used as the major surveillance tool, adults (8-65 years old) were also assessed. Unlike the children, adults showed a decrease of the CFA prevalence from 4.9% (39/800) to 3.5% (28/795) and 2.8% (50/1,812) respectively in 2009, 2011 and 2012 (Trend Chi2= 7.361, p=0.0067) though microfilaremic adults were found within ICT positive subjects 2.6% (1/39) in 2009 and 8.3% (3/36) in 2011. These data are consistent with a small but real degree of Wb transmission 5 years after cessation of MDA in a previously highly endemic area of Mali that met the stopping criteria. Most of this transmission appears to be driven by a relatively few microfilaria carriers among the adult population.

728

DEVELOPMENT AND OPTIMIZATION OF THE SENTINEL MOSQUITO ARBOVIRUS COLLECTION KIT (SMACK)

Brian J. Johnson[1], Tim Kerlin[2], Sonja Hall-Mendelin[3], Jamie McMahon[3], Giles Cortis[4], Gerhard Ehlers[5], Scott A. Ritchie[1]

[1]James Cook University, Cairns, Australia, [2]Department of Agriculture, Australian Government, Cairns, Australia, [3]Public Health Virology, Forensic and Scientific Services, Department of Health, Queensland Government, Brisbane, Australia, [4]Private Contracting Engineer, Canberra, Australia, [5]Tropical Public Health Services, Queensland Health, Cairns, Australia

Sentinel animals have long been are used throughout the world to monitor arbovirus activity in remote areas. However, there are ethical and safety implications associated with using the animals, and cross-reactions

in serological assays make it difficult to distinguish closely related viruses. Mosquito traps are a viable alternative, but most require batteries and are often set overnight, thus making them unsuitable for remote locations. To overcome these challenges, our goal was to develop a passive sentinel mosquito arbovirus collection kit (SMACK) that allows for the detection of arboviruses on honey-baited nucleic acid preservation cards (Flinders Technology Associates; FTA) that can compete with standard battery-powered light traps. The efficacy of the SMACK as a mosquito trap was tested against the CDC light trap, EVS light trap, and CDC blacklight (UV) trap in a field trial conducted in tropical north Queensland, Australia. The SMACK caught comparable numbers to both CDC traps when CO_2 was supplied either by a gas cylinder (500ml/min) or dry ice (1kg), and captured significantly more mosquitoes (pooled data) (t_7=0.98, P=0.02) than the EVS trap. Daily survival of field-collected mosquitoes was significantly greater (t_{12}=2.68, P=0.01) in the SMACK (93.1±3.6%) compared to a standard passive box trap (PBT) (31.4±5.4%). This increased survivorship will maximize the number of sugar-feedings on honey-baited FTA cards as it was determined that 66.8±16% of field-collected mosquitoes sugar-feed at least twice over a period of 72hr. We are currently testing the ability of the SMACK to serve as a sentinel arbovirus surveillance platform at three locations in the remote Cape York area of northern Australia. Thus far, 7 FTA cards have tested positive for Kunjin virus (KUNV) and 2 have tested positive for Murray Valley Encephalitis (MVEV), with both MVEV and KUNV virus being detected from a single trap on one occasion. The simplicity and longevity of the SMACK, combined with its ability to detect arbovirus activity in remote locations, makes it a viable alternative to sentinel animal programs and a practical substitute for standard light traps.

729

EXPERIMENTAL HUT ENTRANCE AND RESTING BEHAVIOR OF *ANOPHELES DARLINGI* FROM ZUNGAROCOCHA, LORETO, PERU

Fanny Castro-Llanos[1], Nicole L. Achee[2], John P. Grieco[2], Karin Escobedo-Vargas[1], Victor López[1], Craig A. Stoops[1], Frederick M. Stell[1], Gissella Vásquez[1]

[1]U.S. Naval Medical Research Unit - 6, Lima, Peru, [2]University of Notre Dame, Department of Biological Sciences, Notre Dame, IN, United States

Anopheles darlingi is the most important malaria vector in the Amazon region, therefore rigorous characterization of factors contributing to its vector competence is vital to its control and prevention of human-vector contact. Patterns of ***An. darlingi*** human landing rates (inside and outside of homes), house entry, and indoor resting were described using experimental huts located in Zungarococha village, a malaria-endemic area in Loreto, Peru. Landing rates (mosquitoes caught/person/hour) were evaluated for three days each month during a 12-month experimental period. Entry behavior (mosquitoes caught/trap/hour) was evaluated for six days each month during the same time period using interception traps placed on experimental huts windows and doors. Indoor resting behavior of wild-caught and colonized adult females was observed for six days each month during a 3-month period using a mark-release study design to record preferences on wall, ceiling, window, door, floor and other sites within huts. Results of these studies indicated a primarily peak in landing rates inside and outside of homes between 2100h to 2300h, and occasionally between 1800h-2000h outside homes; no defined peaks in hut entry were recorded. In fact, entry rates were very low compared with landing rates inside homes. The peak of indoor resting behavior for both wild-caught and colonized ***An. darlingi*** occurred between 1800h to 2100h with a preference for resting in the lower part of hut surfaces (door and wall) in both populations. Results from this study provide useful insights into the behavior of ***An. darlingi*** in malaria-endemic area in the Peruvian Amazon, which can help guiding vector control strategies in the region.

730

BRUGIA MALAYI INFECTION INFLUENCES VECTOR LONGEVITY, FECUNDITY AND HOST-SEEKING BEHAVIOR

Lisa Reimer, Katherine Gleave, Darren Cook, Mark Taylor

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Understanding vector-parasite interactions is increasingly important as we move towards the eradication of lymphatic filariasis. While mass drug administration is reducing the parasite burden within populations to low levels it is necessary to determine the effects of reduced microfilaria (mf) density on disease epidemiology and vector behavior. ***Aedes aegypti*** mosquitoes were exposed to the filarial parasite ***Brugia malayi*** at low (5,450 - 7,750 mf/ml), moderate (10,550 - 15, 400 mf/ml) and high (15,900 - 17,900 mf/ml) levels of microfilaremia, while control mosquitoes were fed uninfected blood. The effect of an infection on host-seeking behavior was examined using a short range host assay. The proportion of mosquitoes responsive to a human host at different developmental periods in the parasite life cycle was recorded and a subset dissected to determine parasite prevalence and mean intensity. Volume of ingested blood and fecundity were also compared between infected, exposed and control mosquitoes. Mosquito mortality was observed for 16 days post-exposure, and each mosquito dissected to record infection status. We observed a 5 fold increase in host receptivity when infective stage larvae (L3) were present as opposed to developing stage (L1 and L2) ($p<0.001$). In control mosquitoes, a reduction in receptivity was observed during the same period. Furthermore, receptivity was density dependent with non-receptive mosquitoes harboring a greater burden of L1 and L2 while receptive mosquitoes harbored a greater number of L3 ($p<0.001$). Density dependent decreases in mortality ($p<0.001$) and fecundity ($p<0.01$) were observed, but the ability of mosquitoes to feed to repletion remained unaltered.

731

TESTING THE EFFECTS OF LATITUDE ON LIFE HISTORY OF ARBOVIRAL VECTORS *CULEX PIPIENS* AND *CULEX QUINQUEFASCIATUS*

Virginia Chu[1], Joseph Vineis[2], Laura D. Kramer[2], Carl D. Schlichting[3], Jan E. Conn[2]

[1]Department Biomedical Sciences, State University of New York, Albany, NY, United States, [2]Wadsworth Center, New York State Department of Health, Slingerlands, NY, United States, [3]Department Ecology and Evolutionary Biology, University of Connecticut, Storres, CT, United States

The mosquito species ***Culex pipiens*** and ***Cx. quinquefasciatus*** (Diptera: Culicidae) are important vectors of arboviruses worldwide, including West Nile Virus. Together, these sibling species span the entire United States and, where they overlap geographically, there is evidence for hybridization between the two. We conducted laboratory experiments to investigate the adaptability of mosquito populations to temperature, in order to examine population differentiation. ***Culex*** egg rafts were collected from 6 sites spanning three regions along the Eastern U.S. coast (north, central, south). These eggs were reared at two fixed temperatures (16°C and 26°C). Three life history traits were analyzed: larval growth rate (days to pupation), adult body size (correlated with pupal weight), and preadult developmental time (days to emergence). Mosquitoes from the three regions differed significantly in pupal weight, with southern mosquitoes smaller than the others ($p = 0.009$). Region effects on development time and growth rate were marginally significant, with generally faster development and higher growth rates for northern mosquitoes ($p = 0.099$). Both rearing temperature and sex were highly significant for all three traits ($p < 0.001$). Highly significant interactions between region and temperature for all three traits ($p < 0.001$) indicate a region-specific plastic response to temperature variation. In conclusion, these experiments highlight the plasticity of these two vector species. Their individual abilities to adapt to

different temperatures may help elucidate the impacts of climate change on the biological traits of these mosquitoes associated with vectorial capacity and arbovirus transmission.

732

POPULATION ECOLOGY OF A RIFT VALLEY FEVER VIRUS VECTOR: A COMPREHENSIVE ANALYSIS OF ENVIRONMENTAL DRIVERS OF *AEDES MCINTOSHI* ABUNDANCE IN KENYA

Lindsay P. Campbell

University of Kansas, Lawrence, KS, United States

One disease of great economic and human health importance in East Africa is Rift Valley Fever virus (RVFV). Current mosquito forecasting models focus on climate and vegetation monitoring at broad temporal scales, but this approach assumes mosquito population dynamics are homogenous between species, and many questions remain regarding environmental drivers of individual species emergence. One example is the mosquito species ***Aedes mcintoshi***, identified as the primary vector of RVFV in East Africa. We hypothesized that environmental drivers at fine temporal scales contribute to ***Ae. mcintoshi*** counts at specific locations and that these drivers can be measured using existing remotely-sensed environmental data. We analyzed relationships between ***Ae. mcintoshi*** abundance counts from repeat sampling conducted by the United States Army Medical Research Unit - Kenya (USAMRU-K) at 28 georeferenced locations across Kenya and a suite of remotely sensed environmental data, using a generalized linear mixed modeling (GLMM) approach. Specifically, we analyzed the contributions of Moderate Resolution Imaging Spectroradiometer Land Surface Temperature data, Normalized Difference Vegetation Index data, daily Climate Hazards Group InfraRed Precipitation with Station data, and SPOT Vegetation Small Water Bodies Africa data to abundance. Preliminary results indicated that a relationship exists between ***Ae. mcintoshi*** counts and elevated precipitation approximately 2 weeks prior to the sampling date and elevated LST values up to 32 days prior to the sampling date. Relationships between total area of free water, humid vegetation, or dry land and ***Ae. mcintoshi*** counts was not detected surrounding sampling sites. Future directions include analyses of additional RVFV vectors and spatio-temporal interactions between species. Knowledge of these factors will contribute to a better understanding of the disease ecology of RVFV and complement current forecasting methods, contributing to more efficient vector control applications and distribution of public health resources.

733

ENHANCEMENT OF *PLASMODIUM VIVAX* OOCYST PRODUCTION IN *ANOPHELES DARLINGI* EXPERIMENTAL INFECTIONS

Carlos G. Tong[1], Zaira G. Villa[1], Marta Moreno[2], Pamela Orjuela-Sanchez[2], Brice Campo[3], Elizabeth A. Winzeler[2], Joseph M. Vinetz[2]

[1]Universidad Peruana Cayetano Heredia, Iquitos, Peru, [2]Division of Infectious Diseases, School of Medicine, University of California San Diego, La Jolla, CA, United States, [3]Medicines for Malaria Venture, Geneva, Switzerland

Because ***in vitro Plasmodium vivax*** gametocyte culture is not possible, obtaining infective ***P. vivax*** sporozoites for drug screening and other studies remains a challenge. The recently reported establishment of an ***Anopheles darlingi*** colony in Peru—freely mating and currently in its 24th generation—in proximity to ***P. vivax***-infected humans has the potential to provide stable sporozoite production. This study evaluated methods for standardizing and maximizing the production of ***P. vivax*** sporozoites in laboratory-reared ***An. darlingi***. With regard to enhancing ***P. vivax*** mosquito infected, we tested 1) the effect of anticoagulants EDTA, citrate, and heparin in donor blood samples; 2) the effect of adding penicillin/streptomycin to membrane feeds of mosquito in terms of infection and survival. Non-blood-fed adult female ***An. darlingi*** mosquitoes 3 to 7 days post-emergence were fed on ***P. vivax***-infected blood and maintained up to 15 days on 10% sugar at 27°C and 80% humidity in 12 hour light/dark cycles. Oocysts were enumerated by midgut light microscopy on day 8; whole body sporozoites were quantified in a Neubauer chamber on day 15. ***P. vivax*** midgut infection (***N***=150) assessed by oocyst counts were significantly correlated with donor gametocyte densities. Sporozoite production was highly variable (range 75-21,954 ± 331.6) and was not associated either with oocyst density or with donor sexual or asexual parasitemia. With 3 donors, mean oocyst per mosquito midgut was significantly higher with heparin (90.4) compared to EDTA (59.7) or citrate (42.56). Use of penicillin/streptomycin (20 µg/ml in blood mean; and in 10% sugar solution after blood feeding) (N=6440) did not significantly increase oocyst density but did increase female ***An. darlingi*** survival (54% to 76%) at day 14. The effect of these interventions on sporozoite production is being evaluated.

734

MOSQUITO SALIVA PROMOTES A TH1 IMMUNE RESPONSE IN HUMANIZED NOD-SCID IL2RGAMMA-NULL MICE

Kassandra L. Peterson, Megan Vogt, Mayra Hernandez-Sanabria, Enid Mondragon, Anismrita Lahon, Ravi Arya, Silke Paust, Rebecca Rico-Hesse

Baylor College of Medicine, Houston, TX, United States

Aedes aegypti mosquito saliva increases dengue virus pathogenesis in humanized mice. Since mosquito saliva also acts as a vasodilator and conveys various advantages to mosquito blood feeding, we investigated whether ***Ae. aegypti*** mosquito bite stimulates an immune response in humanized mice. To answer this question, we used flow cytometry to monitor human innate immune responses in the skin, spleen, blood, and bone marrow of humanized mice post mosquito bite. We found that saliva alone increases activation of human dendritic cells in the bone marrow and natural killer cells in the peripheral blood 24 hours post bite. Also, we observed increases in both IL12 and IFN, which lead to a dominant T_h1 immune response. These results suggest that ***Ae. aegypti*** mosquito saliva preferentially promotes a T_h1 immune response in humans to avoid a T_h2 response. Because a T_h1 response promotes an antiviral state, whereas a T_h2 response promotes an allergenic state, viruses dependent on mosquitoes for transmission may have developed mechanisms to counteract the saliva-induced T_h1 immune response. In the future, we will use the same approaches to study these human immune responses in humanized mice bitten by mosquitoes infected with dengue virus.

735

THE HOST FEEDING PATTERNS OF *ANOPHELES* MOSQUITOES FROM MALARIA ENDEMIC VILLAGES IN MADANG PROVINCE, PAPUA NEW GUINEA

John B. Keven[1], Lisa J. Riemer[2], Gussy Koimbu[1], Michelle Katusele[1], Rebecca Vinit[1], Edward Thomsen[2], Peter Siba[3], David Foran[4], James Kazura[5], Peter A. Zimmerman[5], Edward D. Walker[4]

[1]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [4]Michigan State University, East Lansing, MI, United States, [5]Case Western Reserve University, Cleveland, OH, United States

Vector-human contact during the blood-feeding event, where malaria parasites are exchanged between the two hosts, is an important factor that determines malaria transmission. However, in addition to humans, mosquitoes may feed on other vertebrates. The choice of a vector to feed on alternative hosts or to feed only on a subpopulation of humans can influence malaria transmission. Here, we investigated the host-feeding pattern of ***Anopheles*** mosquitoes from five different villages in Madang Province, Papua New Guinea. Mosquitoes were sampled using the barrier screen sampling method. DNA was extracted from blood-fed specimens

and host species were identified by sequencing the mitochondrial cytochrome B gene or a multiplex PCR using host-specific primers. Mosquitoes confirmed to have fed on humans were further evaluated by DNA profiling to determine molecular fingerprints of the individual people from whom they fed. The high human blood index (HBI) for ***An. koliensis*** (HBI = 0.91), ***An. punctulatus*** (HBI = 0.84), and ***An. farauti*** s.s (HBI = 0.63) was consistent with previous findings that showed them to be highly anthropophagic. ***An. longirostris*** (HBI = 0.76), which was considered zoophagic, appeared here to be anthropophagic. ***An. bancrofti*** (HBI = 0.23) appeared consistent with previous findings as a zoophagic species and ***An. farauti*** No. 4 (HBI = 0.58) is reported here for the first time as a generalist feeder. Despite strong preference for humans, these vectors are not strictly anthropophagic as pigs and dogs were also fed upon. Increasing the number of pigs and dogs as alternative hosts along with long-lasting insecticide-treated nets may help reduce malaria transmission in these villages. The DNA fingerprint data based on analysis of 212 human-fed ***An. farauti*** s.s from one village showed that these mosquitoes obtained their bloodmeals from a pool of 69 individual humans (81% males and 19% females). In addition, only 7/69 individuals (10%) contributed to 53% of the bloodmeals. These results showed evidence of aggregated feeding on a subpopulation of humans, a phenomenon that plays an important role in the sustenance and resurgence of malaria transmission.

736

HOUSEHOLD-LEVEL ENVIRONMENTAL CHARACTERISTICS ASSOCIATED WITH *ANOPHELES* SPECIES ABUNDANCE IN MALARIA-ENDEMIC BLANTYRE, MALAWI

Themba Mzilahowa[1], Edward D. Walker[2], Don P. Mathanga[1], Terrie E. Taylor[2], Mark L. Wilson[3]

[1]University of Malawi, Blantyre, Malawi, [2]Michigan State University, East Lansing, MI, United States, [3]University of Michigan, Ann Arbor, MI, United States

Malaria is holo-endemic in southern Malawi, and many cases are reported among residents of Blantyre City. Virtually nothing is known about the ***Anopheles*** spp. present in that setting, including their space-time patterns of abundance and associated peridomestic environmental characteristics. We systematically sampled adult mosquitoes at 64 locations (5 households per location) along 8 transects radiating outward from the city center (~18 km distance) during the rainy and dry seasons of 2015. Each house (n=320) was aspirated and light-trapped, house characteristics (size, construction, screens, room use, animals) were recorded and people were questioned about demographics and anti-malaria efforts (ITNs, treatment). ***Anopheles*** funestus were most abundant; only a few An. aegypti s.l. were found. Light-traps captured ~58-fold more adults than did aspiration. Considerable variation in abundance among households was found, both within- and among the 64 locations. Sporozoite infection prevalence determined by PCR was low, and also varied among households. PCR-based analysis of blood meals, targeting the vertebrate cytochrome B gene, demonstrated that engorged females mostly fed on human blood. House construction was generally predictive of mosquito abundance, with closed eaves and bed net use being protective. Peri-domestic (<50m) habitats with any type of vegetation (vs. buildings or bare ground) were predictive of ***Anopheles*** abundance. These results suggest that fine-scale spatial heterogeneity in malaria risk is determined by complex relationships at the household level across a range of habitat characteristics traditionally considered to be urban.

737

FILLING IN THE VECTOR MAP WITH A LARGE SCALE SURVEILLANCE FOR FIELD-COLLECTED MOSQUITOES IN LIBERIA

Joseph W. Diclaro[1], Reham Tageldin[1], El-Shiamaa M. El-Din[1], Nermeen T. Fahmy[1], James C. Dunford[2], Desmond H. Foley[3], Peter J. Obenauer[4], Fatorma K. Bolay[5], Lawrence S. Fokoli[5]

[1]Naval Medical Research Unit - 3, Cairo, Egypt, [2]Navy Environmental and Preventive Medicine Unit 2, Norfolk, VA, United States, [3]Walter Reed Army Institute of Research, Forest Glen, MD, United States, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Liberian Institute for Biomedical Research, Charlesville, Liberia

A large-scale mosquito surveillance study in Liberia aimed at determining the prevalence of malaria and arboviruses from field-collected mosquitoes was initiated in 2010. Mosquitoes were collected in five counties of Liberia, for seven consecutive days and nights. Collection sites included coastal, forest, urban, and mountain / savannah terrains. At each site, three different traps were used: a CDC UV trap baited with CO2, a Gravid Trap baited with 50% hay infusion, and a Biogent-Sentinel (BGS) Trap baited with a lure. A comprehensive literature search of 37,000 specimens comprised of 70 species and 11 genera were collected and identified. An additional 70 species and three genera were gleaned from the literature, yielding a total of 140 species and 14 genera currently known to occur in Liberia. During this survey, 30 out of the 70 collected species are new records, with the majority of the new records belonging to the genera Culex and Coquillettidia. Due to the morphological indistinguishability of ***Anopheles gambiae*** sensu lato (Giles) complex, DNA was extracted from legs of each specimen with species identification determined by multiplex polymerase chain reaction using specific primers revealing 72.6, 25.5, and 1.9% of ***A. gambiae*** s.s specimens were S, M, and hybrid forms, respectively. Additionally insecticide resistance PCR assays demonstrated 92% RR, 6% SR, and 2% SS from the collected samples. Selected Anophelinae species were also screened for the presence of malaria causing sporozoites using enzyme-linked immuno assay, which showed 4% infection rate. Culicinae mosquitoes were analyzed by performing RNA extraction in the attempt to detect RNA corresponding to DENV 1-4, CHIKV, YFV, RVFV, WNV or families Flavivirus, Alphavirus, Buyavirus will be detected using protocols for realtime or conventional RT-PCR. However no arboviruses were detected in the collected mosquito specimens during this time period.

738

DEVELOPMENT FOR A WEB SYSTEM THAT FACILITATES THE COLLECTION AND ANALYSIS FOR DENGUE RISK FACTORS USING OPEN-ACCESS GEOGRAPHIC INFORMATION SYSTEM

Clara B. Ocampo[1], Neila J. Mina[1], Maria I. Echavarria[1], Ana L. Estrada[1], Neal Alexander[1], Miguel Acuna[2], Jorge I. Ramirez[2], Liliana Estupinan[2], Alexi Caballero[2]

[1]CIDEIM, Cali, Colombia, [2]Corporación para la investigación de la corrosión CIC, Santander, Colombia

In Colombia, the decentralized health system requires local authorities to take important decisions about the prevention and control of dengue. But actions are generally reactive, i.e. undertaken principally in response to disease outbreaks, limiting the opportunity for preventive actions. Additionally, methods of data collection and design of intervention strategies do not involve joint analysis of the biological, ecological, and social needs of each locality. Consequently, at the local level, there is no specific initial assessment which would allow proactive actions and adequate prevention in terms of intervention and control strategies, as well as a lack of continuity in personnel. We are developing a web system that facilitates the collection and analysis of entomological, epidemiological and social data using open-access geographic information systems, allowing spatial analysis of transmission. We will share the

identification of risk factors associated with dengue transmission locally from two intermediate cities in Colombia. We expect that the introduction of local analysis, integrating the various determinants of dengue transmission, and taking advantage of technological tools that facilitate entomological studies and disease surveillance, will allow appropriate prevention and control strategies; giving a greater chance of long-term sustainability. This system will empower dengue surveillance and control programs at the local, provincial and national levels.

739

EMERGING OF CHIKUNGUNYA VIRUS CLADE WITHIN ASIAN GENOTYPE IN THE PHILIPPINES

Chonticha Klungthong, Wiriya Rutvisuttinunt, Prinyada Rodpradit, Piyawan Chinnawirotpisan, Wudtichai Manasatienkij, Maria Theresa Alera, Butsaya Thaisomboonsuk, Anon Srikiatkhachorn, Louis R. Macareo, Jens W. Levy, Stefan Fernandez, In-Kyu Yoon

U.S. Army Medical Component-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Chikungunya virus (CHIKV) is a mosquito-borne pathogen that can cause epidemic fever, rash, and arthritis. In the Philippines, sporadic outbreaks have been reported for several decades with increasing numbers during the 2012-2013. CHIKV has recently spread to the Americas during the 2013-2014. The Asian genotype has been identified in specimens collected during the outbreaks in the Americas and the Philippines. Obtaining more genetic information on Asian genotype will provide more insight into the genetic changes that may have led into the most recent CHIKV epidemic patterns. In this study, we analyzed the complete genomes of five CHIKV isolates from acute illness blood samples collected from a prospective longitudinal cohort study of febrile illnesses conducted in Cebu City, Philippines during 2012-2013. Phylogenetic analysis of the two concatenated open reading frames revealed two clades within the Asian genotype: an older clade (1958-1995) and a modern clade (2006-2014). The modern clade appeared in Malaysia in 2006 and has expanded since 2007 into two separate sub-clades. The five new sequences from the Philippines fell into the newer sub-clade of the modern clade, containing the CHIKV strains found recently on St. Martin, British Virgin Islands, and Mexico. The mutations in each clade of Asian genotype are further described in this study. Our findings increase our understanding of the molecular epidemiology of CHIKV strains responsible for recent geographic spread of chikungunya.

740

IMPORTED CASES OF CHIKUNGUNYA INFECTION AMONG CANADIAN TRAVELERS IN 2014

Michael Drebot, Kimberly Holloway, Kristina Dimitrova, Kai Makowski, Maya Andonova, Robbin Lindsay

Public Health Agency of Canada, Winnipeg, MB, Canada

Since the spring of 2014, a large increase in travel-related Chikungunya cases have been diagnosed in Canada. As of April 1, 2015 over 400 confirmed Canadian cases of imported Chikungunya associated illness had been diagnosed in 2014 with the majority of Canadian provinces identifying at least one imported case. As well, approximately 100 probable and confirmed cases had already been diagnosed among Canadian travellers in early 2015 (as of April 1). Suspect case serum samples from provincial public health laboratories across Canada were screened using a CDC based IgM ELISA. Specimens positive for IgM were confirmed for presence of viral specific antibody using a plaque reduction neutralization test. Serum samples were also tested by real time and conventional RT-PCR for the presence of viral RNA. The confirmed numbers of imported Chikungunya infections identified in 2014 is a significant increase in documented cases as compared to past years when case rates ranged from 1-20 cases a year. Cases in which travel histories were available indicated that the majority of Canadian exposures resulted from travel to the Caribbean where the virus recently emerged, however, cases were also identified in travellers to the Asia – Pacific region where outbreaks are also occurring. Approximately 20 % of the cases were viremic indicating the possibility of local transmission if primary mosquito vectors become established in Canada. Given the continuing expansion of Chikungunya throughout the Americas and Asia a heightened awareness of Chikungunya among clinicians and the public in Canada and other countries is key. Ongoing communications regarding preventative measures when travelling to endemic areas is required to decrease risk of exposure to this emerging mosquito-borne pathogen.

741

DEVELOPMENT OF A QUANTITATIVE, REAL-TIME REVERSE-TRANSCRIPTASE PCR FOR O'NYONG-NYONG VIRUS AND ABSENCE OF VIRUS DETECTION AMONG FEBRILE KENYAN CHILDREN

Jesse J. Waggoner[1], Claire J. Heath[1], Alisha Mohamed-Hadley[1], Julie Brichard[1], Lark L. Coffey[2], A. Desiree LaBeaud[1], Benjamin A. Pinsky[1]

[1]Stanford University, Palo Alto, CA, United States, [2]University of California Davis, Davis, CA, United States

O'nyong-nyong virus (ONNV) is a unique alphavirus as it is transmitted by ***Anopheles*** mosquitoes. ONNV has been detected in two large outbreaks centered in Uganda, and in a recent serological study, high rates of ONNV and chikungunya virus (CHIKV) transmission were detected in villages of coastal Kenya. However, little is known about intra-epidemic ONNV transmission or its contribution to acute febrile illnesses in this region. The purpose of this study was to develop a real-time reverse transcriptase PCR (rRT-PCR) for the detection and quantitation of ONNV and to use this assay to screen acute-phase serum samples from febrile Kenyan children. For assay design, we aligned the complete genomes of available ONNV stains, including one strain of Igbo Ora, in the NCBI Nucleotide database. Highly conserved regions of the non-structural protein 1 gene were selected for primer and probe design. Primer and probe concentrations were optimized using synthesized ssDNA containing the ONNV target, and performance was confirmed with extracted genomic RNA. The assay had a linear range from 8.0 to 2.0 log10 copies/µL with a lower limit of 95% detection of 22.4 copies/µL. Performance was similar when run with only ONNV primers and probe or as an ONNV-CHIKV multiplex. The ONNV assay showed no signal when tested using genomic RNA from dengue, chikungunya, or West Nile viruses. We then randomly selected serum samples from 200 children who were enrolled in an ongoing, acute febrile illness surveillance study in coastal and western Kenya. Patients presented within the first 3 days of fever. No patients had detectable ONNV or CHIKV RNA. Sixty-five patients (32.5%) had malaria by PCR, indicating exposure to ***Anopheles*** mosquitoes. Nucleic acid extraction and the absence of PCR inhibitors were confirmed for all samples in a separate reaction for RNase P. In conclusion, we developed a new rRT-PCR for the detection and quantitation of ONNV. Among 200 febrile Kenyan children, who presented during a non-outbreak period, no cases of acute ONNV infection were identified.

ASIAN GENOTYPE DETECTED IN IMPORTED CHIKUNGUNYA CASES IN ARGENTINA, 2014-2015: A CHALLENGE FOR LABORATORY SURVEILLANCE

Victoria C. Luppo, Cintia Fabbri, Silvana Levis, Delia Enria, Maria Alejandra Morales

Instituto Nacional de Enfermedades Virales Humanas, INEVH, Pergamino, Argentina

Chikungunya virus (CHIKV) is a mosquito-borne pathogen that was endemic in Africa and south Asia until 2005 and 2006, when the virus spread into the Indian Ocean islands, Europa and Asia. In 2013, it emerged

in America as an important public health problem. All the pre-requisites for autochthonous activity of CHIKV are present in Argentina. The objective of this work is present the virological, serological and molecular studies for CHIKV detection in Argentina, during 2014 -2015. A total of 460 patients with signs and symptoms were notified. Acute sera samples were tested using qRT-PCR for CHIKV (nsp1 Asian genotype) and nRT-PCR (degenerate oligonucleotides, nsp4). Virus isolation in VERO C76 cells was attempted in a selection of samples. IgM antibodies were detected by ELISA according whit the algorithm recommended by PAHO. Serological confirmation and cross reactions with Venezuelan Equine Encephalitis virus, Eastern Equine Encephalitis virus, Western Equine Encephalitis virus, Mayaro virus and Una virus were performed by PRNT in VERO C76. CHIKV was detected in 62 patients, 97% (60/62) of them had recent travel to other countries (Dominican Republic, Venezuela, Colombia and Trinidad and Tobago). Cases were classified as confirmed (26, 42%) and probable (36, 58%). No cross-reactions were detected between the Alphaviruses evaluated by PRNT. Nucleotide sequencing of two fragments (155 bp nsp4 gene and 1200-bp E gene) in 3 viral strains isolated was performed and compared to other sequences available in Genebank. The sequences were aligned by the Clustal W method (BioEdit). Phylogenetic tree was performed by Neighbour Joining (MEGA 5) and Bayesian (Mr.Bayes) analysis. The topology of the tress were similar, the strains belong to Asian genotype currently circulating in other Latin American countries. Our results support the hypothesis that a single CHIKV strain introduction of Asian genotype on the Caribbean islands later spread to other American countries. The findings highlight the risk of introduction of this Alphaviruses in Argentina and the need for the health system prepared to give timely and efficient response to potential emergency.

743

EVOLUTION FOR CHIKUNGUNYA VIRUS IN *WOLBACHIA*-INFECTED MOSQUITOES

Matthew T. Aliota[1], Alexander Uribe Yepes[2], Ivan Dario Velez[2], Jorge E. Osorio[1]

[1]University of Wisconsin, Madison, WI, United States, [2]Universidad de Antioquia, Medellin, Colombia

New approaches to preventing chikungunya virus (CHIKV) are needed because current methods are limited to controlling mosquito populations, and they have not prevented the invasion of this virus into new locales. A promising candidate for arbovirus control and prevention relies on the introduction of the intracellular bacterium Wolbachia into ***Aedes aegypti*** mosquitoes. Wolbachia biocontrol has advanced from laboratory experiments demonstrating that Wolbachia reduces virus replication in mosquitoes to deploying and evaluating this strategy in six countries. This primarily has been proposed as a tool to control dengue virus (DENV) transmission; however, Wolbachia infections confer protection for Ae. aegypti against CHIKV. Although this approach holds much promise for limiting virus transmission, at present our understanding of the evolutionary consequences of Wolbachia on any arbovirus is limited; therefore, anticipating evolutionary changes of CHIKV-Wolbachia-mosquito interactions is an important component involved in validating the safety and viability of this approach as a biocontrol mechanism. Herein, we present data assessing the ability of CHIKV to adapt to Wolbachia-mediated suppression in mosquitoes. The choice of CHIKV is timely due to the massive CHIKV epidemic occurring in the Americas. To assess this, we have developed a tractable, laboratory model to begin to understand the selective pressures associated with Wolbachia-mosquito-CHIKV co-adaptation. Wolbachia-infected Ae. aegypti have been established as part of a complementary Eliminate Dengue Program project in Colombia, and preliminary data suggest that the wMel strain of Wolbachia in these mosquitoes blocks CHIKV infection and also reduces the transmission potential of these mosquitoes. As such, we are evaluating the specific CHIKV phenotypes that arise during alternate passage between Wolbachia-infected Ae. aegypti and mice. The demonstration that Wolbachia is effective against CHIKV and that the strategy will not be undermined by virus evolution will represent a significant new development in the fight against Ae. aegypti transmitted arboviruses.

744

EPIDEMIOLOGICAL AND VIROLOGICAL FEATURES FOR CHIKUNGUNYA VIRUS INFECTIONS AMONGST TRAVELERS RETURNING TO SPAIN, 2008-2014

Leticia Franco[1], Maria Dolores Fernandez[2], Mathieu Bangert[1], Jean Paul Carrera[3], Fernando de Ory[1], Anabel Negredo[1], Arantxa Potente[1], Lourdes Hernandez[1], Laura Herrero[1], Fatima Lasala[1], Maria Paz Sanchez[1], Hospitales del Sistema Nacional de Salud

[1]ISCIII, Majadahonda, Spain, [2]Institute Pasteur, Dakar, Senegal, [3]Gorgas Institute, Panama, Panama

Chikungunya fever used to be only endemic in some parts of Africa, Southeast Asia and in the Indian subcontinent. In late 2013, the first documented autochthonous transmission of chikungunya virus was reported in the Caribbean island of Saint Martin and since then the infection has spread quickly in countries and territories in the Caribbean region, North, Central and South America. With the ongoing outbreak in the Caribbean, chikungunya virus is increasingly becoming a European public health threat. Transmission of chikungunya virus to humans occurs through bites of ***Aedes aegypti*** and ***Ae. albopictus*** mosquitoes. In Europe, ***Ae. albopictus*** is established primarily around the Mediterranean basin and has been demonstrated its competency for virus transmission. This resulted in locally-acquired infections in Italy, and in France, as rported previously. In this study, we analyzed six years of imported chikungunya infections in Spain. During the study period (2008-2014), a total of 1311 suspected chikungunya infections were studied and more than half were in 2014 alone. From 2008 to 2013, 30 laboratory-confirmed (PCR, IgM/IgG) chikungunya infections were imported whereas in 2014 there were 195 confirmed cases. Majority of chikungunya cases with known travel history in the period 2008-2013 reported travel to Asia whereas in 2014 the main travel destination were the Americas (Dominican Republic, Haiti and Venezuela). Virus sequencing revealed that all samples from Americas felt into Asian genotype (Caribbean Clade), although Indian ocean genotype was detected in cases imported from Asia and Africa .Most of the positive samples in 2014 clustered around May and October, the activity period for the vector present in Spain. Chikungunya virus is an emerging public health threat to Spain because the conditions for autochthonous transmission are met: presence of competent vector and a large number of travelers returning from affected areas like the Caribbean and northern South America.

SCREENING TESTS DURING CHIKUNGUNYA OUTBREAK IN CARTAGENA DE INDIAS, COLOMBIA

Margarita Maria Ochoa, Yéssika De León, Benjamin Mendoza, Doris Gómez

Universidad de Cartagena, Cartagena, Colombia

Chikungunya virus (CHIKV) and Dengue virus (DENV) are mosquito-borne viruses. Both have similar clinical manifestations including hemorrhagic fever except for the arthralgia more related to CHIKV. Clinical differentiation between dengue and chikungunya from other causes of febrile illness is difficult to achieve during early stages of the illness. In Colombia, access to laboratory tests is limited and diagnosis may rely solely on clinical symptomatology. The aim of this study was to describe clinical manifestations of acute febrile illness and apply a screening test for CHIKV and DENV during an outbreak of Chikungunya fever in Colombia. For this study patients were enrolled during a Chikungunya outbreak in Colombia that began in august of 2014 and persists nowadays. Patients who lived in Cartagena, had a history of fever ≤7 days were eligible. A commercial screening test for CHIKV IgG/IgM Ab and DENV IgA/IgG/IgM and NS1 antigen was performed for each patient at the beginning (acute phase)

and up to 30 days after the onset of the illness (convalescent phase). A total of 38 patients were enrolled, most patients were between 18 and 45 years old (57,9%) and females (55,3%). The duration of the fever during the episode was between 3-7 days (51,7%). Arthralgia (97,4%), chills (81,6%), malaise (81,6%), headache (76,3%), pruritus (60,5%), rash (60,5%) and myalgia (55,3) were the most frequent. Of the total, 53% of the patients had IgM antibodies for CHIKV; 63% had IgG antibodies for DENV; 31,6% had both CHIKV (IgM) and DENV (IgG) Ab and 21% of the samples had both tests negative. No one had NS1 Ag positive. Acute febrile syndrome in tropical areas is always related to arboviral diseases. We found, even when most patients fulfilled the criteria for CHIKV fever, not all of them had a positive result on the rapid test, and a high percentage had IgG Ab for DENV. We are aware that screening test are not approved as diagnostic tools for these diseases, this is why we suggest confirmatory tests. In patients who tested positive for IgG Ab against dengue we concluded that this could be a sign from a past episode not related to the current one, more when nobody one tested positive for NS1 Ag.

746

MOSQUITO SALIVA ENHANCES EARLY ARBOVIRUS INFECTION WITH DIFFERENTIAL CLINICAL OUTCOMES

Alan M. Watson[1], LK Metthew Lam[1], Michael J. Conway[2], Tonya M. Colpitts[3], William B. Klimstra[1], Kate D. Ryman[1]

[1]University of Pittsburgh, Pittsburgh, PA, United States, [2]Central Michigan University, Mount Pleasant, MI, United States, [3]University of South Carolina, Columbia, SC, United States

Mosquito-borne viruses like those in the Togaviridae (Alphavirus genus) and Flaviviridae (Flavivirus genus) families are introduced into the vertebrate host along with saliva from the mosquito vector. Such viruses have evolved infection strategies that leverage salivary proteins to alter the early events in infection and may influence the progression of long-term disease. We have previously demonstrated in a murine model of dengue virus infection that ***Aedes aegypti*** salivary gland extract (SGE) results in an early enhancement of infection. We have now evaluated two additional viruses vectored by Ae. aegypti, yellow fever (YFV) and chikungunya (CHIKV) viruses, in order to understand the short- and long-term implications that SGE plays in pathogenesis and disease. Following infection in the presence of SGE, early YFV replication was as much as 40,000-fold greater in the draining lymph nodes and visceral tissues. In addition, ***in vivo*** imaging studies of CHIKV revealed an enhancement of infection at the site of subcutaneous inoculation and evidence of more rapid dissemination of virus distal to the site of inoculation. Enhanced replication of both viruses was sustained for at least four days following infection. Surprisingly, clinical disease in YFV-infected animals was similar regardless of SGE administration, although animals infected with YFV in the presence of SGE were statistically more likely to survive. Preliminary results of long-term CHIKV studies indicated that mice receiving SGE presented with a more severe musculoskeletal disease as measured by foot-pad swelling. Moreover, SGE may play a role in exacerbating chronic CHIKV disease. Our data suggest that diverse arboviruses may have independently evolved mechanisms to enhance and sustain early replication in the vertebrate host perhaps to increase the efficiency of infection or facilitate the acquisition of progeny by additional vectors. These studies emphasize the importance of developing animal models of mosquito-borne virus infection that consider the effect of the vector on pathogenesis.

747

VENEZUELAN EQUINE ENCEPHALITIS VIRUS INFECTION INDUCES OXIDATIVE STRESS AND LEADS TO ALTERATIONS IN MITOCHONDRIAL DYNAMICS

Moushimi Amaya, Forrest Keck, Aarthi Narayanan

George Mason University, Manassas, VA, United States

The multi-faceted organelles, mitochondria, have been shown to play roles in maintaining cellular metabolism, innate immunity and multiple signaling pathways. Composed of a population of organelles the mitochondria are actively and continuously dividing and elongating (mitochondrial dynamics) and undergoing controlled turnover. Recent studies have demonstrated that viruses have developed mechanisms to modulate the mitochondrial dynamics to facilitate viral replication. We have previously shown that Rift Valley Fever Virus induced oxidative stress activated transcription factors (p65 and p53), which in turn modulated cytokine secretion and apoptotic gene expression profiles leading to cell death. In this study we are investigating the new world alphavirus belonging to the Togaviridae family, Venezuelan Equine Encephalitis Virus (VEEV) where we hypothesize that VEEV infection induces oxidative stress which will interfere with mitochondrial dynamics thus impacting generic mitochondrial processes. Initial experiments using the MitoSOX red reagent indicated that VEEV induced the production of superoxide species in infected cells. Confocal microscopy analysis demonstrated that there is a differential "concentrating" mitochondrial phenotype observed in VEEV infected cells, which was not observed in uninfected cells. Ongoing studies entail defining a putative mechanism to the mitochondrial phenotype observed in VEEV infected cells. This work will aid in future investigations of the effect of mitochondrial dynamics in other alphaviruses and their role in pathogenesis, thus creating an avenue for therapeutic design as there are currently no approved vaccines or therapies to treat the disease.

748

EILAT VIRUS INDUCES BOTH HOMOLOGOUS AND HETEROLOGOUS INTERFERENCE

Farooq Nasar, Jesse Erasmus, Andrew D. Haddow, Robert B. Tesh, Scott C. Weaver

University of Texas Medical Branch, Galveston, TX, United States

Most alphaviruses are mosquito-borne and exhibit a broad host range, infecting many different vertebrates including birds, rodents, equids, humans, and nonhuman primates. Occasionally alphaviruses can spill over into the human population and cause clinical disease characterized by debilitating arthralgia or fatal encephalitis. Recently, we described a unique alphavirus, Eilat virus (EILV), that readily infects mosquito but not vertebrate cell lines. Here, we investigated the ability of EILV to induce homologous and heterologous interference ***in vitro*** and ***in vivo***. Prior infection of C7/10 (Aedes albopictus) cells with EILV reduced virus replication of superinfecting homologous and heterologous alphaviruses. Virus titers of heterologous viruses were reduced by 10-10,000 fold and replication kinetics were delayed by 12-48 hrs. Similar to ***in vitro*** infection, prior ***in vivo*** EILV infection of ***Aedes aegypti*** mosquitoes prevented dissemination of chikungunya virus for 3 days. This is the first evidence of alphavirus-induced heterologous interference in mosquitoes, suggesting that EILV could be developed to reduce and/or prevent alphavirus transmission.

749

EILAT VIRUS DISPLAYS A NARROW MOSQUITO VECTOR RANGE

Farooq Nasar, Andrew D. Haddow, Robert B. Tesh, Scott C. Weaver

University of Texas Medical Branch, Galveston, TX, United States

Most alphaviruses are arthropod-borne and utilize mosquitoes as vectors for transmission to susceptible vertebrate hosts. This ability to infect both mosquitoes and vertebrates is essential for maintenance of most alphaviruses in nature. A recently characterized alphavirus, Eilat virus (EILV), isolated from a pool of ***Anopheles coustani*** s.l. is unable to replicate in vertebrate cell lines. The EILV host range restriction occurs at both attachment/entry as well as genomic RNA replication levels. Here we investigated the mosquito vector range of EILV in species encompassing three genera that are responsible for maintenance of other alphaviruses in nature. Susceptibility studies were performed in four mosquito species: ***Aedes albopictus, A. aegypti, Anopheles gambiae,*** and ***Culex quinquefasciatus*** via intrathoracic and oral routes utilizing EILV and EILV expressing red fluorescent protein (-eRFP) clones. EILV-eRFP was injected at 10^7 PFU/mL to visualize replication in various mosquito organs at 7 days post-infection. Mosquitoes were also injected with EILV at 10^4-10^1 PFU/mosquito and virus replication was measured via plaque assays at day 7 post-infection. Lastly, mosquitoes were provided bloodmeals containing EILV-eRFP at doses of 10^9, 10^7, 10^5 PFU/mL, and infection and dissemination rates were determined at 14 days post-infection. All four species were susceptible via the intrathoracic route; however, replication was 10-100 fold less than typical for most alphaviruses, and infection was limited to midgut-associated muscle tissue and salivary glands. ***A. albopictus*** was refractory to oral infection, while ***A. gambiae*** and ***C. quinquefasciatus*** were susceptible only at 10^9 PFU/mL dose. In contrast, ***A. aegypti*** was susceptible at both 10^9 and 10^7 PFU/mL doses, with body infection rates of 78% and 63%, and dissemination rates of 26% and 8%, respectively. The exclusion of vertebrates in its maintenance cycle may have facilitated the adaptation of EILV to a single mosquito host. As a consequence, EILV displays a narrow vector range in mosquito species responsible for the maintenance of other alphaviruses in nature.

THE SEROPREVALENCE FOR DENGUE FEVER IN SOLOMON ISLANDS IN 2014

Jih-Jin Tsai[1], Tenneth Dalipanda[2], Silent Tovosia[3], Albino Bobogare[2], Hadi Namo[4], Ricky Eddie[5], Yu-Hsuan Wang[6], Ping-Chang Lin[1], Po-Chih Chen[1], Wen-Ter Lai[1]

[1]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, [2]Ministry of Health and Medical Services, Honiara, Solomon Islands, [3]Mission of Seven-day Adventists, Honiara, Solomon Islands, [4]Kilu'ufi Hospital, Malaita Province, Solomon Islands, [5]Gizo Hospital, Western Province, Solomon Islands, [6]Taiwan Health Center, Honiara, Solomon Islands

There was a large scale dengue outbreak in Solomon Islands in 2013. In order to fight against dengue fever, Taiwan government built up the first bio-safety level 2 (BSL-2) laboratory at National Referral Hospital in Honiara, Solomon Islands. This laboratory was designed by the Tropical Medicine Center of Kaohsiung Medical University Hospital. In 2014, we conducted the seroprevalence survey in Solomon Islands under the entrustment of Solomon Islands Government. Under IRB approval, we collected 1079 samples from the community in three different provinces (Guadalcanal Province, Western Province, Malaita Province) in Solomon Islands from September to November. We used dengue Capture IgG ELISA (Standard Diagnostics (SD), Korea) to detect the seroprevalence of dengue fever. The age of enrolled subjects ranged from 18~42 years old with median age of 38 years old. 72.4 % of them are female. The education level of them is the Elementary school (39.1%), Junior high school (26.3%), and Senior high school (22.5%). Only 3.4% of them recalled they ever got dengue fever. 62.2% of them had ever contracted malaria before. Different provinces had different seroprevalence rates of dengue fever. In Guadalcanal Province, we enrolled 306 subjects from different areas, and the mean seropositive rate is 46.4%. The distribution of the seropositive rate in Guadalcanal Province is as the following: Visale 62.5% (80/128), Burns Creek 34.6% (18/52), Betikama 30% (15/50), and Wanderer Bay 38.2% (29/76). In 2013, the dengue fever outbreak was chiefly located in Guadalcanal Province. The seroprevalence of dengue fever in Western Province is 34.1% (217/636) and 12.4% (17/137) in Malaita Province. In Western Province, two areas, Gizo (38.2%, 29/76) and Munda (38.7%, 184/476) are slightly higher than the other areas in seroprevalence. Malaita Province is the relatively lower seroprevalent in dengue fever and the residents might be more susceptible to the infection in the future. The dengue cases in Western Province might be under-estimated and should be more carefully diagnosed.

751

THE EFFECT FOR LAND COVER ON THE ABUNDANCE AND DISTRIBUTION FOR SYLVATIC DENGUE VIRUS VECTORS IN MALAYSIAN BORNEO

Katherine I. Young[1], Steve G. Widen[2], Thomas G. Wood[2], Jane Cardosa[3], David Perera[3], Nikos Vasilakis[2], Kathryn A. Hanley[1]

[1]New Mexico State University, Las Cruces, NM, United States, [2]University of Texas Medical Branch, Galveston, TX, United States, [3]Universiti of Malaysia Sarawak, Kuching, Malaysia

Mosquito-borne dengue virus has emerged from a sylvatic cycle, maintained in non-human primates and arboreal ***Aedes*** mosquitoes, to establish the human-***Aedes aegypti*** cycle that results in nearly 400 million infections annually. The sylvatic ancestors of human-endemic dengue virus continue to circulate in peninsular Malaysia and Borneo, with continual spillover into humans, sometimes causing severe disease. Systematic studies of sylvatic dengue virus in Southeast Asia, conducted in the 1960s-1970s, detected dengue virus in mosquitoes only once, in ***Aedes niveus sensu lato***. In recent decades, Malaysian Borneo has experienced intensive forest clearing, a potential risk factor for spillover of zoonotic viruses. How such clearing may affect sylvatic dengue spillover is unclear due to our incomplete understanding of dengue virus vectors in regard to identity and distribution. To bridge this knowledge gap, we conducted mosquito trapping in rural Sarawak, Borneo during two field seasons, 2013 and 2014, in three land cover types: homestead, agriculture and forest. Specifically, we tested the hypotheses that 1) ***Ae. niveus*** would be most abundant in forests compared to other land cover types, 2) In other land cover types, ***Ae. niveus*** would be most abundant at forest edges, and 3) compared to ***Ae. niveus***, ***Ae. albopictus***, a secondary vector of human-endemic dengue virus and a putative vector of sylvatic dengue virus, would be more evenly distributed throughout all land cover classes. Over 2,000 mosquitoes were sampled, identified morphologically and pooled by location, trap, day and species. Pooled samples were screened for arbovirus infection and used for molecular identification of mosquito species. Over 70% of the mosquitoes sampled in both field seasons were ***Aedes*** species; of these, 70% were ***Ae. albopictus*** in 2013 and 95% in 2014. Insect-specific viruses, including ***Euprosterna elaeasa*** virus, were detected in 7 ***Ae. albopictus*** pools, but sylvatic dengue virus was not detected in any pool. The complete analysis of the relative distributions of ***Aedes*** mosquitoes in this region will be presented.

752

MOLECULAR EPIDEMIOLOGY FOR DENGUE VIRUS IN THE LATIN AMERICAN REGION: A SYSTEMATIC REVIEW

José Ramos[1], Flavia Barreto dos Santos[2], Ruth Martinez[1], Joselito Araujo[3], **Elsa Sarti**[4]

[1]National Institute of Public Health, México City, Mexico, [2]Laboratório de Flavivirus, Instituto Oswaldo Cruz/Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [3]Laboratório de Flavivirus. Instituto Oswaldo Cruz/Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [4]Sanofi Pasteur, México City, Mexico

Dengue is the predominant arthropod-borne viral disease affecting humans. The four serotypes of Dengue virus are antigenically and genetically distinct. The basis of DENV genetic diversity is still under research, but it seems that human and vector infections impose different selective pressures, moreover, epidemiological and enviromental conditions could affect the population structure of the DENV in a particular setting. This study was developed to describe the molecular epidemiological trends of Dengue virus and knowledge generated in specific molecular topics in Latin America and Caribbean islands from 2000 to November 2013. A systematic literature review of molecular epidemiology was conducted. 391 sources were identified, from those, 51 were included as relevant citations. Hyperendemicity arising from circulation of different serotypes in a region may be a factor in the association between dengue infection and severity of disease.Intra-serotype antigenic variation and the resulting differential generation of protective antibodies and immune responses are postulated as one of the reasons for high epidemiological impact of certain DENV serotypes. Distinct lineages with different dynamics were identified in each of the countries and coexistence, extinction and replacement of lineages occurred over the review period, and changes occurred have resulted in substantial genetic diversity with emergence of endemic and epidemic strains in different parts of the region. The extinction of earlier strains and appearance of new epidemic strains suggests genetic bottleneck as a cause of regional replacement. Reasons for the re-emergence of dengue in the Americas: spread of different DENV serotypes in bordering countries; permanent migration flow of viremic travelers, and increase in vector infestation due to inconsistent vector-control strategies. DENV seem to take advantage of diverse mechanisms to generate genetic diversity via genetic variability and host travel, as well as exploiting the increasing density of human hosts and urbanization.

753

DENGUE VIRAL PERSISTENT INFECTION

Guey Chuen Oscar Perng

National Cheng Kung University, Tainan, Taiwan

Dengue has been recognized to be one of the most important vector-borne human viral diseases in recent years globally. Dynamic clinical presentations in dengue virus (DENV) infected patients, ranging from asymptomatic, mild dengue fever, and dengue hemorrhagic fever associated with dengue shock syndrome, have been registered. Recently, it has been reported that infectious DENV can be recovered from healthy blood donors and that asymptomatic human beings could be accounted for the spread of dengue. This line of evidence implies that persistent DENV infection may exist in the natural setting. We utilized fresh HBM to establish humanized model to investigate the persistent infection of DENV. DENV was administered to 8 weeks old humanized mice by IV injection with 10^4 PFU. Peripheral blood was obtained at multiple time points, with two week intervals. With a FACS panel to assay the cells of human origin along with the identification of the infected cell, combined with plaque assay and immunohistochemistry to locate the virus in organs. We showed that the percentage of human cells in circulation was on average at 35% and that viral titers were seen starting from the second week of the infection and reached a mean peak titer at 10^3 PFU/ml, with each peak lasting for about two weeks. The viral titers were fluctuated after the peak, but maintained at a detectable level (above 500 PFU/ml) for 3 months until the mouse died, suggesting that it could be maintained if mice health conditions sustained. FACS analysis indicated that the phenotypes of cells harvesting the dengue viral antigen were of the megakaryocytic lineage, $CD45^+CD41a^+CD61^+$. Autopsy on the DENV infected deceased mice revealed that DENV was present in multiple organs, including liver, spleen, bone marrow, and brain by plaque assay. The highest viral titer was observed in the brain and especially in the region of hippocampus. Results indicated that DENV could reside in the brain of infected humanized mice. The results suggest that persistent infection may exist in the natural life cycle of DENV and that those of the megakaryocytic lineage cells in asymptomatic individuals may become a DENV carrier.

754

SEQUENTIAL INFECTION WITH INFLUENZA AND DENGUE VIRUSES HINDERS IMMUNE CELL RECRUITMENT AND CAUSES LETHAL DISEASE

Michael Schmid[1], Karla Gonzalez[2], Sanjana Shah[1], José Peña[3], **Eva Harris**[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua, [3]Lawrence Livermore National Laboratory, Livermore, CA, United States

Both influenza and dengue are major health problems worldwide. In 2009, Nicaragua experienced a massive and atypical dengue epidemic, even though the dominant dengue virus serotype (DENV3) was the same as in 2008 and 2010. The only identifiable epidemiological difference in 2009 was the influenza A-H1N1 pandemic, which was prolonged, compared to seasonal influenza, and overlapped with the dengue epidemic. We hypothesized that sequential or co-infection of influenza H1N1 and DENV contributed to the atypical and potentially more severe dengue disease. We established a mouse model of dual infection with a Nicaraguan pandemic H1N1 influenza virus isolate and the virulent DENV2 strain D220. DENV suppresses the interferon response, replicates, and causes disease in humans but not wild-type mice; therefore, we used mice lacking the interferon-α/β receptor (***Ifnar***$^{-/-}$) that are susceptible to both DENV2 and influenza virus infection. Sequential infection with influenza virus followed two days later by DENV2 caused 90% mortality in ***Ifnar***$^{-/-}$ mice at virus doses that induce mild disease during infection with either virus alone. The DENV viral load was significantly increased in the lung, liver, and spleen of sequentially infected mice compared to mice infected with only one virus, while influenza viral load was similar. We analyzed the host RNA response using nCounter technology and observed dramatic changes in chemokine and cytokine mRNA expression levels that suggested differences in immune cell recruitment in the lungs. Flow cytometry revealed impaired recruitment of monocytes, neutrophils, NK cells and T cells to the spleen and lung of sequentially infected mice compared to mice infected with only one virus. We are currently manipulating recruitment of different subsets of immune cells to determine the cause of immunopathology in sequentially infected mice. These studies will inform the development of potential treatment and vaccine strategies in endemic areas where dengue and influenza viruses co-circulate.

755

VIRAL REPLICATION AND IMMUNOGENIC POTENTIAL DIFFERENCES BETWEEN TWO DENGUE 1 LINEAGES CO-CIRCULATING IN BRAZIL

Mauricio L. Nogueira[1], Tauyne M. Pinheiro[1], Danila Vedovello[1], Joice Matos M. Biselli-Périco[1], Aripuanã S. Watanabe[1], Mânlio T. Mota[1], Bárbara A. Chaves[2], Paulo F. Pimenta[2], Izabella C. Batista[2], Carlos E. Calzavara-Silva[2]

[1]Faculdade de Medicina, Sao Jose do Rio Preto, Brazil, [2]CpqRR - FIOCRUZ, Belo Horizonte, Brazil

Dengue virus comprises four distinct serotypes (DENV-1-4). Within the serotype 1, previous genetic studies demonstrated the existence of

different lineages grouped into five genotypes. Phylogenetic analysis of the E gene showed that two lineages of DENV-1 (L1 and L6) co-circulated in São José do Rio Preto, São Paulo state, Brazil at least, between 2010 and 2012. This study has compared biological properties of these two lineages. Five cell lines (C6/36, Aag-2, Vero E6, LLC-MK2 and HepG2) have been infected with two DENV-1 isolates representatives of each lineage, at a MOI of 0.1 for growth curves. Additionally, one hundred forty adult female mosquitoes from two populations (PPCampos and Dom Pedro) and C57BL/6 mice have been experimentally infected with the same isolates. Later, qPCR was used to detect these viruses in supernatant of cells and in body and head samples of mosquitoes. FACS was used to analyze mice spleen cells. In silico epitope prediction was performed to evaluate the binding of B and T cell receptors to epitopes of the E gene using bioinformatics tools. Analysis of the growth curves showed that L1 replicated at higher level comparably to L6 in all cell lines tested as well as in Ae. aegypti mosquitoes. L1 presented a viral cDNA copies number significantly higher than L6 in both mosquitoes populations and also exhibited statistically significant higher rates of IR, VC and DIR. IR varied from 92.5% to 100% (L1) and 37.5% to 73.33% (L6). VC ranged from 85.01% to 100% (L1) and 30% to 43.34% (L6). DIR oscillated from 91.9% to 100% (L1) and 59.1% to 80% (L6). L6 had less antigenic potential to B cells while L1 had more antigenic potential to T cells in silico. L6 seemed to suppress B cells activation while L1 was a T cell activator ***in vivo***. These two lineages showed differences in their biological properties. Despite the better growth rate, L1 may elicit a better immune response while L6 with a lower growth rate might evade better the immune system, leading to an equilibrium and co-circulation of these lineages. Further analyses should be conducted to better understand how these characteristics correlate with epidemiological findings in subsequent years.

ACCESSING HEALTH CARE IN VENEZUELA: A COMMUNITY BASED MIXED-METHOD SURVEY ON HEALTH CENTER ATTENDANCE FOR DENGUE AND FEVER

Jelte Elsinga[1], Maria F. Vincenti[1], Erley Lizarazo[1], Luzlexis Arias[2], Masja Schmidt[1], Adriana Tami[1]

[1]Department of Medical Microbiology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]Instituto de Investigaciones Biomédicas, Universidad de Carabobo, Maracay, Bolivarian Republic of Venezuela

Dengue is a major public health problem in Venezuela. Timely health centre (HC) attendance is crucial in reducing mortality and severity of dengue. The health care system in Venezuela comprises a public and a private sector. The public system includes the traditional primary/secondary (Ambulatorios), and tertiary level HCs (Hospitals) and is usually free of charge. To improve limited access to care for the poorer, a parallel public health care system ("Mission Barrio Adentro") was set up in 2003. We assessed the intended HC attendance in the case of fever and suspected dengue in an urban area of high dengue transmission. Between September 2013 and February 2014 a cross-sectional household survey was performed in Maracay, Venezuela. Intended HC attendance and the perceived barriers in the case of fever and dengue of adults and parents/guardians of children were assessed. Data was collected through structured questionnaires from 105 individuals. We show that people would visit several different HCs if needed, and that the health preferences differed throughout the community. The most frequent first choice of health centre was an Ambulatorio, in the case of fever (n=82; 78.8%) and dengue (n=84; 80.8%). Several economic, ethnic, logistic, and quality aspects influenced the preference to access the HCs. Individuals preferred to first attend traditional HCs as they trusted the care given at these institutions, but a barrier was the lack of treatment supplies. Although the lack of supplies was mentioned to a lesser extent in the case of the parallel HCs, people reported not to trust the medical staff, nor the diagnosis and treatment given in these HCs. Furthermore, the private care, which was considered best, was mainly accessible for those with a health insurance. A higher education (fever/dengue: p=0.001/p=0.001) and a non-manual occupation (fever/dengue: p=0.007/p=0.016) were associated with more intended private HC attendance. Access to care in Venezuela is currently a complex situation where individuals need to juggle between the different available public and private HCs in order to obtain proper/timely care and medical supplies.

RELATIONSHIP BETWEEN MATRIX METALLOPROTEINASE EXPRESSION AND VIRULENCE FOR DENGUE VIRUS TYPE-2 INFECTED MOSQUITO AND MAMMALIAN CELLS

Pornsawan Leaungwutiwong[1], James F. Kelley[2], Aucha Sachair[3], Akanitt Jittmittraphap[3], Natthanej Luplertlop[3]

[1]Department of Microbiology and Immunology, Faculty of Tropical Medicine, Mahidol University and Northern Pacific Global Health Program, Bangkok, Thailand, [2]Department of Tropical Medicine, Medical Microbiology and Pharmacology, and Northern Pacific Global Health Program, John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI, United States, [3]Department of Microbiology and Immunology, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Dengue virus infection is mostly asymptotic or produces a mild self-limiting acute febrile illness, dengue fever, or life threatening severe illness, dengue hemorrhagic fever, which is associated with increased vascular permeability in part as the result of elevated matrix metalloproteinases (MMPs). Herein, we characterized MMP-2 and MMP-9 production in mosquito and mammalian cells after infection with three strains of dengue virus type-2 ranging in virulence: the prototype New Guinea C (NGC), 16681, and PDK53 vaccine strain to test variations in viral properties in vaccine candidates and confirm the production of MMP as a possible marker for virulence. A zymogram gelatinolytic activity assay was employed to assess MMP-2 and MMP-9 production. We demonstrated that dengue infected mosquito and mammalian cell lines had unique MMP-2 and MMP-9 production patters depending on the virulence of the dengue strain and time after infection. MMP levels were highest after infection with the known virulent strain D2-16681, followed by the prototype NGC strain in both cell lines. The amounts of MMP appeared to correspond with the relative amount of infectious virions produced later in infection. These findings may contribute to understanding dengue pathogenesis and selecting markers to assist in the development of dengue vaccines.

ANTIBIOTICS WITH UNEXPECTED TALENTS: EFFICACY AND MECHANISM FOR ACTION FOR FLUOROQUINOLONES AGAINST FLAVIVIRUSES

Stacey L. Scroggs[1], Christy A. Andrade[2], Ramesh Chinnasamy[1], Jeffrey B. Arterburn[1], Kathryn A. Hanley[1]

[1]New Mexico State University, Las Cruces, NM, United States, [2]Willamette University, Salem, OR, United States

Flaviviruses are positive-sense, single stranded RNA viruses, many are transmitted by arthropod vectors. Flaviviruses are responsible for some of the most significant vector-borne diseases worldwide, including dengue fever, yellow fever, West Nile encephalitis, and Japanese encephalitis. There are currently no antiviral drugs approved for the treatment of any flavivirus. Repurposing an FDA-approved drug as an antiflaviviral therapy would substantially reduce the time required to bring such a therapy to market. Several fluoroquinolones (FQ), which are broad-spectrum antibacterial drugs, are known to enhance RNA interference (RNAi), an intrinsic antiviral defense. We therefore hypothesized that these drugs might also show antiviral efficacy. To test this hypothesis, HEK-293 cells were inoculated with dengue virus serotype 4 (DENV-4) one virus per cell, after 2 hours the virus was removed and a FQ (enoxacin, ciprofloxacin, and difloxacin) was added using a serial dilution series. After 5 days, the cell supernatant was collected and titered on HEK-293 cells. The effective concentration 50 of these fluoroquinolones against DENV-4 in

HEK-293 cells was 7.6μM, 19.6μM, and 10.1μM, respectively, while the cytotoxic concentration 50 of these drugs was 545.2μM, 753.5μM, and 1513μM. To formally test whether inhibition of dengue virus by these fluoroquinolones is attributable to enhancement of RNAi, we investigated whether drug efficacy was lost when the RNAi pathway was knocked down. We first demonstrated, using Western blotting, that introduction of siRNAs targeting Argonaute 2 (Ago-2), a key effector in the RNAi pathway, depleted this protein in HEK-293 cells and persisted at least 6 days. We next demonstrated, using resazurin dye to assess cell viability, that Ago-2 siRNAs were not toxic to HEK-293 cells alone or in combination with enoxacin, ciprofloxacin, or difloxacin. Presently, we are testing the efficacy of each of the three fluoroquinolone drugs to inhibit DENV-4 replication in HEK-293 cells that have been pre-treated with either an anti-Ago-2 siRNA or a negative control siRNA; results of these experiments will be presented.

DEVELOPMENT OF A PAN-DENGUE DIAGNOSIS PLATFORM USING DIRECT SERUM SAMPLES

Zhuoyu Ni[1], Regina Heineman[1], Theron Gilliland, Jr.[2], Allison Dauner[2], Subhamoy Pal[2], Robert D. Hontz[3], Shuenn-Jue Wu[2]

[1]Agave BioSystems, Ithaca, NY, United States, [2]Naval Medical Research Center, Silver Spring, MD, United States, [3]U.S. Naval Medical Research Unit - 6, Lima, Peru

A single-tube reverse transcription loop-mediated isothermal amplification (RT-LAMP) assay has been developed to detect all four serotypes of dengue virus (DENV) in serum. Transmitted by the Aedes mosquito vector, DENV is the causative agent of dengue fever with symptoms ranging from mild to severe, accompanied by debilitating and potentially fatal outcomes. There is no available vaccine or specific treatment for dengue, and early diagnosis is critical to providing appropriate supportive therapy to manage the disease. Pan-dengue LAMP primer mixtures and reaction compositions were optimized to detect viral RNA of all four dengue serotypes with similar efficiency. The analytical limit of detection (LOD) is 10^4 DENV RNA copies /mL in virus spiked serum. Serum samples from patients with acute dengue infection have about 10^3-10^8 RNA copies /mL, making the RT-LAMP LOD relevant to capturing a majority of clinical cases. With a blind test of 60 clinical serum samples, our assay reached sensitivities and specificities of 96.7% using conventional RT-PCR as the benchmark. The RT-LAMP reaction was performed on a companion portable prototype device with an 8-reaction capacity, thermal control, real-time fluorescence monitoring, and an interactive user interface. The entire assay can be completed in less than 60 minutes with the readout of dengue-positive or dengue-negative results available immediately at the conclusion of the test. The protocol requires minimal sample input (2 μL) and no RNA extraction step, which is another advantage to this method. Our assay represents a major advance in dengue diagnosis, as it combines the specificity and sensitivity of nucleic acid-based technology with the point-of-care diagnostic format.

760

DENGUE-SPECIFIC ANTIBODY AND MEMORY B CELL RESPONSES FOLLOWING IMMUNIZATION WITH V180 TETRAVALENT RECOMBINANT SUBUNIT DENGUE VACCINE

Sheri A. Dubey[1], Jeffrey J. Sachs[2], Andrew J. Bett[1], Kalpit A. Vora[1], Beth-Ann G. Coller[3], Danilo R. Casimiro[1]

[1]Merck & Co., Inc., West Point, PA, United States, [2]Merck & Co., Inc., Rahway, NJ, United States, [3]Merck & Co., Inc., North Wales, PA, United States

A Dengue vaccine that induces long-lasting protection against all four types of Dengue virus (DENV) is needed to protect against Dengue-induced disease. Following vaccination or infection, Dengue-specific humoral immunity is typically measured by IgG binding ELISA and antibody-mediated virus neutralization assay. Measurable antibody titers often wane over time and may become undetectable in the peripheral blood without a booster vaccination or virus exposure. Antibody levels are dependent on the number of memory B cells, and therefore assessment of memory B cells may be a better measure of long term immunity. For this purpose, we developed a sensitive memory B cell ELISPOT assay for each of the four DENV and we employed this assay to evaluate serotype-specific memory B cell levels following vaccination with V180 Tetravalent Recombinant Subunit Dengue Vaccine. In the V180 Phase I vaccine study, flavivirus-naïve subjects received three doses of recombinant envelope glycoprotein (DEN-80E) for all 4 DENV types at three dose levels, with or without adjuvant. Serum was collected at multiple times, including prior to and 28 days after each vaccination, and evaluated for DENV-specific antibody binding and virus neutralization. Prior to first vaccination and at the primary immunogenicity timepoint (28 days post dose 3, PD3), PBMC were collected for memory B cell analysis in a cohort of 18 study subjects in the high dose vaccine group. Preliminary data shows that V180 formulated with ISCOMATRIX™ adjuvant was highly immunogenic as measured in the serum antibody assays and the memory B cell assay, with an apparent balanced response across all 4 DENV types. We will present a comparison of these immunogenicity assays to (1) assess correlation among the assays, (2) analyze balance of immunogenicity in light of possible cross-reactivity between serotypes, and (3) analyze the time course and longevity of the immune response measured by each assay across vaccine groups. Our analysis will explore the relationship between DENV-specific memory B cell levels at 28 days PD3 and long term immunity as measured by antibody titers at 6 and 12 months PD3.

761

HUMAN CD8 T CELL RESPONSES AGAINST THE FOUR DENV SEROTYPES ARE ASSOCIATED WITH DISTINCT PATTERNS FOR PROTEIN TARGETS

Alessandro Sette[1], Cristhiam Cerpas[2], Michael A. Angelo[3], Derek J. Bangs[3], John Sidney[3], Bjoern Peters[3], Esper G. Kallas[4], Lionel Gresh[5], Angel Balmaseda[2], Eva Harris[6], Daniela Weiskopf[3]

[1]La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States, [2]Centro Nacional de Diagnóstico y Referencia, Managua, Nicaragua, [3]La Jolla Institute for Allegy and Immunology, La Jolla, CA, United States, [4]University of São Paulo, Sao Paulo, Brazil, [5]Sustainable Sciences Institute, Managua, Nicaragua, [6]University of California Berkeley, Berkeley, CA, United States

All four dengue virus serotypes are now simultaneously circulating worldwide being responsible for 400 million human infections each year. Previous studies of CD8 T cell responses in HLA-transgenic mice and vaccinees demonstrated a different hierarchy in immunodominance of structural versus non-structural proteins as a function of the infecting serotype. This led to the hypothesis that there are intrinsic differences in the serotype-specific reactivity of CD8 T cell responses. We tested this hypothesis by analyzing serotype specific CD8 T cell reactivity in naturally infected human donors from Sri Lanka and Nicaragua using ***ex vivo*** IFNγ ELISPOT assays. Remarkably similar and clear serotype-specific patterns of immunodominance in both cohorts have been identified. Pooling of epitopes that accounted for 90% of the IFNγ response in both cohorts resulted in a global epitope pool. Its reactivity was confirmed in naturally infected donors from Brazil, demonstrating its global applicability. This study provides new insight in differential serotype-specific immunogenicity of DENV proteins. It further provides a potentially valuable tool for future investigations of CD8 T cell responses in the typically small sample volumes available from acute fever patients and/or children without requiring prior knowledge of either infecting DENV serotype or HLA type.

762

ANTIVIRAL SMALL INTERFERENCE RNA PROFILES FROM LOW AND HIGH VECTOR COMPETENT MOSQUITO LINES FROM MEXICO UPON DENV-2 INFECTION

Selene M. Garcia Luna, Nathan D. Grubaugh, Irma Sanchez-Vargas, Joseph R. Fauver, Gregory D. Ebel, William C. Black

Colorado State University, Fort Collins, CO, United States

The small interference RNA (siRNA) pathway is the major antiviral innate immune response in the DENV vector, ***Aedes aegypti***, and may control the outcome of transmission upon infection (i.e. vector competence). The aim of the work is to determine whether viral siRNA profiles from mosquitoes contribute to the vector competence phenotype. ***Aedes aegypti*** isofemale lines were derived from collections from the state of Veracruz, Mexico, and were assessed for vector competence by plaque assay and RT-qPCR. Three isofemale lines were chosen based on different vector competence phenotypes: isofemale line C/Z 9 does not have a midgut infection or midgut escape barrier (MIB and MEB, respectively) and has a high vector competence phenotype, C/Z 12 has a low vector competence phenotype due to a MEB, and C/Z 22 has a low vector competence phenotype due to a MIB. The isofemale lines were then orally infected with a low passaged Mexican DENV-2 strain, after 14 days post infection (dpi), midguts were dissected, and RNA from individual midguts were screened by RT-qPCR to determine infection status. 46, 48 and 17% of midguts were positive for DENV from the isofemale lines C/Z 9, C/Z 12, and C/Z 22, respectively. siRNA libraries were prepared from infected, exposed but uninfected, and unexposed midguts using the TruSeq small RNA library prep and were sequenced on the Illumina HiSeq platform. We expect to find similar antiviral siRNA profiles between the isofemale lines without a MIB (C/Z 9 and C/Z 12) and without a MEB (C/Z 9 and C/Z 22). This work will help us understand how the ***Aedes aegypti*** antiviral innate immune system contributes to the outcome of infection and DENV transmission.

763

ENHANCING ANTI-DENGUE VIRUS ANTIBODIES TARGETING THE FUSION LOOP DELAY AND UPREGULATE PRO-INFLAMMATORY CYTOKINE PRODUCTION BY FCΓR-BEARING CELLS *IN VITRO*

John S. Schieffelin, Lindsey Bazzone, James E. Robinson

Tulane University, New Orleans, LA, United States

Secondary dengue infection with a heterologous serotype can lead to severe disease characterized by vascular leakage. Antibody-dependent enhancement (ADE) occurs when pre-existing, cross-reactive antibodies enhance viral infectivity. This phenomenon may be responsible for severe disease during secondary infections. The ADE hypothesis has been expanded to include the idea that FcγR-mediated viral entry into host cells can result in suppression of the cellular antiviral response. FcγRIIA-bearing K562 cells were infected with DENV that had been pre-incubated in the presence or absence hMAbs at neutralizing or enhancing concentrations. Infection kinetics were determined over a 120 hour period by plaque assay and qRT-PCR. Cytokine profiles were determined by cytometric bead array (CBA) assay. DENV-specific cytokine production was determined by subtracting the amount of cytokine (pg/ml) produced by mock-infected cell culture supernatants from the amount of cytokine (pg/ml) produced by infected cell culture supernatants. With the exception of cells infected with DENV plus a neutralizing concentration of HmAb 1.6D, all groups exhibited similar infection kinetics with viral titers peaking within 48 hours post-infection. Cells infected under enhancing conditions had viral titers approximately 100-fold higher than those infected without HmAbs present. In addition, cells infected under enhancing conditions significantly greater viral replication as measured by genomic copies than those cells infected under non-enhancing conditions. When compared to K562 cells infected with DENV alone, cells infected under enhancing conditions exhibited delayed pro-inflammatory cytokine production. However, the peak production of these cytokines was greater relative to cells infected with DENV alone. Enhancing hMAbs lead to increased viral replication after dengue infection of FcγRIIA-bearing cells. In addition, hMAbs targeting the fusion loop delay but increase the production of pro-inflammatory cytokines.

764

DENGUE CHAT: AN INFORMATION AND COMMUNICATION TOOL TO PROMOTE COMMUNITY-BASED DENGUE VECTOR CONTROL

Josefina Coloma[1], Eva Harris[1], Harold Suazo-Laguna[2], James Holston[3]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley Berkeley, CA, United States, [2]Sustainable Sciences Institute, Managua, Nicaragua, [3]Department of Anthropology and Social Apps Lab, University of California Berkeley, Berkeley, CA, United States

Integrated vector control strategies that incorporate community-based interventions are currently considered a sustainable approach to try to curb the expansion of dengue. The best agents to eliminate potential and active mosquito breeding sites are the residents of communities affected by dengue. We report the development of Dengue Chat, an interactive cell phone and web platform that combines mobile technology, information, and evidence with game concepts to motivate community residents to report and eliminate mosquito breeding containers. Dengue Chat was developed with a capillary strategy of software production that involved young user-residents in Brazil, Mexico and Nicaragua in the researching, designing, and testing of the application. Dengue Chat crowd-sources the identification and mapping of breeding sites through photographic evidence, generating data that is returned as visual graphs and information to motivate the active management of dengue vector ***foci***. The elimination of the breeding containers is documented by a second photograph. The app and web interface are interactive, allowing residents to create their own profiles and exchange information regarding dengue in their neighborhoods. Dengue Chat also has an educational and social network component that relates to other relevant issues in the community. Players participate in teams and earn badges and points for their documented efforts in eliminating breeding sites. Dengue Chat is being piloted in 5 communities in Managua, Nicaragua, that are heavily affected by dengue and chikungunya. Baseline entomological surveys were carried out prior to implementation. The app is being deployed by teams of volunteer youth brigades under the supervision of a project facilitator and within the intrinsic community health leadership. Preliminary data demonstrates that Dengue Chat has high acceptability and is an effective communication and community engagement tool for dengue control. Results from the pilot studies are informing app re-design and providing direct feedback regarding the limitations and benefits of Dengue Chat, while potential scale-up is considered.

765

SEROSURVEY OF DENGUE, ZIKA AND OTHER MOSQUITO-BORNE VIRUSES IN FRENCH POLYNESIA

Maite Aubry[1], Anita Teissier[1], Claudine Roche[1], Sylviane Teururai[1], Sylvie Paulous[2], Philippe Desprès[2], Henri-pierre Mallet[3], Sébastien Merceron[4], Michael Huart[5], Sébastien Sicard[5], Xavier Deparis[5], Didier Musso[1], Van-Mai Cao-Lormeau[1]

[1]Institut Louis Malardé, Papeete, French Polynesia, [2]Institut Pasteur, Paris, France, [3]Direction de la Santé de la Polynésie française, Papeete, French Polynesia, [4]Institut de la Statistique de la Polynésie française, Papeete, French Polynesia, [5]Université Aix-Marseille, Marseille, France

Since the 40s, dengue virus (DENV) has been the only mosquito-borne virus actually considered as major public health concern in the Pacific

region and more particularly in French Polynesia (FP). In 2013, Zika virus (ZIKV) was detected in FP for the first time and caused the largest outbreak ever reported. In order to anticipate the possible burden of arthropod-borne viruses (arboviruses), we conducted a serosurvey intended to identify the viruses the French Polynesian population is mostly immunologically naïve for or has already been exposed to. During the first semester of 2014, serum samples were collected from 196 participants aged 7-86 years (median 41 years) living in the most inhabited islands of the five archipelagoes of FP, and from 476 school children aged 6-16 years (median 11 years) living on the main island, Tahiti. Serum samples were tested for the presence of specific IgGs against the four different DENV serotypes, ZIKV, Chikungunya virus (CHIKV), Japanese encephalitis virus (JEV), West Nile virus (WNV) and Ross River virus (RRV). Seropositivity rates found among residents and school children were respectively 88% and 50% for DENV-1, 51% and 0% for DENV-2, 67% and 15% for DENV-3, 61% and 15% for DENV-4, 50% and 66% for ZIKV, 3% and 1% for CHIKV, 10% and 1% for JEV, 8% and 3% for WNV, and 35% and 1% for RRV. The level and distribution by age of the seropositivity for the different DENV serotypes is overall consistent with epidemiological data. Most notably, the lower level of seropositivity for DENV-2 compared to the other 3 serotypes may be associated with a higher risk of re-emergence of this serotype in FP. At least half of the residents and children have ZIKV IgGs, showing that most people were immunized during the 2013 epidemic. The results also suggest that RRV may have circulated in FP although it has never been reported. The low level of immunization (10% or less) against CHIKV, WNV and JEV may be associated with a high risk of emergence of these viruses in FP, as confirmed by the occurrence of a large CHIKV outbreak that started in FP in October 2014.

766

LOW VECTOR COMPETENCE OF LOCAL *AEDES ALBOPICTUS* TOWARDS DENGUE VIRUS TYPE 1 STRAINS IN HAWAII

Estelle Martin[1], Shannon N. Bennett[2], Deon Canyon[1], Allison Imrie[3], **Vivek R. Nerurkar**[1]

[1]University of Hawaii, Honolulu, HI, United States, [2]California Academy of Sciences, San Francisco, CA, United States, [3]University of Western Australia, Nedlands, Australia

Dengue is the most important arthropod-borne viral infection of humans, with an estimated 350 million cases reported each year in tropical countries. Dengue virus (DENV) is transmitted primarily by ***Aedes aegypti*** and to a lesser extent by ***Ae. albopictus***, which is associated with small and mild outbreaks. Two different DENV-1 genotypes, I and IV, were introduced in Hawaii in 1943 and 2001, respectively. ***Ae. albopictus*** is the most abundant Aedes species in the Hawaiian Islands. Given its abundance, increased global travel and spread of the virus, the vectorial capacity of ***Ae. albopictus*** towards dengue virus has major epidemiologic significance. However, there is no scientific data on how effective local ***Ae. albopictus*** are at transmitting DENV strains. In this study we investigated the competency of ***Ae. albopictus*** in transmitting DENV-1 strains isolated in Hawaii. Two ***Ae. albopictus*** mosquito populations trapped in Central Oahu (CO) and Southern Oahu (SO) were fed infectious blood meals of DENV-1 from Maui and Oahu isolated in 2001, and DENV-1 from Oahu isolated during the 1943 DENV outbreak. A subset of exposed mosquitoes was examined for virus levels by organ (body, legs/wings, saliva) at day 7 and day 14 after infection, and infection, dissemination and transmission rates were assessed. High levels of infection and dissemination were observed for the two 2001 viral strains from Maui and Oahu, whereas moderate level of infection was observed for the Oahu 1943 strain with low level of dissemination showing a differential response according to the genotype. Overall, low level of transmission was found for all viral strains suggesting the presence of a salivary gland barrier. These results can explain the limited size of the 2001 DENV outbreak in Hawaii. Phylogenetic evidence suggests introduction of DENV-1 from French Polynesia where a large outbreak driven by the vector ***Ae. aegypti*** was occurring at the same time. Interestingly no difference in the DENV genome between the Hawaii and the Polynesian strains were observed suggesting that the mild and small outbreak in Hawaii is directly linked to the low vector competence of the secondary vector ***Ae. albopictus***.

767

COSTS OF DENGUE HOSPITALIZATION AND PUBLIC PREVENTION AND CONTROL ACTIVITIES IN URBAN SRI LANKA

Yesim Tozan[1], Neil Thalagala[2], Hasitha Tissera[3], Paba Palihawadana[4], Ananda Amarasinghe[4], Anuradha Ambagahawita[4], Annelies Wilder-Smith[5], Donald S. Shepard[6]

[1]New York University, Global Institute of Public Health, New York, NY, United States, [2]National Child Health Programme, Family Health Bureau, Ministry of Health, Colombo, Sri Lanka, [3]National Dengue Control Unit, Colombo, Sri Lanka, [4]Epidemiology Unit, Ministry of Health, Colombo, Sri Lanka, [5]Department of Public Health and Clinical Medicine, Epidemiology and Global Health, Umeå University, Umea, Sweden, [6]Brandeis University, The Heller School for Social Policy and Management, Waltham, MA, United States

Dengue has become a major public health problem in Sri Lanka; however, the economic impact of the disease has not been studied in this setting. This study assessed the costs of dengue prevention and control activities and the direct medical costs of dengue hospitalizations in the Colombo District, the most affected district with the highest dengue caseloads in the country. The study was conducted in the epidemic year of 2012. Using information from the official databases of governmental agencies in charge of the dengue prevention and control activities in each administrative unit, we calculated the total financial costs of these activities and the average cost per capita. The direct medical costs of hospitalized dengue cases in the public health sector were derived using operational budgets and a sample of bed head tickets of adult and pediatric patients available from six secondary level hospitals. In 2012, the total financial cost of dengue prevention and control activities in the Colombo District was about $998,000, or $0.43 per capita. The mean direct medical costs to the public health care system per case of hospitalized dengue fever (DF) and dengue haemoraggic fever (DHF) were $221 and $316 for paediatric partients, respectively, and $203 and $272 for adult patients, respectively. These preliminary results highlight the high economic burden of dengue to the public health sector in the Colombo district in Sri Lanka during an epidemic year and contribute to the sparse literature on the economic burden of dengue in affected countries. This research was funded by "DengueTools" of the 7th Framework Programme of the European Community.

768

DENGUE IN BANGLADESH: RESULTS FROM A NATIONWIDE SEROPREVALENCE STUDY

Kishor K. Paul[1], Henrik Salje[2], Shafiul Alam[1], Repon C. Paul[1], Mohammed Z. Rahman[1], Mahmudur Rahman[3], James D. Heffelfinger[4], Emily S. Gurley[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Institute of Epidemiology, Disease Control and Research, Dhaka, Bangladesh, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States

Dengue is endemic in Bangladesh; however, seroprevalence studies in the capital city of Dhaka and one rural area suggest that there is spatial variation in risk. There is limited data on individual- and community-level risk factors in Bangladesh and the epidemiology is poorly understood. To address this gap we conducted a nationwide seroprevalence study during August to December 2014. We randomly selected 70 communities and visited up to 15 randomly selected households within each community. All household residents were asked to provide a blood sample and socio-demographic information. Indirect PanBio IgG ELISAs were used to identify

past dengue infections. ELISA optical densities separated individuals into two distinct groups of persons with and without past dengue exposure. We used bivariate analysis to identify individual risk factors associated with past dengue infection. In total, 2,911 individuals participated in the study with a median age of 26 (range 0 - 90) years. Prevalence of IgG against dengue was 11% in individuals aged ≤10 years, which increased to 18% in individuals aged 11-20 years (p-value=0.002), then further increased to 30% in individuals aged 21-50 years (p-value≤0.001), and remained at 30% in individuals ≥51 years of age. Males were 1.3 (95% confidence interval [CI] 1.1-1.5) times more likely to have been infected than females. Dengue seropositivity was higher in urban areas compared to rural areas (43 vs 19%, risk ratio = 2.2, 95% CI 1.9-2.5). Twenty-five percent of all communities had seroprevalence <10% and 10% had seroprevalence of >50%. Adults were more likely to be previously infected than children, but there were no meaningful differences after age 21, suggesting that endemic transmission may be relatively new to Bangladesh. Urban residents appear to be at much higher risk than rural residents with some rural areas having little evidence of previous dengue transmission. Additional studies to understand community-level differences in vector habitat and human movement could help predict which populations are at highest risk for future dengue outbreaks.

769

PREDICTING POTENTIAL LINEAR B-CELL EPITOPES ON E GLYCOPROTEIN OF DENGUE VIRUS THROUGH IN-SILICO APPROACHES

Mahesha N. Nadugala, Pradeep D. Pushpakumara, Prasad H. Premaratne, Charitha L. Goonasekara

Institute for Combinatorial Advanced Research and Education, General Sir John Kotelawala Defence University and Faculty of Medicine, Ratmalana, Sri Lanka

B-cell epitopes on the E protein of Dengue virus (DENV),the major target of neutralizing antibodies (NAb) and vaccine development for DENV were predicted by in-silico approaches. These bioinformatics analyses are attractive as a first line of screening, in identifying epitopes for therapeutic and diagnostic purposes, featuring for their low cost, convenience etc.Three tools,BepiPred, Ellipro and SVMTrip were used and the results obtained were compared with each other followed by a concise verification against available biochemical-assay positive data. E protein sequences of 50 strains from each DENV serotype with temporal differences (1963-2011) and geographical variation were analyzed. Predictions yielded 23 epitopes (length 6-62 AA). BepiPred and Ellipro predictions showed a higher similarity while predictions of SVMTriP were slightly different. Many of the predicted epitopes, at least partially, overlaps with regions that have been shown to generate Abs or be recognized by natural Abs in other studies. Some epitopes were further found on regions that are important in host cell attachment. The epitopes, EP5 (145-174) and EP6 (165-182) positioned on domain I (DI) showed a higher serotypic conservancy (%) with very low overall conservancy (%), demonstrating a potential target as serotype specific diagnostic markers. EP3 (62-123) and EP4 (65-85) are included in the highly conserved bc loop (73-79) region of DII, which is known to give rise to NAbs. EP11 (279-298) locates in the DI/DII hinge region, which is the principle target of long-lived serotype-specific NAbs that develop in humans after natural DENV3 and DENV4 infections. EP13 (311-316) and EP14 (310-329) on the DIII partially includes the highly conserved peptide sequence (309-320) on AB loop of the DIII and EP19 (371-402) includes highly conserved 393-401 region. EP20 (416-435) in the stem region showed an overall conservancy of 75% with 95% serotypic conservancy. The predicted epitopes by the 3 tools demonstrated good agreement in the results. As such this research concludes that in-silco approach is a recommendable initial step to screen potential linear epitopes in proteins.

LONG HISTORY OF DENGUE TRANSMISSION, NEW GUINEA

Dagwin Luang Suarkia[1], Timo Ernst[2], Glenys Chidlow[3], Shannon Bennett[4], Michael Alpers[5], Ralph Garruto[6], David Smith[3], **Allison Imrie**[2]

[1]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [2]University of Western Australia, Perth, Australia, [3]Pathwest Laboratory Medicine WA, Perth, Australia, [4]California Academy of Sciences, San Francisco, CA, United States, [5]Curtin University, Perth, Australia, [6]Binghamton University, Binghamton, NY, United States

Dengue incidence has increased consistently in Southeast Asia and the Western Pacific in the past decades, and more than 70% of the global dengue burden is currently borne by people who live in this region. Despite presumed endemicity, little is known about the natural history of dengue in Papua New Guinea and there is no ongoing surveillance. We conducted seroprevalence assessments using serum samples collected from northern and southern coastal areas, offshore islands and the highland region of New Guinea between 1959-1963, and 2007-2010. DENV-specific neutralizing antibodies were demonstrated in sera from the northern coast of New Guinea and previous monotypic infection with all four serotypes was identified, however the majority of sera showed evidence of multiple previous DENV infections. No evidence of previous DENV infection was identified in the Asmat villages of the southern coast in sera collected in 1962; these same serum samples were previously found to be seronegative for measles IgG, supporting our finding that these isolated groups, in the absence of significant contact with outside forces, had not been exposed to DENV. DENV-3 was isolated from febrile patients in Madang in 2007-2008, and phylogenetic analysis of whole genome sequences showed these viruses clustered into a distinct group within genotype 1, a pattern suggestive of endemic DENV transmission. DENV-2 (Cosmopolitan genotype) was isolated from a febrile patient from Lihir Island in 2010. These findings confirm that multiple DENV serotypes have circulated along the northern coast of New Guinea for decades and support the notion that dengue has been a significant yet neglected endemic disease in PNG for more than 70 years. In spite of this apparent endemicity, severe dengue has not been reported in PNG. Dengue burden needs to be quantified and assessment of origin and distribution of DENV genotypes undertaken so as to develop an understanding of dengue transmission and virulence in PNG, particularly in the context of emerging dengue vaccines.

THE DENGUE VACCINE INITIATIVE PROJECT: THE PASSIVE FACILITY-BASED SURVEILLANCE AND SERO-PREVALENCE SURVEY FOR DENGUE IN CHILDREN AND ADULTS OF NHA TRANG CITY, KHANH HOA PROVINCE, VIETNAM

Sl-Ki Lim[1], Thi Hien Anh Nguyen[2], Jacqueline K. Lim[1], Kang Sung Lee[1], Jin Kyung Park[1], Bao Ngoc Luong[2], Phu Quoc Viet[2], Duc Anh Dang[2]

[1]International Vaccine Institute, Seoul, Republic of Korea, [2]National Institute of Hygiene and Epidemiology, Hanoi, Vietnam

Dengue is one of the fastest spreading vector-borne viral diseases in the world and it is major health problem in Vietnam. In 2010, Vietnam experienced dengue outbreak with almost 130,000 cases and 110 deaths. In order to comprehensively determine true burden of dengue infection, Dengue Vaccine Initiative (DVI) conducts the passive facility-based fever surveillance, with the sero-prevalence survey in Nha Trang city, Khanh Hoa province in Vietnam. Since the launch of the surveillance in August 2014, we have collected acute and convalescent blood samples from febrile patients between 1-55 years of age to test for dengue fever using IgM and IgG ELISA, followed by RT-PCR. For the sero-prevalence survey, we identified 4400 randomly selected residents between 1-55 years of age to follow over rainy season and collected paired blood samples to estimate sero-conversion rate. To follow the changes in their immunity

status, those samples that show rise in the IgG ELISA undergo PRNT. As of March 2015, 541 patients have been enrolled in the fever surveillance. Laboratory test results are available from 176 subjects and among them, 67 were confirmed with dengue by ELISA IgM/IgG. The preliminary results show that the mean age was significantly higher among the dengue cases compared to non-dengue cases (23.9 vs. 13.0 years, P<0.001). Among dengue cases, only 7.5% (n=5) and 1.5% (n=1) of subjects were clinically diagnosed with DF and DHF, respectively. Rash, fatigue/weakness, and headache were found to be more commonly shown among the dengue cases compared to the non-dengue cases. As for sero-survey, the first bleeding was conducted in September 2014 and the second bleeding is planned in April 2015. After paired sera are collected, laboratory tests will be performed. More information such as circulating serotypes, the age-specific incidence rates and sero-conversion rates will be available for presentation at the conference. The study will provide valuation information on the true burden of dengue in Nha Trang city and will be used as evidence for decision-making for future dengue vaccine introduction in Vietnam.

772

POTENTIAL GROUP AND SEROTYPE SPECIFIC B-CELL EPITOPES OF DENGUE NS1 PROTEIN AS IDENTIFIED BY A BIOINFORMATICS APPROACH

Pradeep D. Pushpakumara[1], Mahesha N. Nadugala[1], Prasad H. Premaratne[2], Charitha L. Goonasekara[2]

[1]Institute for Combinatorial Advanced Research and Education, General Sir John Kotelawala Defence University, Ratmalana, Sri Lanka, [2]Faculty of Medicine, General Sir John Kotelawala Defence University, Ratmalana, Sri Lanka, Ratmalana, Sri Lanka

Linear B-cell epitopes of NS1 protein from Dengue virus were predicted using a bioinformatics approach. The secreted form of Dengue NS1 in the bloodstream has been shown to stimulate a strong humoral response, therefore the utility of NS1 B-cell epitopes and antibodies against them as a diagnostic tool or for clinical management of the disease is of a current interest. Three B-cell epitope prediction tools, Ellipro, BepiPred and SVMTrip, were used to predict linear dengue NS1 epitopes and the predictions were evaluated by comparing the results among the three tools and with currently available data on immunogenic epitopes of NS1 as assayed by biochemical tests. Fifty sequences from each dengue serotype, representing a wide geographic area and a time span, were selected from NCBI gene bank. The sequences were aligned using MEGA6 software, and their conservation was evaluated using IEDB and Weblogo analysis tools. A total of 22 regions on the NS1 protein, ranging 6 to 21 amino acids in size, were predicted by the three prediction tools. The same regions were found to be predicted as epitopes by more than one tool, showing a good agreement in the results among the three tools. Further, many of the epitopes, at least partially, matched with regions, which have been previously identified to be immunogenic in other studies. The epitopes ^{72}NELNHILLENDMKFT^{86}, ^{102}MIRPQPMEYKY^{112} and ^{202}ESEKNET^{208} are highly conserved within each serotype but highly variable among the four serotypes. The results suggest a potential use of these epitopes as serotype specific diagnostic markers. Three epitopes, ^{155}EDYGFGIFT^{163}, ^{230}LWSNGVLESE^{239}, ^{261}TQTAGPWHLGKLELDFDLCE^{280} were more than 85% conserved among the four Dengue serotypes. Further, these epitopes were not conserved with other Flavivirus groups, West Nile Virus and Japanese Encephalitis Virus, demonstrating a potential role as group detection diagnostic markers for Dengue.

773

ESTIMATING DENGUE TRANSMISSION INTENSITY FROM INCIDENCE DATA IN MULTIPLE COUNTRIES

Natsuko Imai[1], Ilaria Dorigatti[1], Simon Cauchemez[2], Neil M. Ferguson[1]

[1]Imperial College London, London, United Kingdom, [2]Institut Pasteur, Paris, France

With an estimated 390 million annual infections worldwide, dengue is a global public health burden. Yet estimates of dengue transmission intensity remain ambiguous. Most primary dengue infections are asymptomatic, but secondary heterologous infection has been identified as a major risk factor for symptomatic and severe dengue. Therefore the majority of cases observed in hospitals or reported via surveillance systems are secondary infections. In many countries incidence data are the only type of data available. Although we hypothesise that seroprevalence data provide a more reliable estimate of the force of infection, in the absence of such data we propose a method of estimating dengue transmission intensity from age-stratified incidence data. We estimated the force of infection by fitting a catalytic model to data from 12 countries using a Metropolis-Hasting Markov Chain Monte Carlo algorithm. We also estimated the relative probability of detecting primary to quaternary infections and found that secondary infections consistently had the highest probability of detection. Basic reproduction numbers ranged between 1 and 6 which was consistent with results we obtained previously from seroprevalence surveys. We additionally estimated age-dependent reporting rates and the age threshold at which reporting rates changed. As expected this varied widely across surveys but reporting rates were consistently higher in the younger age-groups. The baseline reporting rates are indicative of the quality of the surveillance system. However there can be substantial bias in an epidemic year when not all suspected dengue cases will be laboratory confirmed and clinicians may diagnose any febrile illness as suspected dengue fever. Comparison of estimates derived from different data types will help to quantify the importance of silent transmission on dengue burden and identify areas where clinical dengue surveillance may require improvement.

774

DENGUE SEROPREVALENCE IN TWELVE COUNTRIES: BASELINE SEROPOSITIVITY RATES FROM PREVIOUSLY CONDUCTED CLINICAL TRIALS IN ASIA AND LATIN AMERICA

R. Leon Ochiai[1], Maïna L'Azou[1], Remi Forrat[1], Alain Bouckenooghe[2], Fernando Noriega[3], Melanie Saville[1]

[1]Sanofi Pasteur, Lyon, France, [2]Sanofi Pasteur, Singapore, Singapore, [3]Sanofi Pasteur, Swiftwater, PA, United States

Dengue has been spreading rapidly around the globe and now considered endemic in most of the tropics and subtropics. The clinical manifestations of dengue disease are very wide, ranging from asymptomatic cases to fatal outcomes. The information on endemicity often comes from passive reporting and the true burden is relatively unknown. Age-specific seroprevalence data can, therefore, be useful to better understand dengue transmission and to address the extent of dengue burden; however, measuring seroprevalence against dengue is not a common practice in most countries and data are lacking. To obtain a better view of the magnitude of the problem in dengue endemic countries, we have revisited 10 Sanofi Pasteur CYD-TDV dengue vaccine clinical studies where blood was taken from the study subjects to assess the immunogenicity. Using their baseline seropositivity data, prior to receiving the candidate vaccine or placebo, with standardized age grouping (2-5 years, 6-11 years, 12-17 years, and 18-45 years), we evaluated the proportion of subjects being seropositive against dengue IgG or based on PRNT. A total of 3,701 subjects were included in the analysis from 12 dengue endemic countries in Asia and Latin America, where the bleeding had taken place between 2006 and 2011. In most countries where the studies were conducted, approximately 50% or more subjects were seropositive by the age of 5

years. Low seropositivity rate (approximately 20% seropositive by the age of 12 years) was observed from Singapore despite its location in the heart of South East Asia. On the other hand, high seropositivity rates were observed from Indonesia, Philippines, Colombia, and Honduras, where 90% or more subjects were seropositive by the age of 12 years. This highlights the extent of the burden of dengue in children and complements the passive reporting data in these countries. Knowledge of current age-specific seroprevalence rates is important in order to establish public health priorities and to adopt appropriate vaccination policies.

775

COMPARISON OF CLINICAL DIAGNOSIS AND SYMPTOM CLUSTERS FOR DIFFERENTIATING DENGUE FROM OTHER ACUTE FEBRILE ILLNESSES IN IQUITOS, PERU

Sandra Olkowski[1], Stalin Vilcarromero[2], Julia S. Ampuero[1], Carlos Alvarez[3], Robert D. Hontz[4], Amy C. Morrison[1], Thomas W. Scott[1]

[1]University of California Davis, Davis, CA, United States, [2]U.S. Naval Medical Research Unit - 6, Iquitos, Peru, [3]Loreto Regional Health Directorate, Epidemiology Unit, Iquitos, Peru, [4]U.S. Naval Medical Research Unit - 6, Lima, Peru

Non-specific acute febrile illness (AFI) is a common clinical presentation of dengue virus (DENV) infection. This is a challenge for clinical management and timely identification of surges in disease incidence, especially in places where laboratory confirmation of DENV infection is either delayed or absent. We analyzed four years of hospital and clinic data from Iquitos, Peru, to quantify the utility of symptom clusters (such as might be used for syndromic surveillance) compared to clinical diagnosis for differentiating dengue from other AFI. Case data were restricted to patients ≥5 years old, in the first five days of fever, with PCR test results. PCR-confirmed cases were restricted to DENV-2. We used common factor analysis (CFA) to identify symptom clusters in DENV+ patients, and test their utility for differentiating DENV+ (n=1803) from DENV- (n=3939) illness. Presumptive clinical diagnosis was available for a subset of cases (95 DENV+ and 363 DENV-). Symptom cluster diagnosis and clinical diagnosis were evaluated using receiver operating characteristic area under the curve (AUC), where 1.0 is a perfect classification, 0 is the inverse of a perfect classification, and .50 is an arbitrary classification. Three distinct symptom clusters identified by CFA in DENV+ cases corresponded to 'body', 'respiratory', and 'gastrointestinal' symptoms. When these clusters were evaluated individually and in combination, the AUC ranged from 0.47 to 0.54, indicating that the discriminatory power was close to a random guess. Similarly, the AUC for clinical diagnosis was 0.46. Our results emphasize the difficulty of identifying dengue cases based on clinical presentation alone, and highlight the potential for reliable point-of-care diagnostics to improve clinical management, as well as the timeliness and accuracy of epidemiological data.

776

DENGUE VACCINE INITIATIVE: PASSIVE FEVER SURVEILLANCE AND SEROLOGICAL SURVEY FOR DENGUE IN OUAGADOUGOU, BURKINA FASO

Mabel Carabali[1], Jacqueline K. Lim[1], Ahmed Barro[2], Aline Ouoba[3], Marie Munoz[4], Bertrand Campaore[3], Kang Sung Lee[1], Jung Seok Lee[1], Emmanuel Bonnet[5], Valéry Ridde[4], Yaro Seydou[3]

[1]International Vaccine Institute, Seoul, Republic of Korea, [2]AGIR, Ouagadougou, Burkina Faso, [3]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [4]Montreal School of Public Health (ESPUM), Montreal, QC, Canada, [5]Institut de Recherche pour le Développement, Paris, France

Since 2000, there had been periodic notifications of dengue cases in Burkina Faso. Dengue presence has been confirmed and an outbreak was declared in 2013. However, there is limited information on dengue incidence and serotype distribution. To determine the true burden of dengue, a comprehensive epidemiologic study including a passive facility-based surveillance and a serological survey was launched in December, 2014, in Ouagadougou, Burkina Faso. For the fever surveillance, people between 1-55 years of age seeking health care in six health care centers (CSPS) of Ouagadougou, with current fever or history of fever (≤7 days) and without confirmed Malaria were evaluated for dengue infection. Two samples were taken from each patient, an acute sample during the first visit and a convalescent sample during the second visit, with an interval of 10-21 days. All subjects were tested using dengue rapid test (NS1/IGM/IgG) and IgM/IgG Capture ELISA. Those with positive results on any of thetests are further tested with RT-PCR. For the serosurvey, 3000 randomly selected residents of Ouagadougou between 1- 55 years of age were bled over an interval of six months and tested with IgG Indirect ELISA to calculate sero prevalence and subsequently the sero-conversion rate of the catchment population. Sero-converted samples will be tested using PRNT. So far, we have recruited 72 subjects from January to March 2015. The mean age is 23.12 years and 39 (68%) were female. From the 72 samples with lab testing completed, 23 (31.9%) were found to be dengue positive by ELISA, from which 95.7% (n=22) were secondary infections. There will be more data from the surveillance available at the conference. Also, from dengue-confirmed cases that sought care at the facility, direct and indirect cost-of-illness will be estimated and presented at the conference as well. The first serological survey is planned in May 2015 and the second bleeding would be taken around November. Additional data from the serological survey will also be available at the conference.

777

THE EFFECT OF MOSQUITO LIFE STAGES ON THE INVASION DYNAMICS AND SPATIAL SPREAD OF *WOLBACHIA* IN *AEDES AEGYPTI*: IMPLICATIONS FOR DENGUE VECTOR CONTROL

Gemma L. Nedjati-Gilani, Neil M. Ferguson

Imperial College London, London, United Kingdom

With approximately half the global population at risk of dengue infection, control of its primary mosquito vector ***Aedes aegypti*** is vital. One proposed control method is the release of mosquitoes infected with Wolbachia, which increases mosquito mortality, thus reducing the likelihood that dengue infected mosquitoes survive the extrinsic incubation period and transmit the virus. However, the success of this strategy depends on whether Wolbachia can spread spatially through the mosquito population from a few localised release sites. Previous theoretical work has examined how the threshold frequency of Wolbachia required for local fixation depends on the fitness costs associated with Wolbachia infection (i.e. increased mortality, reduced fecundity) and the levels of cytoplasmic incompatibility and maternal transmission. Using a stochastic patch model that incorporates egg, larval and adult stages, we find that for releases of adult mosquitoes, the threshold frequency of Wolbachia-infected adults required to achieve fixation in a single patch is always higher than previously derived values, and that this threshold depends on the oviposition rate, development rates for eggs and larvae, and mortality rates of all three stages as well as the fitness costs associated with Wolbachia. When considering the speed of Wolbachia spread through an array of patches, the wave front moves across the population more slowly that expected if only the fitness costs of Wolbachia are taken into account when predicting the wave speed; in some cases where previous theoretical work has predicted spatial spread would occur, the wave actually contracts and the Wolbachia-infected mosquitoes become extinct.

778

TARGETED FULL GENOME AMPLIFICATION AND SEQUENCING OF DENGUE VIRUSES 1-4 IN SOUTH AMERICA

Cristhopher D. Cruz, Mariana Leguia

U.S. Naval Medical Research Unit - 6, Callao, Peru

Next-generation sequencing of dengue viruses (DENVs) is a powerful tool for dengue epidemiological surveillance around the world. Protocols using targeted approaches to selectively amplify complete DENV-1-4 genomes have been described. However, these published workflows

use primer sets that were specifically developed to detect DENV strains circulating in Asia. DENVs in South America differ from those in Asia. Thus, existing workflows for full genome amplification of DENVs are often inadequately suited to detect South American strains. There is one report of optimized work flows for DENV-2 in Brazil, but nothing for serotypes 1, 3, or 4, which also circulate in the area. Here, we report optimized workflows for full genome amplification of all four serotypes of DENVs in South America. Based on alignments of complete genome sequences available through GenBank, we have modified and expanded previously published sets of primers to generate complete genomes from DENVs 1-4. Following re-design of the primer sequences, cycling conditions were optimized using DENV-positive serum samples collected in Bolivia, Ecuador, Paraguay, Peru and Venezuela since the early 2000s. Full genome coverage in 5 overlapping segments was always possible from DENV-positive serum samples with CT values of ≤ 26 (as determined by McAvin RT-PCR). Samples with CT values higher than 26 required amplification of larger number of overlapping segments of smaller size in order to obtain full genome coverage. A handful of samples with CT values higher than 29 failed to generate complete genomes. The methods described here are sequencing platform-independent, hence, they can be used for next generation sequencing of DENVs circulating in South America using any next-generation sequencing approach. These optimized methods should facilitate both epidemiological surveillance and evolution studies of DENVs in Latin America.

DENGUE VACCINE INITIATIVE PROJECT: THE SERO-PREVALENCE SURVEY AND THE PASSIVE SURVEILLANCE FOR DENGUE IN BANG PHAE, RATCHABURI, THAILAND

Kriengsak Limkittikul[1], Jacqueline K. Lim[2], Chukiat Sirivichayakul[1], Kang Sung Lee[2], Jung Seok Lee[2], Sl-Ki Lim[2], Saravudh Suvannadabba[3], Pornthep Chanthavanich[1]

[1]Department of Tropical Pediatrics, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]International Vaccine Institute, Seoul, Republic of Korea, [3]Department of Disease Control, Ministry of Public Health, Bangkok, Thailand

Dengue fever is a major public health problem in Thailand. With so much awareness and documented high burden, Thailand is likely to be an early adopter of dengue vaccines. In preparation for the upcoming dengue vaccine introduction, the Dengue Vaccine Initiative (DVI) is conducting the passive facility-based fever surveillance and sero-prevalence survey to accurately document dengue disease burden in both adults and children in Bang Phae district of Ratchaburi province in Thailand. The data will provide essential evidence for decision-making for vaccine introduction. The population in the study area is approximately 50,000. In the fever surveillance, eligible febrile patients between 1-55 years-of-age were enrolled. We collected acute and convalescent blood samples to test for dengue infection using IgM/IgG ELISA NS-1 rapid test and RT-PCR. The sero-prevalence survey is conducted on a sample of 2000 randomly selected residents to determine the burden of inapparent dengue. With 6 months interval, the paired sera collected are tested with IgG ELISA and PRNT to assess age-specific sero-conversion rate. Starting October 2011, the surveillance was launched in Bang Phae Community Hospital (BPCH). Thus far, 759 patients were enrolled and 91 subjects were found to be dengue-positive. Most of the patients (n=82) were diagnosed with dengue fever and, among 88 samples that underwent PCR, 82% showed secondary infection (n=72). DENV-2 was the most common serotype. In sero-prevalence survey with 2012 subjects recruited in Bang Phae district, there were 1897 residents by the 4th bleeding among whom 76% of subjects were found to be IgG-positive. Over the study period, the sero-conversion rate was approximately 10% per year. PRNT has been performed for 70 subjects and the majority was from secondary infection (67%) with 57% of these showing homologous secondary infections. More PRNT data will be available for presentation at the conference. The data generated will provide essential evidence for policy-makers to make informed decision-making for dengue vaccine introduction in Thailand.

780

A SOCIAL-EPIDEMIOLOGICAL STUDY TO UNDERSTAND DENGUE TRANSMISSION IN DHAKA, BANGLADESH

Parnali Dhar Chowdhury[1], C. Emdad Haque[1], Robbin Lindsay[2], Antonia Dibernardo[2], Shakhawat Hossain[3], Michael Drebot[2]

[1]University of Manitoba, Winnipeg, MB, Canada, [2]National Microbiology Laboratory, Winnipeg, MB, Canada, [3]University of Winnipeg, Winnipeg, MB, Canada

Considering the complexities involved with dengue transmission, I argued that understanding transmission requires encapsulating different disciplinary knowledge as well as non-academic knowledge. I have applied an Ecohealth approach to investigate dengue transmission dynamics in Dhaka, Bangladesh.Using the Delphi method, all 90 Wards of Dhaka were classified into 'high', 'medium', and 'low' Socio-Economic Status (SES) zones. A total of 1,200 households were randomly selected which represented the SES zones. During 2011-2012, these sampled households were repeatedly inspected for Aedes mosquitoes and to collect blood samples from residing members. This transdisciplinary investigation focused on: i) the rates of human exposure to dengue virus (DENV) by identifying individuals with IgM and IgG antibodies in the serosurvey samples; ii) abundance of dengue vector mosquitoes in the same households; iii) risk perception, and Knowledge, Attitude and Practice (KAP) regarding dengue among community members and experts.KAP survey results indicated that 93.7% of the community members knew that mosquitoes act as the primary vector of its transmission; 87.3% were unaware that Aedes mosquitoes prefer to lay their eggs in water containers. The entomological survey results showed that 26.7% of all surveyed houses in the city were infested with ***Aedes aegypti*** mosquitoes. The ornamental functional categories of containers were most significant containers in producing maximum number of Aedes pupae; this was found to be a significant risk factor for seroprevalence and seroconversion. The examination of IgG seroprevalence revealed that seropositivity was strongly correlated with increased age and number of indoor potted plants. The serosurvey findings showed that seroprevalence was high (79.9%), revealing that most dwellers had been exposed DENV. However, there was no significant association between Aedes positive houses and houses with seroconverted persons. A persistently high rate of dengue infection in Dhaka is being influenced by the lack of knowledge and awareness of the eco-bio-social factors.

781

GLOBAL ECONOMIC COST OF DENGUE ILLNESS

Donald S. Shepard[1], Yara Halasa[1], Eduardo A. Undurraga[1], Jeff Stanaway[2]

[1]Brandeis University, Waltham, MA, United States, [2]University of Washington, Seattle, WA, United States

To quantify the global cost of dengue illness, we systematically assembled and analyzed data on dengue burden across all 141 countries with active dengue transmission. We based numbers of cases on the Global Burden of Disease 2013. We used available empirical country-level data, and extrapolated to other countries based on GDP per capita or other indicators. For example, we derived the proportion of cases treated in other settings based on patterns for fever cases from Demographic and Health Surveys in dengue countries (n=71) and extrapolated to remaining countries based on region and share of births with skilled attendants. We estimated a global case-fatality rate from dengue deaths adjusted for reporting rates (available for 32 countries). We obtained direct and indirect costs from empirical studies in 14 countries and projected to remaining countries based on GDP per capita and treatment site using a log-log specification. We estimated that 58.4 million (95% certainty range 23.4-122.3) dengue cases occurred in 2013, with care distributed among the hospitalized (18%), ambulatory (42%), other (40%) sectors. The year's global direct and indirect cost of dengue illness in 2013 was $7.8 billion (range $3.5-$15.8b) in 2013 US dollars or $1.36 ($0.62-$2.77) per capita,

distributed among non-fatal hospitalized (42%), ambulatory (32%), other sectors (16%), and fatal cases (10%). Of these costs, $3.66b correspond to countries in Southeast Asia, East Asia and Oceania (n=33), $1.82b to Latin America and the Caribbean (n=43), $1.63b to South Asia (n=6), $0.33b to Sub-Saharan Africa (n=44), $0.09b to North Africa and the Middle East (n=6), $0.01b from Central and Eastern Europe and Central Asia (n=4), and $0.24b to high income countries (n=5). As we recognized care in other sectors and resource constraints in most health systems, our global estimate is substantially lower than the $39b of Selck et al (2014) estimated for 2010. Nevertheless, being more costly than rabies ($4.0b, Hampson, 2011), cholera ($3.1b, UPMC, 2010), and rotavirus gastroenteritis ($0.4b, Reingans, 2009), dengue imposes costs greater than several other major infectious diseases.

782

ISOLATION OF A HIGHLY DIVERGENT HANTAVIRUS FROM THE EUROPEAN MOLE (*TALPA EUROPAEA*) IN POLAND

Se Hun Gu[1], Janusz Hejduk[2], Janusz Markowski[2], Marcin Markowski[2], Paweł P. Liberski[3], Richard Yanagihara[1]

[1]University of Hawaii, Honolulu, HI, United States, [2]University of Łódź, Łódź, Poland, [3]Medical University of Łódź, Łódź, Poland

Persistent uncertainties in hantavirus taxonomy result from the paucity of full-length genomes and the dearth of hantavirus isolates. Although referred to as novel viruses, nearly all of the more than 30 hantaviruses (family ***Bunyaviridae***, genus ***Hantavirus***) identified recently in shrews and moles (order Eulipotyphla) and insectivorous bats (order Chiroptera) exist only as viral sequences. Because Nova virus (NVAV), harbored by the European mole (***Talpa europaea***), represents a highly divergent hantavirus lineage which is widespread across Europe, its isolation has been a high-priority. Lung tissue homogenates, prepared from four NVAV-infected European moles captured in Huta Dłutowska in central Poland in 2013, were inoculated onto Vero E6 cell monolayers, then subcultured at two- to four-week intervals, at which time cells and culture media were analyzed for viral RNA by RT-PCR. After several failed attempts, NVAV RNA was detected in cells and culture media at 34 days after inoculation with tissues from one of four European moles. Subsequently, NVAV RNA was detected following inoculation of fresh Vero E6 cells with culture supernatant, indicating virus replication, and typical bunyavirus-like particles, measuring 80–120 nm in diameter, were found by transmission electron microscopy. Hantavirus genomic sequences of the isolate, designated NVAV Te34, were identical to that amplified from the original lung tissue, and phylogenetic analysis of the full-length L, M and S segments, using maximum-likelihood and Bayesian methods, showed identical topologies, with NVAV clustering with the highly divergent bat-borne hantaviruses. Studies to determine the pathogenicity of the NVAV isolate in infant mice are underway. The long-awaited isolation of NVAV, as the first mole-borne hantavirus, will accelerate the acquisition of new knowledge about its evolutionary origin, phylogeography and pathogenicity. Because European moles often reside near human habitation, individuals with known exposures, who develop febrile illnesses or unusual clinical syndromes, are being investigated for evidence of NVAV infection and disease.

783

A PRACTICAL APPROACH FOR MOLECULAR EPIDEMIOLOGICAL STUDIES: ASSORTMENT OF VIRAL PATHOGENS IN SIMULATED ISOLATE ADMIXTURE

Wiriya Rutvisuttinunt[1], Piyawan Chinnawirotpisan[1], Butsaya Thaisomboonsuk[1], Kittinun Hussem[1], Sriluck Simasathien[2], Louis R. Macareo[1], In-Kyu Yoon[1], Chonticha Klungthong[1], Stefan Fernandez[1]

[1]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Phramongkutklao Hospital, Bangkok, Thailand

Deep sequencing by Next Generation Sequencing (NGS) technology has been adopted as a valuable tool in molecular epidemiology to obtain comprehensive and unbiased genetic information from rapidly evolving pathogens. We developed a simulated isolate admixture, established NGS laboratory approaches, and tested four bioinformatics algorithm pipelines to identify and semi-quantify the viral pathogens in a simulated fifteen-virus admixture that can be used in public-health laboratories to develop analytical proficiency. The admixture was designed to simulate pooled respiratory samples collected from large epidemiological studies or specimens with multiple viral co-infections. Host genome depletion procedures consisted of mechanical host removal, enzymatic host removal, and/or virus concentration steps using conventional molecular laboratory equipments. The efficiency of host genome depletion procedures was critically evaluated according to individual pathogens that were successfully identified from the admixture and the quantity of the sequence recovered from the admixture. The percentage of viral pathogens identified from the admixture was consistently greater than 80% regardless of the analytical pipeline. For the sequence recovery, approximately 3.4 fold (95% CI 2.1- 4.7) and 13.3 fold (95% CI 8.4-18.2) viral contigs were identified by meta-IDBA, a read assembler for ***de novo*** metagenomic data, and Trinity, a ***de novo*** assembler of transcriptomes from RNA-seq data, respectively, prior to pathogen identification by blast on GENBANK database using sufficient host genome depletion procedures compared to untreated conditions (p=0.058 and p=0.046, respectively). In addition, host depletion procedures produced an average of 4 fold greater depth of coverage (DOC) of sequence reads by alignment analysis against identified viral pathogens when compared with no treatment. The host depletion steps along with all four analytical algorithm pipelines produced highly accurate viral identification from an admixture that can be applied to laboratory-based surveillance.

IMMUNE RESPONSE TO IPV-OPV VACCINATION IN A BIRTH COHORT IN SOUTH AFRICA: THE MAL-ED STUDY

William K. Pan[1], Christel Hoest[2], Jessica Seidman[2], Emanuel Nyathi[3], Amidou Samie[3], Mustafa Mafuz[4], Stacey Knobler[5], Richard Guerrant[6], Michael Gottlieb[7], Mark Miller[5], Carl Mason[8], Pascal Obong Bessong[3]

[1]Duke University, Durham, NC, United States, [2]Fogarty International Center, Bethesda, MD, United States, [3]University of Venda, Thohoyandou, South Africa, [4]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [5]Fogarty International Center, Bethesda, MD, United States, [6]University of Virginia, Charlottesville, VA, United States, [7]National Institutes of Health, Bethesda, MD, United States, [8]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

In 2009, the South African National Vaccination Program introduced inactivated polio vaccine (IPV) in addition to oral polio vaccine (OPV) to ensure protection against polio. IPV is administered at 6, 10 and 14 weeks, and at 18 months, while OPV is given at birth and 6 weeks. Methods to study vaccine response have been described elsewhere (Hoest et.al 2014); briefly, the MAL-ED Study recruited a birth cohort in which vaccine history, monthly anthropometry, enteric infection, and breastfeeding practices were compared against polio antigens 1, 2, and 3 measured at 7 and 15 months. In South Africa, 250 children were enrolled, with 233 receiving

at least two OPV doses by their first blood draw (range 0-3 OPV doses) and 198 receiving at least three IPV doses (range 0-4 IPV doses). Analysis is restricted to children with at least 2 OPV doses and titers are converted to log2 scale. There is a significant decrease in titers from 7 to 15 months across all antigens: from 9.42 to 8.71 for antigen-1 (p=0.001); 9.84 to 9.38 for antigen-2 (p=0.006); and 9.80 to 9.07 for antigen-3 (p<0.0001). At 7M there is a significant positive trend between IPV doses and titers across all antigens with mean titers for 1, 2 or 3 IPV doses being 8.85, 9.18 and 9.56 for antigen-1; 9.21, 9.56 and 9.95 for antigen-2; and 9.18, 10.07 and 9.84 for antigen-3, respectively. At 15 months, this relationship is not significant and is negative for antigen-2: mean titers for 1, 2 or 3 IPV doses are 8.54, 8.50 and 8.73 for antigen-1; 9.58, 9.63and 9.32 for antigen-2; and 8.96, 9.38 and 9.00 for antigen-3, respectively. Compared with other MAL-ED sites, which only use OPV for immunization yet with varying schedules, South African children have lower average polio antigen-1 titers compared with Bangladesh, Brazil, Nepal, and Pakistan; higher antigen-2 titers vs. India, Pakistan and Tanzania; and significantly higher antigen-3 titers vs. all other sites. Variations by nutrition, enteric infection and breastfeeding practices will be discussed. Results provide insight into the merits of IPV use in conjunction with OPV for global polio immunization efforts.

REPORT OF CIRCULATING GENOTYPE C STRAINS AND ONE UNKNOWN DIVERGENT STRAIN OF COXSACKIEVIRUS A16 IN PERU

Gladys R. Carrion, Jose L. Huaman, Maria Silva, Julia S. Ampuero, Robert D. Hontz

U.S. Naval Medical Research Unit - 6, Lima, Peru

Coxsackievirus A16 (CVA16) is a major etiological agent of hand, foot, and mouth disease (HFMD), as well some neurological infections. In recent years, the number of studies investigating the etiology and molecular biology of this virus has increased. This work has focused primarily on CVA16 emergence from the Asian continent. However, information about CVA16 epidemiology in South America is limited. As part of our research investigating respiratory infections in Peru through passive, clinic-based surveillance methods, our laboratory reported the isolation of seven CVA16 isolates between 2005 and 2010 in children under six years of age. These isolates were collected from four ecological regions of Peru: coast, desert, rainforest, and highlands. Molecular epidemiological studies were carried out based on VP1 and/or VP4, and classified into three genotypes: A, B and C, and additionally subgenotypes B1-B2 and C1-C3. Using complete VP1 and VP4 gene sequences, we were able to molecularly characterize all seven of the CVA16 isolates. Six out of the seven isolates were genogroup C. To our knowledge, this study represents the first report of CVA16 molecular characterization in Peru, demonstrating that the primary circulating CVA16 strain in Peru is genotype C. However, we also found one divergent strain that did not cluster in any of the three genotypes reported so far. For future work we would like to complete a more complete phylogenetic analysis, including nucleotide analysis, with more strains from Peru and Latin America. This would allow for a more complete characterization of the possibility of an emergence of a new CVA16 genotype.

786

EPIDEMIOLOGY OF ARBOVIRUSES IN THE NORTHEAST AMAZON BASIN OF PERU 2010-2014

Crystyan Siles[1], Stalin Vilcarromero[1], Yojani Aguilar[2], Carlos Alvarez-Antonio[3], Amy C. Morrison[4], Robert D. Hontz[5], Carolina Guevara[5], Manuel Cespedes[6], Eric S. Halsey[5], Julia S. Ampuero[5]

[1]U.S. Naval Medical Research Unit - 6, Iquitos, Peru, [2]Universidad Cayetano Heredia, Yurimaguas, Peru, [3]Direccion Regional de Salud, Loreto, Peru, Iquitos, Peru, [4]U.S. Naval Medical Research Unit - 6, University of California, Davis, USA, Iquitos, Peru, [5]U.S. Naval Medical Research Unit - 6, Lima, Peru, [6]Instituto Nacional de Salud, Lima, Peru

Arthropod-borne virus (arbovirus) infections continue to be a leading cause of morbidity and mortality around the world. Arbovirus infections are the primary cause of acute undifferentiated febrile illness (AUFI) in urban areas; dengue virus alone accounts for one hundred million cases each year, including more than 20,000 fatalities. Despite the public health relevance, the geographic range, relative impact, and epidemiologic characteristics associated with arbovirus infections are poorly described in many regions of the world. Here we describe the epidemiological data for arbovirus infection in patients with AUFI enrolled in a clinic-based surveillance study in Iquitos and Yurimaguas--the two largest cities of the northern Peruvian Amazon. Between December 2010 and October 2014, 2,328 samples screened positive for viral infection (PCR or viral isolation or ELISA IgM 4-fold increase between acute and convalescent samples); of these, 2,201 (94.5%) were positive for dengue virus infection while 127 (5.5%) were positive for other arboviral infections. These included Venezuelan equine encephalitis virus (VEEV), Mayaro virus (MAYV), group C viruses, and Guaroa virus (GROV). VEEV was the most common among the other arboviruses found. During 2011-2014, small but separate outbreaks of MAYV, VEEV, and GROV were detected. Seventy five percent (75%) of these non-dengue arboviruses were detected in residents from peri-urban and rural areas. Although 16-30 year olds were the most commonly affected age group for both dengue and other arbovirus infections, the cases of MAYV, VEEV, and GROV infections were higher among 31-45 years olds (X2=15, p=0.005). All arboviral infections appeared to impact males and females equally. In an effort to prevent futures outbreaks it remains important to continue existing febrile surveillance in the Peruvian Amazon Region where these arboviruses are present.

787

A CRITIQUE OF EBOLA PREPAREDNESS AT A LEVEL ONE TRAUMA CENTER IN THE SOUTHEASTERN UNITED STATES

Tatiana R. Eversley[1], Daniel E. Mauck[1], David P. Adams[2]

[1]Armstrong State University, Savannah, GA, United States, [2]Armstrong State University/Medical College of Georgia, Savannah, GA, United States

The Ebola Virus was first discovered in Africa in 1976. Since that time, more than twenty outbreaks have been reported. We are currently in the middle of the worst Ebola epidemic on record. In the past year alone, a number of cases have been identified outside of Africa, specifically in Western Europe and North America. One of the most notable cases involved the death in Texas of an individual who reported a recent travel history to Liberia. Many Ebola patients will seek care at hospitals that may not be equipped properly for the high level of infection control that is required.To better prepare these facilities, the World Health Organization (WHO) and the Centers for Disease Control and Prevention (CDC) have published guidelines for caring for Ebola-infected cases. These guidelines are designed to maximize containment of the infection and the prevention of its spread. This presentation will examine the protocols for handling Ebola patients at a Level 1 trauma center located in a major metropolitan area in the Southeastern United States. More specifically, we will highlight protocols for Ebola treatment and containment and assess these guidelines against the WHO and the CDC recommendations.

788

THE BURDEN OF JAUNDICE IN PREGNANCY-RELATED MORTALITY IN RURAL AND URBAN KENYA AND POSSIBLE ROLE OF HEPATITIS E, 2002-2014

Sinead C. Isaacson[1], Emily Gurley[2], Frank Odhiambo[3], Samuel Oti[4], Leonard Cosmas[5], Joel Montgomery[5]

[1]Centers for Disease Control and Prevention and Association of Schools and Programs of Public Health, Atlanta, GA, United States, [2]International Center for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [3]KEMRI/Centers for Disease Control and Prevention Research and Public Health Collaboration and KEMRI Center for Global Health Research, Kisumu, Kenya, [4]African Population Health and Research Center, Nairobi, Kenya, [5]Global Disease Detection Division, Kenya Office of the US Centers for Disease Control and Prevention, Nairobi, Kenya

Maternal mortality is an area of severe health inequity, with 62% of global maternal deaths occurring in sub-Saharan Africa. Hepatitis E virus (HEV) infection also occurs disproportionately in impoverished settings and is the only cause of acute jaundice that increases maternal mortality. An outbreak in Dadaab refugee camp in 2012 indicated the presence of HEV in Kenya and infection has been consistently reported in nearby countries, but because of lack of surveillance, population-level mortality burden remains unknown. To estimate the proportion of pregnancy-related mortality associated with jaundice in Kenya we analyzed results of verbal autopsy (VA) interviews of family members, designed to determine the cause(s) of a recent death. We analyzed VA data from three sites: the Nairobi Urban Health and Demographic Surveillance System (HDSS) (data from 2003-2012) and a Population-Based Infectious Disease Surveillance site (2009-2014) in Nairobi's urban slums, and the rural Western Kenya HDSS (2002-2011). From all deaths among women of reproductive age, we identified those occurring during pregnancy or within 42 days of termination. We calculated the proportion associated with jaundice and pregnancy-related mortality ratios as the number of deaths per 100,000 live births. Of 5,601 verbal autopsies conducted for women of reproductive age we identified 400 pregnancy-related deaths. In the Western Kenya HDSS, 17% (45/263) were associated with jaundice and the pregnancy-related mortality ratio associated with jaundice was 93 per 100,000 live births. At both urban sites the proportion of pregnancy-related deaths associated with jaundice was 25% (16/65 and 2/8). The pregnancy-related mortality ratio associated with jaundice was 80 per 100,000 births in the Nairobi Urban HDSS. Therefore, jaundice is frequently associated with pregnancy-related deaths in both rural and urban Kenya, at similar proportions to those found in other HEV-endemic countries. HEV is preventable and an effective vaccine exists; laboratory-based studies to document the burden of HEV in Kenya and to verify use of VA data to estimate HEV mortality are warranted.

789

UNGROUPED AUSTRALIAN ARBOVIRUSES

Wenjun Liu[1], Paul Pickering[1], **John Aaskov**[2]

[1]Australian Army Malaria Institute, Brisbane, Australia, [2]Queensland University of Technology, Brisbane, Australia

In the early 1960s, the Rockefeller Foundation began support for a program of discovery of arboviruses in Australia which resulted in the identification of twenty-four viruses that were new to science and a number of arboviruses that had not been identified previously in Australia. When this program concluded with Dr Ralph Doherty's retirement as Director of the Queensland Institute of Medical Research, 50 agents recovered from mosquitoes, and several from a bird, which caused death or paralysis in new-born mice remained "unclassified". Viruses now have been propagated in cell culture from 23 of these. Nucleotide sequencing is in progress and has identified 8 strains of Sindbis (SINV), 6 of Murray Valley encephalitis (MVEV), 4 of Bovine viral diarrhoea (BVDV), 3 of Kunjin (KUNV) and one each of Kokobera (KOKV, multiple isolates from the tissues of a bird) and Ross River viruses (RRV). The BVDV isolates are believed to be contaminants from incompletely inactivated, locally collected, foetal calf serum rather than genuine isolates. There are no previous reports of the flavivirus KOKV being recovered from birds or of birds playing a role in its natural cycles of transmission. The nucleotide sequences of the isolates made from the various tissues of the bird were almost identical and were most closely related to a strain of KOKV recovered in Papua New Guinea in 1966 (MK 7979). Nucleotide sequencing of a further thirteen, previously unstudied, KOKV isolates from Australia, failed to identify KOKV similar to the bird isolates. The SINV isolates included a novel Australian lineage and the nsP3 genes of these viruses are being sequenced to identify lineage specific insertions, deletions and duplication events which have been described for almost all alphaviruses and which may distinguish Australian SINV lineages and/or be associated with lineage replacements. Phylogenetic analyses of the RRV and three KUNV are in progress. Nothing in the properties of the viruses, identified to date, explains why the serological methods of the day failed to identify them.

790

POTENTIAL TRIGGERS OF DENGUE HEMORRHAGIC FEVER IN PATIENTS FROM BANGKOK, THAILAND

James F. Kelley[1], Pornsawan Leaungwutiwong[2], Vivek R. Nerurkar[1], In-Kyu Yoon[3], Piyarat Suntarattiwong[4], Anon Srikiatkhachorn[5]

[1]Department of Tropical Medicine, Medical Microbiology and Pharmacology, and Northern Pacific Global Health Program, John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI, United States, [2]Department of Microbiology and Immunology, Faculty of Tropical Medicine, Mahidol University and Northern Pacific Global Health Program, Bangkok, Thailand, [3]Department of Virology, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [4]Infectious Diseases Unit, Department of Pediatrics, Queen Sirikit National Institute of Child Health, Bangkok, Thailand, [5]Department of Medicine, University of Massachusetts Medical School, Worcester, MA, United States and Northern Pacific Global Health Program, Bangkok, Thailand

Dengue fever (DF), a mosquito-borne disease, is among the most significant global health challenges. After dengue virus (DENV) infection, patients may progress to dengue hemorrhagic fever (DHF) within days. Evidence suggests that vascular endothelial cell dysfunction, coagulation disorders and increased plasma leakage occur rapidly after peak viremia and at defervescence, corresponding with elevated levels of circulating chemokines and cytokines. We seek to determine key triggers of DHF as part of an ongoing case-control study at the Queen Sirikit National Institute of Child Health in Bangkok Thailand. Our central hypothesis is that DHF cases demonstrate an elevated proportion of inflammatory (M1) compared to resting (M2) macrophages and demonstrate a unique cytokine expression profile early during infection that exacerbates endothelial cell permeability compared to DF controls. To date, we have enrolled eight hospitalized febrile patients, collecting both acute and convalescent blood samples. Aliquots of fresh blood were used to assess the frequency and vasoactive mediator expression profiles of CD14+ cells and subsets by flow cytometry. Preliminary results demonstrate an elevated M1 frequency and increased expression of TNF-alpha and VEGF in acute samples from DHF cases compared to controls. These data demonstrate that an early shift to M1 in DENV-infected patients may be critical to subsequently elevated vasoactive mediator levels and disease severity.

791

MONKEYPOX VIRUS INFECTIONS IN HEALTHCARE WORKERS

Andrea M. McCollum[1], Toutou Likafi[2], Christine M. Hughes[1], Jennifer Bass[1], Inger K. Damon[1], Darin Carroll[1], Joelle Kabamba[3], Beatrice Nguete[2], Marcel Pie Balilo[2], Jean Malekani[4], Kay Radford[1], D. Scott Schmid[1], Whitni B. Davidson[1], Kimberly Wilkins[1], Yu Li[1], Elisabeth Pukuta[5], Frida Nkawa[5], Stomy Karhemere[5], Jean-Jacques Muyembe Tamfum[5], Robert Shongo Lushima[6], Emile Wemakoy Okitolonda[2], Mary G. Reynolds[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [3]Centers for Disease Control and Prevention, Kinshasa, Democratic Republic of the Congo, [4]University of Kinshasa, Kinshasa, Democratic Republic of the Congo, [5]INRB, Kinshasa, Democratic Republic of the Congo, [6]Ministry of Health, Kinshasa, Democratic Republic of the Congo

Human monkeypox (MPX) is caused by monkeypox virus (MPXV), a zoonotic ***Orthopoxvirus***. MPXV is endemic in western and central Africa; however, the overwhelming majority of human infections are reported from the Democratic Republic of the Congo (DRC). Healthcare workers (HCWs) are at risk of infection if they are providing consultation and care for patients. Infrastructure and resources for healthcare facilities are poor in DRC, and, therefore, there may be a heightened risk of infection if workers are unable to apply optimal infection control measures. Fourteen suspect monkeypox (MPX) cases in HCWs were identified in Tshuapa District, DRC between 2009 and August 2014. Diagnostic specimens were collected from 12 of the suspected cases; real-time polymerase chain reaction assays were conducted to assess MPXV and varicella zoster virus infection status. Exposure information was retrieved from the case report or collected retrospectively using an interview tool. Seven of the twelve suspect cases with laboratory testing results (58.3%) were classified as confirmed MPX. Five of the seven confirmed MPX cases (71.4%) had a smallpox vaccination scar. Considering all suspect MPX cases reported and investigated between January 2011 and August 2014, the overall proportion of HCW cases was 0.8% (range 0.6-1.8% by year). Among confirmed cases of MPX, the proportion represented by HCWs was 0.8% (range 0.3-3.1% by year). The estimated annual HCW incidence of MPX was 17.4/10,000. Three of the confirmed MPX cases (42.8%) reported exposure during the course of their duties at work, and four confirmed cases (57.1%) reported exposure while caring for an ill family member or friend. Ill HCWs put their families and close household contacts at risk, as well. Reinforcement of infection control practices should not only be emphasized for methods at a clinic, but also their work at home, should a family member become ill and need care. The use of vaccines to prevent occupationally-acquired infections should be considered as a first-line defense against infection for HCWs in DRC.

792

FIRST EVIDENCE OF UNA VIRUS INFECTIONS IN INDIGENOUS AND NON-INDIGENOUS COMMUNITIES IN LORETO, PERU

Carolina L. Guevara[1], Erik Jhonston[2], Alfredo Huaman[1], Maria Silva[1], Jorge Gómez[3], Victor A. Laguna-Torres[3], Daniel G. Bausch[1], Sergio Recuenco[4], Julia S. Ampuero[1]

[1]Naval Medical Research Center Detachment, Lima, Peru, [2]Dirección Regional de Salud, Loreto, Peru, [3]Ministerio de Salud, Lima, Peru, [4]National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States

In the Amazon region, humans are exposed to sylvatic transmission by mosquitoes or small mammals, with arboviral diseases being most common illness transmitted in those areas. Arboviruses are classified according to antigenic relationships, and all cause febrile illness. This study aimed to understand possible arbovirus exposures in populations comprised of residents from two rural villages around Iquitos, Peru (non-indigenous), as well as riverside indigenous communities in Datem del Marañon province in Loreto, Peru. In collaboration with CDC rabies branch, Epidemiology Directorate of the Peruvian Ministry of Health (MoH), the Virology and Emerging Infectious Department of the U.S. Naval Medical Research Unit No. 6 in Lima conducted surveillance activities in these areas to identify antibodies to known arboviral pathogens, including alphaviruses, flaviviruses, and bunyaviruses. Informed consent was obtained from all study participants. All 364 samples were tested for ELISA IgG arboviral antibodies including the following groups: flavivirus (dengue virus (DV)), ilheus virus (IV), Saint Louis Encephalitis virus (SLEV), West Nile Virus (WNV), yellow fever virus (YFV)); alphaviruses (Venezuelan Equine Encephalitis Virus (VEEV), Mayaro Virus (MAYV), UNA Virus, Eastern Equine Encephalitis Virus (EEEV)); arenaviruses (Allpahuayo Virus (ALLV), and Tacaribe Virus (TCRV)), and orthobunyaviruses (bunyavirus, caraparu virus, maguari virus, murututu virus, oropouche virus), hantaviruses (Andes Virus (ANDV), and Rio Mamore Virus (RMV)). Samples were positive for alphavirus EEE = 2 (0.5%), UNA = 8 (2.2%). May = 6 (1.7%), and cross reactivity between VEE/MAY/WEE/UNA/EEE = 21 (5.8%). For hantavirus RMV = 67 (18.4%), for Arenavirus TAC = 4 (1%), ALL = 4 (1%), flaviviruses and bunyaviruses presented a high cross reactivity. We demonstrate the first evidence of UNA Virus circulating in humans, however, more tests are needed to confirm this serological result.

793

SUSCEPTIBILITY OF POTENTIAL VERTEBRATE HOSTS TO HEARTLAND VIRUS INFECTION

Angela M. Bosco-Lauth[1], Amanda E. Calvert[2], Tom Gidlewski[3], J. Jeffrey Root[3], Atis Muehlenbachs[4], Brigid Bollweg[4], Sherif Zaki[4], Richard A. Bowen[1], **Aaron C. Brault**[2]

[1]Colorado State University, Fort Collins, CO, United States, [2]Centers for Disease Control and Prevention, Fort Collins, CO, United States, [3]U.S. Department of Agriculture, Fort Collins, CO, United States, [4]Centers for Disease Control and Prevention, Atlanta, GA, United States

Heartland virus (HRTV; Bunyaviridae, Phlebovirus) has emerged as a causative agent of thrombocytopenia/ leukopenia in humans. Preliminary serological assessment of vertebrate sera obtained from areas adjacent to two index human cases in northwestern Missouri identified HRTV antibody positivity in raccoons (42.6%), horses (17.4%) and deer (14.3%). In order to further assess potential amplification hosts and potentially to develop an animal model for tick transmission studies, experimental inoculation of mice, rabbits, hamsters, chickens, goats and raccoons were performed. Inoculated rabbits, hamsters and chickens (104 PFU of HRTV s.c.) failed to demonstrate viremia from 1 to 7 dpi or neutralizing antibodies at 28 dpi. All species were boosted at 28 dpi with 104 PFU of HRTV. No detectable HRTV neutralizing antibodies were detected in chickens through 42 dpi after boost inoculation, but ELISA titers were evident (1:500-1500). PRNT80 10-20 titers were observed in boosted rabbits with ELISA titers up to 1:13,500. All boosted hamsters demonstrated neutralizing titers (1:10-80) and ELISA titers ranging from 1:13,500 to 1:≥ 45,000. Despite the high HRTV neutralizing antibody response identified in the field for raccoons, none of the six experimentally inoculated developed detectable viremias and only 2 had PRNT80 titers of 1:10, 20. Both goats experimentally inoculated with 104 PFU of HRTV failed to generate detectable viremias, but both generated low (1:20) neutralizing immune responses following the boost inoculation. All 3-week old C57BL/6 mice survived i.p. viral challenge with no demonstrable viremias and antibody responses were evident with up to 1:40 and 1:121,500 titers observed by PRNT and ELISA, respectively. In contrast, interferon receptor deficient AG129 mice demonstrated a dose-dependent mortality profile (LD50 of 9 PFU) and viremias of up to 108 PFU/mL sera were observed. While PRNT titers from sera taken from surviving mice were low, ELISA titers were as high as 1:40,500. Inoculated AG129 mice demonstrated gross hemorrhagic lesions with enlarged spleens associated with marked presence of HRTV antigen identified by IHC.

794

SURVEILLANCE FOR NOROVIRUS AND OTHER ENTERIC VIRAL AND BACTERIAL PATHOGENS AS ETIOLOGIES OF ACUTE GASTROENTERITIS AT U.S. MILITARY RECRUIT TRAINING CENTERS AND ABOARD ACTIVE U.S. NAVY SHIPS (2011-2015)

Ramona L. McCaffrey[1], Diana J. Lee[1], Krista M. Brooks[1], Reza Zeighmami[1], Jade Bratcher[1], Elizabeth Markowitz[1], Dennis Faix[1], Mark S. Riddle[2], Chad K. Porter[2], Shannon D. Putnam[1]

[1]Henry M. Jackson Foundation for the Advancement of Military Medicine/ Naval Health Research Center, San Diego, CA, United States, [2]Naval Medical Research Center, Silver Spring, MD, United States

Acute gastroenteritis (AGE) is defined as the rapid onset of diarrhea with or without accompanying symptoms, such as nausea, vomiting, fever, or abdominal pain. An estimated 179 million cases of AGE occur each year in the United States. AGE is commonly reported within both training and deployed U.S. military populations; even outbreaks described as mild can have significant impacts on the health, readiness, and operational effectiveness of military personnel. Given the disruptive effect of AGE upon military training, readiness, and performance, it is crucial to establish a firm understanding of its causes among these "at-risk" populations so that we may better predict, prevent, and respond to future outbreaks. To this end, the Naval Health Research Center Enteric Disease Surveillance Program (EDSP) initiated clinic-based passive surveillance at five U.S. military training facilities for both sporadic and outbreak-associated AGE starting in April 2011. Recruits attending sick-call with the chief complaint of AGE/gastrointestinal (GI) symptoms were screened against the case definition, per protocol. Those meeting case definition who chose to volunteer signed an informed consent form, completed a case report form, and submitted a clinical stool specimen or rectal swab. Forms and specimens were transported to the EDSP laboratory, where standard culture-based and molecular assays were conducted to identify enteric pathogen etiology_the primary pathogen of interest being norovirus. From April 2011 through March 2015, a total of 1,391 cases were enrolled; median age was 19 years, 77% were male, and 64% were Caucasian. An enteric pathogen was identified in 450 cases, with norovirus accounting for 87%, followed by ***Salmonella*** spp. (6%). The overall norovirus-attack rate was 28% across all field sites. Ultimately, data derived from the EDSP will facilitate the development of more targeted and effective AGE prevention and/or intervention policies and programs that will help mitigate the impact and burden of infectious AGE/GI disease, not only in U.S. military recruits and operational forces but in the general population as well.

795

CHARACTERISTICS ASSOCIATED WITH RUBELLA INFECTION AMONG CHILDREN IN THE DEMOCRATIC REPUBLIC OF CONGO

Kamy K. Musene[1], Reena H. Doshi[2], Patrick Mukadi[3], Nicole A. Hoff[2], Emile Okitolonda-Wemakoy[3], Jean-Jacques Muyembe-Tanfum[4], Elisabeth Pukuta[4], Sue Gerber[5], Anne W. Rimoin[2]

[1]University of California Los Angeles-DRC Research Program, Kinshasa, Democratic Republic of the Congo, [2]University of California Los Angeles, Los Angeles, CA, United States, [3]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, [4]INRB, Kinshasa, Democratic Republic of the Congo, [5]Bill & Melinda Gates Foundation, Seattle, WA, United States

Although the burden of rubella is unknown in sub-saharan Africa, there are approximately 110,000 congenital rubella cases occurring yearly worldwide. Rubella is vaccine preventable disease with the primary objective to prevent congenital rubella syndrome in infants. In the Democratic Republic of Congo (DRC), the rubella vaccine has not yet been introduced; therefore we assessed characteristics associated rubella infection among vaccine-naïve children 9-36 months of age in DRC. We used the Case-Based measles surveillance system with laboratory confirmation of disease to assess risk factors for rubella infection among children with suspected measles from January 1, 2010 to December 31, 2012. Children testing negative for measles were subsequently tested for rubella IgM antibodies. Rubella is present throughout the country with variable prevalence rates. We used Maniema as the reference for comparing odds of disease acquisition in the other 10 provinces. All of the other provinces had a greater chance for observing a case, Kinshasa (9.97 times), Bas-Congo (7.75 times), South- Kivu (4.94 times), Bandundu (4.27 times), Kasai-occidental (3.64 times), North-Kivu (3.62 times), Oriental Province (3.59 times), Equateur (3.51 times), Katanga (2.91 times) and Kasai-Oriental (2.44 times). Given that little else is known about the prevalence of Rubella in the DRC, surveillance data suggest that the virus is circulating in all 11 provinces in children. However, we continue to have no information about the prevalence of CRS. If DRC is to introduce a rubella vaccine, routine immunization should be strengthened for children, and CRS surveillance should be introduced. A main concern when introducing the rubella vaccination in just children is the coverage may decrease virus circulation, thus sufficiently shifting both the average exposure to rubella and susceptibility from children to older age groups including women of childbearing age, and therefore may increase the prevalence of CRS.

796

EPIDEMIOLOGIC AND MOLECULAR CHARACTERISTICS OF HEALTH CARE-ASSOCIATED RESPIRATORY SYNCYTIAL VIRUS INFECTIONS IN KENYA

Lilian M. Mayieka

Kenya Medical Research Institute, Nairobi, Kenya

Human respiratory syncytial virus (RSV) is a leading cause of lower respiratory tract infection in infants and young children, with highest burden in low-income countries. RSV is an important cause of nosocomial respiratory infections; however data on hospital-acquired RSV in Africa are limited. We sought to describe the epidemiologic and molecular characteristics of health care-associated RSV infections in 3 urban hospitals in Kenya (2 in Nairobi and 1 in Kisumu). From September 2009 to September 2012 we collected nasopharyngeal and oropharyngeal samples from patients with hospital-onset fever (≥ 38°C) after≥ 3 days admission), plus cough or sore throat. RSV testing and subgrouping (RSV A or B) were done using real time polymerase chain reaction (RT-PCR). Where subgroup was identified, sequencing and phylogenetic analysis of G glycoprotein was performed. Among 41 RSV-positive cases, the median age was 11.4 months [IQR 7.2-24] and 63% were male. Thirty seven (90%) out of the total (41) had fever onset > 6 days after admission. Eight cases (19%) died. Among 16 (39%) samples successfully sequenced, 9 (56%) were RSV A and 7 (44%) were RSV B. RSV A strains diversified into two main clades, AN1 and ON1, with 8 isolates belonging to the NA1 genotype and 1 isolate belonging to ON1. All the sequences in group B belonged to the BA1 genotype. We observed 3 RSV A and 2 RSV B cases clustered by time (same admission date), places (same ward) and molecular characteristics suggesting possible case-to-case transmission. Others had same date of onset but were of different genotypes suggesting different sources of infection. Our data suggest that nosocomial transmission of RSV is occurring among urban hospitals in Kenya, posing a threat to hospitalized children. Further research is needed to identify sources of infection, which may include health care workers, visitors and other patients. Strengthening infection control measures could prevent nosocomial spread of RSV.

797

MOBILE SUITCASE LABORATORY FOR RAPID DETECTION OF EBOLA VIRUS AT LOW RESOURCE SETTINGS

Ahmed Abd El Wahed[1], Pranav Patel[2], Oumar Faye[3], Oliver Nentwich[4], Andy Wende[5], Olaf Piepenburg[4], Amadou A. Sall[3], Manfred Weidmann[6]

[1]Georg-August University Goettingen, Goettingen, Germany, [2]Robert Koch Institute, Berlin, Germany, [3]Pasteur Institute, Dakar, Senegal, [4]TwistDx Ltd., Cambridge, United Kingdom, [5]Qiagen GmbH, Hilden, Germany, [6]University of Stirling, Stirling, United Kingdom

The current outbreak of Ebola has killed over 10,000 people in Guinea, Sierra Leone and Liberia. Early identification and isolation of the infected Ebola cases are the most important control measures. Detection of the Ebola virus by using the rapid antigen lateral flow tests is an easy to be applied at the point-of-care. Nevertheless, the results must be confirmed by additional laboratory tests. Laboratory diagnosis mainly depends on Ebola RNA detection by reverse transcription real-time polymerase chain reaction (RT-PCR), which is available in central laboratories and has a turnaround time of more than three hours. For decentralized low resource settings, there is a need for a simple molecular point-of-need test. In this study, a mobile suitcase laboratory (62x49x30 cm) containing all reagents and equipment for the detection of Ebola RNA was developed. Moreover, it was operated by a solar power battery. All reagents were cold-chain independent in order to ease the use at poor resource settings. RNA extraction was performed by a magnetic bead based method, in which a simple fast lysis protocol was applied. In one reaction tube, the reverse transcription step as well as the DNA amplification and detection by the recombinase polymerase amplification (RPA) assay was achieved. Using spiked plasma samples, down to 15 Ebola RNA copies were detected in less than 30 minutes, while samples containing Crimean-Congo-Hemorrhagic-Fever, Yellow Fever, Lassa, Marburg, Rift Valley Fever, Dengue, Chikungunya and Zika viruses and ***Plasmodium falciparum*** were negative. In conclusion, the mobile suitcase laboratory is ideal for rapid sensitive and specific detection of Ebola virus especially at low resource settings. Currently, two mobile suitcase laboratories are being used in Guinea.

CONTACT PATTERNS DRIVING EBOLA TRANSMISSION IN WEST AFRICA

Harriet Mills[1], World Health Organisation Ebola Response Team[2]

[1]Imperial College London, London, United Kingdom, [2]Imperial College London and World Health Organization, London and Geneva, United Kingdom

Over 22,000 confirmed, probable and suspected cases of Ebola have been reported in West Africa as of early 2015. Cases are asked if they have had exposure to sick individuals (reported contacts) in a funeral or non-funeral context prior to becoming ill. Exposures are reported by nearly a third of cases, here we analyse these data. The proportion of cases reporting a funeral exposure has decreased over time in some districts. We found a strong positive correlation between this proportion in a district for a given month and the within-district transmission intensity, quantified by the estimated reproduction number. We also found a strong positive correlation between within-district transmission intensity and the district's proportion of hospitalised cases admitted within <=3 days of onset of symptoms. There was no correlation between these two proportions, suggesting that both reduced funeral attendances and faster hospitalisation have independently influenced the intensity of local transmission. We were able to identify 16% of named contacts in the line-list of case report data collated by WHO. Linking cases to the contacts who potentially infected them provided partial information on the Ebola transmission network, which revealed a high to extreme degree of super-spreading. Multivariable regression models allowed us to identify predictors of being named as a non-funeral contact: severe symptoms, death, non-hospitalisation and older age; or a funeral contact: non-hospitalisation, older age and travelling prior to onset. Non-funeral exposures are strongly peaked around the death of the contact, with a high proportion of exposures occurring after hospitalisation. We found that non Ebola Treatment Units (ETUs) have been worse than ETUs at preventing exposure from hospitalised and deceased. Achieving elimination will require sustained safe funerals and fast hospitalisation. Continued real-time data capture, reporting and analysis is vital to track transmission patterns, inform resource deployment, and thus hasten elimination of the virus from the human population.

799

A DESCRIPTIVE AND QUANTITATIVE ANALYSIS OF POTENTIAL UNDERESTIMATION OF HUMAN MONKEYPOX CASES IN THE PASSIVE SURVEILLANCE SYSTEM IN THE DEMOCRATIC REPUBLIC OF CONGO

Nicole A. Hoff[1], Benoit Kebela-Ilunga[2], Philip Eckhoff[3], Patrick Mukadi[4], Mathais Mossoko[2], Jean-Jacques Muyembe-Tamfum[4], Emile Okitolonda-Wemakoy[5], Reena H. Doshi[1], Anne W. Rimoin[1]

[1]University of California Los Angeles Fielding School of Public Health, Los Angeles, CA, United States, [2]Ministry of Health, Kinshasa, Democratic Republic of the Congo, [3]Institute for Disease Modeling, Seattle, WA, United States, [4]National Institute for Biomedical Research, Kinshasa, Democratic Republic of the Congo, [5]Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

A major objective of disease surveillance systems is to provide critical information on burden of disease that will inform prevention and control policy and focus of public health efforts. In limited resource settings, such as the Democratic Republic of Congo (DRC), reported diseases might only represent a fraction of the total cases. We present a novel computational method using a scenario tree to model gaps in DRC's disease reporting system, using monkeypox (MPX) as an example. Case counts of MPX reported from January 1st, 2013 to December 31st, 2013 to the Direction of Disease Control in the Ministry of Health (MoH) were used. Parameters of health care utilization and disease reporting at all levels (from when a person becomes ill to when the information is received at the national level) were identified and quantified using health utilization surveys, personal interviews and expert opinion. In 2013, a total of 2,460 cases of suspected human MPX virus were reported to the Integrated Disease Surveillance and Response (IDSR) unit, in the simulated model, the actual number of cases could be 5.0 to 15.2 (mean 9.4) times higher than what was observed in the IDSR at the national level. According to our estimates the true number of suspected cases would have ranged from 12,380 to 37,600 (average=23,280) suggesting a far more severe picture of human MPX in DRC than currently thought. Our model found that most of the cases are lost during the health care ascertainment phase, in that 60% of the total cases may not seek any treatment. Additionally, many cases may be missed if they visited a private facility or were unable to pay for services at their public facility, and further cases were lost once reported to the health zone as there are no sanctions if weekly reports are not sent in. Improved involvement of community workers for disease surveillance, integration of private facilities into the reporting system, and identifying health zones which consistently do not send in reports could lead to a major increase in the numbers of cases reported to the national level and an improvement in surveillance accuracy.

FIGHTING AGAINST ANTIMALARIAL RESISTANCE IN EARLY DRUG DISCOVERY

Laura M. Sanz, Maria Linares, Benigno Crespo, Virginia Franco, Maria G. Gomez, Francisco J. Gamo

GlaxoSmithKline, Tres Cantos, Madrid, Spain

Current antimalarial therapy is built upon only a few differentiated chemotypes and clinical resistance is emerging continuously threatening

the efficacy of antimalarial treatments. Antimalarial mode of action is intimately linked to the appearance of resistance in the field. Historically those antimalarials that inhibit defined molecular targets (e.g. antifolates or mitochondrial Cytb inhibitors) have selected for resistance much more rapidly than those drugs exhibiting complex modes of actions (e.g. endoperoxides or chloroquine).Recent studies have demonstrated that antimalarials with complex mode of actions display a fast killing profile when parasite viability is monitored after drug treatment. However compounds like atovaquone, pyrimethamine or DHODH inhibitors display a much slower rate of killing surely because they are affecting single targets inside of the parasite. As rate of killing profile is linked to the specific antimalarial mode of action it could be a relevant parameter to anticipate propensity to develop resistance by emerging antimalarials. Although robust technologies to determine killing rates exist in the field we have develop a novel medium-throughput assay that allows robust identification of fast acting compounds. This assay has been used to study a set of ca. 50 compounds that are being used as tool compounds to select for ***in vitro*** resistance in a target identification consortium supported by Bill & Melinda Gates Foundation. Preliminary results point out a much higher success for resistant selection with compounds displaying a slow or moderate killing rates vs those with a fast mode of action. These results suggest that antimalarial speed of action could be used as surrogate of the propensity to select for resistance.

801

EVALUATING THE PREVALENCE OF DRUG RESISTANCE IN INTERMITTENT PREVENTIVE TREATMENT FOR MALARIA DURING PREGNANCY

Chinedu Onyedikachukwu Oraka[1], Jane O. Onyemaechi[2]

[1]Build Africa Research Capacity, Nnamdi Azikiwe University Teaching Hospital, Nnewi, Anambra, Nigeria, [2]Build Africa Research Capacity, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Due to the poor patient compliance with prophylaxis and increasing resistance of parasite strains to chloroquine, administration of intermittent preventive treatment in pregnancy (IPTp) with sulfadoxine/pyrimethamine is now recommended for all pregnant women living in areas with stable malaria transmission. However, resistance to sulfadoxine/pyrimethamine is on the increase which risks the drug being compromised. Thus, an urgent need exists to assess alternative drug regimens for IPTp. Numerous molecular epidemiologic studies showed that resistance to pyrimethamine is associated with the acquisition of mutations in ***Plasmodium*** spp. dihydrofolate reductase (dhfr) genes while resistance to sulfadoxine is associated with 3 mutations in dihydropteroate synthase (dhps gene). Each mutation leads to a decrease in sensitivity to pyrimethamine (dhfr gene) and sulfadoxine (dhps gene). On a systematic review, results indicated that 2 doses of IPTp with sulfadoxine/pyrimethamine retained activity to reduce placental malaria and low birthweight amongst pregnant that visited the clinic. About >72% of the pregnant women that visited the clinic benefited with 2 doses of IPTp in the proportional reduction of peripheral parasitaemia at delivery compared with that at enrolment while the rate of resistance was at <30%; and the proportion of placental infection was reduced by 75% compared with the efficacy of chloroquine prophylaxis administered the previous year. An alternative approach involves systematic detection of placental infection at delivery by using blood smear, rapid diagnostic test, or PCR with placental blood. Conversely, placental infection prevalence may change with time because of changes in sulfadoxine/pyrimethamine efficacy (likely to decrease) and quality of IPTp implementation (likely to increase). Such an approach would also provide baseline data to assess efficacy of all preventive measures against pregnancy-associated malaria, including IPTp and use of insecticide-impregnated bed nets, and will enable assessment of these effects in a specific population.

802

INVESTIGATING CANDIDATE MOLECULAR MARKERS OF PIPERAQUINE RESISTANCE IN A NORTHERN CAMBODIAN COHORT WITH A HIGH RATE OF DIHYDROARTEMISININ-PIPERAQUINE TREATMENT FAILURE

Jonathan B. Parr[1], Sujata Balasubramanian[1], Suwanna Chaorattanakawee[2], Panita Gosi[2], Charlotte A. Lanteri[2], Eric Barnett[1], Michele Spring[2], Char Meng Chuor[3], Chanthap Lon[2], Jonathan J. Juliano[1], David L. Saunders[2], Jessica T. Lin[1]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

Dihydroartemsinin-piperaquine (DP), one of the last remaining effective drugs for multidrug-resistant ***Plasmodium falciparum,*** has been the first-line artemisinin combination therapy (ACT) in Cambodia since 2012. However, alarming rates of DP failure accompanied by a rise in piperaquine IC_{50}s have already been reported. We are investigating whether DP failures in the region are associated with sequence or copy number variation in candidate molecular markers of piperaquine resistance, including ***pfmdr1, pfcrt***, ***pfmrp2,*** and the X5r domain. 107 isolates from a DP trial with a 42-day PCR-corrected recrudescence rate of 54% are being analyzed. Preliminary analysis shows near fixation of the 184F mutant (98%) and wild type alleles only at codon 86 in ***pfmdr1***. Increased ***pfmdr1*** copy number (CN) is present in 15% of isolates and appears to be associated with greater ***in vitro*** susceptibility to piperaquine, though the association did not reach significance (median PPQ IC50 21.8nM vs. 30.7nM in samples with CN>1 and CN≤1, respectively, p=0.09). None of the nine patients with ***pfmdr1*** CN>2 developed recrudescence. A duplication at the X5r locus on chromosome 5 has been observed in drug-pressured parasites that acquired piperaquine resistance. Using digital droplet PCR, we found no increase in CN at four genes within the X5r domain. Analysis of codon 350 of ***pfcrt*** and a microindel in ***pfmrp2*** is ongoing. A clinically validated molecular marker of piperaquine resistance is urgently needed to determine the role of the partner drug in DP failures. Genome-wide association studies may be necessary to inform molecular surveillance worldwide.

803

THE PROTECTIVE EFFICACY OF SEASONAL MALARIA CHEMOPREVENTION IN AN AREA OF EXTENDED SEASONAL TRANSMISSION IN THE ASHANTI REGION OF GHANA: AN INDIVIDUALLY RANDOMIZED TRIAL

Harry Tagbor[1], Gifty Antwi[1], Princess R. Acheampong[1], Daniel Chandramohan[2], **Matthew Cairns**[2]

[1]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom

Seasonal malaria chemoprevention (SMC) is recommended by the World Health Organisation for the control of malaria in young children in areas of highly seasonal transmission in the Sahel and sub-Sahel. However, there is a large burden of malaria in areas with a longer transmission season that could potentially benefit from SMC with modified delivery schedules. We undertook an individually randomised, placebo-controlled trial of seasonal malaria chemoprevention in the Ashanti Region of Ghana, where the malaria transmission season peaks over a period of five to six months. Children under five years of age received SMC or placebo on five occasions during the rainy season. SMC was delivered from a central point in each community for the first three rounds, and from a central point in combination with community health workers for the last two rounds. Community health workers managed cases of malaria with artemisinin-based combination therapies, using rapid diagnostic tests to confirm infection prior to treatment. Relative to the placebo group, children who received SMC were less likely to carry malaria parasites after the rainy

season (19.9% vs. 12.4%, prevalence ratio 0.62 (95% CI: 0.49, 0.80); p<0.001). However, the distribution of haemoglobin and prevalence of anaemia was very similar between the two groups. During the rainy season, the incidence of malaria was reduced by around 40% in children in the SMC group, and by around 60% in children who received all five rounds of SMC. However, there was still an important burden of malaria before and after the period when SMC was administered. Our results suggest that SMC may be a valuable malaria control tool for areas with a longer transmission season, but further optimisation of SMC schedules may be needed to maximise impact. Achieving high coverage is crucial to the success of SMC programmes, and it appears that delivery through community health workers will be better able to achieve this aim.

804

CONFIRMED *PLASMODIUM VIVAX* RESISTANCE TO CHLOROQUINE IN CENTRAL VIETNAM

Pham Vinh Thanh[1], Nguyen Van hong[1], Nguyen Van Van[2], Melva Louisa[3], Kevin Baird[4], Ta Thi Tinh[1], Nguyen Xuan Xa[1], Koen Peeters Grietens[5], Le Xuan Hung[1], Tran Thanh Duong[1], Anna Rosanas-Urgell[5], Niko Speybroeck[6], Umberto D'Alessandro[7], **Annette Erhart**[5]

[1]NIMPE, Hanoi, Vietnam, [2]Provincial Malaria Station, Tam Ky, Vietnam, [3]University of Indonesia, Jakarta, Indonesia, [4]Eijkman Oxford Clinical Research Unit, Jakarta, Indonesia, [5]ITM, Antwerp, Belgium, [6]University Catholic of Louvain, Brussels, Belgium, [7]Medical Research Council, Fajara, Gambia

Plasmodium vivax resistance to chloroquine (PvCQR) is currently reported in almost all vivax endemic countries. In Vietnam, little evidence has been published so far on ***P. vivax*** susceptibility to CQ, and only one study in the early 2000s reported PvCQR in the Southern central region. Despite the paucity of published data, the national malaria control program is closely monitoring antimalarial drug resistance since 1995, and all 28-day ***in vivo*** studies carried out since 2003 on PvCQR in several sentinel sites reported late parasitological failures between 0-5.7%. Between May 2009 and December 2011, a 2-year cohort study was conducted in Central Vietnam to assess the recommended radical cure regimen based on a 10-day course Primaquine (0.5mg/kg/day) together with 3 days CQ (25mg/kg). We hereby report the results of the first 28-day follow-up estimating the cumulative risk of P.vivax recurrences together with the corresponding CQ blood concentrations among other endpoints. Out of 260 recruited P.vivax patients, 240 completed treatment and were followed up to day 28 according to the WHO guidelines. Eight patients (3.45%) had a ***P. vivax*** recurrent infection, at day 14 (n=2), day 21 (n=1) and day 28 (n=5). Chloroquine blood concentrations, available in 3/8 recurrent infections (day 14,21,28) were above the minimal inhibitory concentration (>100ng/ml whole blood) in all of them. Fever and parasitaemia (both sexual and asexual stages) were cleared by day 3. Anemia was common at day 0 (35.8%) especially in children below 10 (50%) and hemoglobin (Hb) recovery at day 28 was significant among anemic patients (median change d28-d0 =+1.7g/dl; IQR[+0.7; +3.2]). This report confirms for the first time ***P. vivax*** CQ resistance in Central Vietnam, and calls for further studies using standardized protocols for accurately monitoring the extend and evolution of PvCQR in Vietnam. These results, together with the mounting evidence of artemisinin resistance in Central Vietnam, further highlight the increasing threat of antimalarial drug resistance on malaria elimination in Vietnam.

805

DIHYDROARTEMISININ-PIPERAQUINE VS ARTESUNATE-AMODIAQUINE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN GHANAIAN PREGNANT WOMEN: A NON-INFERIORITY, SAFETY AND EFFICACY TRIAL

Joseph Osarfo[1], Pascal Magnussen[2], Michael Alifrangis[2], Harry Kwami Tagbor[1]

[1]School of Public Health, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [2]Center for Medical Parasitology, University of Copenhagen, Copenhagen, Denmark

Dihydroartemisinin-piperaquine (DHA-PPQ) has potential for use as treatment for uncomplicated falciparum malaria in pregnancy. However, there is a paucity of safety data on the use of this drug combination in pregnancy and only two studies have reported its use in pregnancy so far. We assessed the safety and efficacy of DHA-PPQ in 417 second and third trimester pregnant women with uncomplicated malaria and compared these outcomes to those seen with artesunate -amodiaquine (ASAQ) in a non-inferiority trial using a margin of 5%. Pregnant women who tested positive for ***Plasmodium falciparum*** infection using both a rapid diagnostic test and microscopy were recruited, individually randomized to DHA-PPQ or ASAQ, and followed up actively on days 1, 2, 3, 7, 14, 28 and 42, at delivery and 6 weeks post-partum. During this period, assessment of adverse events, sampling of blood for haematological and parasitological assessments and data collection on neonatal morbidity and mortality were performed. Uncorrected parasitological efficacy by day 42 for DHA-PPQ was 89.0% (95%CI: 83.6, 93.0) and for ASAQ it was 86.5% (95%CI: 80.6, 91.2) in the per protocol population and 87.4% (95%CI: 81.9, 91.8) and 86.7% (95%CI: 80.8, 91.3) respectively in the modified intention-to-treat analysis. DHA-PPQ was non-inferior to ASAQ at both days 28 and 42 in both sets of analyses. There was no evidence of hepatic/ renal toxicity or white blood cell dyscrasia in either study arm. DHA-PPQ was better tolerated than ASAQ; vomiting (19.5% vs 29.4%; p=0.02), dizziness (14.5% vs 26.6%; p=0.003) and anorexia (12.0% vs 22.3%; p=0.007). No harms were associated with DHA-PPQ in the second and third trimesters and though the PCR-corrected estimates were not reported, the study is expected to contribute significantly to the evidence that will guide a policy decision on the use of DHA-PPQ use in pregnancy.

806

UNDERSTANDING THE HISTORICAL SPREAD OF MOLECULAR MARKERS OF SULPHADOXINE-PYRIMETHAMINE RESISTANCE IN AFRICA

Lucy Okell

Imperial College London, London, United Kingdom

The dispersal of ***Plasmodium falciparum*** strains resistant to sulphadoxine-pyrimethamine (SP) occurred at a time when molecular analysis techniques were sufficiently developed to map the spread of molecular markers of resistance for the first time. Understanding what influenced SP resistance in the past could help inform predictions on the possible spread of resistance to artemisinin and its partner drugs, and lead to better resistance containment strategies. We are developing a mathematical transmission model of the temporal spread of drug resistance to SP, incorporating rates of SP treatment, transmission intensity, asymptomatic infections, multiple clone infections, human immunity, and fitness costs of resistance. We fitted our model using Bayesian Markov Chain Monte Carlo methods to 274 prevalence data points of the dhps540E mutation in 35 locations in Africa which had multiple measures over time. We incorporated local data from 93 household surveys on use of SP and data on transmission intensity from the Malaria Atlas Project. The rate of increase in dhps540E frequency varied considerably between locations. SP intake was very high in some areas; we estimate that the number of SP treatments in under fives was more than 5-fold higher than

the number of clinical malaria episodes in parts of East Africa during the 2000's. There were no clear univariate statistical associations between the rate of increase in dhps540E frequency and SP use or transmission intensity. However, initial modelling results are able to reproduce the dhps540E prevalence patterns in most sites by taking into account multiple factors simultaneously, including SP use, transmission intensity, an estimated time of introduction of the mutation and pre-existing partial resistance to SP due to other mutations in dhfr and dhps. In a few locations, the reported SP use was too low to support the observed dhps540E prevalence, indicating there are further factors not currently captured by the model or the data, possibly including use of other sulpha drugs. Validating a mathematical model against historical data helps increase its applicability to modelling drug resistance in the field.

807

LACK OF ARTEMISININ RESISTANCE IN *PLASMODIUM FALCIPARUM* IN UGANDA BASED ON PARASITOLOGICAL AND MOLECULAR ASSAYS

Roland A. Cooper[1], Melissa D. Conrad[2], Quentin D. Watson[3], Stephanie J. Huezo[1], Harriet Ninsiima[4], Patrick Tumwebaze[4], Samuel L. Nsobya[4], Philip J. Rosenthal[2]

[1]Dominican University of California, San Rafael, CA, United States, [2]University of California, San Francisco, CA, United States, [3]University of California, Berkeley, CA, United States, [4]Infectious Diseases Research Collaboration, Kampala, Uganda

Artemisinin-based combination therapies (ACTs) are standard treatment for falciparum malaria. The efficacies of these regimens are threatened by resistance to the artemisinin component, exemplified by delayed clearance of parasitemia after therapy, in southeast Asia. The resistance phenotype has recently been associated with two parasite features. First, in freshly cultured isolates, resistant parasites demonstrated increased parasitemias, compared to those in sensitive parasites, 66 h after a 6 h pulse with dihydroartemisinin (DHA). Second, polymorphisms in propeller domains of the recently described ***Plasmodium falciparum*** kelch (K13; PF3D7_1343700) gene were associated with resistance. However, delayed parasite clearance after therapy with ACTs has not been clearly documented in Africa. To better characterize resistance markers in Africa, we studied ***ex vivo*** susceptibility to DHA and examined K13 propeller polymorphisms in ***P. falciparum*** isolates collected in Kampala, Uganda from May-July, 2014. By standard ***in vitro*** assays all studied isolates were highly sensitive to DHA (IC_{50} 0.4-2.7 nM). Sensitivities to chloroquine varied widely (IC_{50} 9.8-1060 nM), with sensitivities consistent with genotypes at the ***pfcrt*** K76T allele. Using the ring-stage survival assay, after a 6 h, 700 nM DHA pulse, parasitemia was undetectable in 40/43 cultures at 72 h; most cultures followed beyond 72 h demonstrated parasites after 2-4 weeks. Two of 53 isolates had non-synonymous K13 propeller polymorphisms, but not the mutations associated with artemisinin resistance in Asia. In summary, consistent with clinical trial results from Africa, we did not observe parasitological or molecular evidence of artemisinin resistance in recent ***P. falciparum*** isolates from Uganda.

808

SURVEILLANCE OF TRAVELERS: PREVALENCE OF ANTIMALARIAL DRUG RESISTANCE MARKERS AMONG IMPORTED *PLASMODIUM FALCIPARUM* CASES DIAGNOSED IN THE UNITED STATES, 2013

Luciana M. Silva-Flannery[1], Dragan Ljolje[1], Karen A. Cullen[1], Maniphet Xayavong[2], Blaine A. Mathison[1], Henry Bishop[1], Alexandre J. DaSilva[3], Paul Arguin[1], John W. Barnwell[1], Venkatachalam Udhayakumar[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Lifesource Biomedical, Anchorage, AK, United States, [3]Food and Drug Administration, Center for Food Safety and Applied Nutrition, Laurel, MD, United States

CDC conducts surveillance to detect molecular markers associated with drug resistance among ***Plasmodium falciparum*** parasites imported into the US. These data may inform prevention and treatment guidelines for US travelers visiting malaria endemic countries. Blood samples from persons with malaria diagnosed in the US were submitted to CDC for molecular characterization. ***P. falciparum***-positive samples were genotyped for genetic polymorphisms associated with resistance to chloroquine (***pfcrt***), sulfadoxine (***pfdhps***), pyrimethamine (***pfdhfr***), mefloquine (***pfmdr1*** and copy number), atovaquone (***pfcyt b***) and artemisinin (***K13- propeller***) using Sanger sequencing and real-time PCR methods. The genotype data were connected with epidemiologic data. In 2013, CDC received a total of 136 samples from 29 states for malaria reference diagnosis and genetic characterization of resistance markers. CDC corrected/determined the species for 87 (64%) samples. ***P. falciparum*** was identified in 101 (74%) samples (including 2 mixed infections), ***P. vivax*** in 14 (10%), ***P. ovale*** in 14 (10%), and ***P. malariae*** in 6 (4%). Travel history was reported for 106 cases (78%); 96 (71%) traveled to Africa. Only 22 cases had reported some malaria chemoprophylaxis use. From 57 cases with information on treatment, 23 (40%) received atovaquone/proguanil, 20 (35%) doxycycline, and 5 (9%) chloroquine, including other combination therapies. Among the ***P. falciparum***-positive cases, 89 (88%) had genetic polymorphisms associated with resistance to pyrimethamine, 74 (73%) to sulfadoxine and 53 (52%) to chloroquine. No pre-treatment samples had ***pfcyt b***, ***K13-propeller*** mutations or multiple ***pfmdr1*** copies associated with resistance to atovaquone, artemisinin and mefloquine, respectively. These findings highlight the problem of antimalarial drug resistance and the importance of active surveillance for drug resistance among imported malaria cases in the US.

809

IMPACT OF DRUG RESISTANCE MEDIATING *PLASMODIUM FALCIPARUM* POLYMORPHISMS ON CLINICAL PRESENTATIONS OF PARASITEMIC CHILDREN IN UGANDA

Stephen Tukwasibwe[1], Patrick Tumwebaze[1], Melissa Conrad[2], Samuel L. Nsobya[1], Emmanuel Arinaitwe[1], Moses R. Kamya[1], Grant Dorsey[2], Bryan Greenhouse[2], Philip J. Rosenthal[2]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California San Francisco, San Francisco, CA, United States

Plasmodium falciparum genetic polymorphisms that mediate altered sensitivity to antimalarials may impact upon parasite virulence. In a recent cross-sectional study of parasitemic Ugandan children, isolates with mutant sequences at ***pfcrt*** K76T, ***pfmdr1*** N86Y, or ***pfmdr1*** D1246Y had one-fourth the odds of association with symptomatic malaria compared to wild type (WT) parasites. However, these results may have been confounded by selection of WT parasites by recent use of artemether/lumefantrine for prior episodes of malaria. To further explore these associations, we evaluated polymorphisms in samples from paired episodes of asymptomatic and symptomatic parasitemia in 114 cohort subjects aged 4-11 years from Tororo District, with the two episodes occurring within 3-12 months, and no prior treatment for malaria within

60 days. The N86Y mutant genotype was less commonly found with symptomatic (4/110, 3.6%) than asymptomatic (13/111, 11.7%; p = 0.028, Fisher's exact test) infection, compared to mixed or wild type genotypes; significant associations were not seen for the K76T or D1246Y alleles. Considering paired episodes in the same subject, thus controlling for host factors, the odds of symptomatic malaria were lower for mutant compared to WT or mixed sequence at N86Y (OR 0.23, 95% CI 0.04-0.84, p = 0.021, McNemar's exact test), but not the other alleles. However, symptomatic episodes (which have higher densities) were more likely than asymptomatic to be mixed (for N86Y OR 2.0, 95% CI 1.04-4.0, p = 0.036), likely explaining the higher prevalence of WT/mixed infections in symptomatic children. Excluding mixed infections, prevalences of WT and mutant alleles did not differ between symptomatic and asymptomatic episodes. Thus, associations seen between WT/mixed ***pfmdr1*** N86Y genotype and symptomatic disease were likely explained by confounding due to greater parasite densities in symptomatic children, arguing against an impact of ***pfmdr1*** and ***pfcrt*** genotypes on clinical outcomes, and highlighting the value of cohort studies for best assessing associations between parasite factors and clinical outcomes.

810

RESPONSIVENESS OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* INFECTIONS IN ANEMIC AND NON-ANEMIC NIGERIAN CHILDREN TO ARTEMISININ-BASED COMBINATION TREATMENTS: EVIDENCE FOR HEMATOCRIT CONSERVATION IN ANEMIC CHILDREN

Kazeem Akano[1], Godwin Ntadom[2], Adejumoke Ayede[1], Temitope Aderoyeje[3], Akintunde Sowunmi[3]

[1]University of Ibadan, Ibadan, Nigeria, [2]National Malaria Control Programme, Federal Ministry of Health, Abuja, Nigeria, [3]University College Hospital, Ibadan, Nigeria

The efficacy, hematocrit conservation and anemia recovery times were evaluated in 909 non-anemic and 437 anemic malarious Nigerian children <15 years old during a 7-year period of adoption of artesunate-amodiaquine and artemether-lumefantrine as first line treatments. Overall, fever and parasite clearance were significantly faster following treatment with AA (P = 0.002, P < 0.0001, respectively). Fever but not parasite clearance, and parasite reduction ratio 1 day after treatment began were significantly faster (P = 0.031) and higher (P < 0.001), respectively, in non-anemic compared to anemic children. Polymerase chain reaction-corrected parasitological cure rate on day 28 was similar in non-anemic and anemic children (96.1% (95%CI 91.2 - 101.1) versus 97.5% (95%CI 92.4 - 102.6)); P = 0.30) and were similar for both treatment groups. Fall in hematocrit/1000 asexual parasites cleared from peripheral blood were significantly lower in anemic compared to non-anemic children (P = 0.038) suggesting much hematocrit conservation in anemic children. Delayed anemia occurred in 2% of the children. Mean anemia recovery time was 15 days (95%CI 13.3 - 17.4) and it did not correlate with FIH/1000 asexual parasites cleared from peripheral blood (r = 0.004, P = 0.61). Kinetics of the deficit in hematocrit from 30% was estimated by a non-compartmental model. Declines in the deficit were monoexponential with a mean elimination half-time of 1.4 days (95% CI = 1.2-1.6). Anemia half-time correlated significantly positively with anemia recovery time in the same patients (r = 0.69, P < 0.0001). Bland-Altman analysis of 10 multiples of anemia half-time and anemia recovery time showed narrow limit of agreement with insignificant biases (P = 0.07). Artesunate-amodiaquine and artemether-lumefantrine are efficacious treatments of uncomplicated falciparum infections in anemic and non-anemic children and they may conserve hematocrit and hasten recovery from malaria-associated anemia.

811

CROSS-SECTIONAL SURVEILLANCE FOR DRUG RESISTANCE-MEDIATING *PLASMODIUM FALCIPARUM* POLYMORPHISMS IN UGANDA

Patrick Tumwebaze[1], Stephen Tukwasibwe[1], Melissa D. Conrad[2], Grant Dorsey[2], Emmanuel Arinaitwe[1], Moses R. Kamya[1], Samuel Nsobya[1], Philip J. Rosenthal[2]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California, San Francisco, CA, United States

Antimalarial drug resistance, mediated in part by known ***Plasmodium falciparum*** genetic polymorphisms, is of great concern in Uganda. Of interest is whether resistance determinants vary across the country and whether, with replacement of chloroquine/sulfadoxine-pyrimethamine (SP) by artemether/lumefantrine (AL) as the national treatment regimen, beginning in 2006, resistance determinants are changing. We analyzed samples from cross-sectional surveys in children 5-15 years of age in 3 districts with wide variation in malaria transmission (Tororo, Jinja, and Kanungu) in 2012 and 2013. The prevalence of transporter polymorphisms was similar at the 3 sites, and the prevalence of WT alleles increased at each site. Overall, WT/mixed sequences increased between 2012 and 2013 for ***pfcrt*** K76T (7.5% to 17.5%, p<0.0001), ***pfmdr1*** N86Y (75.5% to 89.1%, p<0.0001), and ***pfmdr1*** D1246Y (80.9% to 91.7%, p<0.0001). WT prevalences were much greater than those measured at multiple sites in Uganda in prior years. The changes are all consistent with the selective pressure of increasing use of AL in the country. For antifolates, in the partial results now available the prevalence of 5 mutations (***pfdhfr*** N51I, C59R, S108N; ***pfdhps*** A437G, K540E) that have been common since initial studies over a decade ago remained high. Only in Kanungu, two additional mutations that predict a greater level of resistance to SP, and which previously were rare in Uganda (mixed/mutant ***pfdhfr*** I164L 15%, ***pfdhps*** A581G 47%), were seen. Taken together, our results demonstrate significant changes in the prevalence of transporter polymorphisms with increasing use of AL to treat malaria, persistent prevalence of 5 common antifolate mutations despite decreased use of SP to treat malaria, and the presence of additional antifolate mutations that predict high level resistance in Kanungu. Another cross-sectional survey is now underway, and results for 2015 will be compared with those from prior years. Considering changing use of antimalarials and recent evidence for changing relative drug efficacies in Uganda, continued surveillance for drug resistance markers is an important priority.

812

RISK OF CARDIOTOXICITY WITH REPEATED DOSING OF DIHYDROARTEMISININ-PIPERAQUINE FOR INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN UGANDAN SCHOOLCHILDREN

Samuel Gonahasa[1], Catherine Maiteki Sebuguzi[1], Afizi Kibuuka[1], Steven Okello[1], Florence Nankya[1], Jaffer Okiring[1], Eva Maria Hodel[2], Francesca Aweeka[3], Grant Dorsey[3], Moses R. Kamya[4], Sarah G. Staedke[5]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]University of California, San Francisco, CA, United States, [4]School of Medicine, Makerere University College of Health Sciences, Kampala, Uganda, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

Intermittent preventive treatment (IPT) for malaria in schoolchildren offers a promising option for malaria control. Although studies suggest that repeated dosing of dihydroartemisinin-piperaquine (DP) for IPT is safe and effective, questions about the potential risk for cardiotoxicity remain, particularly when DP is administered with food. We conducted a cardiac monitoring and pharmacokinetic (PK) study alongside a cluster-randomized trial to evaluate monthly IPT of schoolchildren with DP in Jinja, Uganda. A sub-set of intervention participants was recruited using

convenience sampling. ECGs were performed at baseline (prior to DP), and on Day 1 (before DP), and Day 3 (4-5 hours after DP) for each IPT round. Information on food intake and recent medications was also collected. In reading ECGs, the duration of the QT interval was corrected using Fridericia's formula. In the final IPT round, piperaquine levels were measured on Days 1 (trough) and 3 (peak), from whole capillary blood samples collected by fingerprick into heparinized microtubes. In 2014, 197 children from 8 schools were screened, and 191 children were enrolled; 6 were excluded due to an abnormal baseline ECG (n=5), or lack of consent (n=1). The mean age of participants was 9.95 years (range 5 to 19 years), and 86 girls (45%) were included. A total of 1701 ECGs were performed. A QTcF interval of >450ms was detected in 31 (2%) ECGs, including 18 grade 1 (450-464ms), 8 grade 2 (465-479ms), and 5 grade 3 (>480ms) abnormalities; all were asymptomatic. Of those children with a QTcF >464ms, 12 (92%) were male, with a mean weight of 34.4 kg; 6 (46%) reported taking food within a 6-hour window around the DP dose, while 7 (54%) took DP while fasting. A total of 156 (82%) participants in the cardiac monitoring sub-study were enrolled into the PK study; blood samples were obtained from all participants, and analysis of the samples is ongoing. Full results, including the association between food intake, piperaquine drug levels, and QTcF prolongation, will be presented and their implications on the safety of DP for chemoprevention will be discussed.

813

CAROTENOID BIOSYNTHESIS INHIBITION IN THE ASEXUAL INTRAERYTHROCYTIC STAGES OF *PLASMODIUM FALCIPARUM* BY FLURIDON

Richard Nortey-Mensah

University of Ghana, Accra, Ghana

Malaria remains a major health concern despite extensive efforts spanning over a century to combat the disease. ***Plasmodium falciparum***, like other Apicomplexans have retained a relict plastid known as the apicoplast and this organelle is only present in the parasite and not the human host. The isoprenoid biosynthetic pathway has been annotated to this organelle and the pathway results in the synthesis of isoprene units which can be channelled into carotenoid synthesis. This pathway could be a good target for the chemotherapeutic treatment of malaria. ***P. falciparum*** 3D7 clone were cultured as described by Trager and Jensen. The parasites were initially synchronised at the ring stages by treatment with 5% D-sorbitol and maintained in culture until they developed into trophozoites or schizonts. The various stages were then treated with different concentrations of fluridon (0, 120 and 150μM) and incubated for different time intervals (0, 12, 24, 48 and 60hrs). Parasite population was monitored by microscopy after the incubation and IC50 determined. The fluridon treated cultures had a decrease in parasite population as compared to the control and this was observed in all the asexual stages. The decrease in population was more evident as incubation time increased. The effective fluridon concentration was observed to be at 150μM. There was also a significant (95% CI, p=0.023) delay in the parasite life cycle from the rings through to the schizonts stage. The fluridon seem to inhibit the carotenoid biosynthetic pathway in these stages which suggests that the pathway is essential for parasite survival. The reduction in parasite population was observed in all the asexual intraerythrocytic stages of the parasite. This suggests a stage-specific dependence on carotenoid synthesis and this is the first time it has been demonstrated. The effect of the drug was profound on the ring stages suggesting that they require carotenoids for their development. The carotenoid biosynthesis pathway is inhibited by fluridon in all the asexual intraerythrocytic stages of ***P. falciparum***. This opens up new opportunities for developing chemotherapeutic agents for the treatment of malaria.

814

EVALUATION OF *PLASMODIUM FALCIPARUM* ARTEMISININ RESISTANCE IN WESTERN THAILAND AS PART OF A DOD MULTI-CENTER TRIAL

Krisada Jongsakul[1], Michele Spring[1], Ilin Chuang[1], Sha Law[2], Sabaithip Sriwichai[1], Worachet Kuntawunginn[1], Saowaluk Wongarunkochakorn[1], Pattaraporn Vanachayangkul[1], Alaina Halback[3], James Cummings[3], David Saunders[1], Mark Fukuda[3]

[1]Armed Forces Research Institute of Medical and Sciences, Bangkok, Thailand, [2]Kwai River Christian Hospital, Kanchanaburi, Thailand, [3]Armed Forces Health Surveillance Center, Silver Spring, MD, United States

Artemisinin-resistant ***Plasmodium falciparum*** threatens the effectiveness of all artemisinin-based combination therapies. A multi-center artesunate-mefloquine (A+M) efficacy trial is on-going in three US DoD laboratories in Peru, Kenya, and Thailand, to compare parasite clearance rates at 72 hours after artesunate initiation. Participants receive 4 mg/kg artesunate at 0, 24, and 48 h, 15 mg/kg mefloquine at 72 h, and, at 84-96 h, 10 mg/kg mefloquine plus 0.5 mg/kg primaquine for transmission blocking. To calculate parasite clearance half-life ($PC_{1/2}$), parasite density is assessed by microscopy every 4h for the first 12h after first artesunate dose and eve-ry 6h for 72h or until two consecutive negative smears. Efficacy outcomes over 42 days are also assessed. Between Oct 31, 2013, and Jan 7, 2015, we enrolled 45 of 59 planned patients in Sangkhlaburi district near the Thai-Myanmar border. We found that AS-MQ combination ther-apy as administered was still highly efficacious in this region, with 100% adequate clinical and parasitological response (ACPR) at 42 days. However, the median $PC_{1/2}$ of 4.9 hours is approaching that used to define artemisinin resistance (5 hours). Further, 15% of patients had PC1/2 >5 hours, and 20% remained parasitemic at 72 hours (Day 3), thus meeting the WHO definition for suspected artemisinin resistance. Evidence of resistance based on ***in vitro*** drug-sensitivity testing and molecular resistance markers is also being evaluated. While our data suggest that clinical effectiveness has yet to be compromised, ongoing surveillance in this area is needed.

815

A MULTI-STAGE PRECLINICAL CANDIDATE FOR THE POTENTIAL TREATMENT OF MALARIA

Neil R. Norcross[1], Beatriz Baragaña[1], Irene Hallyburton[1], Raffaella Grimaldi[1], Maria Osuna-Cabello[1], Suzanne Norval[1], David W. Gray[1], Alan H. Fairlamb[1], Paul Willis[2], Kevin D. Read[1], Ian H. Gilbert[1]

[1]Drug Discovery Unit, University of Dundee, United Kingdom, [2]Medicines for Malaria Venture, Geneva, Switzerland

Malaria is a devastating parasitic disease causing widespread mortality and morbidity across many parts of the developing world. Many medicines for the treatment of malaria are failing due to the increasing development of resistance and new therapies for both treatment and prevention of this deadly disease across all of its life cycle stages are urgently needed. In the search for new antimalarials, a collaborative project between the University of Dundee and Medicines For Malaria Venture (MMV) was initiated with the high throughput phenotypic screening (HTS) of an in-house library of protein kinase scaffolds. Initial screening identified multiple structurally diverse chemical series that blocked asexual blood stage parasite viability and served as a catalyst for a new drug discovery programme. Using a focussed medicinal chemistry approach involving drug design, chemical synthesis, biological testing and rigorous compound profiling, we identified a highly efficacious compound with potent activity against multiple life cycle stages. Efforts reported herein reveal a small molecule inhibitor of ***Plasmodium falciparum*** malaria with good pharmacokinetic properties and excellent possibilities for chemoprotection, single dose blood stage treatment and transmission blocking.

816

THE EFFECTIVENESS OF CHLOROQUINE AND PRIMAQUINE FOR THE TREATMENT OF VIVAX MALARIA; A STUDY IN A TERTIARY CARE HOSPITAL IN THAILAND

Hariharan Subramony, Noppadon Tangpukdee, Chaweewan Pengruksa, Nanthaporn Phophak, Chatnapa Duangdee, Thanee Raknam, Sorose Pengruksa, Polrat Wilairatana, **Srivicha Krusood**

Faculty of Tropical Medicine, Bangkok, Thailand

Malaria is an infectious disease that continues to be a major public health problem, and occurs throughout the tropical regions of the world. Chloroquine in combination with primaquine is the first-line treatment for ***Plasmodium vivax*** malaria in Thailand. In view of the declining efficacy of chloroquine in many ***P. vivax*** endemic areas, the possibility of emergence of chloroquine-resistant ***P. vivax*** in Thailand is a concern. The aim of this study was to assess the trends in therapeutic efficacy of chloroquine and primaquine for the treatment of uncomplicated ***P. vivax*** malaria. A retrospective review of medical records of patients admitted and treated for uncomplicated ***P. vivax*** malaria, during 2004 - 2013, was conducted at the Bangkok Hospital for Tropical Diseases (BHTD), Faculty of Tropical Medicine, Mahidol University, Thailand. A total of 335 uncomplicated ***P. vivax*** malaria patients were enrolled into the study, 362 patients achieved an adequate 28-day clinical and parasitological response (ACPR). 3 cases were classified as early treatment failure. The minimum-maximum of median parasite clearance time and median fever clearance time over the 10 year period was 46-59 hours and 14-28 hours respectively. There was no significant increasing trend of parasite clearance time over this time period. We concluded that treatment of ***P. vivax*** infection with a combination of chloroquine and primaquine has remained efficacious in Thailand. Increasing time-trends in parasite clearance times may be useful as an early warning mechanism for emergence of chloroquine-resistant ***P. vivax*** strains.

817

SULFADOXINE-PYRIMETHAMINE AVAILABILITY AND (MIS) USE IN SUB-SAHARAN AFRICA: ANTIMALARIAL MARKET DATA FROM EIGHT COUNTRIES

Megan Littrell, The ACTwatch Group

Population Services International, Washington, DC, United States

As evidence of reduced chloroquine efficacy against ***Plasmodium falciparum*** mounted in the 1990's, sulfadoxine-pyrimethamine (SP) became first-line malaria treatment in many endemic countries in sub-Saharan Africa (SSA). Between 2002-2005, countries in SSA adopted artemesinin combination therapies (ACT) as first-line treatments. SP is still recommended by the WHO and used across SSA for intermittent preventive treatment of malaria during pregnancy (IPTp). As such, availability and use of SP should currently be limited to distribution for IPTp at antenatal care (ANC) clinics. However, multi-country data collected by ACTwatch show widespread availability and use of SP outside of health facilities. Multiple malaria medicine outlet surveys were conducted between 2009-2014 in Benin, the DRC, Kenya, Madagascar, Nigeria, Tanzania, Uganda and Zambia. A census of outlets with potential to distribute antimalarials was conducted among a representative sample of administrative units. A drug audit documented product information, reported retail price and amount distributed to consumers in the past week for all antimalarials in stock. Across project countries, the vast majority of antimalarial-stocking private sector outlets including pharmacies, drug shops, and retailers were stocking SP. Conversely, SP availability was typically lower among public health facilities as compared with these private sector outlets. In some contexts, SP availability among public health facilities declined in recent years. SP is commonly distributed to patients by private sector outlets and accounts for one-quarter to one-half of antimalarials distributed. In some cases, SP market share has actually increased in recent years including in Madagascar, where SP distribution increased with the decrease in distribution of chloroquine. We examine trends over time and across 8 project countries regarding where SP is found, the origins of available SP (manufacturer and country of manufacture), and private sector price of SP compared with first-line ACT treatment. Implications for policies and strategies to ensure SP use is restricted to IPTp delivery will be discussed.

818

PARASITE CLEARANCE AND EFFICACY OF ARTEMISININ-BASED COMBINATION FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN BOBO-DIOULASSO, BURKINA FASO

Frederic W. Nikiema, Fabrice A. Some, Issaka Zongo, Daniel Y. Compaore, Noel Rouamba, Jean-Bosco Ouedraogo

Institut de Recherche en Science de la Sante/Bobo Dioulasso, Bobo Dioulasso, Burkina Faso

Artemisinin-based combination treatments (ACTs) main feature is their ability to accelerate the clearance of ***Plasmodium*** ring stage infected erythrocytes. Recent emergence of Artemisinin-resistance in Cambodia may represent a major threat to the global effort to malaria control and elimination. Artemisinin-resistance polymorphisms have been associated with delayed parasite clearance following artemisinin combination therapy. We investigated the association between parasite clearance and ACTs efficacies in 200 uncomplicated malaria patients randomized. We sampled per-protocol 42 days follow-up data from patients of a Phase IIIb/IV clinical trial to assess the safety and efficacy of repeated administration of pyronaridine-artesunate, artemether-lumefantrine and dihydroartemisinin-piperaquine in patients with acute uncomplicated ***Plasmodium falciparum*** Malaria conducted in Bobo-Dioulasso. Parasitaemia at Hour 0, 12, 24, 36, 48, 60 and 72 counts were shared on WWARN Parasite Clearance Estimator online tool according to WWARN terms of use to generate parasite clearance half-life. Therapeutic efficacy has been evaluated according to the presence or not of asexual forms of malaria parasites on a blood smear during follow-up. The geometric mean of parasite clearance half-life is significantly lower in recovered patients group, 2.68 h (95% CI 2.28-3.08) versus 2.90 h (95% CI 2.45-3.35), p-value=0.035. Overall, in parasitological treatment failure group, there was a significant correlation between the failure day and the parasite clearance; the slope half-life decreases significantly with the timeout of treatment failure. Very Late treatment failure would be more due to recrudescent than new infections. Parasite clearance is a good tool for the evaluation of artemisinin-based combination efficacy for the treatment of uncomplicated ***P. falciparum*** malaria. The raising of the parasite clearance half-life, calculated with the three-day parasitemies after treatment, can determinate parasitological treatment failure during follow-up.

819

SYSTEMATIC SAMPLING APPROACH REVEALS FEWER FALSIFIED FIRST LINE ANTIMALARIALS THAN PREVIOUSLY REPORTED

Harparkash Kaur[1], Michael D. Green[2], Facundo M. Fernández[3], ACT consortium - Drug Quality Team[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Georgia Institute of Technology, School of Chemistry and Biochemistry, Atlanta, GA, United States

Malaria is a curable disease provided patients have timely access to efficacious drugs, namely artemisinin based-combination therapies (ACTs), recommended as first line treatment by the World Health Organisation (WHO). The threat posed by falsified and substandard drugs is drawing increasing international attention, heightened by reports indicating that up to 35% (796 of 2,296) of antimalarial drugs purchased following the convenience approach from 21 Sub-Saharan African countries failed

content analysis. To investigate the threat we purchased over 10,000 ACTs using three sampling approaches (convenience, mystery client and overt) and updated sampling frames, to provide comprehensive surveillance of ACTs available in a given geographical region. The ACTs were collected in 6 countries - Cambodia, Ghana (Kintampo), Equatorial Guinea (Bioko Island), Nigeria (Enugu metropolis and Ilorin city), Rwanda and Tanzania (nationwide). Content analyses using mass spectrometry (qualitative) and high performance liquid chromatography with photo-diode array detection (quantitative) were used to measure the amount of active pharmaceutical ingredients (APIs) in 3 independent laboratories. Results were expressed as percentage of APIs stated on the packaging and used to categorise each sample as quality assured, substandard, degraded, or falsified. Our findings were reassuring in that out of the 10,092 samples (142 brands) we only found falsified formulations that did not contain the stated APIs in 2 countries: Nigeria (both Enugu state [1%] and Ilorin city [0.8%]) and Equatorial Guinea (Bioko Island [7.3%]). In contrast, although substandard drugs were found in all 6 countries, this did not exceed 7% of the samples analysed from Africa. The results were disseminated to the country-specific Ministry of Health, as well as the stated manufacturers and WHO. Data will be presented to illustrate that a representative sampling approach is essential, and that both mystery client and overt sampling approaches can be used, to accurately quantify and track the scale of ineffective drugs which jeopardise treatment of a life threatening disease.

820

IN VIVO AND EX VIVO EFFICACY OF ARTEMETHER-LUMEFANTRINE ON *PLASMODIUM FALCIPARUM* ISOLATES IN MALI

Souleymane Dama, Hamidou Niangaly, Issaka Sagara, Sekou Sissoko, Oumar Bila Traore, Amadou Bamadio, Niawanlou Dara, Moussa Djimde, Mohamed Lamine Alhousseini, Siaka Goita, Hamma Maiga, Ogobara Doumbo, Abdoulaye Djimde

University of Sciences Techniques and Technology of Bamako, Bamako, Mali

In Mali, previous studies showed high frequency of recurrent parasitemia after treatment with artemether-lumefantrine. We hypothesized that, recurrent parasites after treatment have a reduced sensitivity to artemether-lumefantrine. We conducted a longitudinal study on 641 volunteers recruited in Sotuba and Kolle, Mali. In-vivo sensitivity of ***Plasmodium falciparum*** to artemether-lumefantrine was measure as per WHO protocols. Polymerase chain reaction was used for molecular correction and to assess Pfcrt K76T and Pfmdr1 N86Y allele polymorphism. K13 propeller genotypes were assessed by sequencing. Ex-vivo field isolates sensitivities to artemether and lumefantrine were assessed using the hypoxanthine isotopic test. The 28-day uncorrected Adequate Clinical and Parasitological Response (ACPR) cure rates were statistically different between Sotuba and Kolle, respectively 96.31% (313 of 325 patients; 95% CI, 94.25 - 98.36) and 78.16% (247 of 316 patients; 95% CI, 73.59 - 82.73), $p < 0.001$. PCR corrected ACPR rates were comparable between the two study sites 98.77% (321 of 325 patients; 95 % CI, 97.4 - 99.9) and 97.47% (308 of 316 patients; 95 % CI, 95.73 - 99.2) in Sotuba and Kolle respectively ($p = 0.181$). The pfmdr1 86N allele was selected after treatment with artemether-lumefantrine (71% versus 91%, $p = 0.0012$) but not pfcrt 76T (76.8% versus 75.2%, $p = 0.09$). Fifty (50) ***P. falciparum*** isolates from 641 volunteers were successfully cultured ex-vivo. All of the isolates tested ex-vivo were sensitive to artemether and lumefantrine. Means values of IC_{50} for artemether were 1.8 nM in pre-treatment isolates versus 3.8 nM in post treatment isolates ($p = 0.001$) and 1.9 nM versus 6.9 nM ($p = 0.014$) for lumefantrine Field ***P. falciparum*** isolates were sensitive in-vivo and ex-vivo to artemether and lumefantrine but recurrent parasites had significantly higher IC_{50} for both components of AL.

821

K13 MUTATIONS IN *PLASMODIUM FALCIPARUM* PERSISTING AFTER ACT TREATMENT OF KENYAN CHILDREN

Khalid B. Beshir[1], Julian Muwanguzi-Karugaba[1], Patrick Sawa[2], Colin Sutherland[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Human Health Division, International Centre of Insect Physiology and Ecology, Mbita, Kisumu, Kenya

Studies in the greater Mekong sub-region reported a strong relationship between polymorphisms at the propeller domain of the Kelch 13 (K13) protein encoded by the pfk13 locus and delayed parasite clearance after artemisinin treatment. In Africa, ***Plasmodium falciparum*** remain susceptible and combination therapy regimens which include an artemisinin component display good efficacy. In 2009, we observed using parasite detection by qPCR that sub-microscopic persistence of ***P. falciparum*** occurred in about one third of children treated with artemisinin combination therapy (ACT) in western Kenya, and these children were much more likely to develop recrudescent patent parasitaemia 4 or 6 weeks after treatment. Mutation in the pfk13 locus was rare in the parasite population captured by this study, and there was no evidence variants of pfk13 contribute to the persistence phenotype we observed. A similar study was carried out in the same site in 2013 in order to monitor any change in parasite clearance time and in the emergence of any mutations at pfk13 and other key genes. The parasite clearance phenotype as well as the prevalence of mutations in pfk13, pfmdr1, pfcrt1 and pfap2μ will be presented. Any association between sub-microscopic parasites on day 3 after ACT treatment and mutations on those genes will be evaluated and results presented.

822

DURATION OF ARTEMISININ COMBINATION THERAPY INFLUENCES PARASITOLOGICAL OUTCOME IN A MOUSE MODEL OF MALARIA

Leah A. Walker[1], Paul D. Roepe[2], David J. Sullivan[1]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Georgetown University, Washington, DC, United States

The clinically active derivatives of artemisinin reduce the total parasite burden more rapidly than other antimalarials. The short plasma half-life of the artemisinin derivatives and the dosing duration (number of days of treatment) of artemisinin combination therapy (ACT) result in most of the artemisinin being cleared during a single 48 hour asexual cycle of ***Plasmodium falciparum***. Our laboratory hypothesizes that the ACT regimen duration plays a significant role in clinical outcome, keeping total dose of ACT constant. To better understand the role of treatment duration on clinical outcome, we have adapted a novel murine model of malaria, which utilizes a luciferase-reporter ***P. berghei*** at high parasitemia to study the rate of parasite killing ***in vivo***. Unlike other drug efficacy assays which assess cytostatic activity, our assay more accurately mimics high parasitemia infections and cytocidal drug activity in the field. Using this model, we have determined the effect of two different artesunate duration regimens on parasite clearance and survival. Unlike ***P. falciparum***, which has a 48-hour asexual cycle***, P. berghei*** has a 24-hour asexual cycle in the mouse. Three doses of 50 mg/kg artesunate were administered to BALB/cJ mice with 6-10% parasitemia at two different duration regimens: 3 doses at 0, 8, and 20 hours, and 3 doses at 0, 24, and 48 hours. We have found that extending single-drug artesunate treatment from 1 asexual life cycle to over 3 asexual life cycles significantly prolongs time of absent parasitemia and results in a slower parasite multiplication rate for recrudescent parasites. In combination with quinoline partner drugs, the longer dose duration of artesunate effects cure measured at 30 days, whereas recrudescence is observed in combination with the shorter dose duration. Also, pyronaridine was shown to have a single dose cure with one tenth of the human equivalent dose. Lengthening dose duration to span three lifecycles makes existing artemisinin treatment more effective.

823

IMPACT OF INTEGRATING THE DELIVERY OF SEASONAL MALARIA CHEMOPREVENTION WITH NUTRITION SUPPLEMENTATION IN NORTHERN NIGERIA ON HEALTH OUTCOMES: A PRAGMATIC INTERVENTION TRIAL

Abigail V. Ward[1], Andrea Guillot[1], Justin C. Graves[1], Kathleen Maloney[1], Omowunmi F. In 2012 WHO recommended Seasonal Malaria Chemoprevention (SMC) with sulfadoxine-pyrimethamine and amodiaquine (SP-AQ) to prevent childhood malaria in the Sahel sub-region. As malnourished children are twice as likely to die from malaria, there is potential for improving malaria and nutrition outcomes by combining the delivery of SP-AQ with Lipid-based Nutritional Supplements (LNS). From August to November 2014, SP-AQ was delivered monthly door-to-door to children under five years old by community volunteers in seven wards of Madobi, Kano State, northern Nigeria. In three of the wards, children 6-24 months old were also provided LNS. About half of the 4000 children 6-24 months old who received SMC also received LNS. Cross-sectional baseline and endline household surveys conducted in August and November 2014 collected data on demographics, anthropometric measurements, coverage, recent fever history, and adherence to interventions among children aged 6-24 months at baseline. We measured the impact of adding LNS on coverage estimates, recent fever incidence, and nutrition outcomes using multivariable logistic regression models. SMC coverage was 88% (95% CI 87-89%, n=1594) with no observed difference between the two arms; LNS coverage was estimated at 83% (95% CI 81-84%). Reported adherence to the 3-day course of SP-AQ was 82% across both arms, but adherence to LNS measured by consumption the day before was 57%. At baseline 78% of 1700 children were stunted, 54% were underweight and 15% were wasted. Adjusting for demographic factors and baseline, children who received four rounds of SMC and LNS had similar nutrition outcomes to children who received SMC only in preliminary analyses. Adding LNS to SMC resulted in a significant drop in fever incidence between August and November compared with SMC alone (p=0.02). Co-packaging SMC and nutritional supplements is operationally efficient, but no benefit in terms of coverage or nutrition outcomes was observed. Further study should explore subgroups and whether four rounds of LNS with observed adherence is sufficient to address the high prevalence of malnutrition observed in this population.

EMERGING OF MUTATIONS IN K13 PROPELLER GENE OF *PLASMODIUM FALCIPARUM* ISOLATES FROM DAKAR, SENEGAL IN 2013-2014

Bruno Pradines[1], Agathe Boussaroque[1], Bécaye Fall[2], Marylin Madamet[1], Cheikhou Camara[2], Nicolas Benoit[1], Mansour Fall[2], Aminata Nakoulima[2], Pierre Dionne[2], Kadidiatou Ba Fall[2], Bakary Diatta[2], Yaya Diémé[2], Boubacar Wade[2]

[1]Institut de Recherche Biomédicale des Armées, Brétigny sur Orge, France, [2]Hôpital Principal de Dakar, Dakar, Senegal

Malaria resistance to most antimalarial drugs has developed in Southeast Asia and has spread to Africa. Since 2005, the World Health Organization recommended artemisin-based combination therapy (ACT) as first-line treatment in malaria. In Senegal since 2006, ACT is recommended by the Senegalese National Malaria Control Programme as first-line treatment for uncomplicated malaria. The emergence of ***Plasmodium falciparum*** resistance to artemisinin and its derivatives, manifested as delayed parasite clearance following the treatment with artesunate monotherapy or ACT, has recently developed in Southeast Asia. Recently, mutations in the propeller domain of the Kelch 13 (K13) gene (PF3D71343700) were associated with ***in vivo*** and ***in vitro*** resistance to artemisinin in Southeast Asia. Four mutations, Y493H, R539T, I543T and C580Y, were recently correlated to ***in vivo*** and ***in vitro*** artemisinin resistance in Southeast Asia. While no mutation was found in ***Plasmodium falciparum*** isolates from Dakar, in 2012-2013, three mutations, N554H, Q613H and V637I, were identified among 92 isolates (12%) in 2013-2014. Five polymorphisms were identified in the ***Plasmodium***/Apicomplexa-specific domain (K123R, N137S, N142NN/NNN, T149S and K189T/N). The mutations associated with ***in vitro*** resistance in Southeast Asia such as Y493H, R539T, I543T and C580Y were not observed, nor than the M476I mutation obtained ***in vitro*** on a Tanzanian strain. Further studies are needed to better characterize the role of these mutations in artemisinin resistance.

825

EVALUATION OF K13-PROPELLER POLYMORPHISMS IN *PLASMODIUM FALCIPARUM* PARASITES FROM NIGERIA

Mary C. Oguike[1], George O. Ademowo[2], Catherine O. Falade[3], Colin J. Sutherland[1]

[1]Immunology and Infection Department, London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Institute for Advanced Medical Research and Training, College of Medicine, University of Ibadan, Ibadan, Nigeria, [3]Department of Pharmacology and Therapeutics, University of Ibadan, Ibadan, Nigeria

Drug resistance is indeed a raging 'monster' in the battle against malaria. As a result, artemisinin combination therapies (ACTs) have been globally adopted for antimalarial chemotherapy. ACT is known to be very potent but recent reports have observed in the form of slow parasite clearance in Southeast Asia that these drugs may not be as effective as in the recent past. As part of the measures to curb antimalarial drug resistance, the World Health Organisation (WHO) recommended continuous molecular surveillance of resistance markers to these drugs in order to detect early warning signs. In Nigeria, artemether-lumefantrine (AL) and artesunate-amodiaquine (ASAQ) have been adopted as preferred ACT options. Until recently, there was no candidate marker for artemisinin resistance rather, candidate markers for their combination partners were used to evaluate efficacy. ***Plasmodium falciparum*** chloroquine resistance transporter (pfcrt) and ***P. falciparum*** multidrug resistance gene 1 (pfmdr1) are associated with decreased sensitivity to amodiaquine and lumefantrine, but effects of these polymorphisms on therapeutic responses to artesunate-amodiaquine (ASAQ) and artemether-lumefantrine (AL) have not been clearly defined. Recently, the ***P. falciparum*** K13-propeller was identified as a key determinant of delayed parasitological clearance after artemisinin treatment, and single nucleotide polymorphisms (SNPs) in K13 were associated with ***in vitro*** and ***in vivo*** resistance in Asia. As part of molecular surveillance of resistance markers to ACTs, we investigated by direct sequencing, the mutations in K13-propeller region in 150 ***P. falciparum*** positive blood spots from Nigerian children treated with ACTs in a clinical trial between 2007-2008. The results will serve as preliminary data on the interplay between recurrent parasitaemia and polymorphism in the ***P. falciparum*** K13-propeller gene in Nigeria.

826

EVALUATION OF THE CAPACITY OF SENEGAL'S MALARIA DIAGNOSTIC ALGORITHM TO IDENTIFY PATIENTS WITH MALARIA PARASITEMIA

Julie I. Thwing[1], Fatou Ba[2], Alou Diaby[3], Younouss Diedhiou[4], Daouda Ndiaye[4], Mame Birame Diouf[5], Seynabou Gaye[2], Alioune B. Gueye[2], Assane Sylla[3], Guelaye Sall[3], Mady Ba[2]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]National Malaria Control Program, Dakar, Senegal, [3]Institut de Population, Developpement, et Sante de la Reproduction, Dakar, Senegal, [4]University Cheikh Anta Diop, Dakar, Senegal, [5]United States Agency for International Development, Dakar, Senegal

Appropriate case management of malaria depends on access to an accurate diagnostic test. Malaria rapid diagnostic tests (RDTs) enable point-of-care testing nearly as sensitive and specific as reference microscopy and permit accurate diagnosis at every healthcare level. The Senegal National Malaria Control Program introduced RDTs in 2007, along with a diagnostic algorithm stipulating that if a febrile patient of any age has symptoms indicative of a febrile illness other than malaria (e.g., cough or rash), they would not initially be tested for malaria, but treated for the apparent illness and receive an RDT if they return in 48 hours without improvement. We conducted a year-long study in 16 epidemiologically representative health posts to determine the algorithm's capacity to identify cases of confirmed malaria. Health post personnel enrolled patients of all ages with fever (>37.5 C) or history of fever in the past 2 days. After clinical assessment, the nurse determined whether the patient would have received an RDT according to the diagnostic algorithm, but performed an RDT for all enrolled patients. Over one year, 6039 patients were enrolled; 47% were under 5 years, and 58% required an RDT according to the algorithm. Overall, 23% had a positive RDT, 34% during rainy season and 9% during dry season. The algorithm identified 78% of patients with a positive RDT, but this varied according to transmission season (rainy 80%, dry 70%), epidemiologic strata (high transmission 75%, low transmission 95%), and age group (under five years 68%, five years and older 84%). In all but the lowest transmission zone, use of the algorithm results in an unacceptably large proportion of patients with malaria who do not receive timely diagnosis and treatment. While the algorithm was adopted within a context of malaria control, with the goal of treating patients with symptomatic malaria, Senegal has now adopted a goal of malaria elimination. In the context of malaria elimination, the paradigm of case management needs to shift toward the identification and treatment of all patients with malaria parasitemia, and case management policy has been changed to reflect this.

827

EVIDENCE OF NON-FALCIPARUM MALARIA IN KEDOUGOU, SENEGAL

Rachel F. Daniels[1], **Awa B. Deme**[2], Katelyn Durfee[1], Julie Thwing[3], Fatou Ba Fall[4], Mady Ba[4], Dyann F. Wirth[1], Sarah K. Volkman[1], Daouda Ndiaye[2]

[1]Harvard School of Public Health, Boston, MA, United States, [2]University Cheikh Anta Diop, Dakar Fann, Senegal, [3]President's Malaria Initiative at Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Programme National de lutte contre le Paludisme, Dakar Fann, Senegal

Expanded efforts to control malaria in Senegal have resulted in increased used of rapid diagnostic tests to identify the primary disease-causing ***Plasmodium*** species, ***P. falciparum***. However, these tests do not detect other malaria-causing species such as ***P. ovale*** and ***P. malariae*** that have previously been reported in Senegal. Current studies on species circulating in Senegal are lacking; and, assessing the population prevalence of malaria using appropriate diagnostic methods is essential for assessing the need for health care services. Based on this, we developed real-time polymerase chain reaction speciation assays and analyzed 475 HRP2-based rapid diagnostic tests collected between 2013 and 2014, from a single site in southern Senegal, Kedougou, a hyper endemic region with malaria prevalence greater than 10%,. We observed ***P. malariae*** (n=3) and ***P. ovale wallikeri*** (n=2) as co-infections with ***P. falciparum*** among patients with positive rapid diagnostic tests (n=187 positive tests), including one patient positive for all three species. Among 288 negative tests, both ***P. ovale curtisi*** (n=3) and ***P. ovale wallikeri*** (n=1) were identified, as well as ***P. malariae*** (n=1). Furthermore, approximately 10% of the negative samples had detectable levels of ***P. falciparum*** by real-time PCR. These findings suggest that non-falciparum malaria is of concern in this country, particularly in light of reduced incidence of ***P. falciparum*** nationwide. Use of a specific rapid diagnostic test does not necessarily provide an accurate view of malaria transmission in Kedougou, Senegal; and, more sensitive and specific methods are required.

828

DIFFERENTIAL RESPONSE OF TOTAL IGG LEVELS IN SERUM FROM *PLASMODIUM FALCIPARUM* INFECTED INDIVIDUALS IN THE AMAZON REGION AGAINST PROTEINS EXPRESSED IN A BACULOVIRUS EXPRESSION SYSTEM

Katherine Torres, Katherine Garro, Jorge Bendezu, Sandra Morales, Beronica Infante, Elizabeth Villasis, Dionicia Gamboa

Universidad Peruana Cayetano Heredia, Lima, Peru

Erythrocyte invasion by the merozoite is a multiple steps process that involves specific interactions between erythrocyte receptors and parasites ligands. Therefore proteins related to invasion are important vaccine candidates and/or targets for diagnostic tool development. A recent study carried out in Peru assessed the protective immune response in plasma of Asymptomatic vs. Symptomatic ***Plasmodium falciparum*** infected individuals, using Protein microarrays against 850 asexual recombinant proteins derived from ***P. falciparum*** strain 3D7. The results of this study indicated a higher immune responses for asymptomatic individuals in comparison with the symptomatic ones against 52 proteins, including invasion proteins EBA-175 and RH2b; MSP-10 protein was immunoreactive for both groups.The aim of this study was to evaluate the total IgG levels in 30 serum samples from ***P. falciparum*** infected individuals (symptomatic and/or asymptomatic) against proteins PfRH2b, EBA-175 and MSP-10 by ELISA. The proteins were expressed in a baculovirus-recombinant protein system using Sf9 insect cells. All serum samples confronted against proteins PfRH2B, EBA-175 and MSP-10, showed a differential total IgG response against these recombinant proteins individually. These preliminary results demonstrated that recombinant ***P. falciparum*** invasion proteins synthesized by the baculovirus expression system were well recognized by patient serums, suggesting that this methodology could be a useful tool for the synthesis of ***P. falciparum*** proteins to be used as vaccine candidate proteins and/or as new targets for the development of Rapid Diagnostic Test.

829

EXPRESSION OF *PLASMODIUM FALCIPARUM* - RECOMBINANT PROTEINS (RH2B, EBA-175 AND MSP-10) USING BACULOVIRUS SYSTEM IN SF9 INSECT CELLS

Jorge Bendezu, Sandra Morales, Beronica Infante, Katherine Torres, Elizabeth Villasis, Manolo Fernandez, Dionicia Gamboa

Universidad Peruana Cayetano Heredia, Lima, Peru

Malaria caused by ***Plasmodium falciparum*** kills over 1 million people a year. A recent study carried out in Peru indicated a higher immune responses for asymptomatic individuals in comparison with the symptomatic ones against 52 proteins by Protein Arrays, including invasion proteins EBA-175 and RH2b; MSP-10 protein was immunoreactive for both groups. The aim of the present study was to standardize a baculovirus-recombinant protein system expression in Sf9 insect cell. We designed specific primers for the pfrh2b, pfeba175 and pfmsp10 genes. DNA products were cloned in order to be expressed using the Bac-to-Bac

system (Life TechnologiesTM). The expressed proteins were his-tag purified using iMAC system (BioRad). In order to evaluate the immunoreactivity of these proteins ten positive sera from symptomatic patients positive to ***P. falciparum*** by microscopy were used. Eight out of ten were positive for PfRH2B, four out of ten were positive for PfEBA-175 and all ten were positive for PfMSP10 recombinant protein. These preliminary results demonstrated that the recombinant proteins obtained using baculovirus system were recognized by patient serum, however more serological evaluation are necessary for further validation. This protein expression system is a useful tool to produce recombinant proteins that can be used as candidates to develop rapid diagnostic test to detect ***P. falciparum***, since the current rapid diagnostic test, mainly base on pfHRP2 are no longer useful for the Amazon region where the parasites circulating in this area do not have this gene.

ANTIGEN DISCOVERY OF NOVEL SEROLOGICAL MARKERS OF RECENT *PLASMODIUM VIVAX* INFECTION

Connie S. Li Wai Suen[1], Eizo Takashima[2], Carla Proietti[3], Rhea Longley[1], Leanne J. Robinson[1], Camila Franca[1], Inoni Betuela[4], Andrea Kuehn[5], Masayuki Morita[2], Gordon Smyth[1], Ding Xavier[6], Peter M. Siba[4], Iveth J. González[6], Marcus Lacerda[7], Jetsumon Sattabongkot[8], Denise Doolan[3], Takafumi Tsuboi[2], **Ivo Mueller**[1]

[1]Walter and Eliza Hall Institute, Parkville, Australia, [2]Proteo-Science Center, Ehime University, Matsuyama, Japan, [3]Queensland Institute of Medical Research, Herston, Australia, [4]PNG Institute of Medical Research, Madang, Papua New Guinea, [5]Institute of Global Health, Barcelona, Spain, [6]Foundation for Innovative New Diagnostics, Geneva, Switzerland, [7]Fundação de Medicina Tropical Dr. Heitor Vieira Dourado, Manaus, Brazil, [8]Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

As countries near elimination, the identification of sporadic pockets of ongoing malaria transmission becomes a challenge in the growing number of low prevalence areas, especially for ***Plasmodium vivax***. In addition, ***P. vivax*** elimination will be difficult without being able to identify and target asymptomatic carriers of ***P. vivax*** hypnozoites. Current tools focus either on the diagnosis of ***P. vivax*** bloodstage infections, limited in duration and number, or on the measure of past cumulative exposure, using long-lasting serological markers, none of which are suited to the identification of transmission pockets or hypnozoite carriers at risk of relapse. To close this gap, we have conducted a large-scale antigen discovery screen to identify new serological markers able to specifically detect recent (0 to 9 months old) ***P. vivax*** infection. Two large libraries of ***P. vivax*** antigens, collectively representing 1,600 individual proteins and more than 2,600 protein fragments, were deployed for high throughput screening of serum samples using an AlphaScreen™ liquid array system (307 wheat germ cell-free protein fragments) or custom-made protein microarrays (2,320 E. coli cell-free protein fragments). The immunoreactivity profiles of 31 children (5 to 10 years old) from Papua New Guinea and 60 Thai and Brazilian patients >7yrs. of age following radical cure of PCR-confirmed ***P. vivax*** infection were investigated for candidate antigens displaying an ideal profile for serological markers: either significant seroreversions or >4-fold drops in antibody concentration from 0 to 9 months after radical cure. This study proves the principle of serological markers of recent exposure to ***P. vivax*** infections. The resulting panels of antigens will be investigated for their performance in detecting concurrent and recent infections using plasma samples from longitudinal studies in 4 different ***P. vivax*** endemic settings.

831

DEVELOPMENT AND OPTIMIZATION OF A NEW QUANTITATIVE GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY ASSAY FOR THE SAFE TREATMENT OF *PLASMODIUM VIVAX* HYPNOZOITES

James O'Donnell[1], Andrew J. Guy[1], Vashti Irani[1], Ismael S. Barreto[2], Joe Manitta[3], Paul A. Ramsland[1], Chuong Tran[4], Celine Barnadas[5], James G. Beeson[1], **Jack S. Richards**[1]

[1]Burnet Institute, Melbourne, Australia, [2]National Health Laboratory, Dili, Timor-Leste, [3]Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [4]Royal Children's Hospital, Melbourne, Australia, [5]Walter and Eliza Hall Institute, Melbourne, Australia

A major challenge to achieving successful global elimination of malaria is the treatment of the ***Plasmodium vivax*** hypnozoite reservoir. Primaquine, an 8-aminoquinoline compound, has been available for many years and has proven efficacy in killing hypnozoites. Its use however, can induce haemolysis in patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency. This X-linked disease is the most common human enzymatic deficiency; prevalence of up to 30% has been observed in some malaria endemic areas. Fears of G6PD deficiency and drug-induced haemolysis have greatly decreased the uptake of primaquine therapy in ***P. vivax*** endemic countries, resulting in high burden ***P. vivax*** as a consequence. This risk of haemolysis can be dramatically reduced with G6PD testing prior to treatment or identifying homogeneous populations with low risk of G6PD deficiency. Each of the current G6PD testing methods have significant limitations either in their ability to be technically implemented or in their affordability in resource-poor settings. Consequently, there is a need for an accurate, robust, and inexpensive G6PD test that can be deployed in resource-poor settings. We describe the optimisation and validation of a new quantitative G6PD test with an integrated quantitative haemoglobin (Hb) test. This new combined test showed strong agreement with the current gold-standard tests but can be performed with much less sophisticated equipment at a fraction of the cost. Field evaluations of this new G6PD test are currently being conducted.

832

EVALUATION OF GENEDIA® MALARIA P.F/PAN AG RAPID TEST RELATIVE TO MICROSCOPY IN A MALARIA ENDEMIC AREA ETHIOPIA

Abeba G. Reda

EPHI, Addis Ababa, Ethiopia

Early and accurate diagnosis of malaria followed by prompt treatment reduces morbidity and mortality in endemic regions. Presumptive treatment of malaria is widely practiced where microscopy or rapid diagnostic tests are not readily available. Introduction of rapid diagnostic tests (RDTs) for the treatment of malaria in many low-resource settings need evaluation of their performance. This study evaluated the performance of GENEDIA® Malaria P.f/pan Ag Rapid Test in malaria endemic area Ethiopia. This study ws undertaken to evaluate the diagnostic performance of GENEDIA® Malaria P.f/pan Ag Rapid Test relative to microscopy for the diagnosis of ***Plasmodium falciparum*** and ***P. vivax*** malaria in Ethiopia. In this cross-sectional study from November to December 2013, patients who had malaria symptoms and visited malaria control center in Adama, Oromia Region were recruited. Thin and thick blood smears were prepared from finger prick and stained by 10% Giemsa. Microscopic examination was done under 100x magnifications for ***Plasmodium*** species identification and determination of parasitaemia. The RDT was performed as per the manufacturers instructions. A total of 417 febrile patients were diagnosed, of which 149 were microscopy positive for Pf (n=47) , Pv (n=93) and P.f and P.v or mixed(n=9) The sensitivity, specificity, positive and negative predictive value of GENEDIA® Malaria P.f/pan Ag rapid test was 95.3%, 96.6%, `94.0%, 97.4 % respectively. In conclusion, the diagnostic performance of GENEDIA® Malaria P.f/pan Ag

rapid test has sensitivity, specificity, positive and negative predictive value of 95.3%, 96.6%, `94.0%, 97.4% respectively with respect to malaria microscopy in this study.

833

A SYSTEMATIZED REPRESENTATIVE SELECTION QUALITY CONTROL PROTOCOL FOR THE QUANTITATIVE ASSESSMENT AND IMPROVEMENT OF MALARIA MICROSCOPY IN TANZANIAN MILITARY HEALTH FACILITIES

Saidi Mgata[1], Derryck Klarkowski[2], Lucas Mahikwano[1], Lucky Temu[1], George Amoo[3], Sarah Chiduo[1], Akili Kalinga[4], Christopher Mswanya[5], Lalaine Anova[6], Charles Mwanziva[5], Eyako Wurapa[2], Dennis Janga[5]

[1]Walter Reed Malaria Programme-Tanzania, Dar es Salaam, United Republic of Tanzania, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]Amethyst Technologies LLC, Baltimore, MD, United States, [4]National Institute for Medical Research, Tukuyu Research Centre, Tukuyu, United Republic of Tanzania, [5]Tanzania Peoples Defence Forces, Dar es Salaam, United Republic of Tanzania, [6]ClinicalRM, Hinckley, OH, United States

Malaria microscopy is the gold standard methodology for confirmation of malaria parasites in human blood. It enables accurate detection, quantification and identification of species to support treatment and patient management, as well as research efforts to understand malaria prevalence. The accuracy and reliability of results are critically dependent upon the quality of blood film preparation, staining procedure, microscopist's expertise and reading time. Studies have demonstrated poor malaria microscopy performance in Africa, including Tanzania. The Walter Reed Army Institute of Research (WRAIR) and Tanzania Peoples Defence Forces (TPDF) have established a Quality Monitoring and Improvement Program of malaria diagnostics at select TPDF camps. A key objective is to perform crosschecking of malaria slides prepared in current and future research sites. Malaria microscopy QC programs generally focus exclusively on reading accuracy. In contrast, the WRAIR/TPDF protocol includes quantitative assessment of preparation, staining and reading. All blood films prepared for routine testing are stored and monthly QC samples are selected in situ from the laboratory registers and crosschecked by the Walter Reed Malaria Program on a quarterly basis. 10 negative and all positive slides for each month are selected using a random representative sampling protocol. Representative sampling ensures that the QC slides are selected (in a random manner) from the start, middle and end of the working day, and from various days distributed across the month. The quality of blood films are quantitatively assessed macroscopically for blood film preparation quality, and microscopically for staining quality and reading accuracy. Over a 4 month period, the mean smear and staining quality were 74.3% (53.6-86.7) and 72.2% (50-86, n=251) respectively, mean sensitivity was 38.7% (33-45, n=160), and specificity was 82% (70-100, n=25).Results shows that the improvement or drop in quality of performance over months can be depicted and monitored using a systematized random sampling protocol with an objective selection of smears prepared in different times.

834

QPCR DETECTION OF SUB-MICROSCOPIC *PLASMODIUM FALCIPARUM* PARASITEMIA AFTER ARTEMISININ COMBINATION THERAPY IN MALI

Nouhoum Diallo[1], Khalid Beshir[2], Bakary Fofana[1], Bakary Sidibe[1], Sekou Toure[1], Niawanlou Dara[1], Francois Dao[1], Amadou Togo[1], Bouran Sidibe[1], Moctar Coulibaly[1], Issaka Sagara[1], Colin Sutherland[2], Ogobara Doumbo[3], Abdoulaye Djimde[1]

[1]Malaria Research and Training Center, Bamako, Mali, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Malaria Research and Training Center, USTTB, Bamako, Mali

Parasite clearance time (PCT) after artemisinin-based combination therapy (ACT) is increasing in Asian settings. The association between parasite clearance following ACT with increased transmission to mosquitoes and parasite recurrence was demonstrated. The prevalence of sub-microscopic ***Plasmodium falciparum*** parasitemia in Malian people after ACT is less documented. Since October 2011 we have conducted prospective studies of four artemisinin combination therapies in Kollé and Bougoula, Mali. We determined parasite clearance dynamics by duplex quantitative polymerase chain reaction (qPCR) for patients for whom a complete set of day 0, 1, 2, and 3 dried blood spots were available. We obtained 208 and 186 patients for episodes 1 and 2, respectively. Residual parasitemia on day 3 after initiation of treatment was observed during episode 1 in 22% and 27% at Kollé and Bougoula respectively. For episode 2, residual parasitaemia was detected in 10% and 30% of patients respectively for Kollé and Bougoula. Our results indicate that sub-microscopic parasitaemia persists in 10 - 30% of patients at day 3 post-ACT treatment in Mali. The implications of these observations for ACT efficacy will be discussed.

835

ULTRASENSITIVE MOLECULAR SCREENING FOR *PLASMODIUM VIVAX* INFECTION IN PREDOMINANTLY DUFFY NEGATIVE POPULATION IN MALI, WEST AFRICA

Amadou Niangaly[1], Mark A. Travassos[2], Youssouf Tolo[1], Amy Mu[2], Matthew Adams[2], Bourema Kouriba[1], Matthew B. Laurens[2], Antoine Dara[2], Issa Diarra[1], Modiba Daou[1], Mody Sissoko[1], Amed Ouattara[2], Drissa Coulibaly[1], Karim Traore[1], Christopher V. Plowe[2], Mahamadou A. Thera[1], Ogobara K. Doumbo[1]

[1]Malaria Research and Training Center, Bamako, Mali, [2]Center for Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

The preponderance of Duffy-blood-group negative populations in the Sahel has led to the assumption of very low prevalence or no ***Plasmodium vivax*** malaria infection in this region based on the resistance of Duffy negative people to ***P. vivax*** infection. This reasoning has long been widely accepted, and may have resulted in a diagnostic bias and mis-diagnosis of ***P. vivax*** in West Africa by microscopy. Molecular tools enable us to detect species-specific infection including submicroscopic low-density parasitemia of ***P. vivax***. Molecular screening may offer an efficient tool for investigating ***P. vivax*** infection to inform malaria elimination policies in Africa. Blood samples were collected from 400 children aged 0-14 years during quarterly scheduled visits in prospective cohort studies from 2009 to 2012 in Bandiagara, Mali. An ultrasensitive Pf_Pv-multiplex qPCR using Roche LightCycler 480 was carried out using DNA extracted from filter paper samples. ***P. vivax*** positive results were repeated three times for confirmation. Our preliminary data have detected four cases of vivax infection in 2009. One patient among the four positives was chronically infected by ***P. vivax*** during consecutive quarterly visits. These results suggest that ***P. vivax*** may be more common than previously believed in this setting. Sensitive molecular tools have the potential to provide important information for planning malaria elimination strategies in the Sahel.

836

EVALUATION OF NEXT GENERATION INFECTION DETECTION TESTS FOR MALARIA ELIMINATION AND ERADICATION

Smita Das, Ihn Kyung Jang, Katherine Imus Misiuda, Paul LaBarre
PATH, Seattle, WA, United States

Over the last decade, increased funding for malaria control has resulted in the adoption and scale-up of interventions, leading to a worldwide decrease in mortality cases. However, it has recently become evident that in both low and high transmission settings, there is a large proportion of individuals who harbor low density infections that are not detected by microscopy or rapid diagnostic tests (RDTs). Other diagnostic tools such as PCR, ELISA, and RT-PCR lack affordability, ease of use, rapid time to results, and portability, all of which are essential for large scale use in resource-limited settings. As a result, infected individuals that are undetectable with current tools remain a reservoir of infection and contribute to continued malaria transmission within a population. Clearly, there is a need for more accurate tests. The Infection Detection Test (IDT) Development Initiative seeks to enable access to the most appropriate diagnostic tools that will support regional elimination and global eradication of ***Plasmodium falciparum*** malaria. The IDT Initiative is focused on the development and commercialization of a high quality, low cost, easy to use, and highly sensitive ***P. falciparum*** diagnostic test by 2017. Similar to existing RDTs, the IDT will implement a lateral flow format, and will utilize the HRP2 biomarker because HRP2 persistence in peripheral blood suggests recent infection. Currently, commercial RDTs have a limit of detection (LOD) of 800 pg HRP2/mL. The goal of the IDT Initiative is to produce a new diagnostic tool that has an LOD of 80 pg HRP2/mL, and this work has led to the development of five promising prototypes. Each prototype includes developments or improvements to one or more of the following: alternative reporters, workflow innovations, advanced capture agents, sample preparation, and non-invasive sampling. Using native and recombinant HRP2 proteins, as well as clinical samples, we evaluated the performance of these prototypes. Here, we present the preliminary results of the IDT prototype evaluation and identify the relative advantages of several design approaches.

837

ASSESSMENT OF NON-ADHERENCE TO ANTIMALARIAL TEST RESULTS IN PUBLIC AND PRIVATE HEALTH FACILITIES IN NIGERIA

Martin Meremikwu[1], Iwara Arikpo[1], Sonachi Ezeiru[2], Chukwudi Uche[3], Issa Kawu[3], Ernest Nwokolo[2], Jennifer Anyanti[2], Nnenna Ezeigwe[3]
[1]University of Calabar, Calabar, Nigeria, [2]Society for Family Health, Abuja, Nigeria, [3]National Malaria Elimination Programme, Abuja, Nigeria

Current global guidance requires that all suspected malaria cases should be confirmed by microscopy or rapid diagnostic test (RDT) before treatment. The Nigerian National Malaria Elimination Programme is implementing strategies to promote availability of quality assured microscopy and mRDTs in public and private health facilities across the country but there are concerns that the failure of health workers and prescribers to adhere to results of these confirmatory tests undermines the benefits of these interventions. This study was performed to assess the practice and reasons for non-adherence to malaria test results. Non-adherence rate was defined as percentage of cases that tested negative by microscopy or mRDT who received antimalaria treatment despite the test result. Record of microscopy or mRDT test results, and treatments given to the most recent cases of suspected malaria seen in 61 health facilities sampled from all the six geo-political zones of Nigeria were analyzed. The included facilities received regular supplies of quality-assured mRDTs from the National Malaria Elimination Programme or through the implementer of the grant-supported initiative to improve malaria diagnosis and treatment in the private sector. Confirmatory tests (mostly mRDT) were performed in 431 of 610 eligible cases; 169 had no test. Results showed 285 (66.1%) had malaria parasitaemia and 146 (33.9%) had no parasitaemia. Thirty one patients who had negative test results were treated with antimalarial drug (ACT) giving a non adherence rate of 21.2%. Top three reasons given by prescribers for non-adherence were (i) low confidence in accuracy of mRDT, (ii) disregarding test results when illness symptoms are "too obvious"; and (iii) insistence by some patients to be treated despite their negative test results. These findings would be helpful in developing interventions to address non-adherence and draw attention to the need for more in-depth studies of this practice.

A STUDY OF DIFFERENT METHODS FOR ESTIMATING OF BLOOD MALARIA PARASITE DENSITY

Kyaw Swar Oo, **Noppadon Tangpukdee**, Kirana Paohintang, Kwanyuen Putraprasert, Putza Chonsawat, Suntaree Pengruksa, Apaipun PooNgoen, Polrat Wilairatana, Srivicha Krudsood
Faculty of Tropical Medicine, Bangkok, Thailand

A retrospective study of malaria parasitaemia estimation by using actual and different assuming number of WBC and RBC counts was conducted at the Bangkok Hospital for Tropical Diseases, Faculty of Tropical Medicine, Mahidol University, Thailand. Clinical data from 512 patients, who infected either falciparum or vivax malaria and diagnosed of malaria by using thick and thin blood smears, were analyzed. The application of a WHO recommended 8,000 WBCs/μL and assuming RBC number for estimating malaria parasitemia led to overestimation and resulted in low reliability when compared to the actual counts of WBC and RBC. The difference in the geometric mean parasitemia calculated by using actual WBC and RBC counts and compared to parasite densities with assuming number of WBC and RBC counts were significantly lower and higher except for assuming WBC 5900/μL in thick blood film; assuming RBC 4,800,000/μL in thin blood smears in male patients and assuming RBC of 4,300,000/μL in female patients.

Malaria remains endemic in Uganda and Nigeria, with over 80% of the population at risk of disease in both countries. The two countries have adopted the WHO recommendation of universal parasitological confirmation before treatment. The recommendation includes the private sector where 40-60% of febrile patients seek care. However, adherence to case management guidelines following a negative test result remains unclear especially in the private retail outlets offering malaria testing services. Mystery patient surveys, an effective method for assessing provider's behavior, were conducted to understand providers' case management following a negative mRDT result. The surveys were conducted in November 2014 and December 2013 in Nigeria and Uganda respectively, as part of a broader multi-country private sector mRDT project. In both countries, mystery patients were confirmed malaria negative, healthy adults consenting to at most 3 malaria tests over a one week period. They were trained to present at randomly selected private retail outlets known to offer malaria diagnostic services and act as patients, presenting with symptoms likely to indicate suspected malaria thus leading the provider to recommend a malaria test. Their experiences were later recorded through an interviewer administered questionnaire. A total of 131 visits from 63 mystery patients were made in Nigeria and 193 visits from 65 mystery patients in Uganda. In Both countries, the

outlets were mainly drug shops and clinics. In Nigeria, all visits received a test whereas 176/193 (91%) of visits in Uganda received a test. Despite a negative confirmatory result prior to the visit, 53/131(40%) and 62/176 (35%) of cases tested were given a positive test result in Nigeria and Uganda respectively. Among cases testing negative, 26/78(33%) in Nigeria and 27/114(24%) in Uganda were given an anti-malarial, predominantly ACTs. Adherence to non-malaria case management guidelines is still sub optimal. Evidence suggests alteration of negative results. There is need for to further understand the factors driving anti-malarial prescription despite negative results

BUILDING A SYSTEM OF QUALITY ASSURED MALARIA DIAGNOSTICS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Filiberto Hernandez

Centers for Disease Control and Prevention, Atlanta, GA, United States

Using a parasitological test for suspected cases of malaria is increasingly becoming the norm in the Democratic Republic of the Congo. However, assuring that tests - both microscopy and malaria rapid diagnostic tests (RDTs) - are done properly and the test results are used appropriately, remains a difficult challenge in the country. To address this, the President's Malaria Initiative (PMI) through the PATH-led MalariaCare partnership has supported the National Malaria Control Program (NMCP) to develop and implement a system of quality- assured malaria diagnostics. This system is designed on continuous improvement principles and includes update training, certification of trainers, on-site supportive supervision linked with regular review and feedback by Quality Assurance (QA) supervisors. MalariaCare has worked with the NMCP to train a cadre of diagnostics experts in microscopy skills and in quality RDT performance. Best performers - from both central and provincial reference laboratories - are then trained as on-site supervisors. They then work with local laboratory and clinical staff at health facility level to perform on-site outreach training and supportive supervision (OTSS) in health facilities in six of the DRC's eleven provinces. The OTSS visits focus on skills observation and on the spot problem solving. The primary goals have been to improve preparation and accuracy of malaria slide reading, assurance of appropriate RDT results, and adherence by clinicians to the test results. Recently a cadre of clinician supervisors has also been trained and joined the laboratory experts in providing regular on-site supervision visits. To assure steady quality improvement in the program the supervisors meet to review outcomes and plan improvements during annual lessons learned workshops. While the largest portion of the facilities are new, a subset with two years of representative data have shown steady improvements in the quality of diagnostic and clinical indicators. Consequently, the QA system is being expanded to include on-site proficiency testing and linkage of community health worker networks to QA program health facilities.

WHO recommends the use of malaria Rapid Diagnostic Tests (mRDTs) for malaria diagnosis at all levels of the health system and use of rectal artesunate (RA) at community level as a pre-referral treatment for severe malaria. We conducted this mixed method study to assess the feasibility, acceptability and impact of integrating mRDTs and RA into community case management on quality of care and utilization of CCM services. During the study, mRDTs/ RA were available in 97% of the village clinics and 96% of mRDTs were correctly performed by community health workers. Cross sectional surveys showed that care seeking from community health workers increased from 36.8% before the intervention to 89% after the intervention whilst the proportion of caregivers that sought care from informal sources of care declined from 16.5% to 1.9%. Prompt access to care (within 24 hours) increased from 42% to 93%. For children that received RA, 79% complied with referral when assessed within 24 hours to 7 days of referral advice. Non compliance to referral increased with distance from the health centre. Both mRDTs and RA were highly accepted by caregivers and community health workers, and reasons given included the provision of diagnostic services and timeliness of treatment at community level. This study has shown that integration of mRDTs and pre-referral rectal artesunate into community case management is both acceptable and feasible. The intervention improves utilization of child health services, malaria diagnosis, treatment and compliance to referral advice among children less than five years of age in hard to reach areas of Malawi.

The World Health Organization has released revised Integrated Management of Childhood Illnesses(IMCI) case management algorithm that incorporate the use of malaria rapid diagnostic test. Adherence to the revised guidelines is critical to proper diagnosis and management of malaria and non-malaria fevers, including the rational use of antibiotics. As part of an implementation research in the middle-belt of Ghana, we conducted an observation study to assess the extent of adherence to the revised guidelines. Between April and July 2013, we conducted structured observation of clinical practices in the management of under-five children reporting with fever to eighteen (18) health centers in the Brong Ahafo Region of Ghana. Data was collected using a structured checklist and the data was matched against the standard set in the revised WHO guidelines. A total of 4111 observations were carried out among children 3-59 months. Among children diagnosed with malaria and prescribed ACT, only 26% had RDT performed. Only 28% had their ability to eat, drink or breastfeed assessed. History of convulsion or convulsing at presentation was checked for approximately 22%. Just about 18% were assessed for ear problems while only 14.7% got assessed for malnutrition and anemia. 16% of the observed children received better than average IMCI assessment (7 or more of the 11 IMCI task). Adherence to the revised IMCI guidelines is sub-optimal in this area in Ghana. Innovative approaches are needed to increase clinician adherence and ensure appropriate management of under-five febrile illnesses in the era of test-based management of malaria.

THE USE OF FIONET™ TECHNOLOGY AS A TOOL IN IDENTIFYING THE PROBLEMS WITH RDT QUALITY IN MILITARY HEALTH FACILITIES OF TANZANIA

Akili Kalinga[1], Christopher Mswanya[2], Lucky Temu[3], Lalaine Anova[4], Eyako Wurapa[5], Colin Ohrt[5], Sarah Chiduo[3], George Amoo[6], Charles Mwanziva[2], Ian Fine[7], Geeta Bhat[7], Dennis Janga[2]

Over 93% of the Tanzanian population is at risk for malaria infection. In the past, malaria diagnosis in health facilities below hospital level relied on clinical diagnosis and rarely microscopy. The World Health Organization advocates the use of Rapid Diagnostic Tests (RDTs) where microscopy is not feasible. Despite the promising use of RDTs, quality control (QC) is challenging. While cross-checking malaria slides is a common external QC method, cross-checking RDTs by off-site personnel can be unreliable because RDT result lines begin degrading within hours. Fionet™ technology is a web-based workflow guidance system that addresses RDT quality control issues. The system uses the Deki Reader™ (DR) and standard mobile devices to provide step-by-step guidance for performing RDTs, and to capture and transmit digital records of each test. Web-based oversight of RDT performance is enabled through Fionet™ to provide real time reporting and case management. RDT QC through Fionet™ was implemented at selected Tanzanian military facilities in collaboration with the US Army. Images of RDTs performed at the sites were viewed through the web portal for preparation problems and discordant results between device and human interpretations. Concerns were communicated remotely with health workers at the point of service for improvement. In 2014, 2.9% (960/32655) and 0.1% (26/32655) of all uploaded images were identified to have quality problems related to interpretation of results and RDT preparations respectively. Of the false results, 56% (539/960) were false negative and 44% (421/960) were false positive. False positive interpretations were commonly found in mixed species infections (64.5%; 247/383); false negative interpretations were found more in single species infections (54.5%; 294/539). The main factors leading to errors in RDT interpretations were assumption of presence of imaginary positive line (44.5%; 150/337) and missing weak positive test lines (35.9%; 121/337).
